CONTENTS

2015 ASCO ANNUAL MEETING PROCEEDINGS

continued on following page

Journal of Clinical Oncology (ISSN 0732-183X) is published 36 times a year, three times monthly, by the American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Periodicals postage is paid at Alexandria, VA, and at additional mailing offices. Publication Mail Agreement Number 863289.

Editorial correspondence should be addressed to Stephen A. Cannistra, MD, *Journal of Clinical Oncology*, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Phone: 703-797-1900; Fax: 703-684-8720. E-mail: jco@asco.org. Internet: www.jco.org.

Journal of Clinical Oncology® is a registered trademark of American Society of Clinical Oncology, Inc.

POSTMASTER: ASCO members should send changes of address to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Nonmembers should send changes of address to *Journal of Clinical Oncology* Customer Service, 2318 Mill Road, Suite 800, Alexandria, VA 22314.

2015 annual subscription rates, effective September 1, 2014: United States and possessions: individual, $625 one year, $1,188 two years; single issue, $40. International: individual, $867 one year, $1,647 two years; single issue, $50. Institutions: bundled (print + online): Tier 1: $977 US, $1,356 Int'l; Tier 2: $1,127 US, $1,495 Int'l; Tier 3: $1,627 US, $1,981 Int'l; Tier 4: contact *JCO* for quote. Institutions: online only, worldwide: Tier 1: $831; Tier 2: $952; Tier 3: $1,374; Tier 4: contact *JCO* for quote. See www.jco.org/ratecard for descriptions of each tier. Student and resident: United States and possessions: $303; all other countries, $421. To receive student/resident rate, orders must be accompanied by name of affiliated institution, date of term, and the signature of program/residency coordinator on institution letterhead. Orders will be billed at individual rate until proof of status is received. Current prices are in effect for back volumes and back issues. Back issues sold in conjunction with a subscription rate are on a prorated basis. Subscriptions are accepted on a 12-month basis. Prices are subject to change without notice. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. *JCO* Legacy Archive (electronic back issues from January 1983 through December 1998) is also available; please inquire.

American Society of Clinical Oncology
51st Annual Meeting

2015 Abstracts

Descriptions of Scientific Sessions

Plenary Session
The Plenary Session includes abstracts selected by the Scientific Program Committee as having practice-changing findings of the highest scientific merit.

Highlights of the Day Sessions
Highlights of the Day Sessions invite expert discussants to present key findings, put abstracts into clinical context, and provide an overview of the previous day's Oral Abstract Sessions.

Oral Abstract Sessions
Oral Abstract Sessions include didactic presentations of abstracts of the highest scientific merit, as determined by the Scientific Program Committee. Experts in the field serve as discussants and provide comprehensive themed discussions of the findings from the abstracts.

Clinical Science Symposia
Clinical Science Symposia provide a forum for science in oncology, combining didactic lectures on a specific topic with the presentation of abstracts. Experts in the field serve as discussants to place studies in the appropriate context and critically discuss the conclusions in terms of their applicability to clinical practice. New this year, three special Clinical Science Symposia will be designated around specific pathways that cut across cancer types.

Poster Discussion Sessions
Select posters from the Poster Sessions will be discussed by expert discussants, with the abstract authors participating as panel members. These sessions will be followed by networking with the discussants and authors.

Poster Sessions
Poster Sessions include selected abstracts of clinical research in poster format. Trials in Progress (TPS) abstracts are presented within a track's Poster Session.

Publication-Only Abstracts
Publication-only abstracts were selected to be published online in conjunction with the Annual Meeting, but not to be presented at the Meeting.

All presented and publication-only abstracts are citable to this Journal of Clinical Oncology *supplement. For citation examples, please see the Letter from the Editor.*

This publication contains abstracts selected by the ASCO Scientific Program Committee for presentation at the 2015 Annual Meeting. Abstracts selected for electronic publication only are available in full-text versions online through ASCO.org and JCO.org. The type of session, the day, and the session start/end times are located to the right of the abstract number for scheduled presentations. To determine the location of the abstract session, refer to the Annual Meeting Program or the iPlanner, the online version of the Annual Meeting Program, available at am.asco.org.

Dates and times are subject to change.
All modifications will be posted on am.asco.org.

The deadline for abstract submission for the 2016 Annual Meeting is
Tuesday, February 2, 2016, at 11:59 PM (EST).

Letter from the Editor

The *2015 ASCO Annual Meeting Proceedings Part I* (a supplement to the *Journal of Clinical Oncology*) is an enduring record of the more than 2,800 abstracts selected by the ASCO Scientific Program Committee for presentation at the 51st ASCO Annual Meeting. Accepted abstracts not presented at the meeting are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org.

The majority of abstracts selected for presentation are included here in full and are categorized by scientific track. After the Annual Meeting, abstracts can be accessed online through ASCO University's Meeting Library (meetinglibrary.asco.org/abstracts). Online abstracts include the full list of abstract authors and their disclosure information.

Late-Breaking Abstracts are represented here by abstract title and presenting author only. The full-text versions of these abstracts will be publicly released through ASCO.org during the Annual Meeting. Late-Breaking Abstracts will also be included in the *2015 ASCO Annual Meeting Proceedings Part II*, an online supplement to the June 20 issue of *Journal of Clinical Oncology* on JCO.org. Print versions of these abstracts will be available onsite at the Annual Meeting in the *ASCO Daily News*.

All abstracts carry *Journal of Clinical Oncology* citations. The following are citation examples for print and electronic abstracts:

J Clin Oncol 33:5s, 2015 (suppl; abstr LBA1)

J Clin Oncol 33, 2015 (suppl; abstr e12000)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Important Tiers and Pricing Notes
Additional rates along with tier descriptions are available online at www.jco.org/ratecard

1. Prices are in effect from September 1, 2014, through August 31, 2015. Prices are subject to change.
2. Print-only subscriptions or additional print subscriptions are available for $827 in the US and $1,196 outside the US.
3. Institutional online access, whether an online-only or bundled subscription, is for a single-site license, which allows an unlimited number of concurrent users from that site.
4. For multisite licenses, please contact the appropriate agent for a quote.
5. Subscribers outside the US, add $100 per print subscription for expedited delivery.
6. Single-issue price: $40 US, $50 international.
7. Prices quoted are in US dollars and payments must be made in US dollars.
8. Except on Tier 5 orders, the publisher allows for a 5% discount to recognized subscription agents.

Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. Back issues sold in conjunction with a subscription are on a prorated basis.

ASCO Abstracts Policy

Public Release of Abstracts

The abstracts published in the *2015 ASCO Annual Meeting Proceedings Part I*, including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 13, 2015. These abstracts are publicly available online through ASCO.org, the official website of the Society. Late-Breaking Abstracts (LBAs), which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a press briefing or scientific presentation on Friday, May 29, will be publicly released Friday, May 29, through ASCO.org at 2:00 PM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation on Saturday, May 30, will be publicly released Saturday, May 30, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation on Sunday, May 31, will be publicly released Sunday, May 31, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation on Monday, June 1, or Tuesday, June 2, will be publicly released Monday, June 1, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on ASCO.org.

Abstract Notice

All abstracts presented at and published in conjunction with the Annual Meeting are included in online supplements to the *Journal of Clinical Oncology*. The abstracts released on May 13, 2015, are included in the May 20 (Vol. 33, No. 15S) issue (*2015 Annual Meeting Proceedings Part I*), and the Late-Breaking Abstracts, released on a daily basis during the Meeting, are included in the June 20 (Vol. 33, No. 18S) issue (*2015 Annual Meeting Proceedings Part II*).

ASCO's Policy for Relationships with Companies

In compliance with standards established by ASCO's Policy for Relationships with Companies (Conflict of Interest; J Clin Oncol. 2013;31[16]:2043–2043) and the Accreditation Council for Continuing Medical Information (ACCME), ASCO's intent is to promote balance, independence, objectivity, and scientific rigor through the disclosure of financial and other interests, and in the identification and management of potential conflicts. According to the ASCO's Policy for Relationships with Companies, all authors are expected to provide general disclosure information for 11 disclosure categories of relationships with for-profit health care companies.

The requirements in ASCO Conflict of Interest Policy apply to all abstract authors. Authors may enter their own disclosures using the ASCO Disclosure Management System online at coi.asco.org. By establishing a disclosure on coi.asco.org, authors will have a unified disclosure across all ASCO activities, including volunteer service, journals, and abstracts submissions. If an author has provided disclosure through ASCO Disclosure Management System, the information will automatically populate in the submission site.

Alternatively, a submitting author can enter disclosure information from coauthors who opt not to use the ASCO Disclosure Management System through the Abstract Submitter program. Copies of the Disclosure Form can be sent to coauthors for completion and returned to the submitting author before submission of the abstract.

Per the Implementation Plan to Manage Relationships with Companies for CME Activities, all oral abstract presenters will be subject to the same disclosure review and management strategies as faculty who participate in ASCO CME activities.

Please visit asco.org/rwc for more information on the ASCO Conflict of Interest Policy and the Conflict of Interest Policy Implementation Plan for CME Activities.

Additional Disclosure Questions for First, Last, and Corresponding Authors of Original Research

The first, last, and corresponding authors are required to answer additional questions specific to their abstract. ASCO will not enforce restrictions listed in ASCO's Policy for Relationships with Companies on first, last, and corresponding authors and will reconsider whether to do so after a period of data gathering and analysis that will continue at least through April 22, 2016. Financial relationships of first, last, and corresponding authors are still required to be disclosed and will be managed in accordance with ASCO procedures.

PD-1 pathway blockade: A common denominator for cancer therapy.

Suzanne L. Topalian, MD; Johns Hopkins Kimmel Cancer Center; Johns Hopkins Kimmel Cancer Center, Baltimore, MD

In the current era in oncology emphasizing personalized therapy, PD-1 pathway blockade is distinguished by its "common denominator" approach. The genetic diversity found in most human cancers creates challenges for therapies directed against individual mutations but exposes a panoply of new targets for potential immune recognition. However, immune cells that recognize and are poised to attack cancer cells are held in check at the tumor site by suppressive molecular pathways (so-called "immune checkpoints"). Nearly twenty years ago, laboratory studies revealed that blocking the prototypical immune checkpoint Cytotoxic T-Lymphocyte Antigen 4 (CTLA-4) could mediate tumor regression in murine models, leading to the clinical development and approval of anti-CTLA-4 (ipilimumab) for treating patients with advanced melanoma in 2011. More recently, drugs blocking the distinct checkpoints Programmed Death 1 (PD-1) and its major binding partner PD-L1 have shown great promise in treating diverse cancer types. The realization that non-small-cell lung cancer is susceptible to anti-PD-1/PD-L1 immediately broadened the horizon for cancer immunotherapy as a general treatment modality–lung and other common epithelial cancers had not previously responded to various immunotherapies and were thought to be relatively "non-immunogenic." Durable regressions of advanced treatment-refractory kidney, bladder, ovarian, and head and neck cancers, as well as melanoma and Hodgkin's lymphoma, following PD-1 pathway blockade have fueled the intensive examination of predictive biomarkers and a growing cohort of unique checkpoint molecules as potential drug targets. These translational research efforts have provided new treatment options and are revo-lutionizing therapeutic algorithms. The complex biology of immune checkpoint pathways still contains many mysteries, and the full activity spectrum of drugs blocking these pathways, used alone or in combination, is unknown. Armed with a new scientific understanding and unprece-dented clinical opportunities, the field of immunotherapy is now standing on the threshold of even greater advances in the war against cancer.

Science of Oncology Award and Lecture
Sunday, May 31, 1:00 PM

Immune checkpoint blockade in cancer therapy: New insights and opportunities.

James P. Allison, PhD; University of Texas MD Anderson Cancer Center, Houston, TX

The existence of multiple nonredundant I inhibitory pathways that limit T cell responses offers novel strategies for mobilizing the immune system to attack cancer cells. The best characterized of these immune checkpoints is CTLA-4, which inhibits CD28 mediated costimulation. Antibodies to CTLA-4 have proven effective against multiple tumor types in both preclinical and clinical studies. Ipilimumab, an antibody to human CTLA-4, showed long term (>4.5 years) survival benefit in about 23% of patients in a randomized, placebo-controlled trial in late stage melanoma. In 2011 it was approved by the FDA for treatment of late stage melanoma and is now a standard of care for that disease. The mechanism(s) of action of anti-CTLA-4 are still being elucidated. CTLA-4 blockade results in an increase in the frequency of CD4 T cells expression ICOS (inducible costimulator) in both tumor tissues and blood. This population contains that vast majority of tumor-specific cells that produce IFNγ and TNFα Using mouse models, we have shown that the ICOS/ICOSL pathway is critical for optimal antitumor activity of anti-CTLA-4 and that ICOS is a compelling molecule to develop as a target for agonistic targeting of costimulatory checkpoints. PD-1, another checkpoint, works by interfering with T cell antigen receptor signaling, a completely different mechanism that CTLA-4. It has two ligands, PD-L1 and PD-L2, which are both expressed on dendritic cells. However, many tumor cells also express PD-L1. Antibodies to PD-1 and PD-L1 have both shown objective responses against several tumor types in clinical trials with response rates of about 25%. A recent phase II trial of a combination of anti-PD-1 and anti-CTLA-4 in melanoma showed objective responses in about 50% of late stage melanoma patients. Our studies of the mechanisms involved in the antitumor effects and of more effective combinations will be discussed.

ASCO–American Cancer Society Award and Lecture
Monday, June 1, 11:30 AM

Cancer prevention as our first best hope: Action in prevention research and cancer control.

Ernest Hawk, MD, MPH; Division of Cancer Prevention and Population Sciences, University of Texas MD Anderson Cancer Center, Houston, TX

The global context of cancer is rapidly changing as the population ages and progressively adopts unhealthy lifestyles. It is anticipated that low-to middle-income countries will bear the majority of the future cancer burden. Cancer prevention will be critical to address this growing challenge. But in order to do so, concerted efforts are needed on two fronts: (1) discovery: to better understand at a molecular and cellular level what initiates and drives early cancer development to find effective screening tools and interventions that can be administered much earlier in the disease process; and (2) dissemination: to use existing evidence to formulate and implement effective community-oriented programs involving public policy, public education, and clinical preventive services that reduce cancer risks. NCI-designated cancer centers are in a unique position to collaboratively advance prevention research and cancer control, and the Affordable Care Act is providing unprecedented opportunities to reimburse for clinical delivery of evidence-based preventive interventions. In both the clinical and population contexts, the ultimate goal is safe, timely, effective, efficient, equitable, patient-centered or culturally-tailored preventive care, sustainable across time and populations. Together, the two complementary approaches of molecular prevention and cancer control offer an optimal approach to cancer - combining adoption and maintenance of healthy lifestyles, evidence-based screening and early detection, with precision treatment of early-stage lesions. Growing evidence supports the importance of such a strategy, demonstrating significant reductions in cancer risk as well as cardiovascular-, cancer-related, and all-cause mortality in those adhering to cancer prevention recommendations. To this end, we must aspire to elevate cancer prevention and control as the first strategy to address cancer, in every regard, everywhere, and by all means—whether through molecular prevention, lifestyle modifications, screening and early detection, or policy and educational initiatives.

B. J. Kennedy Award and Lecture for Scientific Excellence in Geriatric Oncology
Sunday, May 31, 9:45 AM

Transforming data into activities designed for older cancer patients.

Silvio Monfardini, MD; Istituto Palazzolo, Fondazione Don Gnocchi, Milano, Italy

Clinical oncologists should be well prepared for the inevitable increase of older cancer patients in the next decades. Extensive data have been provided by many studies on the results of treatment for elderly patients in most tumor types and on the special approach needed to evaluate such patients. As a result, the International Society of Geriatric Oncology issued appropriate guidelines. Tools helping to predict treatment-related toxicity have been studied and a specific methodology for clinical trials in the elderly is now available. To acquire these data the interaction between oncologists and geriatricians has been essential. In the United States, ASCO and NCI-NIA nationwide initiatives have been emphasizing dual training and research, whereas in France a centralized universalistic approach aims to the collaboration between geriatricians and oncologists. In some other European nations, several models of care delivery and cooperation have been developed. The integrated approach built up with these national initiatives needs to be reinforced and spread, providing the background for the implementation of new research projects. Main obstacles to take action in the United States and Europe are the geriatricians shortfall and their time constraint due to being engaged with other multiple tasks at their institutions other than overhelming numbers of older cancer patients. Local health care situations differ, but the best suited modality of cooperation among oncologists, geriatricians, and allied health professionals should always be found. Innovation through interaction with geriatricians should be brought into surgical oncology and even more in radiotherapy. A greater interaction is also necessary to study how to deliver optimal post-treatment care to older cancer survivors. Studies are also needed for frail cancer patients, the majority of whom are located in nursing homes.

Pediatric Oncology Award and Lecture Childhood cancer survivors: A lifetime of risk and responsibility.
Saturday, May 30, 1:15 PM

An autobiography of "we."

Stephen E. Sallan, MD; Dana-Farber Cancer Institute, Boston, MA

Simultaneously stunning and yet unsurprising, over the past 40 years the collective endeavors of a relatively small community of pediatric investigators have fundamentally impacted the field of childhood cancer. Cure is expected for the vast majority of affected children. Today's research focuses on currently intractable variants of disease, more precisely targeted therapies, and diminution of the sequelae of curative treatments. With an emphasis on training and mentorship, and in recognition that every successful endeavor represents the intertwined and inseparable contributions of many individuals, this presentation will encompass the common ground and collective attributes of the pediatric oncology community. The community's commitment to discovery in the context of clinical trials and the importance of the two-way street between clinical investigators and basic science laboratories will be addressed. In essence, the presentation will consider the too often overlooked "sociology" of our community: Who are we? How did we get here? How do we accomplish our work? Where are we going?—An overview of our collective career journeys as one transitions from "I to We to Them."

ABSTRACTS
American Society of Clinical Oncology
51st Annual Meeting
May 29–June 2, 2015
McCormick Place
Chicago, Illinois

LBA1 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Efficacy and safety results from a phase III trial of nivolumab (NIVO) alone or combined with ipilimumab (IPI) versus IPI alone in treatment-naive patients (pts) with advanced melanoma (MEL) (CheckMate 067). *First Author: Jedd D. Wolchok, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, May 31, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA2 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Reduction in late mortality among 5-year survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Gregory T. Armstrong, St. Jude Children's Research Hospital, Memphis, TN*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, May 31, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA3 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Elective versus therapeutic neck dissection in the clinically node negative early oral cancer: A randomised control trial (RCT). *First Author: Anil D'Cruz, Tata Memorial Hospital, Mumbai, India*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, May 31, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA4 **Plenary Session, Sun, 1:00 PM-4:00 PM**

NCCTG N0574 (Alliance): A phase III randomized trial of whole brain radiation therapy (WBRT) in addition to radiosurgery (SRS) in patients with 1 to 3 brain metastases. *First Author: Paul D. Brown, The University of Texas MD Anderson Cancer Center, Houston, TX*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Sunday, May 31, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. 102 **Clinical Science Symposium, Sun, 9:45 AM-11:15 AM**

Overall survival in COMBI-d, a randomized, double-blinded, phase III study comparing the combination of dabrafenib and trametinib with dabrafenib and placebo as first-line therapy in patients (pts) with unresectable or metastatic BRAF V600E/K mutation-positive cutaneous melanoma. *First Author: Georgina V. Long, Melanoma Institute Australia and The University of Sydney, North Sydney, Australia*

Background: This phase III study (NCT01584648) of dabrafenib (D) + trametinib (T) compared with D + placebo (P) demonstrated superior progression-free survival (PFS) for D+T compared with D+P (HR = 0.75 ; 95% CI: 0.57–0.99; p = 0.035) in pts with BRAF V600E/K mutant, metastatic melanoma at the primary analysis (N Engl J Med 2014;371: 1877). The interim overall survival (OS) favored D+T (40 deaths on D+T vs 55 on D+P), but did not cross the pre-planned stopping boundary for efficacy. Median time on study at the primary analysis was 9 months (0–16 months). Rates of adverse events (AEs) were similar for both arms. More pts had AEs leading to dose modifications with D+T vs D+P, and fewer hyperproliferative skin AEs were reported with D+T. The study was continued after the primary analysis to evaluate OS without crossover from D+P to D+T. **Methods:** Pts were randomized 1:1 to receive D (150mg twice daily) + T (2mg once daily) or D+P as first-line therapy. Eligible pts were age 18 or older, ECOG performance status ≤ 1, and had histologically confirmed unresectable stage IIIC or IV, BRAF V600E/K mutant cutaneous melanoma. The primary endpoint was investigator-assessed PFS; secondary endpoints were OS, overall response rate (ORR), duration of response (DoR), and safety. The final statistical OS comparison was to be initiated when 220 events were reported. **Results:** From May 2012 to January 2013, 423 pts were randomized (211 to D+T, 212 to D+P). The 220th death was reported on Jan 12, 2015; analysis is expected to be completed in Mar 2015. Estimated median time on study at data cut off is 20 months (0-31 months). **Conclusions:** The statistical analysis will evaluate the superiority of D+T vs D+P for OS. A 2-year OS landmark analysis, updated PFS, ORR, DoR, and safety will be presented. Clinical trial information: NCT01584648.

103 **Clinical Science Symposium, Sun, 9:45 AM-11:15 AM**

Updated efficacy of the MEK inhibitor trametinib (T), BRAF inhibitor dabrafenib (D), and anti-EGFR antibody panitumumab (P) in patients (pts) with *BRAF* V600E mutated (BRAFm) metastatic colorectal cancer (mCRC). *First Author: Chloe Evelyn Atreya, University of California, San Francisco, San Francisco, CA*

Background: *BRAF* V600E mutations occur in 5–10% of mCRC and confer a poor prognosis. Unlike BRAFm melanoma, BRAF and MEK inhibitors have minimal activity in BRAFm mCRC. Preclinical data suggest that combined inhibition of the EGFR and MAPK pathways is required to maximally inhibit growth of BRAFm mCRC. This study evaluates the activity of the combination of P with D and/or T in BRAFm mCRC. **Methods:** Eligible pts with BRAFm mCRC received doublet, D+P or T+P, or triplet, D+T+P. **Results:** Doublet (D+P): 20 pts received the full doublet dose (D 150mg twice daily [BID] + P 6mg/kg every 2 weeks [Q2W]). Triplet: 35 pts received D+T+P including 24 pts that received full triplet dose (D 150mg BID + T 2mg once daily [QD] + P 6mg/kg Q2W). No dose-limiting toxicities were observed. As of October 20, 2014, the most common adverse events were dermatitis acneiform (Grade [G] 1/2 55%) and fatigue (G 1/2 45%) for D+P, and diarrhea (G1/2 60%, G3 9%) and dermatitis acneiform (G1/2 47%; G3 9%) for triplet. The confirmed response rate for D+P was 10% and for D+T+P was 26% (Table 1). Treatment with either regimen reduced levels of pERK in on-treatment biopsies relative to pre-dose biopsies (median reduction D+P 23%; D+T+P 54%). Pts are currently being enrolled to T+P. Updated results including progression-free survival and duration of response will be presented. **Conclusions:** Encouraging clinical activity with acceptable tolerability is seen with the triplet D+T+P in BRAFm mCRC. Clinical trial information: NCT01750918.

Investigator–assessed best response with confirmation (RECIST 1.1).

104 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

A pharmacokinetic (PK) and pharmacodynamic (PD) biomarker-driven phase I study of intermittent, low dose intensity schedules of the dual MEK/RAF inhibitor, RO5126766 (RO) in patients (pts) with advanced solid tumors. *First Author: Maria Jose de Miguel Luken, Royal Marsden Hospital/ Institute of Cancer Research, Sutton, United Kingdom*

Background: RO5126766 is a novel dual MEK-RAF inhibitor. A previous phase I study explored high dose intensity schedules that were limited by a $t_{1/2}$ of 60 hours and a challenging toxicity profile. We hypothesised that schedules that achieve significant target modulation but a lower dose intensity due to intermittent dosing will lead to clinically effective and tolerable schedules of RO5126766. **Methods:** The aims of this investigator-initiated study (EudraCT: 2012-001040-22) were to determine the tolerability, PK, PD and preliminary antitumor activity of 2 dosing schedules: orally once daily on Mon-Wed-Fri (MWF) and Mon & Thu (MT). An expansion cohort mandated patients (pts) with *K-* or *N-RAS/B-RAF* mutations. Plasma PK and phosphorylated (p)-ERK in peripheral blood mononuclear cell (PBMCs) were analysed. Tumor PD was assessed in pre- and post-treatment tumor biopsies and diffusion-weighted MRI (DWI). **Results:** To date, 29 pts have been treated. MWF schedule; 3.2 mg and 4 mg (n = 7 each) and MT schedule; 4 mg (n = 8) and expansion cohort (n = 7). Dose-limiting toxicities (DLTs) on the MWF schedule were G3 blurred vision (n = 1) at 4 mg, and G3 skin rash and G4 creatine kinase (CK) elevation (n = 2) at 3.2 mg. No DLTs were recorded in the MT schedule. Most common toxicities were rash, CK elevation, fatigue, mucositis and diarrhea. PK profile at 4 mg MT showed a C_{max} of 247 ng/mL and an AUC of 3,580 ng.hr/mL, consistent with growth inhibition in xenograft models. Maximal PD inhibition of p-ERK in PBMCs was 83% at 3.2 mg, thus both 3.2 mg and 4 mg were in the pharmacodynamically active range. Based on the tolerability, PK and PD profiles, 4 mg MT was declared the recommended phase 2 dose (RP2D). At the RP2D, 3/7 (42.9%) pts with *KRAS* mutations (NSCLC, ovarian and endometrial cancers) achieved RECIST confirmed partial responses and DWI showed increased apparent diffusion coefficient (ADC) at 15 days post-dose in these pts. Recruitment to the expansion cohort is ongoing. **Conclusions:** The RP2D of RO5126766 was defined as 4 mg orally, delivered twice a week, MT, and is associated with preliminary promising single agent activity in *KRAS* mutant tumors. Clinical trial information: 2012-001040-22.

105 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Phase I study of combination vemurafenib, carboplatin, and paclitaxel in patients (pts) with *BRAF*-mutant advanced cancer. *First Author: Shumei Kato, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although BRAF inhibitors have demonstrated efficacy, resistance develops in most pts. We hypothesized that BRAF inhibitor vemurafenib, in combination with carboplatin and paclitaxel, would be well-tolerated and overcome resistance. **Methods**: We designed a phase I study (3+3 design) to determine safety of vemurafenib (480-960 mg twice a day) with carboplatin (AUC 5-6 q3 weeks) and paclitaxel (75-175 mg/m^2 q3 weeks). Endpoints included maximum tolerated dose (MTD), dose limiting toxicity (DLT), and response (RECIST 1.1). **Results**: To date, 19 pts have enrolled. Pts received vemurafenib (480-720 mg twice a day), carboplatin (AUC 5-6) q3 wks, and paclitaxel (100-135 mg/m^2) q3 wks. Median age was 53 yrs (range 33-75) with median of 4 prior systemic therapies (range 1-7). Eleven pts (58%) had received prior BRAF inhibitors, 3 pts (16%) MEK inhibitors, 8 pts (42%) platinum therapy, and 3 pts (16%) taxane therapy. Pts (13/19 [68.4%] with melanoma and n = 1 pt each of cholangiocarcinoma, histiocytoma, papillary thyroid [PTC], anal, unknown primary, pancreatic cancer) had *BRAF* V600E (n = 15), V600K (n = 1) or other *BRAF* mutation (n = 1 each for R6712, del N486-P490, and D459G). MTD has not yet been reached. Two pts had DLTs (G2 creatinine elevated >7 days [n = 1], G3 transaminitis and G4 thrombocytopenia [n = 1]). Five pts had grade ≥ 3 drug-related toxicity with neutropenia (n = 5), thrombocytopenia (n = 5), fatigue (n = 4), anemia (n = 3), and hyponatremia (n = 2). Six out of 19 pts (32%) had objective response (all melanoma pts with *BRAF*V600E [n = 5] and V600K [n = 1] mutation), including 1 complete and 5 partial responses. Four of the 6 responding pts had progressed on prior vemurafenib. Of 11 pts who had received a prior BRAF inhibitor, 4 (36%) achieved objective response. One PTC pt with V600E mutation had prolonged stable disease of 24 months. Among pts with melanoma, response rate was 46% (6/13 pts), with median PFS of 4.9 months (range 0.2–18.4). **Conclusions**: Combination vemurafenib, carboplatin, and paclitaxel is tolerated in pts with advanced cancer. Responses were observed in melanoma pts previously resistant to BRAF inhibitors, suggesting that the combination may overcome resistance. MTD has not yet been reached, and dose escalation continues. Clinical trial information: NCT01636622.

106 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Successful implementation of a novel trial model: The Signature program. *First Author: Julio Antonio Peguero, Oncology Consultants PA, Houston, TX*

Background: Here we describe 8 ongoing single agent clinical protocols under Novartis' "Signature" program involving buparlisib (BKM120, PI3Ki), dovitinib (TKI258, multikinase inhibitor), binimetinib (MEK162, MEKi), encorafenib (LGX818, RAFi), ribociclib (LEE011, CDK4/6i), BGJ398 (FGFRi), ceritinib (LDK378, ALKi) and sonidegib (LDE225; SMOi). These are tissue-agnostic, genetic alteration-specific (mutation, amplification, translocation, etc.) protocols using patients (pts) identified via standard-of-care profiling. This brings the 'Protocol to the Patient' for pts with actionable genetic alterations and who would like access to drugs targeting those alterations. **Methods:** Pts with advanced solid and hematologic cancers and no standard therapeutic options are eligible. Pts are preidentified with a local test performed in a CLIA laboratory for an actionable genetic alteration. Indications where existing data showed no benefit, or key studies were planned, were excluded from accrual. The primary objective is to assess clinical benefit (SD or better for ≥ 16 weeks) for each compound. A novel adaptive statistical design is used to cluster pts of like indications into cohorts for independent analysis for futility (minimum 10 pts) or efficacy (minimum 15 pts). **Results:** Between March 2013 – January 2015, 16 academic and 151 unique community/network sites have dosed 368 pts; buparlisib (142), dovitinib (73), binimetinib (90), encorafenib (9), ribociclib (30), BGJ398 (12), ceritinib (3) and sonidegib (9) with completed cohorts for buparlisib (CRC, ovarian, sarcomas, HNSCC, cervix), dovitinib (CRC, GIST), and binimetinib (lung). The average startup timeline was 5.2 weeks.The most frequent genetic alterations were RAS mutation (68%), PIK3CA mutation (55%), and PTEN loss (41%). Preliminary activity was observed in various tumors; buparlisib (vaginal, HNSCC), dovitinib (ovarian), and binimetinib (AML, ovarian, thyroid). **Conclusions:** This program allows rapid enrollment of molecularly profiled pts with genetic alterations linked to cognate targeted agents. Early signs of clinical activity suggest potential for detection of new indications using a pt-sparing design that could lead to subsequent confirmatory trials.

107 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Prospective evaluation of circulating tumor DNA sequencing in pancreatobiliary carcinomas. *First Author: Eric Andrew Collisson, UC San Francisco, San Francisco, CA*

Background: Pancreatobiliary carcinomas (PC) carry a poor prognosis but have not yet benefitted from the revolution in precision oncology, in part because biopsy tissue is often inadequate for molecular characterization. Cell-free DNA (cfDNA) sequencing tests may provide access to genetic testing and monitoring for advanced PC patients. **Methods:** Twenty-five advanced PC patients were enrolled prospectively in a trial to assess the feasibility, accuracy, and clinical utility of cfDNA next-generation sequencing (NGS) of 54 cancer genes. cfDNA mutations were compared to those detected by biopsy-based NGS tests, and the concordance of the two was determined. cfDNA sequencing in disease monitoring was compared to changes in secreted tumor markers in a subset of patients. **Results:** The NGS-based cfDNA test detected cancer mutations in 21 of 25 (84%) advanced PC patients and provided actionable findings for four patients. Multi-gene sequencing data was available from both blood-based and biopsy-based methods for 17 patients. Over 90% of mutations detected by the biopsy-based genetic tests were detected in cfDNA in these 17 evaluable patients. Four additional mutations were detected by cfDNA sequencing that were not detected in tumor tissue. Tumor biopsy NGS failed for 8 patients, equating to a considerably higher failure rate (32%) than the overall failure rate reported by commercial vendors. Three cfDNA mutations in these patients suggested a new therapeutic option. An activating EGFR-exon19 deletion was observed in cfDNA for one patient, which was later confirmed by a biopsy test and empowered successful treatment with erlotinib. The average diagnostic accuracy of cfDNA sequencing was 97%, with 92% average sensitivity and 100% specificity across the cohort. Changes in cfDNA mutation frequencies correlated with changes in tumor marker measurements (Pearson's r = 0.7). **Conclusions:** cfDNA sequencing is a clinically practicable alternative to biopsy-based tumor DNA sequencing in PC. cfDNA from most PCs showed high mutational concordance with tissue biopsy, and showed high tumor-burden concordance with tumor markers. cfDNA sequencing should be considered for prospective therapeutic trials in pancreatobiliary cancers.

108 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Circulating tumor cells (CTC) and pathological complete response (pCR) as independent prognostic factors in inflammatory breast cancer (IBC) in a pooled analysis of two multicentre phase II trials (BEVERLY 1 & 2) of neoadjuvant chemotherapy combined with bevacizumab. *First Author: Jean-Yves Pierga, Institut Curie, Paris, France*

Background: We have reported that CTC detection is an independent prognostic factor in 52 primary HER2+ IBC (Pierga, CCR 2014). We present a pooled analysis of two prospective trials including 152 patients (pts). Predictive and prognostic value of Circulating Endothelial Cells (CEC) for response to bevacizumab was also analyzed. **Methods:** CTC and CEC were detected in 7.5 ml and 4 ml of blood respectively in the neoadjuvant setting in IBC (T4d) pts enrolled in two phase II multicentre trials, evaluating bevacizumab (15mg/kg q3w) in combination with sequential neoadjuvant chemotherapy (CT) of 4 cycles of FEC followed by 4 cycles of docetaxel in HER2 - tumor (BEVERLY 1) or docetaxel, trastuzumab in HER2 + (BEVERLY 2). The CellSearch System, combining EpCAM immunomagnetic selection followed by anti-cytokeratin (A45B/B3) and anti-HER2 staining for CTC and CD146 IMS and CD105 staining for CEC. **Results:** From 10/08 to 09/10, 152 pts were included and 137 were evaluable for CTC and CEC. Median follow-up was 43 months. At baseline, 55 pts had ≥ 1 detectable CTC (39%). After 4 cycles of CT, a dramatic drop in CTC to a rate of 9% was observed. pCR rate was 40% and was associated with absence of hormonal receptor and HER2 + status. No correlation was found between CTC and CEC levels or pCR rate. CTC detection at baseline independently predicted 3-year disease-free survival (DFS): (70% vs. 39% for pts with < 1 vs. ≥ 1 CTC/7.5 mL [$p < 0.001$, HR 2.80 (1.65-4.76)]) and 3-year overall survival (OS) (92% vs 56% HR 4.28 $p < 0.001$). At multivariate analysis, independent prognostic parameters for DFS were absence of hormonal receptors, no pCR, and CTC detection at base-line. CEC level at baseline or variations during treatment had no prognostic value. **Conclusions:** This is the largest prospectives trial in non-metastatic IBC evaluating CTC detection. We observed a high CTC detection rate of 39%, with a strong and independent prognostic value for DFS and OS. Combination of pCR after neoadjuvant treatment, with CTC at baseline, isolates a subgroup of IBCwith excellent survival. CTC count should be part of IBC stratification in prospective trials. Clinical trial information: NCT00820547.

LBA109 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM

Phase III, randomized trial (CheckMate 057) of nivolumab (NIVO) versus docetaxel (DOC) in advanced non-squamous cell (non-SQ) non-small cell lung cancer (NSCLC). *First Author: Luis Paz-Ares, Hospital Universitario Virgen Del Rocio, Sevilla, Spain*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 PM (EDT) on Friday, May 29, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

200 **Special Session, Fri, 1:00 PM-5:45 PM**

Randomized controlled trial of comparing gastrectomy (Gx) plus chemotherapy (CTX) with CTX alone in advanced gastric cancer (AGC) with a single non-curable factor: JCOG 0705/KGCA01 study (REGATTA). *First Author: Han-Kwang Yang, Department of Surgery, Seoul National University Hospital, Seoul, South Korea*

Background: The prognosis of AGC with non-curable factors is poor. Chemotherapy is the standard-of-care for those patients. However, literatures suggest that Gx may improve patients' survival. Based on these, we conducted an international randomized trial to test the role of Gx in AGC with a single non-curable factor. This trial was performed in Japan, Korea, and Singapore. **Methods:** Eligibility criteria included histologically proven gastric adenocarcinoma, cT1-3, presence of a single non-curable factor confined to either liver (H1), peritoneum (P1), or para-aortic lymph node (16a1/b2) confirmed by both CT scan and laparoscopy/laparotomy, no other distant metastasis, aged 20-75, and PS 0-1. Eligible patients were randomized to Gx followed by CTX or CTX alone. Gx with D1 lymph node dissection was recommended without resection of metastatic lesions. CTX regimen was S-1 80 mg/m2/day on days 1-21 plus CDDP 60 mg/m2 on day 8 repeated every 5 weeks. The primary endpoint was overall survival (OS). The planned sample size was 165 cases per arm, with one-sided alpha of 5%, and an 80% power detecting a 2y-survival difference of 10% (20% with CTX alone vs. 30% with Gx and CTX). **Results:** Between Feb 2008 and Aug 2013, 175 patients (95 in Japan, 80 in Korea) were randomized. 89 pts were randomized to Gx and CTX, and 86 pts were randomized to CTX alone. The first interim analysis was performed in Sep 2013, with 37% (110/294) of the planned events observed, and JCOG DSMC recommended early termination of the trial based on the overall futile effect. In the updated analysis in Dec 2014 with a median follow-up period of 14.5 months, the 2y-OS were 25.1 (95% CI: 16.2 to 34.9) % with Gx followed by CTX and 31.7 (95% CI: 21.7 to 42.2) % with CTX alone ($p = 0.68$). However, subgroup analyses suggested gastrectomy might be beneficial especially for patients with L lesion or cN2/N3. **Conclusions:** In all randomized patients, Gx followed by CTX has no survival benefit over CTX alone for AGC patients with a single non-curable factor. There is a room to re-evaluate the additional gastrectomy confined to the patients in whom distal gastrectomy suffices for tumor resection. Clinical trial information: UMIN000001012.

LBA500 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Primary results, NRG Oncology/NSABP B-35: A clinical trial of anastrozole (A) versus tamoxifen (tam) in postmenopausal patients with DCIS undergoing lumpectomy plus radiotherapy. *First Author: Richard G. Margolese, NRG Oncology/NSABP, and The Jewish General Hospital, McGill University, Montréal, QC, Canada*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

501 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Phase III trial evaluating the addition of bevacizumab to letrozole as first-line endocrine therapy for treatment of hormone-receptor positive advanced breast cancer: CALGB 40503 (Alliance). *First Author: Maura N. Dickler, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Preclinical data suggest estradiol modulates angiogenesis under both physiologic and pathologic conditions. High vascular endothelial growth factor (VEGF) levels in breast tumors have been associated with decreased response to endocrine therapy (ET). We performed a multicenter, open label phase III trial of the addition of bevacizumab (B) to first-line letrozole (L) in patients (pts) with hormone-receptor positive (HR+) advanced breast cancer to test the hypothesis that anti-VEGF therapy may delay progression on ET. **Methods:** Pts were randomized 1:1 to L (2.5 mg orally daily) or L+B (15 mg/kg intravenously every 3 weeks) within strata defined by measurable disease (Yes/No) and disease-free interval ($\leq$ / $>$ 24 months (mo)). Pts electing to receive tamoxifen by physician choice were enrolled in a parallel, randomized phase II trial. The primary endpoint was progression-free survival (PFS), defined as time from randomization to progression (RECIST v1.0) or all-cause death. Secondary endpoints were response rate, clinical benefit rate, overall survival (OS) and adverse events (CTCAE v3.0). Three hundred and fifty-two pts and 274 events were needed for 90% power to detect a hazard ratio (HR) of 0.67 (corresponding to an increase in median PFS from 6 to 9 mo). **Results:** From May 2008 to November 2011, 350 pts were randomized to the phase III trial. 343 pts received treatment and are included in the efficacy analysis. Median age was 58 (25-87). After 36 mo of additional follow-up, 258 PFS events were observed. Median PFS for L+B was 20 mo vs. 16 mo for L (HR = 0.74, 95% CI: 0.58 - 0.95; p = 0.016). There was no significant difference in OS (L+B, 47 mo vs. L, 41 mo; HR = 0.84; 95% CI, 0.61 - 1.15; p = 0.27). The most frequently reported grade 3/4 toxicities on L+B and L, respectively, were hypertension (23 vs 2%) and proteinuria (11 vs 0%). **Conclusions:** Adding B to first-line L improves PFS in HR+ advanced breast cancer with increased B-related toxicity. Updated data will be presented. Correlative studies are underway to identify potential biomarkers of response or resistance to therapy. Supported by U10CA180821, U10CA180882, CA31946, CA180888, CA180858, CA180820, CA180785. Clinical trial information: NCT00601900.

LBA502 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

PALOMA3: A double-blind, phase III trial of fulvestrant with or without palbociclib in pre- and post-menopausal women with hormone receptor-positive, HER2-negative metastatic breast cancer that progressed on prior endocrine therapy. *First Author: Nicholas C. Turner, Royal Marsden, London & Surrey, United Kingdom*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

503 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Phase III trial of bisphosphonates as adjuvant therapy in primary breast cancer: SWOG/Alliance/ECOG-ACRIN/NCIC Clinical Trials Group/NRG Oncology study S0307. *First Author: Julie Gralow, University of Washington/ Seattle Cancer Care Alliance, Seattle, WA*

Background: Randomized trials and a recent meta-analysis suggest that adjuvant bisphosphonates can decrease recurrence and death, primarily in a postmenopausal population. SWOG S0307 compares efficacy of 3 bisphosphonates in early stage breast cancer. **Methods:** Patients with stage I-III breast cancer receiving adjuvant systemic therapy were randomized to receive 3 years of clodronate (CLOD) (1600 mg po qd), ibandronate (IBAN) (50 mg po qd) or zoledronic acid (ZA) (4 mg IV q month x 6, then q3 months x 2.5 years). The primary endpoint was disease-free survival (DFS). The target accrual of 5,400 gave $\geq$ 86% power to detect a statistically significant difference (2-sided α = 0.05) among the arms in an ITT analysis. **Results:** Late rapid accrual led to over-accrual, 6,097 patients were enrolled between 1/06-02/10. Median age was 53 with 58% post-menopausal or age 50+. 77% of tumors were ER positive, 17% HER2 positive, 16% triple negative, and 49% lymph node positive. There were more patients with grade 3/4 events with IBAN (10.5%) than CLOD (8.3%) or ZA (8.8%). Rates of ONJ were highest for ZA (1.2%), then IBAN (0.6%), followed by CLOD (0.3%). Fractures were equal across arms. 73% of patients indicated a preference for oral versus intravenous formulation if all agents showed equal efficacy. At the fourth formal interim analysis, with 56% of 1,314 expected events, the DSMC concluded that there was no realistic chance of a statistically significant difference and recommended early reporting of the trial outcomes. The primary outcome DFS did not differ across arms in a log-rank test (p = 0.71). 5-year DFS was 88% in the CLOD and ZA arms, and 87% in the IBAN arm. Overall survival was 93% in all 3 arms. Additional analyses based on age and menopausal status show no evidence of treatment differences. **Conclusions:** We found no evidence of differences in efficacy by type of bisphosphonate either in the intent to treat analysis or based on age and menopausal status. Despite differences in the type of toxicity, overall grade differed little across arms. Given that the oral study drugs are preferred by patients and approved elsewhere, efforts to make them available in the U.S. should be considered. Clinical trial information: NCT00127205.

504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Adjuvant denosumab in breast cancer: Results from 3,425 postmenopausal patients of the ABCSG-18 trial. *First Author: Michael Gnant, Medical University of Vienna, Vienna, Austria*

Background: Adjuvant endocrine therapy compromises bone health in pre- and postmenopausal breast cancer (BC) patients. Treatment-induced osteopenia, osteoporosis, and fractures are frequent side effects particularly of aromatase inhibitors (AI). Anti-resorptive treatments such as bisphosphonates have been shown to prevent and counteract these side effects of endocrine therapy, and to potentially improve survival outcomes in postmenopausal BC patients. The aim of this trial was to investigate the effects of adjuvant anti-RANK-ligand Denosumab in postmenopausal patients with early hormone receptor+ (HR+) BC receiving AI treatment. **Patients and Methods:** 3,425 postmenopausal patients with HR+ BC receiving AI were recruited in 58 sites into this prospective, randomized, double-blind, placebo-controlled, phase-III trial. Patients were randomized 1:1 to either Denosumab 60mg or placebo q6mo s.c. The primary endpoint was time from randomization to first clinical fracture, secondary endpoints included outcome (DFS, OS) and bone effects (BMD changes, vertebral fractures). **Results:** Denosumab significantly delayed the time to first clinical fracture compared to placebo (HR = 0.5, 95% CI 0.39-0.65, p $<$ 0.0001). The observed reduction in fractures between Denosumab and placebo arm (overall 92 vs 176) was similar in prognostic patient subgroups, e.g. in patients with normal bone health at baseline (n = 1,872, HR = 0.44, p $<$ 0.0001) and in patients who started the trial already osteopenic (n = 1,548, HR = 0.57, p = 0.0021). Denosumab also significantly increased BMD of the lumbar spine (9.99%), total hip (7.88%) and femoral neck (6.49%) at 36 months (compared to placebo, all adjusted p-values $<$ 0.0001). There were no differences between the Denosumab and placebo groups with respect to patient incidence adverse events (1366 vs 1334), or serious adverse events (521 vs 511). Despite proactive adjudication of potential ONJs by an independent expert panel, no ONJ case was observed. **Conclusion:** Adjuvant Denosumab significantly reduces fractures in postmenopausal BC patients receiving AI, and improves bone mineral density. Adjuvant Denosumab can be administered at this schedule with a favorable safety profile. Clinical trial information: NCT00556374.

505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Five-year analysis of the phase II NeoSphere trial evaluating four cycles of neoadjuvant docetaxel (D) and/or trastuzumab (T) and/or pertuzumab (P). *First Author: Luca Gianni, Oncologia Medical, Ospedale San Raffaele IRCCS, Milan, Italy*

Background: InNeoSphere, four cycles of T+D, P+T+D, P+T, or P+D, followed by surgery and adjuvant chemotherapy plus conventional T, were evaluated in 417 women with locally advanced, inflammatory, or early HER2-positive breast cancer. The addition of P to T+D led to a statistically significant and clinically meaningful 16.8% increase (95% confidence interval [CI], 3.5–30.1; $P = .0141$) in pathologic complete response rate (pCR) in the breast (bpCR, ypT0/is; primary endpoint), and a 17.8% increase in total pCR in the breast and axilla (tpCR, ypT0/is, ypN0). **Methods**: A pre-planned descriptive intent-to-treat analysis was conducted 5 years after randomization of the last patient, to evaluate disease-free survival (DFS; time from surgery until progression or death) and progression-free survival (PFS; time from randomization until progression or death, equivalent to the commonly used definition of event-free survival). **Results:** Three-year survival rates, hazard ratios (HRs), and 95% CIs for the main analysis of P+T+D compared with T+D are summarized in the table. In the P+T and P+D arms, respectively, 3-year survival rates were 88% and 84% for DFS, and 81% and 82% for PFS. Across all four treatment arms pooled, for all patients who achieved tpCR versus all patients who did not achieve tpCR, the HR for DFS was 0.68 (95% CI, 0.36–1.26) and the HR for PFS was 0.54 (95% CI, 0.29–1.00). **Conclusions:** Longer-term outcomes as defined by three-year survival rates, are in line with the results of the primary endpoint (bpCR), suggesting a benefit of P added to T+D that persists over time despite use of identical adjuvant therapy in the P+T+D and T+D arms. These results also support the association between pCR and improvements in long-term outcomes. Clinical trial information: NCT00545688.

506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Efficacy of 12-weeks of neoadjuvant TDM1 with or without endocrine therapy in HER2-positive hormone-receptor-positive early breast cancer: WSG-ADAPT HER2+/HR+ phase II trial. *First Author: Nadia Harbeck, University of Munich, Otterfing, Germany*

Background: Evidence suggests differential efficacy of standard neoadjuvant chemo- + targeted therapy in HER2+ early breast cancer (eBC) according to hormone-receptor (HR) status. ADAPT HER2+/HR+ aims to identify responders to dual targeted therapy, which has not been widely explored. **Methods:** 380 patients (pts) receive 12 weeks of neoadjuvant therapy. Arms A/B: T-DM1 (3.6 mg/kg q3w) ± endocrine therapy (ET) (pre-: tamoxifen; postmenopausal: aromatase inhibitor); Arm C (control): q3w trastuzumab + ET. After surgery, pts are to receive 4xEC – 12xpaclitaxel weekly (investigators' discretion) and complete 1y trastuzumab. Trial tests pCR (yPN0 and ypT0/is) in Arms A and B compared to control (C). Biomarkers are measured at baseline and after 3 weeks. **Results**: Pre-planned interim analysis (n = 130) aimed to identify an early-response biomarker (e.g. Ki-67 drop) and to validate trial assumptions. Median age was 49 years; 55% were pre-menopausal; 40% had cT1 tumors, 51% cT2; 68% had cN0, 27% cN1; 75% had G3. Median baseline Ki67 was 30%. In all arms, 95-100% received all 4 therapy cycles. 15 SAEs occurred in 12 pts (A:4; B:6; C:2), majority are CTC grades 2 (9) or 3 (4); all pts completely recovered without sequelae. Overall pCR rate was 30.8%: A: 40.5%, B: 45.8%, C: 6.7%. The difference between either arm A or B vs. C was significant (p $<$ 0.001), but not A vs. B. Exploratory analysis suggests benefit of adding ET to T-DM1 in pre- (pCR: 28.6% for T-DM1 single agent vs. 47.6% with ET) but not in postmenopausal pts (pCR: 64.3% vs. 50%). Ki-67 quantification in the 3-week biopsy was not possible in 43.1%, mostly due to low tumor cell counts ($<$ 500); of the remaining tumors, 21.6% (16/74) had Ki-67 ≤ 10% after first cycle. Final data set is required to substantiate these findings which may also be impacted by the different ET options (Tam vs. AI). **Conclusions:** The interim analysis demonstrates for the first time clinically meaningful pCR rates ($>$ 40%) after only 12 weeks of T-DM1 ± ET without systemic chemotherapy in HER2+/HR+ eBC. Ongoing biomarker analyses include PI3K mutations and intrinsic subtypes. In 1/2015, registration phase was completed at 449 pts. Clinical trial information: NCT01745965.

507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III, randomized study of trastuzumab emtansine (T-DM1) ± pertuzumab (P) vs trastuzumab + taxane (HT) for first-line treatment of HER2-positive MBC: Primary results from the MARIANNE study. *First Author: Paul Anthony Ellis, Guy's Hospital and Sarah Cannon Research Institute, London, United Kingdom*

Background: In phase II and III studies, treatment with T-DM1 or with P + H + docetaxel has shown statistically significant increases in progression-free survival (PFS) and overall survival (OS) vs control regimens in patients with HER2-positive MBC. The combination of T-DM1 + P resulted in synergistic inhibition of tumor cell line proliferation in vitro. This and preliminary data from a phase II clinical trial provided the rationale for further study. **Methods:** In MARIANNE (NCT01120184), patients with centrally assessed HER2-positive (IHC3+ or ISH+) progressive/recurrent locally advanced BC or previously untreated MBC with a ≥ 6-month interval since treatment in the (neo)adjuvant setting with taxanes or vinca alkaloids were randomized 1:1:1 to HT (docetaxel or paclitaxel + H), T-DM1 (T-DM1 + placebo, hereafter T-DM1), or T-DM1 + P, at standard doses. The primary end point was PFS assessed by independent review. Comparisons between HT and T-DM1 or T-DM1 + P were considered separately. PFS was tested first for non-inferiority and for superiority only if non-inferiority was achieved. **Results:** At the clinical cutoff date, September 16, 2014, 365 patients had been randomized to HT, 367 to T-DM1, and 363 to T-DM1 + P. In each arm, approximately 31% of patients had prior (neo)adjuvant treatment with HER2-directed therapy. Approximately 37% overall had de novo disease. The study met the PFS non-inferiority end point, but not the superiority end point. OS was similar across treatment arms. **Conclusions:** These data demonstrate non-inferiority in PFS between T-DM1–containing arms and control. T-DM1–containing regimens were associated with a different toxicity profile than the control regimen. Clinical trial information: NCT01120184.

508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Neratinib after adjuvant chemotherapy and trastuzumab in HER2-positive early breast cancer: Primary analysis at 2 years of a phase 3, randomized, placebo-controlled trial (ExteNET). *First Author: Arlene Chan, Breast Cancer Research Centre - WA & Curtin University, Perth, WA, Australia*

Background: Neratinib (N) is an irreversible pan-HER tyrosine kinase inhibitor with clinical efficacy in trastuzumab (T) pre-treated HER2-positive (HER2+) metastatic breast cancer. In HER2+ early breast cancer (EBC), a significant proportion of patients (pts) recur with invasive disease despite T-containing adjuvant therapy. **Methods:** Women with stage 1–3c EBC with the last T dose ≤2y (later modified to stage 2–3c and ≤1y, respectively) and locally confirmed HER2+ were eligible. Pts were randomized to N 240mg PO once daily or placebo (P) for 12m, stratified by ER/PR, nodal status and T schedule. A global amendment reduced follow-up to 2y from study entry. A current amendment restores the original 5-y follow-up. Invasive DFS (IDFS) at 2y is the primary endpoint and other secondary endpoints include DFS + DCIS, distant DFS (DDFS), CNS incidence, and patient-reported outcomes. Overall survival (OS) is an event-driven secondary endpoint. Efficacy analyses were ITT using a stratified Cox model and log-rank test (1-sided α=0.025). **Results:** 2,821 pts were randomized between 07/2009 and 10/2011 (1,409 N; 1,412 P). Median time from last T was 4.4m N vs 4.7m P. Baseline characteristics were balanced between arms. Efficacy results are shown below. Pre-planned subset analyses showed a lower IDFS HR in ER/PR+ pts (n=1,616; HR=0.51 [0.33–0.77]) and in a centrally confirmed HER2+ cohort (HR=0.52 [0.34–0.79]). Diarrhea was the most common adverse event (AE) for N pts with 40% G3 (1pt G4). Other individual AEs ≥G3 occurred in < 4% N pts. Ejection fraction decrease ≥G2 was seen in 1.3% N vs 1.1% P pts. Mean relative dose intensity (RDI) was 88% in N vs 98% in P pts. **Conclusions:** ExteNET demonstrates that 12m of N following standard chemotherapy + T improves IDFS and DFS-DCIS at 2y in HER2+ EBC. Diarrhea, the most common AE, was manageable. Additional follow-up will allow assessment of 5-y IDFS and OS. ClinicalTrials.gov: NCT00878709. Clinical trial information: NCT00878709.

Efficacy endpoint	2-y rate, % N (n=1,409)	2-y rate, % P (n=1,412)	HR (95% CI)	P-value (1-sided) stratified log rank
IDFS	93.9	91.6	0.67 (0.50–0.91)	0.0046
DFS-DCIS	93.9	91.0	0.63 (0.46–0.84)	0.0009
DDFS	95.1	93.7	0.75 (0.53–1.05)	0.0447

509 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Meta-analysis of breast cancer expression data using published gene signatures to reveal key cellular processes implicated in chemosensitivity and resistance. *First Author: Daniel G. Stover, Dana Farber Cancer Inst, Brookline, MA*

Background: Although many pathways and cell states are implicated in therapeutic resistance, predicting response to chemotherapy remains a challenge. **Methods:** We assembled expression data and pathologic complete response (pCR) versus residual disease (RD) status for 1,507 breast cancer samples collected prior to neoadjuvant chemotherapy. For each sample, we evaluated 118 published gene signatures including signaling, lineage, cell state, immune, and microenvironmental processes. **Results:** Among all signatures, the strongest predictors of pCR vs. RD were proliferation-related. Microarray data from a breast epithelial cell morphogenesis assay demonstrated that five separate proliferation signatures correlated with in vitro proliferation. To assess how proliferation contributes to chemosensitivity, we evaluated genes differentially expressed in patients with pCR versus RD (FDR-adjusted $p < 0.05$, limma) before and after normalizing data for proliferation using two distinct proliferation signatures. Among ER+ breast cancer and ER+ subsets Luminal A and B, > 95% of differentially expressed genes were proliferation-associated, suggesting that proliferation differences account for most of the variation in ER+ chemosensitivity. In comparison, among triple-negative breast cancers (TNBCs) and the basal-like subset, only 72.0% and 35.4% of differentially expressed genes, respectively, were proliferation-associated. For TNBCs, signatures associated with chemotherapy response clustered into five key areas: proliferation, mesenchymal phenotype, TGF-beta signaling/stromal features, cyclin and Src activation, and ER signaling (possibly low-level not detected by IHC). Stratifying 175 TNBCs with zero (N0) or few positive lymph nodes (N1) by high versus low activity of three signatures—proliferation, epithelial-to-mesenchymal transition, and Src signaling—was highly predictive of failure to achieve pCR (negative-predictive value 0.965; 95% CI 0.912-0.990). **Conclusions:** Interrogating multiple signatures in a large expression data set allows insights into key processes associated with chemoresistance and sensitivity in breast cancer.

510 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Prognostic significance of tumor-infiltrating CD8+ and FOXP3+ lymphocytes in residual tumors and alterations in these parameters after neoadjuvant chemotherapy in triple-negative breast cancer. *First Author: Minoru Miyashita, Tohoku University Graduate School of Medicine, Sendai, Japan*

Background: A reliable marker is needed to identify high-risk patients eligible for post-neoadjuvant trials of new investigational drugs for breast cancer. We investigated the prognostic value of CD8+ TILs and FOXP3+ TILs in residual tumors after neoadjuvant chemotherapy (NAC) and changes in these parameters before and after NAC in patients with triple-negative breast cancer (TNBC). **Methods:** One hundred and thirty-one TNBC patients who received NAC were identified. CD8+ TIL and FOXP3+ TIL in residual tumors and biopsy specimens were investigated. The CD8+ TIL and FOXP3+ TIL status of the residual tumors was assessed, and the rates of changes in these cancers caused by NAC were calculated. **Results:** TNBC patients with high CD8+ TIL levels or a high CD8/FOXP3 ratio in residual tumors had significantly better recurrence-free survival (RFS) and breast cancer-specific survival (BCSS) than patients with low values of these parameters. In multivariate analyses, CD8+ TIL exhibited strong prognostic significance for RFS, with a hazard ratio (HR) of 3.44 (95%CI, 1.74-7.19, $P = 0.0003$). The CD8/FOXP3 ratio was also significantly correlated with RFS (HR = 2.00, 95%CI, 1.01-4.26, $P = 0.049$). TNBC with larger residual tumor size and positive lymph node status was independently associated with worse RFS ($P = 0.0032$ and $P = 0.0090$, respectively). High CD8+ TIL levels were a markedly powerful indicator of improved BCSS, with an HR of 3.58 (95%CI, 1.48-9.58, $P = 0.004$). Nodal status was also associated with BCSS ($P = 0.003$). TNBC with a high rate of CD8+ TIL changes was associated with significantly better RFS compared to the low group ($P = 0.011$). Higher rates of changes in the CD8/FOXP3 ratio were significantly correlated with both better RFS and BCSS compared to lower rates ($P = 0.011$ and $P = 0.023$, respectively). **Conclusions:** This study is the first to demonstrate that high CD8+ TIL and a high CD8/FOXP3 ratio in residual tumors and increases in these parameters after NAC accurately predict improved prognosis in TNBC patients with non-pCR following NAC. These parameters may be a surrogate for adjuvant treatment in patients with residual disease in the neoadjuvant setting.

511 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Correlation of *PIK3CA* mutation with pathological complete response in primary HER2-positive breast cancer: Combined analysis of 967 patients from three prospective clinical trials. *First Author: Sibylle Loibl, German Breast Group, Neu-Isenburg, Germany*

Background: The predictive value of *PIK3CA* mutations in HER2+ BC has been shown conclusively. Data on subgroup analyses are lacking. **Methods:** We combined data from three studies evaluating *PIK3CA* mutations as predictor for pCR: the neoadjuvant GEPAR studies (n = 504) (Loibl et al. *JCO* 2014), the Neo-ALTTO study (n = 355) (Majewski et al. *JCO* 2015) and the CHERLOB study (n = 108) (*ESMO* 2014). Patients received either trastuzumab (T), lapatinib (L) or the combination T/L in addition to taxane-based chemotherapy. *PIK3CA* was genotyped in tumor biopsies prior to therapy. **Results:** 967 patients were included. Median age was 48 (range 21-80); most tumors were cT1-2 (69.5%); cN+ (61.7%); ductal invasive (93.4%), grade 3 (56.2%); HR+ (56.2%). Overall, 21.7% had at least one mutation, 7.2% in exon 9 and 14.5% in exon 20. *PIK3CA* mutations were equally frequent in the HR+ compared to the HR- group: 21.7% in both groups. Overall, pCR rate was significantly lower in the *PIK3CA* mutant (mut) compared to the wild type (wt) group (16.2% vs 29.6%; $p < 0.001$). There was no difference in pCR rate whether the mutation was in exon 9 (15.7%) or exon 20 (16.4%). Within the HR+ subgroup the *PIK3CA* mut pts had a pCR rate of only 7.6% compared to 24.2% in the wt group ($p < 0.001$). In contrast, the difference in pCR (27.2% vs 36.4%) according to *PIK3CA*mutation status was not significant in the HER2+/HR- group ($p = 0.125$; interaction $p = 0.036$). The pCR rate for mut vs wt was 20.3% vs 27.1% for T ($p = 0.343$); 11.3% vs 16.9% for L (0.369) and 16.7% vs 39.1% for T/ L ($p < 0.001$). In the HR+ T/L group the pCR rate was 5.5% vs 33.9% (interaction $p = 0.008$). **Conclusions:** This metaanalysis confirms a significantly lower pCR rate in HER+, *PIK3CA* mutant tumors after anti-HER2 treatment. Patients with a HER2+/HR+/*PIK3CA* mutant tumor had a pCR rate of 5.5% only when treated with double-blockade and might be considered for alternative treatment. The project was funded within the EU-FP7 project RESPONSIFY No 278659.

Predictive biomarkers of everolimus efficacy in HER2+ advanced breast cancer: Combined exploratory analysis from BOLERO-1 and BOLERO-3. *First Author: Dennis J. Slamon, School of Medicine/Translational Oncology Research Laboratory, University of California, Los Angeles, Los Angeles, CA*

Background: Two phase 3 trials BOLERO-1 and BOLERO-3 evaluated the addition of everolimus (EVE) to trastuzumab (TRAS) + chemotherapy in HER2+ advanced breast cancer (ABC). In BOL-3, heavily pretreated patients (pts) derived a statistically significant benefit from EVE, while BOL-1 (first-line EVE) did not meet the primary endpoints. This analysis aimed to identify biomarkers predictive of EVE efficacy using data from both trials. **Methods:** Exons of 282 cancer related genes were analyzed by next generation sequencing (NGS). PTEN levels were determined by IHC. Hyperactive PI3K pathway was defined as pts with low PTEN or known PIK3CA or AKT1 E17K mutation (narrow def) or mutation in any member of the PI3K/Akt/mTOR pathway (broad def). Correlations between biomarkers and PFS were evaluated by uni- and multi-variate Cox models. **Results:** Five hundred and sixty-one archival tumor samples (BOL-1 302; BOL-3 259) were successfully analyzed. PI3K pathway gene alterations were seen in ~45% of samples. A trend of greater benefit from EVE was observed in pts with PI3K pathway activation (individual trials). In a combined analysis from both trials, pts with PIK3CA mutations (HR = 0.69) or low PTEN (HR = 0.5) derived more benefit from EVE. A robust positive correlation between PI3K hyperactivity and PFS benefit was observed using both narrow def (HR = 0.67 vs normal PI3K activity HR = 1.2) and broad def (HR = 0.61 vs normal PI3K activity HR = 1.38). In a multivariate analysis, interaction between PI3K status and treatment effect was statistically significant (p = 0.016). **Conclusions:** This exploratory analysis suggests that pts with hyperactive PI3K signaling pathway derive greater benefit from adding EVE to TRAS + chemotherapy in HER2+ ABC. Clinical trial information: NCT00876395, NCT01007942.

513 Poster Discussion Session; Displayed in Poster Session (Board #1), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Validation of prediction of distant recurrence (DR) by Prosigna (PAM50) in subgroups of a Danish Breast Cancer Cooperative Group (DBCG) cohort of node-positive (N1), hormone receptor positive (HR+), postmenopausal early breast cancer (EBC) patients allocated 5yr of endocrine therapy (ET). *First Author: Bent Ejlertsen, The Danish Breast Cancer Cooperative Group, DBCG Secretariat, Rigshospitalet, Copenhagen, Denmark*

Background: N1, HR+ EBC patients are routinely treated with both ET and chemotherapy (CT). Identification of N1 patients with good outcome who may be spared CT remains an elusive goal. In a combined analysis of 2 randomized trials, Prosigna (PAM50) risk of recurrence (ROR) score identified low risk N1 patients with outcome equivalent to N0 disease. We examined the ability of ROR to predict 10yr DR for patients with 1, 2 or 3+ nodes in a comprehensive nationwide cohort from Denmark to identify N1 women who may be spared overtreatment with CT. **Methods:** Using the population based DBCG database primary FFPE tumor blocks and follow-up data were collected from all Danish women diagnosed from 2000-2003 with HR+, postmenopausal, N1 EBC treated with ET alone (N = 1,480). PAM50 on the NanoString nCounter Analysis System categorized patients as Low, Intermediate, or High risk using pre-specified cutoffs varied by number of positive nodes. Multivariate analyses were performed to assess the ability of PAM50 to predict DR in patients with 1, 2, or 3+ nodes. **Results:** 1,466 (99%) passed PAM50 QC. Median follow-up was 9.25 years. Risk of 10yr DR based on the number of positive nodes and PAM50 is shown in the Table. Including ROR in a Fine and Gray's multivariate proportional sub-hazards model improved outcome prediction for patients with 1, 2, and 3+ nodes (P < 0.0001, 0.0001, 0.008 respectively). **Conclusions:** Prosigna (PAM50) improves outcome prediction in N1 patients over standard variables. PAM50 can identify at least 37% of patients with 1 and 15% with 2 positive nodes who have an excellent prognosis and may be spared adjuvant CT in a real world setting.

	DR risk by Risk Group % [95%CI]			DR risk by Subtype % [95%CI]

514 Poster Discussion Session; Displayed in Poster Session (Board #2), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Final analysis of a randomized comparison of letrozole (Let) vs observation (Obs) as late reintroduction of adjuvant endocrine therapy (AET) for postmenopausal women with hormone receptor positive (HR+) breast cancer (BC) after completion of prior AET: ANZBCTG 0501 (LATER). *First Author: Nicholas Zdenkowski, Australia and New Zealand Breast Cancer Trials Group, Newcastle, Australia*

Background: AET for postmenopausal women with HR+ early BC has until recently been limited to 5 yrs of tamoxifen, an aromatase inhibitor or a sequential combination of these. However, after 5 yrs of AET, BC events continue to occur at a high rate (2% per yr) for at least another 10 yrs. The LATER trial was designed to compare 5 yrs of Let 2.5mg daily as late reintroduction of AET to Obs (= usual care) in postmenopausal women after ≥ 4 yrs of AET. **Methods:** LATER was a prospective open label randomized trial for postmenopausal women who were BC free and had completed ≥ 4 yrs of AET for HR+ early BC more than 1 yr prior to study entry. The primary outcome was the rate of invasive BC events (defined as new invasive primary, local, regional or distant recurrence or contralateral BC) for Let arm compared to Obs. Secondary outcomes included disease-free survival (DFS), overall survival (OS) and toxicity. To reject the null hypothesis in favor of a 60% reduction in the primary outcome with β = 0.10 and 2α = 0.05, 1700 patients were required. In Oct 2014 the independent data and safety monitoring committee recommended to cease trial follow up and to release the data for analysis due to a low event rate. **Results:** Between May 2007 and March 2012, 360 patients were randomized (181 Let; 179 Obs), after which enrolment ceased due to a low accrual rate. Patients completed prior AET a median of 2.5 yrs before randomization. N+ 33.9%, N- 60.0%, unknown 6.1%. Prior AET was aromatase inhibitor only in 11.1%, SERM in 50.6% and a sequential combination in 38.3%. In the ITT population, at a median 3.0 yrs follow-up, 1.1% of patients in the Let arm had experienced an invasive BC event vs 8.4% in the Obs arm (difference 7.3%, 95% CI 2.9-11.6, p = 0.001, conditional binomial exact test). DFS events occurred in 6.1% vs 11.7% (p = 0.06) and death in 1.7% vs 2.2% (p = 0.70) in the Let and Obs arms respectively. **Conclusion:** In postmenopausal women who had completed ≥ 4 yrs of AET for HR+ early BC, Let significantly reduced the incidence of late invasive BC events. Clinical trial information ACTRN 012607000137493. Clinical trial information: 01260700013749.

Ovarian function suppression, symptom burden, and quality of life in young women with breast cancer: A prospective study. *First Author: Shoshana M. Rosenberg, Dana-Farber Cancer Institute, Boston, MA*

Background: Recent clinical trial data have demonstrated that ovarian function suppression (OS) in addition to tamoxifen (T) or aromatase inhibitors (AI) can improve breast cancer free survival in young women with hormone positive (HR+) breast cancer. We evaluated the impact of OS on quality of life (QOL) in young women, a population at risk for worse QOL outcomes and survival. **Methods:** Patient reported symptom and QOL data were collected 1 year after dx as part a cohort study enrolling women newly dx'd with breast cancer age ≤40. Severity of symptoms (Breast Cancer Prevention Trial checklist) was compared between women on OS+T vs. T alone by Fisher's exact test. For QOL (Cancer Rehabilitation Evaluation System (CARES) physical, psychosocial, sexual subscales), differences in mean scores between groups were compared with t-tests. All were stratified by receipt of chemotherapy. Due to small numbers, women on AIs were excluded. **Results:** Of444 women with Stage 0-III, HR+ disease on T, 106 (24%) reported OS use. The Table details symptom prevalence (% at least moderately bothersome) by group. Among women who had chemo (n=333), women on OS had higher (p≤.05) mean CARES scores (worse QOL) on all 3 subscales. Mean scores for women who did not receive chemo (n=111) were not significantly different between groups. **Conclusions:** Young breast cancer survivors on endocrine therapy have a high symptom burden which should be considered in treatment decision making and survivorship care. Women on OS+T experience more vasomotor and (in those who received chemo) greater cognition issues, and poorer QOL in the early survivorship period compared to T alone. Early intervention to reduce symptom burden should be offered to young women to potentially improve QOL, enhance adherence and optimize survival.

Tumor *PIK3CA* genotype and prognosis: A pooled analysis of 4,241 patients (pts) with early-stage breast cancer (BC). *First Author: Dimitrios Zardavas, Breast International Group, Brussels, Belgium*

Background: *PIK3CA* mutations (mt) are frequently observed in BC but their clinical relevance is unclear. We performed an individual pt data pooled-analysis to evaluate the prognostic impact of *PIK3CA* status on early-stage BC. **Methods:** Participating studies were identified by literature search. Associations of *PIK3CA* status with clinicopathologic characteristics were tested. Cox regression models were applied adjusting for age, tumor size, nodes, grade, ER and HER2 status, treatment and study. Invasive disease-free survival (IDFS) was the primary endpoint, followed by distant disease-free survival (DDFS), overall and by BC subtypes. **Results**: Data from 16 studies were included. Median age was 56yrs (18-96) and median follow-up was 6.5yrs; 1384 pts (33%) received chemotherapy, 1147 (27%) endocrine monotherapy, 816 (19%) both and 894 (21%) none/unknown. *PIK3CA* mt occurred in 26.9%: 55.2% exon 20 and 36.2% exon 9. They were associated with ER+ tumors, increasing age, lower grade (all $p < 0.001$) and smaller size ($p = 0.04$). Incidence of *PIK3CA* mt was 15%, 23%, 32% in the ER-/HER2-, HER2+ and ER+/HER2- subtypes respectively ($p < 0.001$). In the univariate analysis, *PIK3CA* mt were associated with better IDFS: HR = 0.85 [95%CI:0.75-0.96]; p = 0.0009. A statistically significant non-proportional prognostic effect was observed ($p = 0.02$): during the first 3 yrs *PIK3CA* mt had better IDFS (HR = 0.73 [0.60-0.88]) compared to after 3yrs (IDFS HR = 0.96[0.8-1.1]; P interaction:0.03). There was no significant interaction by BC subtype ($p = 0.6$) and no significant differences by exon 9 or 20 site ($p = 0.7$). In the multivariate analysis, *PIK3CA* status did not remain statistically significant overall (HR = 0.94 [0.8-1.2]; p = 0.6) nor in the first 3 yrs. Results were similar for the DDFS endpoint. In further analyses, a significant interaction between *PIK3CA* status and age was found, remaining after adjustment ($P = 0.04$). *PIK3CA* mutant BCs had significantly better IDFS in women $\leq$ 50yrs (HR = 0.65 [0.4-0.95]) but not $>$ 50yrs (HR = 1.10 [0.9-1.4]; Pint = 0.01). **Conclusions:** *PIK3CA* mutations are associated with a better prognosis. This effect is greatest in young women for whom *PIK3CA* status could potentially refine treatment decisions.

HER3 and paxillin signaling in ER+ HER2- metastatic breast cancer (MBC) patients receiving letrozole (L) vs letrozole plus dasatinib (L+D) in a randomized phase II trial. *First Author: Joyce O'Shaughnessy, Baylor Sammons Cancer Ctr US Onc, Dallas, TX*

Background: BC invasion is mediated by Src and its downstream target, the adhesion protein, paxillin (Pax). A randomized phase II trial of L + the Src inhibitor dasatinib demonstrated that L+D improved median PFS to 20 mos from 10 mos with L alone as first-line therapy for ER+ HER2-negative MBC (Paul D. SABCS 2013, S3-07). We conducted reverse phase protein microarray (RPMA) on pts' primary BCs to identify phosphoproteins associated with recurrence and with outcome on L vs L+D. **Methods:** 48 pts' FFPE primary breast cancers were acceptable for RPMA at a CLIA-certified laboratory (Theranostics Health, Rockville, MD). Immunostaining was carried out with 20 antibodies directed against HER pathway proteins, MET, Src, and Pax. Student t-test or Mann-Whitney U test and Spearman correlation coefficient (ρ) were used to assess biomarker association with PFS $<$ 6 mos vs $>$ 6 mos by treatment arm (unpaired 2 tails, p value). **Results:** Median PFS for the 48 pts was 19.2 mos for L+D (N=21) vs 9.2 mos for L (N=27). ~90% of the BCs overexpressed HER3, p-mTOR, p-4EBP1, p-JAK2, p-STAT3 and 50% overexpressed p-Pax. Across all pts, protein linkage Pearson correlations (r) showed strong associations between p-Pax & p-HER2 (r=0.74), HER3 & p-HER2 (r=0.79), p-HER1 & p-HER2 (r=0.82), HER3 & p-MET (r=0.72) and p-Pax & p-MET (SR=0.93). Evaluating all 48 pts, PFS $<$ 6 mos was correlated with HER3 expression ($p< 0.01$), p-HER3 (p=0.02), p-HER2 (p=0.04) and HER1 (p=0.05). Evaluating L vs L+D pts, PFS $<$ 6 mos was associated with HER3 ($p< 0.01$), p-HER3 (p=0.03), p-HER2 (p=0.07), HER1 (p=0.05), p-Pax (p=0.02), and p-Met (p=0.05) expression only in L alone pts and not in L+D pts. PFS $<$ 6 mos with L+D was associated with p-Src (ρ=0.9, p=0.04) and p-Pax (ρ=0.71, p=0.11)]. p-Pax expression was inversely correlated with prolonged PFS in L alone (ρ= -0.7, p=0.04) but not in L+D pts. **Conclusions:** Primary ER+ HER2- BCs that recurred expressed high levels of HER3 and downstream phosphoproteins. HER3 overexpression correlated with p-HER2, p-HER1, p-MET, and p-Pax expression and predicted for short PFS with L alone but not with L+D. These findings suggest that dasatinib may inhibit HER3 signaling in ER+ HER2- MBC pts.

DNA methylation in serum as an independent marker of outcome and treatment response in TBCRC 005: A prospective study in metastatic breast cancer (MBC) patients. *First Author: Kala Visvanathan, Johns Hopkins Kimmel Cancer Center and Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Accurate markers are needed to assess the effect of therapies early in MBC. Emerging studies suggest that methylated tumor DNA in blood can predict poor prognosis. In the TBCRC 005 multi-site prospective biomarker study we tested whether serum DNA methylation assessed by the cMethDNA assay (PMID 2437128) is predictive of disease outcomes in MBC and compared our results to circulating tumor cells (CTC). **Methods:** Serum was collected from 2007-2009, and methylation of *AKR1B1, HOXB4, RASFGR2, RASSF1A, HIST1H3C, TM6SF1* loci were determined in duplicate serum samples from 141 women with measurable MBC at baseline, week 3-4 and week 8-12. For each patient, the cumulative methylation index (CMI) was calculated, log-transformed, and modeled as a continuous or binary variable. The study specific cut-point was based on maximally selected logrank statistic and unbiased point estimates were obtained by cross-validation. Cox proportional hazard models were used to evaluate association between CMI at baseline and week 3-4, with PD at first re-staging, PFS, and OS. The added value of CMI to prognostic factors including CTC was assessed using the likelihood ratio test and concordance probability estimates. **Results:** Median age was 56 years; 89% white; 60% HR+/HER2-. Patients with high CMI at week 3-4 had a median OS of 12.8 months compared to 22.6 months among those with a low CMI. PFS results were similar. An increase in CMI units at 3-4 weeks was associated with PD ($P = 0.003$), PFS ($P = 0.008$), and OS ($P < 0.001$) in multivariate analyses. In joint models both CMI and CTC were predictive of PFS and OS. Furthermore, an increase in CMI from baseline to week 3-4 was significantly associated with PD (HR 1.58, CI 1.21-2.05, $P < 0.001$), worse PFS (HR 1.22, CI 1.10-1.35, $P < 0.001$) and OS (HR 1.10, CI 0.99-1.22, $P = 0.077$). Change in CTC between the same time points was not associated with disease outcomes. **Conclusions:** This is the most comprehensive study to date of DNA methylation in blood of MBC patients. The cMethDNA CMI of this gene marker set is an independent prognostic factor in MBC and is promising as useful marker for risk stratification and early assessment of treatment.

Oncotype DX in *BRCA*-associated vs. sporadic breast cancers: Differences based on germline mutation status and potential implications for adjuvant systemic therapy (AST). *First Author: Payal Deepak Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Biological differences between *BRCA*-associated and sporadic breast cancer (BC) could warrant different recommendations for AST among patients (pts) with phenotypically similar cancers. Onco*type* DX (Genomic Health Inc., CA) is prognostic, quantifies predicted benefit of AST, and is used to guide clinical decisions in pts with early-stage hormone receptor-positive (HR+) BC. The results of this assay have not been described in pts with deleterious germline *BRCA(gB)* mutations. **Methods:** Pts seen at MSKCC for HR+, stage I/II, node-negative BC with Onco*type* DX results, were retrospectively ascertained and medical records reviewed. *B1/2* mutation carriers (cases) were identified and matched 1:2 to noncarriers (controls), based on age at diagnosis and tumor size. Two sample nonparametric tests were used to compare *B1* vs. *B2* pts. Conditional logistic regression (SAS v 9.4) assessed differences in Oncotype DX recurrence scores (RS) and risk stratification by mutational status. **Results:** 50 cases (*B1*: n = 19, *B2*: n = 31) and 100 controls were included. Cases and controls were well-matched for age ($p = 0.9$) and tumor size ($p = 0.6$). Cases were more likely to have high-grade tumors ($p = 0.004$). Median RS was 23 for *B1* and 24 for *B2* carriers ($p = 0.6$). Stratification into low-, intermediate-, and high-risk categories was similar between *B1* and *B2* carriers ($p = 0.3$). Median RS was significantly higher for cases than for controls (RS 24 vs. 16, $p < 0.0001$). Risk stratification also differed based on mutational status ($p = 0.0002$). Cases had more high-risk (28% vs. 7%) and intermediate-risk (56% vs. 36%) disease than controls. Cases had less low-risk disease than controls (16% vs. 57%). Cases were significantly more likely to receive AST (74% vs. 46%, $p = 0.002$). **Conclusions:** Presence of a *gB1/2* mutation may be a biomarker for intrinsically less favorable disease in pts with early-stage, HR+ BC. Few affected *gB* carriers have RS indicating clear absence of benefit from AST. Increased use of, and benefit from, AST in *gB* carriers may mitigate otherwise inferior outcomes, accounting for the similar prognoses for carriers and noncarriers reported in the literature.

Efficacy of the PARP inhibitor (PI) ABT-888 (veliparib [vel]) either with carboplatin (carb) or as a single agent followed by post-progression therapy in combination with carb in patients (pts) with *BRCA1*- or *BRCA2*-(*BRCA*)-associated metastatic breast cancer (MBC). *First Author: George Somlo, City of Hope, Duarte, CA*

Background: Based on the concept of synthetic lethality combining platinum agents and PIs should benefit patients (pts) with *BRCA*-associated MBC. We report mature outcomes with vel alone, or with carb. **Methods:** Pts with germline *BRCA*-associated MBC, ECOG performance status of ≤ 2, without prior PI treatment were included. In phase I the maximum tolerated dose (MTD) of carb (AUC of 5) IV every 21 days, and vel 150 mg BID were defined. In phase II, pts received vel 400 mg BID and upon progression, carb and vel at the MTD. **Results:** Between 6/2010 and 4/2014, 72 evaluable pts (28 in phase I, 44 in phase II) with *BRCA1* (34 patients) or *BRCA2* (37 patients) mutations (1 pt had both) and with MBC were enrolled. The median age was 44-years (range; 28-68); 49% of pts had hormone receptor + MBC. Pts received a median of 1 (0 – 5) prior chemo-regimen for MBC. Response rate (RR) for the 28 pts in phase I was 50% [CR rate 18%] and 2 pts remain in CR at 43+ and 34+ cycles, both are on vel maintenance, alone; median progression-free survival (PFS) was 8.5 mos (95% CI 7.3-10.1), and median TTF was 8.3 mos (6.9-9.5). For 44 phase II pts treated with vel, the median PFS was 5.2 months (4.0-6.4) and including their cross-over carb/vel treatment the cumulative TTF was 6.7 months (4.6-8.5); 13/44 (30%) responded to vel; 2 pts are still on vel (1 with a PR at 14 cycles, 1 with a CR at 25 cycles); 1 pt converted to PR after cross-over to carb/vel. OS was 18.8 months (95% CI 15.0-26.3) for the 28 pts treated with the combination of carbo/vel, and 12.6 months (95% CI 11.7-NR) for the 44 pts treated with vel followed by carbo/vel ($p < 0.1$). In phase I, dose delay or adjustment was needed in 1/3 of the pts treated at the MTD within the first 3 cycles due to cytopenias. In phase II, 8/44 (18%) required dose adjustment on single agent vel, and 5 pts required dose adjustment after cross-over to carb/vel. **Conclusions:** The trend for longer TTF with the carb/vel combination first vs. vel followed by carb/vel, combined with the improved time OS suggest that carb/vel followed by vel maintenance deserves further testing in a randomized prospective trial. Clinical trial information: NCT01149083.

DNA repair deficiency biomarkers and identification of ER-positive breast cancer patients who may benefit from veliparib/carboplatin: Results from the I-SPY 2 trial. *First Author: Laura van't Veer, UC San Francisco, San Francisco, CA*

Background: In the I-SPY 2 TRIAL, HER2- patients were adaptively randomized to receive standard chemotherapy or the PARP inhibitor veliparib with carboplatin (V/C) and chemotherapy. V/C graduated in the triple-negative (TN) subtype, and we've previously shown that DNA repair deficiency signatures [BRCAness and PARPi-7] may predict V/C response. Here we combine these signatures into a composite measure of DNA repair deficiency. **Methods**: 115 HER2- patients (V/C: 71 and concurrent controls: 44) are considered in this analysis. BRCA1/2 germline mutation is assessed by Myriad Genetics. The PARPi-7 and BRCAness signature scores are computed from Agilent 44K array data. A patient is predicted DNA repair deficient if carrying a BRCA1/2 mutation or BRCA-like or PARPi7-high. We modify the I-SPY 2 Bayesian model to include DNA repair deficiency status to estimate the predictive probability of V/C demonstrating superiority to control in a 1:1 randomized phase 3 trial of 300 'biomarker-positive' patients. Our study is exploratory with no claims for generalizability and does not adjust for multiplicities of other biomarkers outside this study. **Results:** 15 patients are BRCA1/2 mutation carriers, of which 13 are PARPi7-high or BRCA-like. Comparing PARPi7 and BRCAness (62 PARPi7-low, 53 PARPi7-high; 59 non-BRCA1-like, 56 BRCA1-like) we find only moderate concordance (64%; kappa = 0.29). Altogether, 77 patients are predicted to be DNA repair deficient by one of these measures. 38% (21/56) of HR+/HER2- patients are predicted DNA repair deficient, along with nearly all (56/59) TN. In the V/C arm, 5/13 HR+/HER2- DNA repair deficient patients and 22/38 TN patients had a pCR (vs 0/8 and 5/21 controls respectively). When DNA repair deficient HR+/HER2- patients are added to the TN subset, the probability of phase 3 success is 94%, which is comparable to the graduating TN signature [97% in this model] while increasing patient prevalence. **Conclusions:** Our exploratory analysis suggests that 38% of HR+/HER2- patients in I-SPY 2 are DNA repair deficient and may benefit from V/C. If validated, DNA repair deficiency biomarkers may be used to select HR+/HER2- patients for future PARP inhibitor trials.

A phase Ib study of abemaciclib with therapies for metastatic breast cancer. *First Author: Sara M. Tolaney, Dana Farber Cancer Institute, Boston, MA*

Background: Abemaciclib, an inhibitor of cyclin dependent kinases CDK4 and CDK6, demonstrated safety and clinical activity as a single agent for hormone receptor positive (HR+) metastatic breast cancer (MBC) irrespective of *HER2* amplification (Tolaney, SABCS 2014). This study (NCT02057133) evaluates safety, pharmacokinetics (PK), and antitumor activity of abemaciclib combined with endocrine or HER2-targeted therapies for MBC. **Methods:** Patients (pts) in 6 cohorts received abemaciclib 150-200 mg every 12 hours (Q12H) with letrozole 2.5 mg/d (Part A), anastrozole 1 mg/d (Part B), tamoxifen 20 mg/d (Part C), exemestane 25 mg/d (Part D), exemestane 25 mg/d + everolimus 5 mg/d (Part E), or trastuzumab 6-8 mg/kg every 21 days (Part F). Pts in Parts A-E had HR+, HER2- MBC and in Part F had HER2+ MBC. Eligibility included measurable disease or nonmeasurable bone disease by RECIST v1.1, ECOG performance status ≤ 1, no prior chemotherapy for metastatic disease (Parts A-E), and ≥ 1 chemotherapy regimen for metastatic disease (Part F). Abemaciclib was given continuously until progression. Patients were assessed every 28 days in Parts A-E and every 21 days in Part F. Dose escalation cohorts of ≥ 3 pts receiving abemaciclib at 150 mg and 200 mg Q12H were included in Parts E and F. **Results:** A total of 65 pts started treatment with abemaciclib (200mg Q12H) by 16-Dec-2014 in Parts A-D. Pts had a median age of 57 years (range: 28-77) and a median of 3 prior systemic therapies (range: 1-8) for breast cancer. The most common ($\geq$ 20% overall in Parts A-D) possibly related treatment-emergent adverse events (TEAEs) (all grades %, G3 %) were diarrhea (95, 31), fatigue (71, 14), nausea (62, 6), neutropenia (31, 17), abdominal pain (31, 3), decreased appetite (29, 0), vomiting (28, 3), and anemia (25, 0). Diarrhea was manageable with antidiarrheal agents or dose reduction. No G4/5 TEAEs occurred. The disease control rate (CR + PR + SD) was 67% for Parts A+B [nonsteroidal aromatase inhibitors (36 pts)] with 2 confirmed PRs and 75% for Part C [tamoxifen (16 pts)]. Safety, PK, and efficacy results will be updated at presentation. **Conclusions:** Combinations of abemaciclib with endocrine therapies demonstrate manageable safety and early clinical evidence of antitumor activity. Clinical trial information: NCT02057133.

523 Poster Discussion Session; Displayed in Poster Session (Board #11), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Updated findings of a first-in-human, phase I study of margetuximab (M), an Fc-optimized chimeric monoclonal antibody (MAb), in patients (pts) with HER2-positive advanced solid tumors. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: Fc-dependent mechanisms such as antibody-dependent cellular cytotoxicity (ADCC) may be important for the activity of MAbs. M is a MAb to HER2 engineered for increased Fc-domain binding affinity to both low affinity variants of the activating Fcγ receptor, CD16A. In preclinical studies, M showed enhanced ADCC compared to an unmodified precursor. Results from the initial dose escalation have previously been reported. Here we describe pharmacokinetics (PK), safety and activity data for the expansion cohort and an alternative schedule, including responses in patients with refractory breast cancer (BC). **Methods:** Pts with refractory carcinomas that overexpress HER2 for whom no standard therapy was available were enrolled. Pt cohorts received escalating doses of M weekly for 3 of every 4 weeks (Regimen A) or every 3 weeks (Regimen B) by intravenous infusion in a 3+3 (Regimen A) or 6+6 (Regimen B) design. Additional safety and activity data were obtained in expansion cohorts of each regimen. Tumor response was determined using RECISTv1.1. PK was evaluated during all cycles. **Results:** Fifty-two patients received M (34 patients received 0.1 to 6.0 mg/kg in Regimen A and 18 patients received 10 to 18 mg/kg in Regimen B). The maximum tolerated dose was not exceeded for either regimen. Treatment was well-tolerated, with mostly Grade 1 and 2 toxicities consisting of infusion-related reactions and constitutional symptoms such as pyrexia, nausea, anemia, diarrhea, and fatigue. Partial responses were observed in 8 patients and stable disease in 21 patients. Tumor reductions were observed in 11 of 19 patients with BC, including 4 patients with confirmed partial responses, 3 of whom had received prior trastuzumab and lapatinib, with several durable responses of $>$ 30 weeks. Median progression free survival for patients with BC was 169 days. PK analysis showed that doses of 3 mg/kg in Regimen A and all doses in Regimen B achieved steady state trough levels sufficient to inhibit HER2 signaling. **Conclusions:** The results indicate that M is tolerated well and has promising activity in HER2-positive tumors including BC. Further development is ongoing. Clinical trial information: NCT01148849.

524 Poster Discussion Session; Displayed in Poster Session (Board #12), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Adaptively randomized trial of neoadjuvant chemotherapy with or without the Akt inhibitor MK-2206: Graduation results from the I-SPY 2 Trial. *First Author: Debu Tripathy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A key node of growth and survival signaling pathways is the Akt serine/threonine kinase that activates mTOR and downstream effectors. I-SPY 2 is a randomized neoadjuvant trial to test agents and combinations added to standard chemotherapy. Pathological complete response (pCR) defined as absence of invasive cancer in breast and nodes is the primary endpoint. We report efficacy results for allosteric Akt inhibitor MK-2206. **Methods:** Women with invasive breast cancer ≥2.5 cm on exam or ≥2 cm on imaging were adaptively randomized to 12 weekly paclitaxel (and trastuzumab if HER2+) cycles (control) or in combination with one of several experimental agents followed by doxorubicin/cyclophosphamide x 4. Patients (pts) are stratified to 8 subsets based on hormone-receptor (HR), HER2, and MammaPrint statuses, with combinations of subsets defining agent signatures. MK-2206 135 mg daily by mouth was evaluated in all 8 subsets. Adaptive assignment to the experimental arms was based on current Bayesian probabilities of superiority over control. Graduation by signature and futility stopping was based on Bayesian predictive probability of success in a 2-arm, N=300 Phase 3 randomized 1:1 trial with pCR endpoint. **Results:** MK-2206 graduated in the first 3 signatures in the table. Accrual ended with 93 patients assigned to that arm and when 56 pts had been concurrently randomized to control. Final posterior and predictive probabilities are shown for all 10 signatures. **Conclusions:** MK-2206 improves pCR rates compared to standard chemotherapy in several breast cancer signatures, defined mostly by HR- and HER2+, sufficiently for evaluation in a Phase 3 neoadjuvant trial powered for event-free survival. Safety data will be presented. Clinical trial information: NCT01042379.

Signature	Estimated pCR Rate			Probability MK2206 Superior to Control	Predictive Probability Success Phase 3
	MK-2206 N=93	Control N=56	Difference		
HR-/HER2+	64.1	35.7	28.4	97.3	87.0
HR-	46.7	26.1	20.6	98.6	82.7
HER2+	49.6	28.9	20.7	95.1	77.7
HR-/HER2-	40.2	22.4	17.8	96.8	75.9
MP+	39.3	22.5	16.8	97.0	74.1
All	35.2	21.1	14.1	97.9	68.6
HR+/HER2+	35.8	22.4	13.4	85.4	61.3
HER2-	29.3	18.0	11.3	95.0	59.0

HR+/HER2-	17.1	13.0	4.1	72.7	31.7

525 Poster Session (Board #13), Sat, 8:00 AM-11:30 AM

Molecular profiling of ER weakly-positive breast cancer. *First Author: Brandon S. Sheffield, University of British Columbia, Department of Laboratory Medicine and Pathology, Vancouver, BC, Canada*

Background: The estrogen receptor (ER) is a key predictive biomarker in the treatment of breast cancer. Luminal subtypes of breast cancer express *ESR1*, and are eligible for hormonal therapy. Standard laboratory assessment of ER status is currently immunohistochemistry (IHC)-based. Since the introduction of ER IHC, the threshold for positivity has decreased from 10% to ≥ 1% of tumor cells whilst methodological advances have increased the sensitivity of IHC detection. These trends have led to considerable uncertainty regarding the use of hormonal therapy in the setting of ER weakly-positive tumors. We report intrinsic subtype classification on a cohort of ER weakly-positive early stage cancers and discuss the implications on clinical treatment. **Methods:** Consecutive cases of untreated, surgically resected primary breast cancer were retrospectively identified from 4 tertiary care centres in British Columbia, Canada. All participating centres engage in routine external proficiency testing for breast biomarkers. Based upon the semiquantitative Allred score, combining staining intensity and percentage of tumor cells, ER-negative (Allred 0 and 2) and ER weakly-positive (Allred 3-5) cases were included. Gene expression profiling was performed using qRT-PCR. Intrinsic subtype prediction was made based upon the PAM50 gene expression signature. **Results:** 153 cases were included in the series; 62 cases originally diagnosed as ER weakly-positive and 91 ER-negative. Weak ER signal by IHC correlated poorly with *ESR1* gene expression by qRT-PCR (R^2 =0.2 [0.1-0.3, 95% CI]). Of the 62 cases originally assessed as ER weakly-positive, only 6 (10%) were confirmed as luminal subtype by gene expression profiling with the remaining cases showing basal-like or HER2-enriched subtypes (90%). In this highly enriched ER weakly-positive cohort, the positive predictive value of low-level ER staining for luminal subtype was extremely poor (8% [3%-18%, 95% CI]). **Conclusions:** Weak ER expression by IHC is a poor correlate of both luminal subtype and *ESR1* expression in breast cancer. In the setting of highly sensitive and robust IHC methodology, cutoffs for ER status determination and subsequent systemic therapy may need to be revisited.

526 Poster Session (Board #14), Sat, 8:00 AM-11:30 AM

Correlation of Breast Cancer Index HOXB13/IL17BR (H/I), ER, PR and HER2 and prediction of relative endocrine benefit from tamoxifen and anastrozole in HR+ breast cancer: A TransATAC study. *First Author: Yi Zhang, bioTheranostics, San Diego, CA*

Background: Estrogen receptor (ER) expression is a critical determinant of endocrine response, however additional biomarkers are needed to complete the molecular picture of treatment benefit, response and resistance to better individualize care. Previous studies have demonstrated that H/I expression ratio predicts benefit for ER+ breast cancer patients from tamoxifen in the Stockholm adjuvant trial and from letrozole in the MA.17 extended adjuvant trial. In this correlative study, H/I was compared with ER, PR, and HER2 expression in assessing relative benefit from adjuvant anastrozole (ANA) vs tamoxifen (TAM) in HR+, LN- patients from the prospective randomized ATAC trial. **Methods:** Tumor samples from 742 HR+, LN- patients treated with 5 y of TAM or ANA were examined. Expression levels for H/I, ER, PR and HER2 were determined by RT-PCR. Cox proportional hazards models assessed the significance of the interaction between treatment and each biomarker as continuous variables, with 10-year risk of distant recurrence estimated within the 2 treatment arms separately. No adjustment for multiple testing was made. **Results:** The interaction between H/I and treatment was statistically significant ($p = 0.024$) whereas the interaction for all other biomarkers was non-significant (ER, $p = 0.17$; PR, $p = 0.054$; HER2, $p = 0.72$). Consistent with this finding, the 10-year distant recurrence rate as a function of continuous H/I indicated that the endocrine benefit with ANA compared to TAM correlated with increasing H/I. H/I expression was not highly correlated with ER, PR or HER2. **Conclusions:** In this retrospective study, H/I was the only factor that predicted differential benefit of ANA vs TAM in the adjuvant setting. Consistent with previous IHC results in TransATAC, molecular ER, PR, and HER2 were not predictive of relative treatment benefit. Taken together with previous data, these results suggest that H/I may be a useful indicator of absolute or differential endocrine benefit depending on the clinical setting. Data on utility of H/I for prediction of relative benefit require further validation.

527 Poster Session (Board #15), Sat, 8:00 AM-11:30 AM

FES PET/CT analysis to evaluate the impact of localization of breast cancer metastases on ER expression. *First Author: Hilde H. Nienhuis, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Recent data suggests that differences in locations of metastases could have implications for tumor characteristics and thus for therapy response. Limited knowledge is available in this respect about heterogeneity of the estrogen receptor (ER). ^{18}F-fluoro-17β-estradiol (FES) uptake on positron emission tomography (PET), reflects ER expression. We aimed to analyze FES uptake in tumor lesions at different sites in metastatic breast cancer patients. **Methods:** Eligible patients: biopsy proven ER positive breast cancer, post-menopausal, metastases outside the liver, no history of another metastatic malignancy, no use of ER antagonists for ≥ 5 weeks prior to FES PET. They had undergone FES PET with 64-slice mCT within the UMCG (Jan 2009 - Sept 2014). We re-analyzed FES PET and CT scans for metastases. A lesion with maximum absolute standardized uptake value (SUV_{max}) ≥ 1.5 was considered ER positive. Background tracer uptake was measured for normal tissues. CT lesions with diameter ≥ 10 mm were included. Liver lesions were not evaluated on PET given high background signal. **Results:** In 67 patients, 1,338 lesions were identified by CT (120 patients), PET (913 patients) or both (305 patients) in bone (79%), lymph nodes (15%), lungs (3%) and liver (2%). SUV_{max} of FES positive lesions varied maximally 10-fold between patients (median 1.61-15.61), and up to 11-fold within individual patients (range 1.8-19.4). Median SUV_{max} of bone, lymph nodes and lung lesions were respectively 3.21 (range 0.44-24.3); 3.26 (0.75-19.4) and 2.41 (0.54-6.46). For bone metastases median SUV_{max} varied for the sites with highest uptake in cervical spine (4.17) and lowest in sternum (2.55). Also background SUV_{max}levels differed per location with highest level in lumbal spine (1.46) and lowest in fat tissue (0.65). Lung metastases were more frequently FES negative (20%) than bone (7%, $p < 0.01$) and lymph nodes metastases (5%, $p < 0.01$). **Conclusions:** FES uptake in breast cancer metastases is heterogeneous within and between patients and differs per localization in the body, indicating the need for whole body metastases evaluation for precision medicine. *Supported by Dutch Cancer Society grants RUG 2010-4739 and 2012-5565 and ERC Advanced grant 293445.*

528 Poster Session (Board #16), Sat, 8:00 AM-11:30 AM

Breast cancer recurrence in older patients with clinically node-negative T1-T2 tumors managed without sentinel node biopsy (SNB) and without adjuvant radiation therapy. *First Author: Mervat Nabil Saleh, Memorial Hospital of Rhode Island, Pawtucket, RI*

Background: Older patients (pts) with small breast cancers who receive endocrine therapy can omit radiation without a survival disadvantage. SNB adds additional burden and may not be necessary for pts who are not planning adjuvant radiation or chemotherapy. The objective of our study was to evaluate recurrence rate with or without SNB in those pts. **Methods**: We retrospectively reviewed records of pts ≥ 60 years (y) old, diagnosed at our center between 2000 and 2014 with T1-T2, clinically node-negative, estrogen receptor-positive breast cancer, who did not receive adjuvant radiation or chemotherapy. We used Fisher's exact test to compare characteristics, and Gray's test for cumulative incidence function (CIF) for cancer recurrence, with 95% confidence intervals. **Results**: We identified 364 pts. Those managed without SNB were significantly older, more often with apocrine, mucinous or papillary histology and less likely to undergo mastectomy, with no significant differences in other characteristics. There were 5 recurrences (4 local, 1 axillary) in pts without SNB and 16 (11 local, 2 axillary, 3 distant) with SNB. CIF for recurrence at 5 years was 4.8% (CI, 2.6-8.0) for all pts, 6.6% (CI, 1.7-16.3) without SNB and 4.3% (CI, 2.1-7.8) with SNB, not significantly different ($P = .80$). Positive SNB (in 12%) was not prognostic for recurrence ($P = 0.94$). CIF for death from competing causes was twice as high in pts without SNB (24.6 *vs* 11.1%, $P = .0001$), resulting in lower overall survival (77.5 *vs* 89.3%). **Conclusions**: Overall recurrence rate was similar to prior clinical trials. Pts selected for management without SNB have a high risk of death from non-cancer causes, which reflects their advanced age and comorbidities, but they experience no significant increase in the risk of recurrence. Our results, if confirmed in a larger dataset, suggest that SNB does not provide useful prognostic information in older pts who are not planning multimodality adjuvant therapy, and could be omitted.

SNB	N	Median age	Low-risk histology	High grade	HER2-positive	LVI†	Mastectomy	Positive margin
Yes	283	73	7%	14%	6%	13%	39%	3%
No	81	82*	21%*	10%	3%	7%	7%*	5%

* $P < .001$; † Lymphovascular invasion

529 Poster Session (Board #17), Sat, 8:00 AM-11:30 AM

Role of pazopanib (PZ) in modulating hormone resistance in advanced breast cancer (ABC). *First Author: Melanie Catherine Majure, UC San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Hormone resistance develops in nearly all patients (pts) with hormone receptor positive (HR+) ABC. Preclinical data suggests that higher levels of vascular endothelial growth factor (VEGF) are associated with hormone resistance. We conducted a phase II trial to evaluate the clinical benefit (CB) from adding PZ, a VEGF receptor tyrosine kinase inhibitor (TKI) to a nonsteroidal aromatase inhibitor (NSAI) in pts with ABC progressing on NSAIs. **Methods:** Eligibility included postmenopausal women with HR+ ABC and evidence of progressive disease after at least one month of NSAI therapy. Treatment was PZ 800 mg/day plus either letrozole or anastrozole. The primary endpoint was CB rate (CBR) at 12 weeks (wks). Secondary endpoints were progression free survival (PFS) and safety. A CBR of 20% was considered a clinically meaningful comparison to the expected CBR of < 5% with continued therapy after progression on an NSAI. Using a 2 stage design, stable disease in at least one of the first 13 pts allowed continued enrollment to a planned 27. **Results:** Thirty pts were enrolled; 27 are evaluable for study endpoints. The median age was 58 years. Pts were heavily pre-treated with a mean of 2.6 lines of prior hormone therapy (range 1-6) and 1.6 lines of chemotherapy (range 0-8). Eight pts (30%) stopped treatment due to toxicity including hypertension (HTN), fever, transaminitis, and pulmonary embolism; 6 pts progressed prior to wk 12. The CBR at 12 wks was 44.4% (11 SD, 1 PR), and at 24 wks was 22.2% (4 SD, 2 PR). Median PFS for pts with CB at 12 wks was 30 wks (95% CI 20-40); 6 pts had PFS > 6 months (26, 32, 32, 36, 48, and 78 wks). Three pts remain on study at 20, 32 and 78 wks. The most common adverse events (AE) were nausea (52%), fatigue (41%), arthralgia (26%), back pain (26%), and HTN (26%). Grade 3/4 AE included HTN (11%), transaminitis (11%), and headache (7%). **Conclusions:** The addition of PZ to a NSAI resulted in a CBR of 44% at 12 wks, and 22.2% at 24 wks in pts with heavily pre-treated hormone resistant ABC, suggesting that the antiangiogenic TKI PZ can modulate resistance to hormone therapy. Expected toxicities resulted in early discontinuation in 30% of pts, which limited drug exposure. Evaluation of biomarkers and immune signatures is ongoing. Clinical trial information: NCT01466972.

530 Poster Session (Board #18), Sat, 8:00 AM-11:30 AM

Evaluation of possible linkage between everolimus benefit in estrogen receptor (ER)-positive breast cancer and genomic alterations of the PI3K/AKT/mTOR pathway. *First Author: Esther P. Black, University of Kentucky, Lexington, KY*

Background: Everolimus, which inhibits mTOR, is used to treat metastatic ER-positive breast cancer after aromatase inhibitor failure. Because not all patients benefit and toxicity can be prohibitive, it is critical to identify biomarkers of sensitivity to this treatment strategy. **Methods**: We studied 36 tumors from patients enrolled on protocol NCT00570921 using fulvestrant and everolimus for metastatic ER-positive breast cancer. There were 15 pretreatment tumors from 11 patients who experienced benefit and 14 from 10 patients who did not. DNA was extracted from FFPE tumor tissue and subjected to next-generation-based comprehensive genomic profiling using the FoundationOne assay and alterations were then compared. **Results:** 9 out of 11 responders (82%) had at least one genomic alteration in the PI3K/AKT/mTOR pathway vs. 7 out of 10 nonresponders (70%). Mutations detected in the responder group were 7 *PIK3CA* and 1 *AKT1*, and 1 *PTEN* truncation, while in nonresponders there were 5 *PIK3CA* and 2 *AKT1* mutations, and 1 *RICTOR* amplification (in association with a *PIK3CA* mutation). Interestingly, none of the responders had more than one alteration in individual components of this pathway, while 2 of the nonresponders had more than one alteration observed (one with a concomitant *PIK3CA* mutation and *AKT3* amplification, and one with a *PIK3CA* mutation and *RICTOR* amplification). Other notable alterations include mutations in *TP53* and *GATA3*, and amplification of CCND1, with no specific association with everolimus benefit. Additional analysis and frequency of other alterations will be presented in greater detail. **Conclusions:** In this small study, we did not identify predictors for lack of benefit from everolimus, although it appears that the presence of multiple aberrations in the PI3K/AKT/mTOR pathway may promote *de novo* resistance. It is possible that genomic alterations alone may not adequately explain breast cancer response to this strategy without functional signaling analysis. Alternatively, it is possible that everolimus benefit in endocrine resistance may be independent of PI3K/mTOR signaling altogether and its mechanism of action is yet to be fully determined.

531 Poster Session (Board #19), Sat, 8:00 AM-11:30 AM

Efficacy and safety of neoadjuvant docetaxel, carboplatin, trastuzumab/pertuzumab [TCH-P] in non-metastatic HER2+ breast cancer: The Cleveland Clinic experience. *First Author: Shruti Rakesh Tiwari, Cleveland Clinic Foundation, Shaker Heights, OH*

Background: Pertuzumab is FDA approved for use in combination with trastuzumab and chemotherapy as neoadjuvant therapy in women with non-metastatic HER2+ breast cancer. The TRYPHAENA trial reported a pathologic complete response rate (pCR), i.e. ypT0ypN0, of 52% in 77 patients (pts) treated with neoadjuvant TCH-P. Aside from this study, there is limited information regarding the overall safety and efficacy of neoadjuvant TCH-P at FDA approved doses. Our goal was to evaluate the safety and efficacy of neoadjuvant TCH-P in women with non-metastatic breast cancer in a non-clinical trial setting. **Methods:** After IRB approval, a cancer data registry was utilized to identify all pts with HER2+ non-metastatic breast cancer treated at Cleveland Clinic with neoadjuvant TCH-P. pCR was defined as the absence of invasive tumor in both breast and lymph nodes, i.e. ypT0ypN0. **Results:** 71 pts met our inclusion criteria, with a median age of 52 years. Clinical staging was as follows: stage I (8%); Stage II (69%); Stage III (22%). 60% of pts were also hormone receptor (HR) positive (42/71). 89% of pts (63/71) have received all 6 planned chemotherapy cycles without dose reductions, with only 11.2% (8/71) requiring a dose reduction for rash, diarrhea, neuropathy, or thrombocytopenia. Seven pts are currently receiving chemotherapy. No patients had symptomatic cardiac toxicity with TCH-P, with only 6.6% of patients having an asymptomatic reduction in LVEF > 10%. The overall observed pCR rate for neoadjuvant TCH-P was 53% in the 60 patients that have completed all planned chemotherapy, and definitive surgery. As expected, the pCR rate was higher in patients with HR negative breast cancer than in those with HR positive disease: 67% (16/24) vs. 42% (14/33), respectively. **Conclusions:** Neoadjuvant TCH-P was associated with a pCR rate of 53% in a non-clinical trial setting, which was similar to reported rates in the TRYPHAENA trial. Toxicity was manageable, with no patients experiencing symptomatic reductions in LVEF. Long term clinical outcomes are being prospectively followed in all patients being treated with pertuzumab based chemotherapy.

532 Poster Session (Board #20), Sat, 8:00 AM-11:30 AM

Effect of mutations in distinct components of the PI3K/AKT/mTOR pathway on sensitivity to endocrine therapy in estrogen receptor (ER)-positive breast cancer. *First Author: Suleiman Alfred Massarweh, University of Kentucky, Lexington, KY*

Background: Aberrations of the PI3K/AKT/mTOR pathway are common in ER-positive breast cancer and may be associated with endocrine-resistance. We hypothesized that, since the majority of ER-positive breast cancers are actually sensitive to endocrine therapy, the most prevalent aberration in this pathway will more likely be associated with endocrine-sensitivity rather than resistance. **Methods**: We studied 28 tumors from patients enrolled on protocol NCT00570921 using fulvestrant and everolimus after aromatase inhibitor failure; 19 from 13 patients with endocrine-sensitive disease and 9 from 8 patients with resistant tumors. Resistance was defined as relapse within 3 years of adjuvant use or progression within 6 months in the metastatic setting. DNA was extracted from FFPE tumor tissue and subjected to next-generation-based comprehensive genomic profiling using the FoundationOne assay and alterations were then compared. **Results:** 10 of 13 patients with endocrine-sensitive tumors (77%) had at least one alteration in the PI3K/AKT/mTOR pathway vs. 6 of 8 patients with resistant disease (75%). *PIK3CA* mutations were more frequent in the sensitive group; 9/13 (69%) vs. 2/8 (25%) in the resistant group ($p = 0.08$). Interestingly, aberrations of pathway components other than *PIK3CA* were present in only 1 of 13 patients (8%) with sensitive disease vs. 4 of 8 patients (50%) with resistant disease ($p = 0.0475$). These aberrations were 1 activating *AKT1* mutation in the sensitive group and 2 each of *AKT1* activating mutations and *PTEN* loss in the resistant group. Further analysis of additional alterations will be presented in greater detail. **Conclusions:** Alterations in the PI3K/AKT/mTOR pathway are common in both endocrine-sensitive as well as resistant breast cancer but mutations of specific pathway components may distinguish sensitive from disease that is more likely to be resistant. *PIK3CA* mutations, which are relatively common, may be associated with more estrogen-dependent tumor biology while non-*PIK3CA* mutations are potentially associated with endocrine-resistance in ER-positive breast cancer. Further investigation of these findings is warranted.

533 Poster Session (Board #21), Sat, 8:00 AM-11:30 AM

Recurrence score and clinicopathologic characteristics of TAILORx participants by race and ethnicity. *First Author: Maria M Zlobinsky Rubinstein, Montefiore Medical Center, Bronx, NY*

Background: Black race is associated with worse outcomes in localized breast cancer. We evaluated the characteristics of patients enrolled in the Trial Assigning Individualized Options for Treatment (TAILORx) by race and ethnicity. **Methods:** The analysis included 10,071 evaluable patients with Recurrence Score (RS) data. Eligibility criteria included: (1) T1-2, N0 disease, (2) estrogen receptor (ER) and/or progesterone receptor (PR) positive disease that was also HER2/neu negative, (3) age 75 years or younger and medically appropriate for adjuvant systemic chemotherapy. **Results:** The study population included 8,501 whites (84%), 722 blacks (7%), 423 Asians (4%), and the remainder other/unknown race. With regard to ethnicity, 7,916 were non-Hispanic (79%), 919 were Hispanic (9%), and 1,236 were of unreported ethnicity (12%). There was no significant difference in RS distribution ($p = 0.14$), median RS (17 vs. 17), and mean RS (19.6 vs. 18.4) in blacks compared with non-blacks. There was likewise no difference in Hispanic vs. non-Hispanic ethnicity for RS distribution ($p = 0.53$), median RS (17 vs. 17), and mean RS (18.6 vs. 18.4). Blacks were significantly more likely to be younger (39% vs. 30% $<$ 50 years), have larger tumors (37% vs. 31% $>$ 2 cm), poor histologic grade (25% vs. 17%), and PR-negative disease (14% vs. 10%) (Chi square test $p < 0.05$). Hispanic women were also significantly younger (39% vs. 30% $<$ 50 years), and demonstrated marginal but statistically significant differences in tumor size (34% vs. 31% $>$ 2 cm), histologic grade (20% vs. 18% poor), and PR expression (12% vs. 10% negative) (Chi square test < 0.05). In 974 patients with information on body mass index (BMI), there was no correlation between BMI and RS ($r = -0.04$). BMI was higher for blacks than whites (medians 31.6 vs. 28.9, $p = 0.02$, Wilcoxon test), but not in Hispanics. **Conclusions:** In patients selected for participation in TAILORx there were no significant differences in RS by race, ethnicity, and BMI. When compared to white patients, black and Hispanic patients were significantly younger, had tumors that were larger, and more likely to be associated with poor grade. Clinical trial information: NCT00310180.

534 Poster Session (Board #22), Sat, 8:00 AM-11:30 AM

The vitamin D receptor: A therapeutic target for the treatment of breast cancer? *First Author: Alyson M Murray, School of Medicine and Medical Science, University College Dublin, Dublin, Ireland*

Background: Recent studies suggest vitamin D (VD) plays a role in cancer cell growth, with evidence indicating that a deficiency can lead to higher disease risk and a poorer outcome. Activation of the vitamin D receptor (VDR) by the active form of VD (calcitriol) leads to the regulation of anti-cancer genes. Therefore, we propose that VDR could be targeted as a potential therapeutic for treatment of breast cancer. **Methods:** The effects of calcitriol and inecalcitol (Hybrigenics, Paris) on breast cancer (BC) cell growth were investigated in 16 cell lines (TN = 7, Her2+ = 5, luminal = 4) and 7 cell lines (TN = 3, Her2+ = 2, luminal = 2), respectively. Cytotoxicity was determined by MTT assays and cell proliferation by colony formation assays (CFA). VDR expression was measured by ELISA (USCN Life Science Inc.). **Results:** IC_{50} concentrations for treatment with calcitriol, across the 16 cell lines ranged from 0.12 μM to $>$ 100 μM, using the MTT assay. These IC_{50} values were validated by CFA with a significant correlation between the 2 assays ($p = 0.0046$, $r = 0.898$). Sensitivity to calcitriol was higher in ER+ compared to ER- cell lines ($p = 0.0454$) but was independent of HER2 status ($p = 0.8181$). VDR expression in the cell lines varied from undetectable to 10 pg/mg. A significant correlation was found between VDR levels and IC_{50} value ($p = 0.0076$, $r = -0.6401$). IC_{50} concentrations for treatment with the low calcemic-inducing VD analogue inecalcitol ranged from 4.2 nM to 54.4 nM across 7 cell lines. Sensitivity to inecalcitol was higher in ER+ compared to ER- cell lines ($p = 0.0092$), but like with calcitriol, was independent of HER2 status ($p = 0.4745$). A significant correlation was found between IC_{50} values for inecalcitol and calcitriol ($p = 0.0231$, $r = 0.8571$). However, depending on the cell line, inecalcitol was approximately 14 to $>$ 50 fold more sensitive than calcitriol ($p = 0.0006$). **Conclusions:** These preclinical results suggest that calcitriol and inecalcitol can inhibit breast cancer cell line growth. Since inecalcitol, is considerably more potent than calcitriol and has low calcemic potential, it should be further investigated as a treatment for breast cancers expressing VDR.

535 Poster Session (Board #23), Sat, 8:00 AM-11:30 AM

Significance of prospective multicenter decision impact WSG-BCIST Study in postmenopausal ER+ HER2- N0 early breast cancer (EBC) for molecular testing for intrinsic subtype definition. *First Author: Rachel Wuerstlein, University of Munich, Munich, Germany*

Background: Prosigna is a standardized test measuring expression levels of 50 classifier genes (PAM50) in formalin-fixed, paraffin-embedded (FFPE) breast tumor tissue using nCounter Technology (NanoString Technologies, Inc., Seattle, WA). It provides intrinsic subtype and risk of recurrence (ROR) score predicting 10y recurrence probability. It was retrospectively validated by ABCSG 8 and TransATAC. WSG BCIST evaluates its impact on systemic therapy decisions in EBC. **Methods:** 201 consecutive postmenopausal pts. with ER+ HER2- N0 were recruited (11 centers; 10/2013-10/2014). Primary objective was to assess impact of Prosigna vs. standard immunohistochemistry (IHC) on adjuvant chemotherapy recommendations and actual therapy received. Secondary objectives include physicians' confidence in recommendations, patients' decisional conflict, and rate of chemotherapy-related adverse events. Prosigna testing was performed centrally (university) and repeated de-centrally (community-based pathology) for quality control. **Results:** Intrinsic subtypes were highly concordant (95.5%) between the two pathologies. Risk group differed in only 1/9 discordant cases; underlying tumor heterogeneity is being evaluated. In the total cohort (198 patients evaluated), 58.1% of tumors were classified by PAM50 as Luminal A, 39.9% as Luminal B, 1.5% Basal, 0.5% HER2-E. Local IHC classified 18.3% of PAM50 Luminal A as Luminal B, and 39.2% PAM50 Luminal B as luminal A (overall 26.9% discordance). Prosigna results led to a reported change in chemotherapy (CT) indication in 19.2% overall, including 39.2% of PAM50 luminal B patients. Actual CT use and morbidity will be evaluated after scheduled 6-month follow-up. **Conclusions:** In the WSG BCIST prospective decision impact study, Prosigna results led to a 19% change in chemotherapy indication. The 27% discordance in intrinsic subtyping between PAM50 and IHC underlines the importance of molecular testing for optimal systemic therapy indications in EBC. As a pre-planned pooled analysis, WSG BCIST can later be evaluated together with two similar studies currently ongoing in Europe. Clinical trial information: NCT01974856.

536 Poster Session (Board #24), Sat, 8:00 AM-11:30 AM

Incidence and survival for young women with operable breast cancer: SEER 1992-2011. *First Author: Mary Chen Schroeder, University of Iowa, Iowa City, IA*

Background: Recent work has shown an increasing incidence of Stage IV breast cancer (bc) in young women (wm). We examined the incidence and survival of young wm with operable bc. **Methods:** Wm ages 20-39 diagnosed with stages 1-3 bc from 1992-2011 were identified from SEER data and categorized by hormone receptor (HR) status and grade (low = well/moderately differentiated, high = poor/undifferentiated). Those with missing information were excluded. Annual percent change (APC) in age-adjusted incidence rates for the SEER 13 registries were calculated. Kaplan Meier survival curves were estimated by HR and grade. **Results:** We identified 3,566 wm aged 20-29 and 34,508 wm 30-39. For wm 20-29, stages 1, 2, 3 comprised 25.2, 50.5, and 24.3% of the sample versus 30.6, 47.1, and 22.3% for wm 30-39 (all $p < 0.001$). HR status and grade also differed significantly by age. Wm 20-29 were more likely to have HR- disease (40.4 v 34.2%), less likely to have HR+ low grade disease (25.7 v 35.6%) and more likely to have HR+ high grade disease (33.9 v 30.2%) than wm 30-39 (all $p < 0.001$). APC in incidence along with 5- and 10-yr survival is reported in the table. In HR+ disease, regardless of grade, survival decreased more rapidly beyond 5 years from diagnosis for 20-29 than 30-39. This was not seen for HR- disease. **Conclusions:** Wm age 20-39 presented more frequently with Stage II bc. Wm 20-29, unlike wm 30-39, have not seen a decline in Stage III disease. Low and high grade HR+ disease in wm 20-29 also increased with the highest APC in incidence. 10-year survival for 20-39 year old wm with HR+ disease showed continued late deaths. This was most pronounced for wm 20-29.

	20-29 yrs	30-39 yrs	p
APC in incidence

537 Poster Session (Board #25), Sat, 8:00 AM-11:30 AM

An indirect evaluation of bone saturation with zoledronic acid after long-term Q4 week dosing using plasma and urine pharmacokinetics. *First Author: Gabriel N. Hortobagyi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Zoledronic acid (ZA) has a high binding affinity for human bone. This post-hoc analysis from the OPTIMIZE-2 trial evaluated whether there is evidence for bone saturation of ZA following long-term dosing at the standard q 4wk dosing. We hypothesized that if bone saturation of ZA would occur, then 1. Plasma and urinary levels of ZA would increase with prolonged dosing, and 2. Switching to a reduced dosing frequency of q12 weeks would reduce plasma and urinary ZA levels. **Methods:** OPTIMIZE-2 was a randomized, double-blind, multicenter trial in female pts with bone metastases from breast cancer who previously received long term ZA treatment (1 to 7 yrs) with standard q4 wk (infusion time of 15 min). Pts were randomized (1:1) to receive ZA 4 mg IV q4 wk or q12 wk for 1 year. ZA levels were analyzed in plasma and urine during 0-6h after thefirst dose (week 1) and after the week 36 dose in ZA-pretreated (1-7 yrs) pts with evaluable ZA levels (n=38). **Results:** Baseline creatinine clearances were comparable between the ZA q4 wk (N=21) and q12 wk (N=17) groups. Pre-infusion urine and plasma concentrations (ng/mL) at either time point (week 1 and 36) were in most cases near or below the lower limit of quantification. The table shows mean (SE) of ZA excreted in urine (in % of dose) and AUC (in h x mg/L) of ZA plasma concentrations, after the first and week 36 dose of ZA in OPTIMIZE-2. The plasma level s in the two dosing frequency groups (q4 wk and q12 wk) and both time points were similar. Urine ZA level s were also similar between the 2 dosing frequencies at both time points. These plasma and urine levels were also similar to levels from newly dosed patients receiving q 4wk ZA dosing for the first time (Chen et al. J Clin Pharmacol 2002;Skerjanec et al. J Clin Pharmacol 2003). Switching ZA dosing frequency from q4 wk to q12 wk did not reduce plasma and urinary ZA levels. **Conclusions:** Based on plasma and urinary ZA levels with standard and reduced dosing frequencies, our data does not suggest that prolonged treatment with ZA q4 wk results in bone saturation of ZA. Clinical trial information: NCT00320710.

	First dose; q4 wk	Week 36; q4 wk	First dose; q12 wk	Week 36; q 12wk
Plasma AUC 0-6h	0.37 (0.03)	0.43 (0.06)	0.40 (0.02)	0.43 (0.05)
Urine 0-6h	26.0 (4.4)	36.6 (6.6)	23.7 (5.6)	30.8 (4.7)

538 Poster Session (Board #26), Sat, 8:00 AM-11:30 AM

Prospective study of the decision-making impact of the Breast Cancer Index in the selection of patients with ER+ breast cancer for extended endocrine therapy. *First Author: Tara Beth Sanft, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: The Breast Cancer Index (BCI) has been validated to quantify an individualized risk of late recurrence and to predict likelihood of benefit from extended endocrine therapy in ER+ early stage breast cancer.The purpose of this study was to prospectively assess the impact of BCI i) to change treatment recommendations regarding extended endocrine therapy, and ii) to examine its effects on patient anxiety and decision conflict. **Methods:** Patients with stage I-III, ER+ breast cancer treated at the Yale Cancer Center who completed at least 3.5 yrs of adjuvant endocrine therapy were prospectively enrolled over 6 months in 2014. BCI was performed on FFPE samples from the original biopsy (bioTheranostics Inc.). Patients and physicians completed pre- and post-test questionnaires. Patients completed the Traditional Decisional Conflict Scale (DCS) and State Trait Anxiety Inventory Form Y (STAI) pre- and post-test. **Results:** 100 patients[mean age 61y (45-88), 80% postmenopausal, 57% stage I] were included in this study. Integration of BCI resulted in a change in treatment recommendation for 27% of patients. A majority of changes were based on identification of patients with low risk of late recurrence and low likelihood to benefit from extended endocrine therapy. Extended therapy was recommended for 75% patients pre- and for 55% post-testing. No extended therapy was recommended for 25% patients pre-and for 45% post-testing. Satisfaction increased in 38% of patients. After receiving results, 52% of patients changed their treatment decision. Patients experienced less anxiety (53%) and decisional conflict (50%) after receiving results. The STAI ($p = 0.03$) and DCS ($p < 0.001$) scores decreased significantly post testing (mean difference of -2 and -9, respectively) compared to baseline scores (31 and 20, respectively). **Conclusions:** The Breast Cancer Index led to changes in treatment recommendations regarding extended adjuvant endocrine therapy in 27% of cases and resulted in significantly less decision conflict and anxiety for patients. Overall, knowledge of BCI resulted in fewer recommendations for extended therapy and improved patient satisfaction. Clinical trial information: NCT02057029.

539 Poster Session (Board #27), Sat, 8:00 AM-11:30 AM

Case-control study of hormone receptor expression in benign breast and cancer risk. *First Author: Caroline Fenger Healy, Northwestern University, Chicago, IL*

Background: Previous studies have shown that hormone receptor expression in non-proliferative epithelium (NPE) indicates increased breast cancer risk, whereas other studies have been null. We assessed estrogen receptor (ER), progesterone receptor (PR) and Ki67 expression in NPE of newly diagnosed breast cancer cases and benign disease controls using contemporary immunohistochemical (IHC) methods and digital image analysis. **Methods**: Formalin-fixed paraffin-embedded breast samples (171 cases and 169 age-matched controls) were collected from women treated between 1994-1999. 4-μm sections were stained for ER (ThermoScientific/SP1, 1:200-pH6), PR (Dako/M3569, 1:1600-pH6) and Ki67 (Dako/MIB-1, 1:100-pH6) on Leica Bond Max and Dako automated stainers. The NPE portions of the digitized slides were sampled in random fashion and evaluated blindly with Aperio Spectrum software. % positive cells were scored for ER, PR and Ki67 and categorized into quartiles. Wilcoxon rank-sum test and logistic regression with age adjustment were used for pairwise comparison. Spearman's rank correlation test and one-way ANOVA test with Sidak adjustment were used for the correlation and comparison among multiple markers and subgroups. **Results**: The mean age was 49 years for cases and 48 years for controls. Overall, there was no significant difference between the cases and controls for ER, PR or Ki67 expression. In analyses stratified by menopausal (M) status, post-M ER % positivity was significantly higher in cases than controls (34.0 vs 29.8, OR = 1.49, $p = 0.007$). ER was significantly higher in post-M than in pre-M cases ($p < 0.0001$). ER and PR were positively correlated among cases ($R = 0.433$, $p < 0.0001$) and controls ($R = 0.547$, $p < 0.0001$). Ki67 was significantly lower in post-M than in pre-M controls ($p = 0.004$). **Conclusions**: ER expression in benign non-proliferative breast epithelium is significantly higher in postmenopausal cases, suggesting increased ER expression may indicate increased breast cancer risk in older women.

ER % logistic regression on quartile (age-adjusted).

540 Poster Session (Board #28), Sat, 8:00 AM-11:30 AM

Relationship of germline polymorphisms to docetaxel toxicity in the ROSE/TRIO-012 trial. *First Author: Sambasivarao Damaraju, University of Alberta/Cross Cancer Institute, Edmonton, AB, Canada*

Background: TRIO-012 is a double blinded, multinational trial that randomized 1,144 patients with advanced breast cancer to receive first-line docetaxel (Doc) in combination with ramucirumab or placebo. Our objective is to address genetic predisposition to Doc toxicity. In this independent validation study, we selected single nucleotide polymorphisms (SNPs) previously associated with taxane-induced adverse events (AEs; fatigue, myalgia, peripheral neuropathy), including CYP3A5*3 reported by our group to be strongly associated with Doc toxicity. **Methods:** Germline SNPs were studied in participants who gave prospective consent for peripheral blood DNA genotyping. All subjects received Doc until unacceptable toxicity or progressive disease. From these, 399 subjects predominantly of Caucasian origin were analysed here. Toxicity grades 0-1 (controls; low toxicity) vs. grade $>$ 2 (cases, high toxicity) were compared. Dominant genotypic model was assumed; Chi-square test with 10000 permutations were employed using SVS v8.3 and $p < 0.05$ considered statistically significant. **Results:** Each reported variant conferred risk. CYP3A5*3 allele (rs776746; OR 2.16 [1.18-3.96]), TNF-alpha (rs1800629), NAV1 (rs478472), NOS3 (rs1799983) were associated with fatigue. SNPs associated with myalgia were FACND2 (rs7637888), HIF1-alpha (rs11549465) and NDRG1 (rs2233335). XKR4 (rs4737264) showed association with peripheral neuropathy. SNPs in ABCC2, SLCO1B3 and VEGF-R1 genes showed associations with all three individual AEs tested. In a combined analysis of all the AEs, CYP3A5*3 allele retained significance (OR 1.9 [1.08-3.37]; as did IL1-beta (rs16944) and CYP2C8 (rs11572080). **Conclusions:** We confirm our previous finding that CYP3A5*3 genotype determines toxicity by its influence on Doc metabolism (EurJCancer 8(7),175,2010). NDRG1, FACND2 and XKR4, SNPs previously associated with paclitaxel-induced neuropathy, were now associated with Doc-induced myalgia or neuropathy. In conclusion, we report a subset of variants analysed conferring genetic predisposition to both paclitaxel and Doc AEs. The pleotropic drug effects on multiple genes/pathways appear to contribute to the overall phenotype of taxane toxicity.

541 Poster Session (Board #29), Sat, 8:00 AM-11:30 AM

Oncotype DX scores in BRCA1 and BRCA2 associated breast cancer. *First Author: Nicholas Patrick McAndrew, Basser Research Center for BRCA, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: The Oncotype DX score is widely used to evaluate recurrence risk and potential benefit of chemotherapy in stage 1, estrogen receptor (ER) positive, Her2 negative tumors. Oncotype DX was developed and validated in sporadic breast cancer patients. No data are available regarding Oncotype DX results in BRCA1/2 mutation carriers. The purpose of this study is to determine the distribution of Oncotype DX scores in patients with BRCA1/2 associated cancers, as well as subsequent therapy and disease course for this population. **Methods:** 18 patients were identified between 2006-2013 who had deleterious BRCA1/2 mutations and stage 1, ER positive, Her2 negative, node negative invasive breast cancer. Data regarding Oncotype DX scores, subsequent therapy (including local, prophylactic, hormonal, and chemotherapy), and length of follow-up was collected. **Results:** The distribution of Oncotype DX scores was similar in this population as compared to prior published data on patients with sporadic tumors, with approximately 41% of patients having a "low" score, 47% having an "intermediate" score, and 12% having a "high" score. While none of the patients with "low" risk scores had a recurrence of disease at an average of 44.1 months in follow-up, one patient with "intermediate" risk disease had a recurrence 48 months after initial diagnosis. Further molecular analysis of one of the "low" risk tumors failed to demonstrate loss of heterozygosity. **Conclusions:** These findings are suggestive that the Oncotype DX assay is a reliable and applicable clinical decision making tool in patients with certain BRCA 1/2 associated tumors.

There is more to the picture than meets the eye: Population-based study on biopsy verification of suspected breast cancer recurrences. *First Author: Ulla Wilking, Department of Oncology and Pathology - Karolinska Institutet and Cancer Center Karolinska, Stockholm, Sweden*

Background: Core biopsy/Fine needle aspiration (Bx) is recommended to confirm the diagnosis of Recurrent Breast Cancer (RBC). Up to 10% of all Bx are not RBC but benign or other malignancy. Hormone Receptor (HR)/HER2 status is known to change impacting management of RBC. The objective was to study the proportion of benign/other malignancies in suspected RBC, as well as to study the change in subgroup (see Methods) between PBC/RBC and consecutive RBCs from the same patient. **Methods:** In a population-based cohort in Stockholm, Sweden, of women with a diagnosis of RBC during 2007 until 2012 (and PBC before 2007), we reviewed all Bx-reports after PBC diagnosis. Exclusion criteria: stage IV disease, bilateral breast cancer. The trigroup was defined as three subgroups, HR+/HER2-, HER2+ and triple negative (TNBC), and compared between PBC/RBC and multiple RBCs from the same patient. **Results:** Only 60 patients did not undergo Bx and there were a total of 1034 Bx samples in 453 women with RBC. Sites of sample: bone, ascites, lung/pleura, CNS, liver, spleen, GI, gyn, etc. Results of Bx show that suspected RBC may be other malignancy (3%), benign (35%) or inconclusive (6%). Of the 52 lung/pleura samples were 2 lung cancers, 10 were cancers of unknown primary (CUP) and 6 showed inflammation. Of the 56 liver biopsies one was hemangioma and one showed inflammation. Also, one of the 185 local biopsies showed to be a neuroendocrine tumor. Tumor trigroup changed between PBC and RBC in almost one out of three patients as well as between consecutive RBCs (see table). **Conclusions:** For correct clinical management of patients with RBC it is essential to take Bx of any suspected site, since up to 55% of suspected RBC lesions are not RBC. Furthermore, biology changed in around 30% of patients, also between consecutive relapses.

543 Poster Session (Board #31), Sat, 8:00 AM-11:30 AM

21-gene recurrence score assay (RS) and impact on adjuvant chemotherapy (CTx) use among lobular (L) and ductal (D) histology hormone receptor positive (HR+) early breast cancers (EBC). *First Author: Simon Daniel Baxter, BC Cancer Agency, Vancouver, BC, Canada*

Background: RS identifies lower risk HR+ EBCs that may avoid adjuvant CTx. L histology may influence CTx use in intermediate RS cancers given its association with high HR+ expression and hormone therapy benefit. We examined RS and its utility in clinical decisions among L relative to D EBCs. **Methods:** We identified BC Cancer Agency referred pts with a RS performed on their HR+ EBC between 2007 and 2014, as part of routine care (node negative only) or in clinical trials. Multifocal tumors and mixed L-D histology were excluded. Demographic and histopathological variables and rates of CTx were compared for D and L using univariate and multivariate analyses. **Results:** After exclusions, 577 cases (89% D, 11% L) were identified. Compared with D tumors, L tumors were larger, lower grade, had a lower mean RS (20 vs 16 $p = 0.0002$), and fewer had high RS (Table 1). These differences were not significant after adjustment for age, degree of HR+ expression, size, grade, nodal status, LVI. Among 289 pts (256 D, 33 L) with treatment not mandated in a trial based on RS, 82 (28.4%) had CTx, including 5 (15.2%) L and 77 (30.1%) D ($p = 0.10$). Of the 97 with intermediate RS cancers, CTx was given in 3/12 (25%) L and 26/85 (30.6%) D cases. **Conclusions:** The observed frequency of L and D histology in this series mirrors the incidence distribution described in EBC. The overall lower use of CTx in L cancers can be accounted for by lower RS and more favourable histopathological variables. Among intermediate RS cancers, histology did not appear to impact CTx use. In the absence of prospective data, L histology should not influence CTx use for intermediate RS cancers.

Comparison of ductal and lobular cancers.

544 Poster Session (Board #32), Sat, 8:00 AM-11:30 AM

Prediction of late distant recurrence (DR) using the Prosigna (PAM50) test in a Danish Breast Cancer Cooperative Group (DBCG) cohort of postmenopausal women diagnosed with hormone receptor-positive (HR+) early breast cancer (EBC) allocated to 5yr of endocrine therapy (ET). *First Author: Anne-Vibeke Lænkholm, Department of Pathology, Region Zealand, Denmark*

Background: Accurate assessment of the risk of late DR (5-10 yr after surgery) may be used to tailor the duration of ET for patients with HR+ EBC. The Prosigna (PAM50) risk of recurrence (ROR) score was shown to predict late DR for EBC patients treated with 5yr of ET in two randomized clinical trials. Here we assess the ability of PAM50 to predict late DR in a comprehensive nationwide cohort from Denmark consisting of postmenopausal women diagnosed with HR+ EBC allocated to 5yr of ET alone. **Methods:** Using the population based DBCG database FFPE primary tumor blocks and follow-up data were collected from all HR+ EBC patients diagnosed from 2000-2003 who by nationwide guidelines were allocated to 5yr of ET alone (N = 2749). The PAM50 test was run on the NanoString nCounter Analysis System. Multivariate analyses tested the ability of PAM50 to predict late DR. Patients were categorized as Low, Intermediate, or High risk based upon prespecified ROR cutoffs varied by number of positive nodes. **Results:** From 2722 included patients, 2164 were disease free at 5yr and analyzed for risk of late DR. Median follow-up was 4.58 years from completion of ET. High risk patients (N = 870) had a late DR risk of 10.2% [95%CI: 8.0-12.7], compared to 6.1% [4.2–8.6] for Intermediate (N = 650) and 2.4% [1.3–4.1] for Low risk patients (N = 644). When ROR was added to a multivariable model including standard clinical and pathological variables it improved the prediction of late DR (likelihood ratio: $p < 0.0001$; HR for a 20-point change = 1.5 [1.2–1.9]). Luminal B (N = 733, late DR risk = 10.3% [7.8–13.1]) and Her2-enriched patients (N = 132, late DR risk = 8.8% [4.4–15.0]) had a significantly worse outcome than Luminal A (N = 1281, late DR risk = 4.5% [3.3–5.9]), $p < 0.0001$ for LumB and = 0.034 for Her2e. **Conclusions:** We have confirmed the ability of Prosigna (PAM50) to predict late DR for HR+ EBC patients regardless of nodal status in a real world cohort devoid of physician selection bias. PAM50 can reliably be utilized to identify patients who need, or most importantly may be safely spared, extended ET beyond 5yr.

545 Poster Session (Board #33), Sat, 8:00 AM-11:30 AM

Predictive testing for selection of patients for extended endocrine therapy: Clinical utilization of Breast Cancer Index (BCI) in early-stage, ER+, LN- breast cancer. *First Author: Stephen C. Malamud, Beth Israel MedcI Ctr, New York, NY*

Background: Randomized trials have demonstrated significant but modest (3-5%) benefit from extended (10y) endocrine therapy (EET) vs 5y in pts with early stage ER+ breast cancer. Clinical practice guidelines have speculated on the risk vs benefit of EET in pts with a low clinicopathologic risk profile. Breast Cancer Index (BCI) is a gene expression-based test that that is prognostic for risk of late (> 5y) recurrence and predictive of EET benefit. This study examined the clinical utility and utilization of BCI in clinical practice, and its ability to identify pts likely to benefit from EET in an otherwise low risk population. **Methods:** Consecutive cases (N = 853) from LN- pts submitted for BCI prognostic and BCI predictive [HoxB13/IL17BR (H/I) ratio] analyses were investigated. Patient characteristics, clinician testing patterns, and clinical results were analyzed descriptively. **Results:** Patient characteristics are shown in the top table. BCI identified 54% and 46% as having low and high risk of late recurrence, respectively. Predictive testing identified 42% of pts with a high likelihood vs. 58% with a low likelihood of benefit from EET. The bottom table shows the integrated prognostic and predictive results. In the subset of pts with a low clinicopathologic risk profile (LN-, T1, Grade 1-2, HER2-neg; n = 321), BCI identified 23% of pts with both a high risk of late recurrence (mean, 7.1% DRR) and likely to benefit from EET. Physicians utilized BCI across a range of intervals from time of diagnosis: 11% < 2y; 14% ≥ 2 to < 4y; 57% ≥ 4 to < 6y; and 18% ≥ 6y. **Conclusions:** Data from this large retrospective analysis further define BCI clinical utility in selection of which early-stage, ER+ pts are at risk of late recurrence and likely to benefit from EET vs those that may be adequately treated with 5y of endocrine therapy.

Characteristics (N = 853)

Mean Age	57y
> 65y	27%
Size	%
≤ 1cm	26
> 1 - ≤ 2cm	49
> 2 - ≤ 5 cm	23
>5 cm	2%
Grade	%

Low	54%	12%
High	11%	23%

546 Poster Session (Board #34), Sat, 8:00 AM-11:30 AM

Prediction of 10yr distant recurrence (DR) using the Prosigna (PAM50) assay in a Danish Breast Cancer Cooperative Group (DBCG) cohort of postmenopausal Danish women with hormone receptor-positive (HR+) early breast cancer (EBC) allocated to 5yr of endocrine therapy (ET) alone. *First Author: Anne-Vibeke Lænkholm, Department of Pathology, Region Zealand, Denmark*

Background: The Prosigna (PAM50) risk of recurrence (ROR) score has been validated in two randomized clinical trials to predict 10yr DR in EBC patients treated with ET alone. Here we examine the value of PAM50 for predicting risk of DR in a comprehensive nationwide cohort from Denmark consisting of all postmenopausal women diagnosed with HR+ EBC allocated to 5yr of ET alone. **Methods:** Using the population based DBCG database FFPE primary tumor blocks and follow-up data were collected from all patients diagnosed from 2000-2003 (N = 2749) who by nationwide guidelines were allocated to 5yr of ET alone. PAM50 was conducted using the NanoString nCounter Analysis System. Univariate and multivariate analyses tested the ability of PAM50 to predict DR. Patients were categorized as Low, Intermediate, or High risk based upon pre-specified ROR cutoffs varied by number of positive nodes. **Results:** Blocks from 2749 patients were identified and data from 2722 samples (1256 N0, 1466 N1) were included in the analysis (99%). Median follow-up was 9.25yr. High risk patients (n = 1200) had a DR risk of 20.8% [95%CI: 18.3-23.4] at 10 years, compared to 4.3% [2.9-6.2] for Low risk patients (n = 733). These figures were consistent across nodal status. Adding ROR to a Fine and Gray's proportional sub-hazards model containing clinical and pathological variables significantly improved the model (likelihood ratio: $p < 0.0001$; HR for a 20-point change in ROR = 1.7 [1.5-1.9]. Luminal B tumors (N = 977, DR risk = 18.0% [15.4-20.9]) and Her2-enriched tumors (N = 203, DR risk = 27.7% [21.5-34.3]) had a significantly worse outcome than Luminal A (N = 1515, DR risk = 7.7% [6.2-9.3]), both $p < 0.0001$. **Conclusions:** To our knowledge, this is the first genomic study of breast cancer on a comprehensive nationwide population. Prosigna (PAM50) improved the prediction of outcome over and above standard clinical and pathological variables in this DBCG cohort devoid of physician selection bias. PAM50 can reliably identify patients in a real world setting who may be spared overtreatment with chemotherapy.

547 Poster Session (Board #35), Sat, 8:00 AM-11:30 AM

Genetics of ramucirumab-associated hypertension in the ROSE/TRIO-012 breast cancer trial. *First Author: John Robert Mackey, Cross Cancer Institute, Edmonton, AB, Canada*

Background: TRIO-012 is a double-blinded multinational phase III trial that randomized 1,144 patients with advanced breast cancer to receive first-line docetaxel in combination with ramucirumab (anti-VEGFR2) or placebo. We investigated the association of genotype (single nucleotide polymorphisms, SNPs) with the phenotype (hypertension, HT as a treatment-emergent adverse event) to seek genetic predispositions to ramucirumab toxicity. **Methods:** In this study, 220 SNPs were selected from literature related to anti-angiogenic pathways, drug metabolism/transport, immune regulation, and hypertension. SNPs were genotyped using germline DNA on the platforms, Sequenom iPLEX Gold and Pyrosequencing. Genotype data was filtered for deviations from Hardy Weinberg Equilibrium and minor allele frequency of > 0.05. Study subjects provided ethics-committee approved prospective consent for this genetic study. 257 Caucasian subjects were analysed here from the docetaxel-ramucirumab arm. Toxicity grades 0-1 (n = 208 controls; low toxicity) vs. grade > 2 (n = 49 cases, high toxicity) were tested for genetic associations. Dominant genotypic model was assumed; Chi-square test with 10000 permutations were employed (Golden Helix-SVS v8.3) and $p < 0.05$ considered statistically significant. **Results:** VEGF-R2 (rs17709898) conferred protection (OR 0.51 [0.26-0.96]) and rs7691507 conferred risk (OR 2.01 [1.07-3.77]). Polymorphism in ABCB1 (MDR1), rs2235067 conferred risk (OR 2.37[1.21-4.64]). SNPs (rs9508033, rs722503 and rs3794405) in VEGF-R1 and NR1I3 (rs2307418 and rs5085) showed association (risk and protection, respectively). **Conclusions:** The association of VEGF- R2 rs17709898 with HT is consistent with the known mechanism of ramucirumab VEGF-R2–directed antibody. rs17709898 is in linkage disequilibrium with rs1870377, a variant previously shown to be associated with HT. Similarly, the association of VEGF-R1 with HT suggests compensatory pathways may have a role in anti-angiogenic toxicity. None of the polymorphisms in the VEGF ligand (21tagSNPs) were associated with hypertension. Confirmation of these findings in ongoing ramucirumab studies may permit risk stratification of ramucirumab therapy.

548 Poster Session (Board #36), Sat, 8:00 AM-11:30 AM

Impact of combining PgR score and original preoperative endocrine prognostic index (PEPI) score as a prognostic factor of neoadjuvant endocrine therapy using exemestane in postmenopausal ER-positive/HER2-negative breast cancer. *First Author: Sasagu Kurozumi, Division of Breast Surgery, Saitama Cancer Center, Saitama, Japan*

Background: Neoadjuvant endocrine therapies (NAE) using aromatase inhibitors effectively reduce tumor size in postmenopausal ER-positive breast cancer (BC). The utility of PEPI scoring in predicting of the recurrence-free survival (RFS) after NAE is well-known. On the other hand, PgR can be a prognostic factor of ER-positive BC. We compared original PEPI score with PgR status alone, and modified PEPI score including PgR status, as prognostic factors of NAE in postmenopausal ER-positive/HER2-negative BC. **Methods:** Our study included 107 Japanese women with invasive ER-positive/HER2-negative BC who were received NAE with exemestane (25 mg/day) for at least 4 months (median follow-up: 47 months). *Analysis 1:* PEPI score (0-12 points) of each patient was determined using ypT, ypN, Ki67 and ER (Allred score), and patients were divided into 3 risk groups: low (0), moderate (1-3), and high ($\geq$ 4). RFS and cancer-specific survival (CSS) were compared between groups. *Analysis 2:* Cutoff values of PgR were tentatively defined as, 0, 1, 10, 20, 33, 50 or 66%; an effective cutoff value was determined by analysis of RFS and CSS. *Analysis 3:* PgR score (3 to low; 0 to high, using cutoff value determined by analysis 2) and original PEPI score were combined, and RFS and CSS of 3 risk groups were analyzed. **Results:** The PgR staining of 50% was the most significant cutoff value for predicting differences of RFS and CSS (RFS: P = 0.005, CSS: P = 0.003). PEPI score was also significant prognostic factor for CSS and RFS (RFS: P = 0.0009, CSS: P = 0.043). The hazard-ratio (HR) of PEPI score was greater than that of PgR in RFS (PEPI: 13.99 vs. PgR: 7.76), but lower than for CSS (PEPI: 6.28 vs. PgR: 8.74). However, combining PgR score to original PEPI score was the most potent prognostic indicator for both RFS and CSS (RFS: HR 20.35, P = 0.000001 and CSS: HR 18.48, P = 0.000097). **Conclusions:** PgR alone using 50% of cutoff value and original PEPI score might be a significant prognostic indicator for NAE using exemestane. However, combining PgR score and original PEPI score might be more potent prognostic indicator in both RFS and CSS.

549 Poster Session (Board #37), Sat, 8:00 AM-11:30 AM

Bevacizumab maintenance (BM) in first line treatment for metastatic breast cancer (MBC): A multicenter retrospective observational study. *First Author: Lucia Mentuccia, Medical Oncology Unit, Frosinone, Italy*

Background: Bevacizumab (B) combined with paclitaxel (P) is a treatment option in MBC patients (pts). This multicenter observational study was performed in order to evaluate activity of both B-P association and BM after P discontinuation in real world MBC pts. **Methods:** 280 MBC pts treated with weekly dose of P with B, with or without BM after P discontinuation were enrolled from 11 Italian cancer centres and retrospectively evaluated. Firstly, the RR for B-P was calculated, and secondly the PFS and OS were evaluated for all pts and separately for pts with/without BM. Chi-square and Fisher Exact tests were used to evaluate possible associations. OS and PFS were calculated by the Kaplan-Meier product-limit method. Log-rank and Tarone-Ware tests were used to assess differences between subgroups. **Results:** pts median age was 56 yrs (range 27-82), PS 0/1-2 66/44%, ER/PgR positive 83%, TNBC 17%, prior neo/adjuvant taxanes 73%, visceral involvement 60% and bone metastasis alone 11.4%. The median administrations of P and B per pts were respectively 18 (1–39) and 14 (1-52). 14.6% of pts are still receiving B-P and 16.8% pts having PD during B-P are not evaluable for BM. Of the remaining 192 pts, 51.7% received BM after P interruption (withBM). At a median follow-up of 20 mo (range 2-90) 10% pts achieved CR, 54% PR, 18% SD and 12% PD. Disease control rate (CR+PR+SD $\geq$ 6 m) occurred in 74% pts. The RR was significantly different between ER/PgR pos and TNBC (p = 0.03), which had RR respectively of 71% and 52%. No significant difference was found between pts with or without P pretreatment, nor between different P schedules. Overall, median PFS was 14 mo (95% CI, 12-16) and median OS was 41mo (95% CI 30-51). The median duration of BM was 6 mo (range 2-40). A significant difference was highlighted when comparing median PFS among pts withBM (18 mo, 95%CI 16-20) and withoutBM (13 mo 95% CI 7-18). The median OS was 55mo (95% CI 41-69) in pts withBM and 40 mo (95% CI 29-51) in pts withoutBM: the two groups did not differ significantly. **Conclusions:** Our analysis showed that the pts withBM after B-P combination had statistically and clinical significant improvement in PFS. Data collection is ongoing and update results will be presented.

550 Poster Session (Board #38), Sat, 8:00 AM-11:30 AM

Could any pT1a,bN0M0 hormone-responsive, invasive breast carcinomas be safely treated without endocrine therapy? *First Author: Christophe Perrin, Centre Eugène Marquis, Rennes, France*

Background: Overtreatment is a daily concern in the adjuvant setting for breast carcinoma. Most of Hormone Responsive (HR+) pT1a,bN0 breast cancers have an excellent prognosis. The aim of this study was to identify a subset of patients in whom abstention of adjuvant endocrine therapy would be safe. **Methods:** In this bicentric retrospective study, we analysed the prognosis of consecutive patients treated for HR+ pT1a,bN0M0 breast cancer, focusing on the population without adjuvant endocrine therapy. Log rank test was used for univariate analysis and a cox model was used for multivariate analysis. **Results:** 885 patients with HR+ pT1a,bN0M0 breast carcinoma were treated between 1997 and 2007. Local treatment involved either mastectomy or breast conserving surgery followed by breast radiotherapy. 227 patients (25.6%) did not receive any adjuvant endocrine therapy. Comparatively to the group treated with endocrine therapy, these patients were significantly younger (< 50 years old patients), with less grade II or III and less ductal histology. After a median follow-up of 6.4 years, 5 years-invasive disease free survival (IDFS) was significantly lower (89.8%) in the no endocrine therapy group than in the endocrine therapy group (94.6%) with log-rank p = 0.005. Distant Disease Free Survival (DDFS) and Overall Survival (OS) were not significantly different with numerically better results in the no-endocrine therapy group. In multivariate analysis, avoidance of endocrine therapy, grade II-III and young age (under 50 years old) were independent adverse prognostic factors for IDFS. **Conclusions:** In pT1a,bN0 HR+ patients, avoiding adjuvant endocrine therapy was slightly deleterious for IDFS but DDFS and OS were not affected. Discussion about risk/benefit ratio is crucial before proposing adjuvant endocrine therapy in this setting.

551 Poster Session (Board #39), Sat, 8:00 AM-11:30 AM

Influence of immunohistological detection of intratumoral urokinase-type plasminogen activator (uPA) on disease outcome in endocrine-treated postmenopausal patients with hormone receptor-positive early breast cancer. *First Author: Christian F. Singer, Medical University of Vienna, Vienna, Austria*

Background: Elevated intratumoral levels of uPA and PAI-1 in ELISA-based measurements are associated with a high recurrence risk and allow to select patients who might particularly benefit from adjuvant chemotherapy. The clinical utility of ELISA-based uPA/PAI-1 analysis is, however, greatly limited by the requirement of fresh tissue. We have therefore evaluated whether immunohistochemical uPA analysis from formalin-fixed paraffin-embedded (FFPE) tumor samples is also suited to identify women with poor clinical outcome. **Methods:** 547 postmenopausal patients with hormone receptor positive, early breast cancer who had received 5 years of endocrine therapy in the prospective randomized ABCSG-06 trial, and from whom FFPE tumor tissue was available, were included in this analysis. uPA protein expression was evaluated by immunohistochemistry, and was correlated with distant-disease free (DDFS) and overall survival (OS). **Results:** uPA protein was expressed in 296 of 547 (54%) tumors and was associated with size (p = 0.016, Chi Square test) but not with nodal status, grading, age, or receptor status. After a median follow-up of 11.5 years, patients with uPA-positive tumors experienced a significantly shorter DDFS (p = 0.005 log rank test) and OS (p = 0.022). Women with uPA-positive tumors were more likely to experience a shorter DDFS (adjusted HR for distant relapse 1.642; 95% CI 1.046-2.576; p = 0.031 Cox regression analysis) and OS (adjusted HR for death 1.348; CI 0.984-1.846; p = 0.063) than women without uPA expression. **Conclusions:** When measured by immunohistochemistry, intratumoral uPA protein expression predicts poor DDFS and OS in postmenopausal women with hormone receptor positive early-stage breast cancer who receive endocrine therapy. Clinical trial information: NCT00309491.

552 Poster Session (Board #40), Sat, 8:00 AM-11:30 AM

Prognostic significance of Focal Adhesion Kinase (FAK) in node-negative breast cancer. *First Author: Marcus Schmidt, University Hospital Mainz, Mainz, Germany*

Background: Focal adhesion kinase (FAK) is a cytoplasmic tyrosine kinase playing an important role as a key mediator for signal transduction. We examined the subtype specific prognostic significance of FAK in node-negative breast cancer. **Methods:** Using microarray based gene-expression data, we analysed the prognostic significance of FAK (208820_at). The subtype specific prognostic role of FAK was analysed in four previously published cohorts (Mainz, Rotterdam, Transbig, Yu) of node-negative breast cancer patients not treated with adjuvant therapy (n = 824). A meta-analysis of previously published cohorts was performed using a random effects model. Prognostic significance of FAK for metastasis-free survival (MFS) was examined in the whole cohort of patients as well as in different molecular subtypes: luminal A (ER^+/$HER2^-$/aurora kinase A [AURKA]^{low}, luminal B (ER^+/$HER2^-$/$AURKA^{high}$), basal-like (ER^-/$HER2^-$), and $HER2^+$. **Results:** Prognostic significance of FAK was seen in the whole cohort of patients (HR 1.48, 95% CI 1.16-1.87, P = 0.001). Considering the different molecular subtypes, the prognostic effect was most pronounced in luminal B carcinomas (HR 1.67, 95% CI 1.07-2.62, P = 0.0233). FAK expression was neither significantly associated with MFS in luminal A (HR 1.69, 95% CI 0.96-2.98, P = 0.0692), basal-like (HR 0.98, 95% CI 0.64-1.50, P = 0.9400) nor $HER2^+$ (HR 1.63, 95% CI 0.49-5.46, P = 0.8512) carcinomas of the breast. **Conclusions:** A higher expression of FAK was associated with worse MFS in node-negative breast cancer. The prognostic significance was confined to luminal B carcinomas.

553 Poster Session (Board #41), Sat, 8:00 AM-11:30 AM

Medication use trajectories of postmenopausal breast cancer survivors and matched cancer-free controls. *First Author: Kathy Pan, Harbor-UCLA Medical Center, Torrance, CA*

Background: While distinct health issues are associated with breast cancer and related therapies, comprehensive assessment of medication use before and after breast cancer diagnosis compared to age-matched, cancer-free controls has not been reported. **Methods:** From the 93,338 postmenopausal participants in the Women's Health Initiative trials, medication inventories by pill container review were serially obtained before and > 3 years (mean 5.3 + 2.1 SD) after early stage breast cancer in 1730 cases matched with 1730 controls on age, dates of initial and follow-up medication inventories, body mass index, and smoking. Number of medications and medication classes (excluding tamoxifen and aromatase inhibitors [AI]) in cases and controls were compared. **Results:** Medication use (n) was comparable at baseline in both groups and significantly increased at follow-up in both cases (4.12 + 2.73 vs 6.47 + 3.29, P< .0001) and controls (3.92 + 2.59 vs 5.94 + 3.37, P < .0001), with clinically marginal but statistically significant additional medication use 0.53 ± 3.93 by breast cancer survivors (P < .0001). More breast cancer survivors used antidepressants (15.3% vs 12.2%, P = .006) and bisphosphonates and/or calcium/vitamin D (62.2% vs 54.8%, P < 0.001). Use of the following classes did not differ: anti-diabetic, cardiovascular, anti-anxiety, and narcotic and non-narcotic analgesics. Medication use at follow-up inventory by adjuvant endocrine therapy are outlined below. Medication use in breast cancer survivors on tamoxifen was lower than controls while those on AIs used more medications. **Conclusions:** Reflecting age-related co-morbidities, medication use significantly increases over time in both breast cancer survivors and controls. Overall, breast cancer impact on medication use is limited.

	Breast Cancer Cases (n=1730)				Controls (n=1730)
Selected medication classes (non-endocrine treatment) mean ± SD	*All*	*Current Tamoxifen (n=426)*	*Current AI (n=331)*	No Current Endocrine (n=975)	3.95 ± 2.13 (min=0, max=11)
	4.15 ± 2.13 (min=0, max=11)	3.40 ± 1.89 (min=0, max=10), P=.05*	4.85 ± 2.10 (min=0, max=10). P=.002*	4.23 ± 2.14 (min=0, max=11)	

*Adjusted Poisson regression used for test of case-control differences.

554 Poster Session (Board #42), Sat, 8:00 AM-11:30 AM

Detection and functional analysis of estrogen receptor mutations (ESR1-mut) in patients with metastatic breast cancer (MBC). *First Author: Shannon Puhalla, University of Pittsburgh Medical Center, Women's Cancer Program at Magee-Womens Hospital of UMPC, Pittsburgh, PA*

Background: Mutations in ESR1 (ESR1-mut) are a potential resistance mechanism to endocrine therapy, especially aromatase inhibitors (AI). Although these mutations are rare in untreated patients with early breast cancer, they have been observed to develop after exposure to hormonal therapy, suggesting a critical functional role for ER signaling in MBC and the potential to use ESR1-mut as a predictive marker and novel treatment target. **Methods:** Primary (44 patients) and metastatic breast cancers (brain, 38 patients; bone, 15 patients), and plasma (30 patients) samples collected from patients with MBC were examined for the presence of ESR1-mut D538G , K303R, Y537C, Y537N, S463P and Y537S using digital droplet (dd)PCR and Sanger Sequencing. Ten mL of plasma were collected in 4 Streck tubes for the isolation of circulating free DNA (cfDNA). Matched plasma and tissue samples were correlated when both were available. ER overexpression and physiological relevant models through genome editing were used to characterize phenotypes of ESR1-mut breast cancer cells. **Results:** ESR1-mut were found in 7% of ER+ primary cancers, 18% of ER+ brain metastases, 8% of ER+ bone metastases, and 40% of cfDNA collected from patients with ER+ MBC. D538G was the most common mutation found, followed by Y537C. K303R and S463P ESR1-mut were not demonstrated in these samples. We identified tumor and cfDNA that contained more than one distinct ESR1 mutation. The allele frequency ranged from 0.01% to 37%. The lowest allele frequency was in the primary cancers (0.01-0.4%) and likely a reflection of the high sensitivity of ddPCR. All patients with mutations had undergone prior treatment with tamoxifen and/or aromatase inhibitor prior to ESR1-mut analysis. In vitro, ESR1-mut cells were characterized by estrogen-independent signaling, and partial resistance to endocrine therapy. **Conclusions:** There is a high prevalence of ESR1-mut in patients with ER+ MBC acquired following hormonal treatment, particularly in cfDNA, suggesting both an ER signaling dependency for tumor survival and an important mechanism driving endocrine resistance.

555 Poster Session (Board #43), Sat, 8:00 AM-11:30 AM

Adjuvant aromatase inhibitor adherence based on the Morisky Medication Adherence Scale and identification of predictors to adherence. *First Author: Paula Rosenblatt, University of Maryland Marlene and Stewart Greenebaum Cancer Center, Baltimore, MD*

Background: Aromatase inhibitors (AI) improve outcomes in hormone receptor positive breast cancer. Unfortunately, adherence to these oral agents remains difficult for many patients. The Morisky Medication Adherence Scale (MMAS) is a validated eight item questionnaire that measures adherence to medication in many chronic conditions. However, the MMAS has not been studied in the oncology setting. The purpose of this study was to identify the level of AI adherence in breast cancer patients based on the MMAS. Secondary objectives were to identify predictors of adherence. **Methods:** Patients were eligible if they had stage 1-3 hormone receptor positive breast cancer and were being treated at the University of Maryland Marlene and Stewart Greenebaum Cancer Center with AI therapy. Consecutive eligible patients were offered participation on an IRB approved protocol and informed consent was obtained. Participants completed the study questionnaires consisting of the MMAS and demographics. Participants were stratified by duration of AI therapy ≤ 2 years and > 2 years. **Results:** Between March 2011 and November 2014,100 women were accrued. Median age was 59, 37% were African American, and 62% received chemotherapy. Total adherence was 13% low (MMAS < 6), 37% medium (MMAS 6-7), and 50% high (MMAS = 8). There was no association of duration of AI treatment ≤ 2 yrs vs > 2 yrs and adherence level. The cumulative logit model revealed that possibly race and use of chemotherapy have some predictive ability for adherence, however p-values were only of marginal statistical significance. No association was found between adherence level and age, stage, tumor size, lymph node positivity, type of surgery, use of radiation, education level, marital status, insurance status, or comorbid conditions. **Conclusions:** Our study shows that only 50% of our patients on adjuvant AI therapy have high adherence based on the MMAS scale. There is a possible association of improved adherence to AI therapy in white patients and those who received adjuvant chemotherapy. Further research is needed to identify predictors to AI adherence in order to develop effective interventions to optimize compliance.

556 Poster Session (Board #44), Sat, 8:00 AM-11:30 AM

Effect of tumor infiltrating lymphocytes (TILs) and stromal CD68 on trastuzumab (T) benefit in early stage HER2 positive breast cancer (BC). *First Author: Jacques Raphael, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada*

Background: The presence of high TILs has been implicated as a predictor of pathologic complete response (pCR) and decreased recurrence rates in BC patients. However, there is conflicting data for the benefit of T in the adjuvant setting for HER2 positive (HER2+) BC patients with high TILs. In addition, greater numbers of CD68 (+) cells (macrophage marker) in tumor stroma has been shown to be an independent prognosticator for reduced BC specific survival. **Methods:** Core biopsies from52 Her2+ BC patients treated with neoadjuvant (NAT) chemotherapy with or without T were identified. Two pathologists independently quantified stromal TILs and CD68 ratio (inside the TILs population) using Hematoxylin/Eosin and immunohistochemistry respectively. The association of TILs and CD68 with pCR rates was determined by Mann-Whitney U, Chi-square or Fisher's exact test. Prognostic significance of TILs and CD68 ratio on pCR rates, disease free survival and overall survival (OS) was assessed by Kaplan-Meier analysis and log-rank test. **Results:** The median age and follow up for the cohort were 52 and 2.8 years, respectively. In the NAT setting, 40 patients received conventional chemotherapy and T (77%) and 12 patients were treated with chemotherapy alone (23%). Overall the pCR rate in the studied population was 40%. Eight patients (15%) had high levels of TILs ($\geq$ 60%) and 20 patients (38%) had low CD68 ratio ($\leq$ 60%). A high percentage of TILs was significantly correlated to low CD68 ratio ($p < 0.0001$). High levels of TILs and low CD68 ratio were each associated with greater pCR rates for the cohort of patients who received NAT T, respectively ($p = 0.05$, $p = 0.03$). Furthermore, pCR was predictive of better OS ($p = 0.02$) for the patients treated with NAT T. However, these associations were no longer significant when we performed the analysis on the whole population ($p = 0.09$, $p = 0.32$). **Conclusions:** Our results show that high levels of TILs are associated with low CD68 ratio, and both are predictors of pCR in patients with HER2+ BC receiving NAT T. Importantly, pCR as determined by CD68 and TILs translated into an OS benefit. TILs and CD68 ratio represent potential prognostic and predictive markers in patients with HER2+ BC.

557 Poster Session (Board #45), Sat, 8:00 AM-11:30 AM

Tamoxifen (TAM)-induced severe hot flashes (HF): Is dose reduction (DR) a safe and effective strategy? *First Author: Clara Inkyung Lee, Westmead Hospital, Sydney, Australia*

Background: It is recognized that severe HF toxicity due to TAM can compromise compliance. We previously established that HF do not correlate with endoxifen level or *CYP2D6*genotype, though prior reports are varied on this subject. In this pilot study, we reduced TAM dose in patients with severe HF and determined whether HF were ameliorated whilst maintaining a purported therapeutic endoxifen level of $>$ 15nM. **Methods:** Eighteen patients with severe HF on 20mg TAM were enrolled. *CYP2D6*genotype, trough level TAM and metabolites were measured. Loprinzi HF diaries were filled out before and after DR to 10mg TAM, and hot flash scores (HFS) derived. Other data collected included demographics, smoking and alcohol history, breast cancer history, previous chemotherapies, concurrent medications, menstrual history, body mass index (BMI) and other toxicities recognized to be associated with TAM. **Results:** At 20mg dose of TAM, baseline endoxifen levels were 24.5, 27.9, 0-91.9 nM (median, mean, range), consistent with the high variability seen in our previous 122 patient cohort. HFS at baseline were 108, 188, 4-1482 (median, mean, range). Upon dose reduction to 10mg, endoxifen levels fell to 13.2, 18.6, 0.6-71.9 nM (difference in means $p = 0.056$, two-tailed T test). HFS at 10mg fell to 38, 101, 5-864 (difference in means $p = 0.36$, two-tailed T test). Despite this lack of statistical significance, 78% of patients reported subjective improvement of hot flashes with DR. However after DR, the proportion of patients with an endoxifen level below a suggested therapeutic target of 15nM increased from 22% to 50%. HFS did not correlate with several patient characteristics including menopausal state, duration since last menstrual period and BMI (Spearman's rank correlation coefficient). **Conclusions:** In this group of women selected for having significant HF, DR of TAM from 20mg to 10mg daily resulted in halving of endoxifen levels and subjective improvement of HF, however half were below a potential therapeutic level of endoxifen at the reduced dose. Therefore routine DR to ameliorate HF toxicity may not be safe unless therapeutic drug level monitoring is performed.

558 Poster Session (Board #46), Sat, 8:00 AM-11:30 AM

Molecular profiling to identify genetic heterogeneity in synchronous and asynchronous breast cancers. *First Author: Windy Marie Dean-Colomb, Lafayette General Health, New Orleans, LA*

Background: Histologic heterogeneity of tumors is well documented; however, the molecular heterogeneity is not well understood, especially relative to driver mutations within clonal populations and their prognostic and predictive value. **Methods:** Molecular profiling of breast cancers (BCs) at a single institution were analyzed for differences in clonal populations within the same breast, bilateral synchronous BCs, and/or within primary and paired locally recurrent or metastatic tumors. Gene alterations (GAs) were identified by next generation sequencing (NGS). GAs were compared in 9 synchronous BCs and 48 primary/recurrent paired BCs. Estrogen receptor (ER), progesterone receptor (PR), androgen receptor (AR), were evaluated by immunohistochemistry (IHC). HER2 was evaluated by IHC and in situ hybridization (ISH). **Results:** We identified GAs in 11 of 57 cases (19%); 2 were bilateral and 9 were paired primary/recurrent BCs. The 11 cases included 1 primary, 1 primary/locally recurrent, and 9 primary/metastatic pairs. ER, PR, and HER2 status differed in 9 cases (16%), while AR status differed only in 3 (5%).16% 13/57 were negative for ER, PR, and HER2 (triple negative [TN]); of 9 TN BCs with GAs in paired primary/recurrent BCs, 6 of 9 (67%) were TN on both primary and recurrent disease ($p = 0.0135$). *TP53* GAs were identified in 5 of the 11 cases (including the 2 synchronous), *PIK3CA* GAs were identified in 4 (1 synchronous), and *PTEN* GAs were identified in 3 (1 synchronous) cases. Other genes in which GAs appeared in only one of the pairs included *CDH1* (synchronous), *cMET* and *KRAS* (Primary/recurrent pair). Of the 2 synchronously profiled cases, 1 had 2 and 1 had 3 different GAs in the bilateral BCs, and 2 GAs in both BCs. In the primary/metastatic pairs, all discordant GAs were wild type in the primary and pathogenic in the metastasis. **Conclusions:** We identified that common GAs differ in both synchronous primary BCs and in paired primary/metastatic tissues. Such discordance could influence treatment recommendations. These findings highlight the molecular evolution of BC and the importance of evaluating predictive markers of treatment benefit both in synchronous and metastatic BCs.

559 Poster Session (Board #47), Sat, 8:00 AM-11:30 AM

P95HER2 as a predictive marker in the phase III randomized HERNATA trial of trastuzumab and chemotherapy as first-line therapy to metastatic or locally advanced HER2-positive breast cancer. *First Author: Ann S. Knoop, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

Background: HER2+ tumours express a series of carboxy-terminal HER2 fragments (CTFs or p95HER2) lacking the receptor extracellular domain that have been investigated as a potential trastuzumab resistance marker. Utilizing patients with locally-advanced or metastatic HER2+ breast cancer enrolled in the randomized HERNATA study, we assessed the expression of p95HER2 and its association with time to progression (TTP). **Methods:** Immunohistochemical (IHC) staining for p95HER2 was performed using a monoclonal antibody that specifically recognizes 611-CTF variant, blinded to clinical outcome (bioTheranostics Inc.). All slides were scored in consensus with a pre-defined cut-point (10% cells of strong staining) to define positive P95HER status. Additionally, an H-score (0-300) based on IHC staining was calculated with a preselected cut-point, that ensured 30% of the patient to be classified p95HER2 positive. TTP was analysed by Cox proportional hazards models. The model assumption of proportional hazards was investigated by Schoenfeld residuals and was used to evaluate if re-parameterization of p95HER2 by time-dependent variables (cut-point: 1.5 year after randomization) affects the association of p95HER2 status with TTP. **Results:** P95HER2 staining was available from 207 (73%) patients within the HERNATA intention to treat population of 284 patients. 36% of the patients were p95HER2 positive ($\geq$ 10 % strong staining). Kaplan-Meier analysis showed no significant association between p95HER2 status and TTP ($p = 0.68$). However, Cox unadjusted analysis showed a marginally significant association between p95HER2 status and TTP 1.5 year after randomization ($P = 0.04$; HR 0-1.5 year after randomization: 1.04, 95% CI: 0.74-1.46; HR $>$ 1.5-year after randomization: 2.60, 95% CI: 1.23-5.51) – which were confirmed in the adjusted analyses, as seen by similar HR estimates although not significant ($P = 0.07$). Results based on H-score are similar. **Conclusions:** No evidence of p95HER2 as a resistance biomarker for trastuzumab was found in this cohort of HER2+ metastatic breast cancer patients from the randomized HERNATA trial.

560 Poster Session (Board #48), Sat, 8:00 AM-11:30 AM

Long-term rates of ipsilateral breast tumor recurrence (IBTR) for women with ductal carcinoma in situ (DCIS) meeting LORIS trial eligibility criteria undergoing standard therapy. *First Author: Melissa Louise Pilewskie, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Identification of DCIS patients at low risk for progression to invasive carcinoma could obviate the need for standard surgery and radiation therapy (RT). The "Surgery versus Active Monitoring for LOw RISk DCIS [LORIS]" trial is studying the safety of monitoring low-risk DCIS without excision, although IBTR rates in this population undergoing standard therapy are unknown. **Methods:** Women with DCIS treated with breast-conserving surgery (BCS) with or without RT from 1996-2010 were included from a prospectively maintained database. IBTR rates were compared between those who did and did not meet LORIS eligibility criteria (age ≥46yrs, screen-detected calcifications, non-high grade DCIS diagnosed on needle biopsy, absence of nipple discharge, minimal family history). **Results:** 2,537 women were identified; 405 met LORIS criteria. LORIS cohort median age was 60yrs (range 46-86yrs); 210 (52%) underwent RT, 81 (20%) received endocrine therapy. Median follow-up was 5.8yrs (range 0-18yrs). 24 experienced an IBTR (14 DCIS, 10 invasive) (see table for overall IBTR rates). 5 and 10yr invasive-IBTR rates for women meeting LORIS criteria by treatment group were: 1.7% and 5.3% BCS with or without RT; 3.0% and 6.0% no RT; 0.55% and 4.6% with RT, respectively. **Conclusions:** LORIS eligibility criteria identify women with DCIS at somewhat lower risk for IBTR, yet among such women treated with BCS alone, the 10yr overall IBTR rate was 12% and invasive-IBTR rate was 6%. Given that approximately 20% of women with core biopsy proven non-high grade DCIS have invasive cancer at excision, women managed with observation alone would be expected to incur significantly higher rates of invasive cancer development. Additional risk predictors are needed to identify women who do not require intervention for DCIS.

Variation in the use of granulocyte-colony stimulating factor (G-CSF) for dose dense paclitaxel: A single institution retrospective study. *First Author: Flavia Rocha Paes, Oncoclinicas do Brasil, Belo Horizonte, Brazil*

Background: In randomized trials, administration of dose dense (dd) doxorubicin and cyclophosphamide (AC) followed by paclitaxel (T) with G-CSF support improved outcomes compared with every 3 week dosing in the adjuvant treatment of early breast cancer. However, the use of G-CSF in dd regimens is associated with increased cost and its utility for the T portion of this regimen is unclear. We studied patients (pts) treated with ddACT to investigate variation in the use of G-CSF among the medical oncologists at our NCI designated cancer center. **Methods:** Among 523 pts treated with adjuvant chemotherapy from 01/2011 to 12/2013, we identified pts who received ddACT. Descriptive analyses were used to analyze patterns of G-CSF use in the T portion of this regimen, and the impact of G-CSF use on delays, toxicity and treatment completion. **Results**: Overall, 155 pts (29.6%) were treated with ddACT by 26 providers during the study period. Variation in the use of G-CSF by provider and by patient was found. 21 (13.6%) pts did not receive any G-CSF support during the T portion of ddACT, with 11 providers choosing this approach in at least one pt. The majority of pts (134, 86%) received G-CSF support in at least one of the cycles, ranging from 17% of pts receiving G-CSF in one cycle to 48% of pts receiving G-CSF in all 4 cycles. Reasons for omitting of G-CSF included high baseline absolute neutrophil count and pain. Among the 21 pts who did not receive G-CSF with any cycle there were no treatment delays and no reports of febrile neutropenia; 90.4% (n = 19) completed treatment. Among the 134 pts treated with G-CSF during at least 1 cycle, 6 % had a treatment delay and 94.7% (n = 127) completed treatment. **Conclusions:** We identified variation in the use of G-CSF among medical oncologists in the administration of ddACT at our comprehensive cancer center. In addition, many physicians did not utilize G-CSF in a consistent fashion. Omitting of G-CSF was not associated with treatment delays or adverse events, though our sample size was small. To provide data to support uniform institutional practice, a prospective study formally evaluating the feasibility of delivering dd paclitaxel without routine G-CSF support is planned.

562 Poster Session (Board #50), Sat, 8:00 AM-11:30 AM

Tumor infiltrating lymphocytes (TIL) and Ki67 suppression after neoadjuvant therapy for HR+/HER2- breast cancer (BC): Results from two prospective trials. *First Author: Maria Vittoria Dieci, University of Padova, Padova, Italy*

Background: In BC, TIL predict for pCR after neoadjuvant chemotherapy. Since pCR is a suboptimal surrogate for treatment efficacy for HR+/HER2- patients (pts), we evaluate the association between TIL and molecular response after preoperative endocrine or cytotoxic treatment for HR+/HER2- BC. **Methods:** Stromal (Str) TIL were evaluated on H&E slides from diagnostic core-biopsies of 140 HR+/HER2- pts included in two prospective randomized trials. The LETLOB trial randomized 92 HR+/HER2- pts to neoadjuvant letrozole +/- lapatinib. The GIOB trial randomized 90 pts (n=48 HR+/HER2-) to primary anthracycline/taxane +/- gefitinib (Guarneri JCO 2012, BCRT 2008). Pre- and post-treatment Ki67 was centrally evaluated. **Results:** StrTIL were evaluable in 119 cases.Median StrTIL% was 2%. Pts with focal StrTIL or higher (StrTIL>=10%, n=28) were younger (p=0.034), had more frequently BC of ductal histology (p=0.04), high grade (p=0.025) and high Ki67 (p=0.012). After treatment, a significant Ki67 reduction from baseline (Wilcoxon p< 0.01) was observed overall and in each study (mean reduction similar in LETLOB and GIOB, T-test=ns). In the LETLOB trial a significant Ki67 suppression (Wilcoxon p< 0.01) was observed irrespectively of StrTIL, but mean Ki67 reduction was significantly greater in StrTIL>=10% vs < 10% (-13% vs -5%, T-test p=0.012). In the GIOB trial, a significant reduction in Ki67 was observed only for StrTIL< 10% pts (mean reduction -12% vs -0.9%, Wilcoxon p=0.001 and p=0.612 in StrTIL< 10% and >=10%, respectively). There was no difference according to arm in each study. The table reports the association of StrTIL with molecular response (proportional Ki67 reduction from baseline >50%). Test for interaction with treatment (cytotoxic or endocrine) was of borderline significance. **Conclusions:** The presence of TIL correlates with greater Ki67 suppression after neoadjuvant endocrine therapy but seems to prevent a molecular response after chemotherapy for HR+/HER2- pts.

		Ki67 reduction < 50% (%)	Ki67 reduction > 50% (%)	Chi2	Interaction p

563 Poster Session (Board #51), Sat, 8:00 AM-11:30 AM

Hormonal treatment (HT) and late recurrence in early-stage breast cancer (BC) patients. *First Author: Carlos Hernando Barcenas, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BC patients who are disease free after 5 years (Y) of diagnosis still remain at risk of developing a late recurrence. We assessed the effect of HT on the risk of late recurrence in early-stage BC patients with hormone-receptor-positive, HER2-negative disease from a large institutional database. **Methods:** We retrospectively identified a cohort of female early-stage (I to III) BC patients who had hormone-receptor-positive, HER2-negative (or not tested) disease, diagnosed between January 1997 and August 2008, who had received initial treatment at MD Anderson, and had remained disease free for ≥ 5 Y. We excluded patients who had incomplete HT data and those who received > 10 Y of HT. The primary endpoint was recurrence-free survival measured from the initial BC diagnosis to the first local-regional or distant recurrence. HT agents were categorized as aromatase inhibitors (AI), tamoxifen (T), sequential T and AI (T→AI), and other. The length of HT was categorized as " < 5 Y", "5 Y", " > 5- < 10 Y" and "10 Y". We used a multivariable Cox proportional hazard model to calculate hazard ratios (HR) and 95% confidence intervals (CI) for recurrence-free survival adjusted for patient demographics, tumor characteristics and treatments received. **Results:** We identified 2,839 patients; 155 (5.5%) developed late recurrence (median follow-up of 8.8 Y, range 5-16 Y). Compared to patients who received 5 Y of HT (72%), those who received 10 Y (4.4%) had a 79% reduced risk of late recurrence (HR = 0.21, 95% CI = 0.05, 0.88), while patients who received < 5 Y (14%) had an increased risk (HR = 1.88, 95% CI = 1.23, 2.89), with no difference in the HT length category " > 5- < 10 Y". Compared to patients who received T alone (32%), those who received T→AI (26%) had a significantly lower risk of late recurrence (HR = 0.52, 95% CI = 0.32, 0.85), with no difference for patients who received AI alone or other. **Conclusions:** In this retrospective cohort, HT duration of 10 Y, and the sequential use of T→AI were both factors independently associated with a significantly lower risk of late recurrence, after adjusting for several other known prognostic factors.

564 Poster Session (Board #52), Sat, 8:00 AM-11:30 AM

Oncotype-DX recurrence score distribution among breast cancer patients harboring a germline mutation in the BRCA1/2 genes. *First Author: Ron Lewin, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, Israel*

Background: In about 10% of breast cancer (BC) cases, a genetic mutation in the BRCA1/2 genes can be found. BCs associated with BRCA2 mutations present with positive estrogen receptor (ER) status in about 50% of all cases, whereas BCs associated with BRCA1 mutation are more aggressive and more likely to be ER-negative. Oncotype genetic profiling has become a standard of care to predict recurrence and the benefit from chemotherapy in ER positive BC. The role of Oncotype-DX in BRCA mutation-carriers is not clear. Our primary end-point is to compare the RS distribution of BRCA carriers to that of the General Population (GP). **Methods:** Two different data bases were crossed: the list of BRCA mutation-carriers at Rabin Medical Center (n=1,191) with the list of all the oncotype-DX tests which were performed through Kupat Holim Clalit, our HMO (n=5,491), between 2003 and 2015. **Results:** Patients and tumor characteristics, including Oncotype RS are shown in the Table. **Conclusions:** Our study indicates that among BC patients with mutations in the BRCA1/2 genes, the distribution of the RS is different from that of the GP. In these patients a larger portion of the population was shifted toward the intermediate- and high- risk groups. This was more pronounced in the BRCA1 carriers. To our knowledge this is the largest BRCA cohort in which the oncotype-Dx RS has been reported.

	*Non-BRCA n=1,031	BRCA1 n=16	P-value	BRCA2 n=27	P-value

566 Poster Session (Board #54), Sat, 8:00 AM-11:30 AM

Steps in developing Watson for Oncology, a decision support system to assist physicians choosing first-line metastatic breast cancer (MBC) therapies: Improved performance with machine learning. *First Author: Julia Fu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: IBM Watson for Oncology (WFO), trained by Memorial Sloan Kettering (MSK), is a cognitive computing system designed to apply machine learning, informed by MSK expertise, to enhance clinical decision making. We expanded the initial adjuvant therapy prototype to include MBC. Patients with MBC share many common attributes (e.g. age, performance status, receptor status, prior therapy) but receive widely varying therapies. Accuracy of WFO treatment recommendations for similar cases can be improved with machine learning features built on highly influential attributes. **Methods:** 101 manufactured MBC training cases were grouped by biologic characteristics and then analyzed for variation. A set of clinical attributes characterizing disease burden was posited to be influential in selecting the initial systemic therapy for MBC recommended by MSK breast medical oncologists (e.g. endocrine therapy vs chemotherapy for a patient with hormone receptor (HR)+MBC). WFO learned weights characterizing each attribute's importance (e.g. site(s), extent, and size of metastatic lesions, degree of symptoms) through iterative experiments on training cases, and incorporated them into a "disease burden score"). Model performance as quantified by a combination of precision and recall (F1 Score) defined as (2 * true positives) / [(2 * true positives) + (false positives) + (false negatives)], was measured with and without the use of the disease burden score. **Results:** Activation of the disease burden score feature yielded a relative improvement in F1 Score of 11.5% across all cases (n = 101) from 73.6% to 82.1%; 28.8% among HR+ HER2+ cases (n = 32); 9.6% among HR+ HER2- cases (n = 29); 2.8% among HR- HER2+ cases (n = 17) and -1.4% among HR- HER2- cases (n = 23). **Conclusions:** Using training data and medical logic, WFO's machine learning model can assign weights to attributes and features to select therapy for patients that better align with the nuanced decision-making of MSK breast medical oncologists than rules alone. WFO's machine-learned disease burden score is a useful driver of treatment recommendations for HR+ and/or HER2+ MBC.

567 Poster Session (Board #55), Sat, 8:00 AM-11:30 AM

Variations in measured ER, PR, and HER2 status in synchronous and asynchronous paired breast cancer (BC) tumors. *First Author: Clayton Yates, Tuskegee University, Tuskegee, AL*

Background: That tumor heterogeneity exists and evolves over time is well appreciated but how often to biopsy patients' metastatic BC is not well established. **Methods:** Immunohistochemical (IHC) and in situ hybridization (ISH) analysis of estrogen receptor (ER), progesterone receptor (PR), androgen receptor (AR), and HER2 in 337 cases with > 1 asynchronous primary/metastatic BC molecular profiles and in 40 cases with > 1 synchronous molecular profiles was performed at a single institution. We evaluated differences in ER, PR and HER2 status in same or contralateral breast, and in primary vs. locally recurrent or metastatic BC's. **Results:** We identified a change in ER or HER2 status in 8 (31%) synchronous BCs and in 55 (16%) primary/recurrent BCs, including in biopsies of distinct tumor foci within the same breast or metastatic organ site. Of the 8 synchronous bilateral primary BC's, 4 (50%) had discordant ER results (ER, PR, and HER2 negative [TN] vs. ER+); 5 of 18 (28%) with two or more metastatic foci tested within the same organ had discordant ER results; 23% of BCs with biopsies of different organ sites had discordant ER results. Of the 55 paired primary/metastatic BCs, 15% of the discordant findings were in cases with biopsies from two different metastatic sites, 19% were in cases with one metastatic and one primary or local recurrent biopsy, and 23% were from 2 primary biopsies or from primary and locally recurrent disease. Discordance was bidirectional from either TN to ER+ or ER+ to TN, and independent of discordance in HER2. **Conclusions:** Standard systemic treatment of BC relies on reliable assessment by IHC analysis of ER, PR, and HER2. Within a patient, ER and HER2 status are not always concordant between lesions within the same breast, between bilateral BCs, and between distinct foci in a metastatic organ site. Patients are at risk of not being treated for the most clinically important foci of BC if the biopsy(s) obtained are not representative of the more aggressive areas of disease. Profiling should be performed on multiple BC samples both at diagnosis and at each time of recurrence/progression in the cancer continuum, to more accurately reflect the tumor profile at the time of treatment.

568 Poster Session (Board #56), Sat, 8:00 AM-11:30 AM

Meta-analysis of clinical outcomes to second-line endocrine therapy for visceral and non-visceral metastases. *First Author: John Forsyth Russell Robertson, School of Medicine, University of Nottingham, Derby, United Kingdom*

Background: A previous meta-analysis reported that patients with hormone receptor-positive visceral metastases (VMs) who respond to 1st-line endocrine therapy (ET) benefit for as long as those with only non-VMs. Here, we assess outcomes in the 2nd-line setting. **Methods:** We meta-analyzed five phase 3 RCTs of 2nd-line ETs for hormone receptor-positive breast cancer (anastrozole, exemestane and fulvestrant 500 and 250 mg; Table). All reported objective response rate (ORR), CBR, time to progression (TTP) and duration of clinical benefit (DoCB). **Results:** Combined ORR was similar for non-VMs (10%) vs VMs (9.2%) (Peto method p=0.485); only CONFIRM was an exception (ORR: 5.4% [non-VMs] vs 13.2% [VMs]); Tarone's test for heterogeneity: p=0.0014). CBR for non-VMs (38.8%) vs VMs (31.9%) was significantly different (Peto method p< 0.001); Tarone's test: p=0.068. Combined median DoCB was 420 days (non-VMs) vs 338 days (VMs) (odds ratio, 0.79; 95% CI, 0.68-0.91; Yusuf-Peto method p=0.001); Tarone's test: p=0.028. The odds ratio of TTP (non-VMs vs VMs) was 0.71 (0.65-0.77) (Yusuf-Peto method p=0.001); Tarone's test: p=0.022. **Conclusions:** VMs and non-VMs had similar ORRs. Approximately a third of patients with VMs (31.9%) achieve clinical benefit, 7% less than non-VMs (38.8%). VMs which achieve clinical benefit have prolonged periods of disease control, the median being almost 1 year. ET remains the well-tolerated treatment of choice for hormone responsive disease in the 2nd-line setting until newer agents, alone or in combination with ET, exhibit better efficacy than ET monotherapy.

Blinded independent validation of the PAM50-based Chemo-Endocrine Sensitivity Predictor (CESP) in hormone receptor (HR)-positive/HER2-negative (HR+/HER2-) breast cancer following neoadjuvant chemotherapy (NAC). *First Author: Aleix Prat, Medical Oncology Department. Hospital Clinic, Barcelona, Spain*

Background: Pathological complete response following NAC is associated with improved survival. CESP is a novel algorithm derived from the GEICAM 2006-03 clinical trial which is based on the association of treatment response with correlation to each PAM50 subtype centroid. CESP has been validated in two datasets consisting of patients with HR+/HER2- disease treated with either NAC or neoadjuvant endocrine therapy (unpublished data). Here, we examined whether CESP score is associated with chemosensitivity in another independent dataset. **Methods:** 216 pre-/post-menopausal patients from a multi-center Spanish cohort, with banked and centrally-confirmed FFPE HR+/HER2- pre-treatment breast tumor samples, were re-consented. All patients were treated with anthracycline/taxane-based NAC between years 2003-2014. The Prosigna assay was performed on the NanoString nCounter Dx Analysis System at Hospital Universitario Virgen de la Victoria de Málaga and CESP score and cutoffs were determined from those results at Hospital Clínic of Barcelona (blinded from clinical data). Univariate and multivariable analyses were used to evaluate the association of CESP score with centrally determined Residual Cancer Burden (RCB). **Results:** 207 core-needle pre-treatment biopsy samples yielded passing results (95.8%) of which 180 had clinical data including an RCB classification. The overall proportion of RCB-0/I in this patient population was 18.9%. In univariate and multivariate (adjusted for tumor size, age at diagnosis and grade) analyses, CESP as a continuous variable was significantly associated with response ($p < 0.001$ and $p = 0.003$). The rates of response in CESP-high, -med and -low groups were 10.3%, 15.2% and 30.4%, respectively ($p = 0.006$). The odds ratio of the CESP-low group for achieving a RCB-0/I was 3.80 (95% Confidence Interval 1.57-9.18) compared with the CESP-high group. Similar results were obtained after excluding PAM50 non-Luminal disease ($n = 23$). **Conclusions:** CESP is a strong and independent predictor of pathological response in patients with HR+/HER2- disease treated with NAC.

570 Poster Session (Board #58), Sat, 8:00 AM-11:30 AM

Long-term safety profile of palbociclib (P) in combination with letrozole (L) as first-line treatment for postmenopausal patients with ER+ and HER2- advanced breast cancer (ABC) (PALOMA-1/TRIO-18). *First Author: Dennis J. Slamon, School of Medicine/Translational Oncology Research Laboratory, University of California, Los Angeles, Los Angeles, CA*

Background: P is a selective and reversible oral CDK4/6 inhibitor. In a randomized phase (ph) I/II trial comparing P plus L (P + L) to L alone in patients (pts) with ER+ and HER2– ABC who had not received any prior systemic therapy for their ABC (Study 1003), P + L demonstrated significantly longer progression-free survival (PFS) vs L (20 vs 10 m; HR = 0.488, *P*=0.0004). **Methods:** We analyzed reported Adverse Events (AE) from Study 1003 by time interval (0-6m, 6-12m, 12-24, and >24m), cumulatively (12 m, 24 m time points) and assessed latency (event onset) of pertinent Adverse Drug Reactions (ADRs). **Results:** As of Nov 2013, 95 pts received P + L. The median duration of treatment for P was 374 d (range: 63-1682) for Ph1 (n=12) and 420 d (range: 7-1242) for ph2 (n=83). The 6 m interval analysis of the most common (>15%) ADRs (Table 1) indicated that ADRs tend to occur with greater frequency within the first 6 m with some decrease in incidence over time. Comparison of the cumulative incidences between the end of the 2nd year and 1st year shows that the cumulative event rates of the most common ADRs such as neutropenia (76% vs. 76%), fatigue (45% vs 40%), leucopenia (45% vs. 39%) and anemia (34% vs. 30%) were stable. The cumulative event rates for Grade 3/4 events were also stable except for a slight increase in fatigue (5% vs. 3%). The median time to onset of neutropenia was (20d), leucopenia (36d), anemia (168d), and thrombocytopenia (140d). **Conclusions:** Long term safety analysis suggests no evidence of any specific cumulative or late onset of toxicity with the prolonged treatment with P + L as first-line treatment for ER+ and HER2- ABC. Clinical trial information: NCT00721409.

Summary of treatment emergent all causality ADRs by 6-m intervals (>15%).

	P + L Treatment Duration (M)				
Adverse Events	0-< 6 N = 95 %	6-< 12 N = 77 %	12-< 18 N = 59 %	18-< 24 N = 40 %	≥24 N = 29 %
Any AE	97.9	88.3	81.4	72.5	79.3
Neutropenia	69.5	54.5	44.1	40.0	51.7
Leucopenia	33.7	27.3	16.9	20.0	13.8
Fatigue	33.7	14.3	13.6	10.0	10.3
Nausea	23.2	6.5	5.1	2.5	6.9
Anemia	22.1	19.5	15.3	15.0	13.8
Diarrhea	18.9	0	5.1	2.5	10.3
Alopecia	16.8	2.6	1.7	0	3.4

571 Poster Session (Board #59), Sat, 8:00 AM-11:30 AM

Efficacy and safety of first-line palbociclib plus letrozole compared with letrozole alone in patients aged ≥ 65 years with estrogen receptor-positive, HER2-negative advanced breast cancer: A subgroup analysis by age of the PALOMA-1/TRIO-18 trial. *First Author: John Crown, Irish Cooperative Oncology Research Group, Dublin, Ireland*

Background: Of the estimated 232,670 new cases of breast cancer (BC) diagnosed in the U.S. in 2014, 40% will have occurred in women ≥ 65 years. In this population, the most common type of BC is estrogen receptor-positive (ER+), HER2-negative (HER2-) for which endocrine treatment (ET) is currently the treatment of choice. When tumors become refractory to ET, chemotherapy is often initiated; palliative measures might also be suitable. Palbociclib (P) is an oral small-molecule inhibitor of cyclin-dependent kinases 4 and 6 (CDK4/6). In a randomized phase 2 trial (PALOMA-1/TRIO-18; NCT00721409), first-line P plus letrozole (L) showed median progression-free survival (PFS) benefit that was double that shown by L alone in patients (pts) with ER+ and HER2- advanced BC (Finn et al, Lancet Oncol, 2015; 16: 25-35). In the present subgroup analysis, we evaluated the effect of P + L versus L alone in pts aged ≥ 65 years. **Methods:** Postmenopausal women (N = 165) with advanced ER+, HER2-BC were randomized 1:1 to receive P (125 mg/day for 3 weeks, 1 week off) plus L (2.5 mg/day) or L alone (2.5 mg/day). Of the 76 pts aged ≥ 65 years, 37 were assigned to P + L and 39 were assigned L alone. The primary endpoint was investigator-assessed progression-free survival (PFS). **Results:** In pts ≥ 65 years, the median PFS was 26.6 months (95% CI 12.6 – NR) for the P + L arm and 7.7 months (95% CI 3.7 – 10.9) for the L arm (HR 0.505, 95% CI 0.269 – 0.948; one-sided p = 0.0155). In pts eligible for safety analysis, grade 3-4 neutropenia was reported in 56.8% in the P+L arm vs 2.7% in the L arm, leucopenia in 29.7% vs none, and fatigue in 10.8% vs none. In general, neutropenia associated with P+L was short-lived and did not require management with hematopoietic growth factors. **Conclusions:** The median PFS was > 3 times longer in the P+L arm than in the L alone arm for the subgroup of pts ≥ 65 years. The toxicity profile was consistent with that of entire study population. A phase III study evaluating P+L is ongoing; P+L is an important treatment option for elderly, as well as non-elderly, patients with ER+, HER2- advanced BC. Clinical trial information: NCT00721409.

572 Poster Session (Board #60), Sat, 8:00 AM-11:30 AM

The effect of palbociclib (P) in combination with letrozole (L) on bone metastases in women with ER+/ HER2- metastatic breast cancer (MBC): Subanalysis from a randomized phase II study. *First Author: Richard S. Finn, University of California, Los Angeles Medical Center, Los Angeles, CA*

Background: Bone metastases (BM) are common in MBC. They are often the first and only site of distance disease. Patients with BM only usually have a protracted clinical course though increased bone pain and fractures can be debilitating. PALOMA-1/TRIO-18 was a randomized Phase II study, comparing P plus L (P+L) vs L alone as first-line treatment of advanced ER+ / HER2- BC. At final analysis, P+L doubled progression-free survival (Finn et al. Lancet Oncol 2015). In this sub-analysis, we evaluated the effects of P+L on bone metastases. **Methods:** 165 ER+ and HER2- postmenopausal women who were untreated for their ABC were randomized to receive L (2.5 mg/day) (N = 81) or L (2.5 mg/day) plus P (125 mg/day for 3 weeks on/1 week off) (N = 84). The primary endpoint was investigator-assessed PFS. Tumor assessments were performed every 8 weeks and bone scans every 12 weeks. PFS analysis was performed for those patients (pts) with objective progression determined based on the appearance of new bone lesion(s) and/or progression of existing bone non-target lesion(s). Patient reported outcomes (PRO) on pain severity (PS) and pain interference (PI) were assessed with Modified Brief Pain Inventory-Short Form (mBPI-sf). **Results:** 75% of patients had bone disease at baseline (73% P+L vs. 77% L) and 18% had bone only disease (20% P+L vs. 15% L). Median PFS among pts who had objective PD due to the appearance of new BM and/or objective PD in bone as non-target lesion were 18 m (95% CI 9, 28) for P+L (n = 8) vs. 4 m (95% CI 2, 35) for L (n = 16). Among those patients with bone-only disease at baseline, significant prolongation of PFS (NR P+ L vs 13.3 m L, HR = 0.294, 95% CI 0.092-0.945). Numerical differences in PI and PS scores in favor of P + L over L were observed from the PRO data collected from all randomized pts. **Conclusions:** Theaddition of P to L demonstrated a significant improvement in PFS. P+L leads to clinically meaningful delays in progression in the bone. Clinical trial information: NCT00721409.

573 Poster Session (Board #61), Sat, 8:00 AM-11:30 AM

Impact of locoregional therapy among women 70 years or older with early stage hormone receptor positive breast cancer: A population based study. *First Author: Shaheenah S. Dawood, Dubai Hosp, Dubai, United Arab Emirates*

Background: In 2004 the CALGB 9343 trial determined that omission of radiation therapy after lumpectomy in women ≥ 70 years with ER+ T1N0 breast cancer did not significantly impact outcome. This retrospective study aimed to determine trends in locoregional therapy practice in this cohort and to determine its impact on outcome. **Methods:** Using SEER registry we identified 27852 pts who were ≥ 70 years with pT1N0M0 ER+ breast cancer diagnosed between 1990 and 2005. A cutoff of 2005 was chosen to ensure a minimum of 5 years of follow up. Pts were divided into 3 groups based on locoregional therapy received: a) mastectomy, b) lumpectomy plus radiation, c) lumpectomy without radiation. Breast cancer specific survival (BCSS) was computed and Cox models were then fitted to evaluate the association between type of locoregional therapy and BCSS, adjusted for various pt and tumor characteristics. We expanded the cohort to include pts diagnosed until 2010 to look at practice trends in locoregional therapy. **Results:** 11533 (41.4%) pts had mastectomy, 13035 (56.8%) pts had lumpectomy plus radiation therapy and 3284 (11.8%) pts had lumpectomy alone. At a median follow-up of 92 months, 5- year BCSS was 97%, 98% and 97% among pts who had undergone mastectomy, lumpectomy plus radiation and lumpectomy alone, respectively ($p < 0.0001$). Compared to those who underwent mastectomy, there was no significant difference in breast cancer deaths among those who underwent lumpectomy plus radiation (HR 0.89, 95% CI 0.7-1.003, $p = 0.056$) or lumpectomy alone (HR 1.13, 95% CI 0.94-1.36, $p = 0.18$). Comparing 1990, 2005 and 2010, the proportion of pts undergoing mastectomy steadily decreased (74.2%, 27.4% and 25% respectively) while proportion undergoing lumpectomy plus radiation steadily increased (21.1%, 51.5% and 52.7% respectively) as did proportion undergoing lumpectomy alone (4.7%, 21.1% and 22.4% respectively). **Conclusions:** Omission of radiation therapy after lumpectomy in older women did not seem to significantly impact BCSS in this population based analysis. Although the use of lumpectomy without radiation increased over time, post-lumpectomy radiation is still the more favored treatment practice.

574 Poster Session (Board #62), Sat, 8:00 AM-11:30 AM

A combined screening approach of Fracture (Fx) Risk Algorithm (FRAX) and Trabecular Bone Score (TBS) to identify osteoporotic-range fracture risk (ORFR) in breast cancer (BC) patients treated with adjuvant aromatase inhibitor (AI). *First Author: David B. Page, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The NCCN recommends serial bone mineral density (BMD) measurement with dual energy x-ray absorptiometry (DXA) to diagnose and treat AI-associated osteoporosis. The FRAX algorithm identifies additional patients with ORFR who may benefit from anti-resorptive therapy (ART). The TBS, which measures bone microstructure by DXA, is an independent indicator of ORFR. Here, we retrospectively evaluate the utility of a combined screening approach (BMD+FRAX+TBS) in identifying ORFR at baseline and following AI. **Methods:** Breast cancer patients > 60 years, treated with AI and no ART between 2006-12, who had serial DXA at Memorial Sloan Kettering Cancer Center were identified (n= 74). BMD, FRAX, and TBS were evaluated at baseline (< 3 months from AI initiation) and at 12-24 months, and various screening strategies for identifying ORFR were assessed. Based on National Osteoporosis Foundation criteria and Manitoba TBS study fracture rates, ORFR was defined as: BMD T-score≤-2.5; ≥3% hip or ≥20% osteoporosis-associated 10-year fracture risk by FRAX; or TBS score≤1.2 with BMD T-score< -1.0. **Results:** Following AI, lumbar spine (LS)-BMD declined in 75% of patients (median: -2.9%; SD: 4.3%) and TBS declined in 58% of patients (median: -1.0%, SD: 7.7%). Declines in LS-BMD and TBS were not correlated (Spearman r=-.16, p=NS) and were not influenced by age, BMI, ethnicity, or chemotherapy (by Wilcoxon rank-sum). Compared to BMD alone, a combined screening approach (BMD+FRAX+TBS) identified an additional 15% of patients with ORFR at baseline. (table) Following AI, an additional 2% developed ORFR by BMD alone, versus 7% by BMD+FRAX+TBS. **Conclusions:** AIs caused bone loss, leading to ORFR as measured by BMD, FRAX, and TBS. Because FRAX and TBS are derived from DXA and patient history, a combined screening approach may efficiently and cost-effectively identify additional BC patients with ORFR who may benefit from ART.

	Pts with ORFR (%)	
Screening Method	**Before AI**	**After AI**
BMD alone	3/74 (5%)	5/74 (7%)
BMD+FRAX	7/74 (9%)	11/74 (15%)
BMD+TBS	12/74 (16%)	16/74 (22%)
BMD+FRAX+TBS	15/74 (20%)	20/74 (27%)

575 Poster Session (Board #63), Sat, 8:00 AM-11:30 AM

Clinical efficacy and safety profile of palbociclib (P) in combination with letrozole (L) as first-line treatment in patients (pts) with ER+ and HER2- advanced breast cancer (ABC) who have not received any systemic treatment (ST): A subgroup analysis of PALOMA-1/TRIO-18. *First Author: Richard S. Finn, University of California, Los Angeles Medical Center, Los Angeles, CA*

Background: P is an orally active inhibitor of CDK4/6. In a randomized phase II study, P + L significantly prolonged progression-free survival (PFS) vs L alone (20 vs 10 mo; HR = 0.488, $P = 0.0004$; Finn et al, Lancet Oncol, 2015) in ER+/HER2- ABC as first-line treatment. Given that pts who did not receive any systemic treatment (ST) may have different disease biology/course from those treated and relapsed from early stage disease and many pts may initiate endocrine therapy (ET) alone, we investigated the benefit of P + L in this subgroup in the PALOMA-1/TRIO-18 study. **Methods:** 165 ER+ and HER2- postmenopausal pts who are treatment naïve for their ABC were randomized to receive L (N = 81) or P+L (N = 84). A subset of pts did not receive any ST in the adjuvant setting prior to randomization (P+L n = 44, L n = 37). The primary endpoint was investigator-assessed PFS. Tumor assessment was performed every 8 weeks. Tumor tissues were collected for correlative biomarkers. **Results:** Clinical characteristics at baseline were well balanced on median age (P+L vs. L: 63 vs 62), ECOG PS (0/1 59%/41% vs. 49%/51%) and site of disease (visceral/bone only/other: 55%/14%/32% vs. 51%/14%/35%). Observed mPFS was 24 m (95% CI 13, 35) for P+ L vs. 8 m for L (95% CI 6, 13) with HR = 0.315 (95% CI 0.175-0.566) ($p < 0.0001$). Overall response rate (ORR) was 48% (95% CI 33%, 63%) vs. 41% (25%, 58%); clinical benefit rate (PR+SD ≥ 24 wks) was 84% (70%, 93%) vs. 70% (53%, 84%). The most common treatment emerged adverse events (all grades) for P + L arm were neutropenia (67%), fatigue (49%), leucopenia (49%), and anemia (35%), consistent with the overall safety profile. Tissue samples were available in 73 pts. Loss of RB expression by immunohistochemistry was rare (5.4%). Ki67 baseline did not predict response. **Conclusions:** The addition of P to L increased by > 2 the PFS in pts who did not receive ST for their ER+ MBC. The most common AEs are manageable. Favorable risk benefit profile suggests P+L be considered for this group of pts. Clinical trial information: NCT00721409.

576 Poster Session (Board #64), Sat, 8:00 AM-11:30 AM

GHRH-receptor as a new targetable biomarker in breast cancer and its correlation with ER/PR/HER2 status. *First Author: Mehrdad Nadji, University of Miami Jackson Memorial Hospital, Miami, FL*

Background: In addition to its nominative function as a neurohormone acting on the pituitary, growth hormone-releasing hormone (GHRH) has been shown to modify the growth behavior of numerous cancers, including breast. GHRH is produced by tumor cells, acts in an autocrine/paracrine manner, and requires the presence of the GHRH receptor (GHRH-R) on the tumor cells to exert its effects. The aim of this study was to evaluate the relationship of GHRH-R expression in different subtypes of breast cancer (triple negative, HER2-positive and hormone receptor-positive subsets). **Methods:** The cohort consisted of 96 primary breast cancers. Immunohistochemistry for GHRH-R was performed on paraffin sections and the staining results were assessed semi-quantitatively from 0 (negative) to 3+ (strongly positive). Patients with 0 or 1+ GHRH-receptor expression were classified as having low expression, and 2+ or 3+ as high expression. The ER/PR/HER2 levels of each tumor were correlated with the GHRH-R IHC results. **Results:** 62/96 (65%) patients had hormone receptor (HR) positive (ER- and / or PR-positive), 12/84 (14%) had HER2-positive, and25/84 (30%) had triple negative breast cancers (TNBC). 92% of HER2-positive, 68% of HR-positive, and 44% of TNBC had high expression of GHRH-R. HER2-positive primaries had a significantly increased frequency of high (11/12, 92%) vs. low (1/12, 8%) GHRH-R expression compared to HER2-negative primaries ($p = 0.018$). There was no difference in GHRH-R expression by HR status ($p = 0.38$). TNBC had a significantly decreased frequency of high (11/25, 44%) vs. low (14/25, 56%) GHRH-R expression compared to non-TNBC ($p = 0.041$). **Conclusions:** GHRH-R is expressed by the majority of primary mammary carcinomas regardless of their hormone receptor status. HER2-positive tumors were more likely to express high levels of GHRH-R; TNBC expressed lower levels. This finding could potentially serve as a basis for therapeutic approaches using synthetic peptide GHRH-R antagonists that have already shown significant efficacy combined with minimal pharmacologic side effects in experimental models.

577 Poster Session (Board #65), Sat, 8:00 AM-11:30 AM

Activation of PI3K/AKT/mTOR pathway in ER+ breast cancer: Analysis of paired primary and metastatic tumor samples. *First Author: Teresa R. Pacheco, Oncology Division, Hospital de Santa Maria - CHLN and Instituto de Medicina Molecular, Lisboa, Portugal*

Background: The activation of the mammalian target of rapamycin (mTOR) pathway is associated with resistance to endocrine therapy in breast cancer. Our aim was to evaluate changes in activation of the PIK3/AKT/mTOR pathway between primary and corresponding metastatic tumor samples in estrogen receptor (ER) positive breast cancer patients and to test whether phosphorylated protein levels are predictive of overall survival (OS). **Methods**: Phosphorylated forms of AKT (p-AKT) and S6 (p-S6) were assessed by immunohistochemistry on archival paraffin embedded samples of primary breast tumors and distant metastases collected from 132 breast cancer patients in two centers. A semi-quantitative scoring system (H-score) was used, combining the intensity of staining and the percentage of stained cells. The difference between expression of p-AKT and p-S6 in primary and metastatic tumor samples was analyzed using the Wilcoxon signed-rank test and the correlation of expression of p-S6 with OS using the Cox's proportional hazards model. **Results**: Overall, 93 cases ER and/or PR positive were analyzed. The median age was 55 years; 66 patients were treated with endocrine therapy in adjuvant and/or palliative setting. The median time to relapse was 42.7 mo and the median follow-up was 73.4 mo. The median OS from time of metastatic sample collection was 26.2 mo. The p-AKT H-score index was higher in primary tumor samples when compared to metastases ($p = 0.0003$). The p-S6 H-score index at the primary tumor and metastatic samples was not significantly different ($p = 0.26$); concordance between paired samples was 60% using median as cut-off; only metastatic p-S6 H-score index associated with OS ($p = 0.022$) and the association was also significant when analyzed by quartiles ($p = 0.001$). **Conclusions:** Expression levels of p-AKT are significantly lower in metastatic tumor samples. Metastatic p-S6 higher expression might predict worse prognosis in ER+ breast cancer patients, and deserves further study as a novel predictive breast cancer biomarker.

578 Poster Session (Board #66), Sat, 8:00 AM-11:30 AM

A prospective comparison of ER, PR, Ki67 and gene expression in paired sequential core biopsies of primary, untreated breast cancer. *First Author: Alastair Mark Thompson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sequential biopsy of breast cancer is increasingly favoured to assess biomarker effects and drug efficacy. The "window of opportunity" in the preoperative setting is recognised as advantageous to test biomarker changes in response to therapeutic agents in previously untreated cancers. However, tissue sampling over time could confound biomarker effects. This study tested the consistency over time of paired, sequential biomarker measurements on primary, operable breast cancer in the absence of drug therapy. **Methods:** Immunohistochemistry was performed for ER, PR and Ki67 on paired preoperative/operative tumor samples taken from untreated patients within 2 weeks of each other. Additionally, microarray analysis on mRNA extracted from formalin fixed paraffin embedded cores was performed using Affymetrix based arrays on paired core biopsies analysed using Ingenuity Pathway Analysis (IPA) and Gene Set Analysis (GSA). **Results:** In 41 *core/resection* pairs, the recognised trend to lower ER, PR and Ki67 score on resected material was confirmed: concordance for ER, PR and Ki67 without switch in status by Allred or Quickscore was 90%, 74% and 80% respectively. However, in 23 paired *core* samples (diagnostic core v on table core), Ki67 using a cut off of 13.25% was concordant in 22/23 (96%) and differences in ER and PR immunohistochemistry by Allred or Quickscore between the pairs did not impact hormone receptor status. IPA and GSA demonstrated substantial gene expression changes between paired *cores* at the mRNA level, including under expression of ER pathway analysis, despite the absence of drug intervention. **Conclusions:** This study addresses the potential impact of sampling effects over time in the context of preoperative (window of opportunity) trials. Sequential core biopsy of primary breast cancer (but not core versus resection) was consistent and may be appropriate to assess the effects of drug therapy in vivo on ER, PR and Ki67 using immunohistochemistry. Conversely, studies including mRNA expression may require non-treatment controls to distinguish therapeutic from biopsy differences.

579 Poster Session (Board #67), Sat, 8:00 AM-11:30 AM

The pattern of somatic mutations and chromosomal copy number variations (CNV) in young breast cancer (BC) patients (pts). *First Author: Hatem Abdel Azim, Institut Jules Bordet, Brussels, Belgium*

Background: Young age at diagnosis is associated with poor prognosis, different distribution of BC subtypes and unique gene expression patterns. Yet, it is unknown whether young pts have different prevalence of somatic mutations or CNV. **Methods:** This analysis was performed on The Cancer Genome Atlas dataset. We divided pts according to their age into; young (< 45 years) and old (≥ 45 years). We evaluated the association between age as a continuous variable and number of somatic mutations, CNV (amplification, gain, or deletions) using the chi-square test. We examined the genes showing somatic mutations or CNV in young pts and compared it to older pts using t-test. **Results:** 959 (138 $<$ 45y) and 788 (124 $\geq$ 45y) pts were included in the somatic mutation and CNV analyses, respectively. Young age at diagnosis was associated with less number of somatic mutations, mainly in ER- BC ($r = 0.21$, $p = 0.002$). Within young ER+ pts, mutations in *PIK3CA* (32.6%), *GATA3* (16.8%) and *TP53* (16.8%) were the most common with prevalence highly comparable in older pts. Of relevance, higher rates of mutations in *NTRK2* (5% vs.0%, $p < 0.0001$) and *ARID1A* (7% vs.2%, $p = 0.03$) were observed in young compared to old ER+ patients. No major differences were observed in the pattern of somatic mutations in ER- BC according to age, with mutations in *TP53* (67.5%), *RYR2* (13.5%) and *CSMD2* (10.8%) being the most common in young pts. We found more chromosomal amplifications in young pts with amplification events decreasing as a function of age, but only in ER+ BC ($r = -0.13$, $p = 0.007$). 22% of young pts showed *AXIN2* amplification vs. 4% in older patients ($p < 0.0001$). No other relevant associations were observed between CNV and age at diagnosis. **Conclusions:** This is the first analysis to interrogate the impact of young age at BC diagnosis on the pattern of somatic mutations and CNV. We observed that young age at diagnosis is associated with 1) less number of somatic mutations, and 2) more chromosomal amplifications, the latter observed only in ER+ disease. *AXIN2*, which regulates the Wnt/B-catenin pathway appear to be more amplified in young pts and if further validated could represent a potential treatment target in these women.

580 Poster Session (Board #69), Sat, 8:00 AM-11:30 AM

Impact on relapse free survival (RFS) of time to hormone therapy (HTx) after diagnosis (Dx) of low risk hormone receptor positive (HR+) early breast cancer (BC). *First Author: Wen Yee Chay, BC Cancer Agency, Vancouver, BC, Canada*

Background: Retrospective series show worse RFS for adjuvant chemotherapy (CTx) delay. We hypothesized the same effect for delays to HTx in low risk HR+ BC, for which CTx benefit is low. **Methods:** Histopathologic and demographic data were collected for all patients referred to the British Columbia Cancer Agency with a new dx of stage I or II, grade 1 or 2, HR+, HER2 negative BC from 01/2005 to 12/2009. Neoadjuvant-treated, prior or synchronous bilateral BC, no HTx prior to relapse, or $>$ 53 weeks (w) to HTx start were excluded. RFS was calculated for three pre and postmenopausal cohorts (C), defined as 1) 0- $<$ 20 w; 2) 20- $<$ 34 w; 3) 34-53 w from dx to HTx, based on first prescription. Multivariable (M) analysis identified factors significant for RFS. **Results:** Median follow up for the 3737 cases was 6.4 years (y). 80% were stage I: 28% of C1 and 69% of C3 were stage II. 90% were strongly estrogen receptor (ER) positive. Median age was 64, 58, and 51y in C 1, 2, and 3. Most were menopausal (71%) and 23% had CTx ($<$ 1%, 27%, and 76% of C 1, 2, 3). HTx was started $<$ 20 w and $>$ 34 w after dx in 57% and 15%, respectively. Five year RFS was 97.3%, 96.4%, and 95.5% for C1, 2, and 3 (p0.018). The table below shows univariate (U) and M results, M hazard ratios (Hz) and 95% confidence intervals. **Conclusions:** While unnecessary delays to HTx should be avoided, we did not detect a significant impact on RFS of up to 1 year delay in low stage and grade, population-based HR+ HER2 negative BCs. RFS was influenced by stage, PR level (all); grade and ER level (menopausal); and age at dx (premenopausal). If there is an impact on early RFS of HTx delay, it is likely subtle and only in premenopausal women. Our results do not exclude an impact on late RFS or in higher risk disease, or explore impact of longer delays.

Correlation between the DCIS Score and traditional clinicopathologic features in the prospectively-designed Ontario population-based validation study. *First Author: Eileen Rakovitch, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: In the Ontario population based study, the DCIS Score was significantly associated with 10 year risk of an ipsilateral local recurrence (LR - in situ or invasive carcinoma) in women treated with breast conserving surgery (BCS) without radiation (RT) ($P < 0.001$). Here we evaluate correlation between DCIS Score and clinicopathologic (CP) features in the same cohort, and whether DCIS Score provides independent recurrence risk information. **Methods:** The study population included 571 women diagnosed with DCIS in the province of Ontario from 1994 – 2003 prospectively selected for treatment with BCS without RT. CP variables examined included age at diagnosis, DCIS tumor size, DCIS nuclear grade, comedo necrosis (absent, focal, or extensive), histologic type, multifocality, and surgical margin width. The association between DCIS Score and CP variables was examined by spearman rank correlation, and proportional hazards regression models were used to determine variables significantly associated with LR. **Results:** Tumor size ($p = 0.002$), multifocality ($p < 0.001$), histologic type ($p = 0.005$), and nuclear grade ($p = 0.04$) were significantly associated with LR. In a multivariable analysis, including significant CP covariates, the DCIS Score was statistically significantly associated with LR ($p = 0.02$). DCIS Score was moderately correlated with grade ($r_s = 0.47$; 95% CI 0.41,0.54), comedo necrosis ($r_s = 0.43$; CI 0.36,0.50), tumor size ($r_s = 0.24$; CI 0.13,0.35), and multifocality ($r_s = 0.11$; CI 0.03,0.19) but not other features. All CP subgroups showed a wide range of DCIS Scores in each subgroup. **Conclusions:** DCIS Score is only moderately correlated with grade, comedo necrosis, tumor size, and multifocality. DCIS Score provides recurrence risk information independent of CP features, and quantifies risk of local recurrence in individuals treated by BCS alone, validating previous findings from the E5194 clinical trial

582 Poster Session (Board #71), Sat, 8:00 AM-11:30 AM

Cyclin D1 as a biomarker of response to fulvestrant (F) in hormone receptor-positive (HR+) breast cancer (BC). *First Author: Krystal Pauline Cascetta, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Overexpression of cyclin D1 (CD1) occurs in up to 45% of BCs. High cyclin D1 expression (HCD1) has been shown to significantly increase overall survival yet the opposite is observed in HR+ BC patients (pts) with HCD1 who receive tamoxifen (TAM). TAM is the drug of choice for premenopausal pts with ER+ BC. Numerous studies report an association btwn CD1 overexpression & TAM resistance. Thus, a large fraction of pts who receive TAM may not benefit from it. F may serve as an alternative approach for these pts. We hypothesized that pts with HCD1 will have a better duration of response to F compared to those with low expression. In order to address the above, we retrospectively analyzed CD1 expression in HR+ metastatic BC (MBC) pts treated with F at our institution. **Methods:** 20 primary BCs were stained for CD1 expression. IHC was scored based on intensity as 0 (negative), 1+, 2+, 3+ & extent as 0 (< 10%), 1 (11-25%), 2 (26-50%), 3 (51-75%), 4 (76-90%) & 5 (> 90%). A total score was subgrouped as low (0 to 4) or high (5 to 8). A retrospective chart review extracted clinical data. The primary endpoint was duration of response to F as it relates to CD1 expression in HR+ MBC. **Results:** Of the 20 pts (median age 54 years), 40% had low cyclin D1 (LCD1) expression (n = 8) vs. 60% with HCD1 (n = 12). All but 1 pt in the LCD1 cohort had poorly differentiated (PD) invasive ductal carcinoma (IDC) (87.5%). The remaining pt had moderately differentiated (MD) invasive ductal & lobular carcinoma (mixed). 50% of HCD1 pts had PD tumors while 16.7% were MD. In the HCD1 cohort, 41.7% were IDC, 33% ILC and 25% mixed. Four pts were HER2-neu+, 2 in the LCD1 group & 2 in the HCD1 group. 75% in the LCD1 group were postmenopausal vs. 58% in the HCD1 cohort. TAM exposure was higher in the HCD1 group compared to the LCD1 group (58% vs. 25%). LN positivity was higher in the HCD1 group compared to the LCD1 group (58% vs. 37.5%). Median time to progression (TTP) with F was significantly increased in tumors with HCD1 expression compared to those with LCD1 (1149 days vs. 133 days, respectively; $p = 0.027$). **Conclusions:** TTP on F is significantly increased for HR+ HCD1 expressing BC compared to HR+ BC with LCD1 expression. Clinical trials exploring the use of F in BCs with HCD1 expression may be warranted.

583 Poster Session (Board #72), Sat, 8:00 AM-11:30 AM

Docetaxel, cyclophosphamide and trastuzumab as neoadjuvant chemotherapy in HER2-positive primary breast cancer. *First Author: Katsuhiko Nakatsukasa, Department of Endocrine and Breast Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan*

Background: The current standard treatment of primary systemic therapy (PST) in HER2+ breast cancer is anthracyclines and/or taxanes combined with trastuzumab which demonstrates high pathological complete response (pCR). The pCR is considered as a predictive marker of prognosis although results are slightly different depending on the hormone receptor status. The efficacy and tolerability of docetaxel, cyclophosphamide and trastuzumab (HER-TC) as neoadjuvant chemotherapy (NAC) remains unclear. We performed a prospective multicenter study of HER-TC NAC in HER2+ primary breast cancer. **Methods:** Eligible patients had HER2+ invasive breast cancer that measured more than 1cm, less than 7 cm and N0~N1 clinically between July 2011 and February 2014. Four cycles of HER-TC (6 mg/kg loading dose 8 mg/kg, 75 and 600 mg/m^2) were administered intravenously every 3 weeks as NAC. We investigated the pCR of primary breast tumors; pCR was defined as no histological evidence of invasive carcinoma, or the appearance of only ductal carcinoma in situ. Cardiac toxic effects, defined as a decrease in left ventricular ejection fraction (LVEF), were assessed by echo-cardiography at baseline, at the completion of NAC. **Results:** 42 patients were enrolled. The completion rate for 4 cycles of HER-TC was 97.6 % (41 of 42). Relative dose intensity was 98.0 % for HER-TC therapy. Overall pCR rate was 43.9 % (18 of 41). pCR rate for patients with luminal HER2 (ER+, HER2+), and HER2 enriched (ER-, HER2+) were 40.0 % (8 of 20), and 47.6 % (10 of 21), respectively. pCR was achived with about same probability in each subtype. Mean LVEF at baseline and, the completion of NAC were 66.1% and 64.8%, respectively. **Conclusions:** Four cycles of HER-TC might be one of the NAC options for HER2 positive breast cancer. There were no patients with decrease in LVEF during the treatment. Clinical trial information: UMIN000013263.

584 Poster Session (Board #73), Sat, 8:00 AM-11:30 AM

Phase I study of HER3 targeted antibody patritumab in combination with trastuzumab and paclitaxel in patients with HER2-overexpressing metastatic breast cancer (MBC). *First Author: Toshiaki Saeki, Saitama Medical University, Hidaka, Japan*

Background: It is considered that HER2-HER3 heterodimerization is mechanically important in HER2-overexpressing breast cancer. Patritumab is a fully human anti-HER3 monoclonal antibody, which inhibits ligand binding, receptor activation and induces HER3 down-regulation. This study aimed to assess recommended dose for subsequent studies as well as the safety, pharmacokinetics (PK), and preliminary efficacy of patritumab in combination with trastuzumab and paclitaxel in patients with HER2-overexpressing MBC. **Methods:** This study was an open-label, multicenter phase I study in patients with HER2-overexpressing MBC who had progressed after at least one prior chemotherapy regimen including trastuzumab. Patients received patritumab 9 mg/kg or 18 mg/kg i.v. Q3W, trastuzumab 8 mg/kg loading dose, followed by 6 mg/kg maintenance dose i.v. Q3W, and paclitaxel 175 mg/m^2 i.v. Q3W or 80 mg/m^{2}i.v. 2 weeks administration followed by 1 week rest (Q3W). **Results:** Eighteen patients were enrolled in total in this study. As of the October 10, 2014 cutoff, four patients were continuing treatment. All patients had received prior trastuzumab and 66.7% patients had received prior paclitaxel. No DLTs were observed. The most common ($\geq$ 50.0%) adverse events (AEs) were diarrhea (88.9%), alopecia (72.2%), leukopenia (72.2%), neutropenia (66.7%), and rash maculo-papular (50.0%). Some AEs including leukopenia and neutropenia were more frequent in patients received paclitaxel 175 mg/m^{2}i.v. Q3W. These AEs were generally mild and manageable. As a serious adverse event (SAE), cataract was reported in one patient and it was not related to study drugs. All patients were negative for anti-patritumab antibodies. The target trough serum concentration of patritumab was achieved in all patients at a dose of 18 mg/kg. The response rate was 38.9% (2 CR and 5 PR). The median progression-free survival was 274 days. **Conclusions:** Patritumab in combination with trastuzumab and paclitaxel was well tolerated up to 18 mg/kg and the preliminary efficacy was encouraging in patients with HER2-overexpressing MBC. Clinical trial information: JapicCTI-121772.

585 Poster Session (Board #74), Sat, 8:00 AM-11:30 AM

Total pathologic complete response (tpCR) and event-free survival (EFS) with subcutaneous (SC) or intravenous (IV) trastuzumab in HER2-positive early breast cancer (EBC). *First Author: Christian Jackisch, Sana Klinikum Offenbach GmbH, Offenbach, Germany*

Background: HannaH (NCT00950300) compared SC and IV trastuzumab (Herceptin SC [H SC] and IV [H IV]) as neoadjuvant–adjuvant therapy for HER2-positive EBC; the co-primary endpoints, pCR and serum trough concentration, were non-inferior between H SC and H IV. Prior studies have indicated that pCR is reasonably likely to predict for long-term efficacy outcomes in patients (pts) with EBC, and tpCR (absence of invasive neoplastic cells in ipsilateral lymph nodes and the breast) is considered more likely to be predictive than pCR. **Methods:** HannaH is a phase III, open-label, multicenter, randomized trial. Pts received 4 cycles of neoadjuvant docetaxel followed by 4 cycles of 5-fluorouracil/epirubicin/cyclophosphamide administered concurrently with 3-weekly H SC (600 mg fixed dose) or H IV (8 mg/kg loading, 6 mg/kg maintenance doses). Post-surgery, pts received 10 cycles of adjuvant H SC or H IV to complete 1 year of therapy. In an exploratory analysis, we used Cox regression to assess the correlation between the secondary endpoints tpCR and EFS (time from randomization to local, regional, or distant recurrence, contralateral breast cancer, or death). EFS rates per subgroup were estimated using the Kaplan–Meier (K–M) method. **Results:** In all, 297 pts were randomized to the H SC arm and 299 to the H IV arm; intent-to-treat (ITT) populations were 294 and 297 pts, respectively. At 40 months' median follow-up, Cox regression indicated that pts in the ITT population who achieved tpCR had a reduced risk of an EFS event compared with those who did not: H SC arm hazard ratio (HR) = 0.38 (95% CI, 0.22–0.65); H IV arm HR = 0.32 (95% CI, 0.18–0.60). Results were similar between arms: treatment-tpCR interaction $P = 0.67$. Three-year EFS rates according to tpCR are shown in the Table. Results were consistent for pCR and the efficacy per protocol population. **Conclusions:** In each of HannaH's two treatment arms, H SC or H IV, tpCR correlated with improved long-term efficacy outcomes (EFS) in pts who received neoadjuvant–adjuvant therapy for HER2-positive EBC. Clinical trial information: NCT00950300.

	H SC n = 294		H IV n = 297	
	tpCR n = 108	No tpCR n = 186	tpCR n = 94	No tpCR n = 203

586 Poster Session (Board #75), Sat, 8:00 AM-11:30 AM

The co-administration of pertuzumab (P) and trastuzumab (T) as a single infusion, followed by vinorelbine (V), in first-line (1L) treatment of HER2-positive locally advanced or metastatic breast cancer (MBC) patients (pts): VELVET study interim analysis. *First Author: Michael Andersson, Department of Oncology, Rigshospitalet,, Copenhagen, Denmark*

Background: The combination of P + T + chemotherapy has been shown to be more efficacious than T + chemotherapy in 1L HER2-positive MBC. P + T administration is normally undertaken sequentially. A single infusion would reduce treatment time and increase convenience for the patient. In the ongoing VELVET study (NCT01565083), the feasibility of co-administering P + T in the same infusion bag followed by V for 1L treatment of HER2-positive locally advanced BC or MBC is being examined. **Methods:** VELVET is a two-cohort, open-label, multicenter, phase II study; Cohort 1 pts receive P + T as separate IV infusions and Cohort 2 (C2) pts receive, after the first cycle, P + T in a single 250 ml IV infusion bag given over 60 mins. Pts had not received prior non-hormonal anticancer therapy in the metastatic setting. The initial dose of P was 840 mg followed by 420 mg q3w; the initial dose of T was 8 mg/kg followed by 6 mg/kg q3w; V was administered at 25 mg/m^2 in Cycle 1 followed by 30–35 mg/m^{2}on Days 1 and 8 of each subsequent cycle. The primary endpoint is investigator-assessed objective response rate (ORR) based on RECIST 1.1. Secondary endpoints include PFS, OS, and safety. Interim analyses for C2 are reported. **Results:** C2 was fully enrolled with 107 pts. At initial diagnosis, 25% of pts had de novo MBC. In (neo)adjuvant settings, 32% had received chemotherapy and 24% had prior T exposure. As of Jan 22, 2015, the median number of cycles received was 15 for P + T and 9 for V (range: 2–28). AEs were reported in 99% of pts. Grade ≥ 3 AEs were reported in 78% of pts. Grade ≥ 3 AEs in ≥ 5 pts were neutropenia (30.8%), hypertension (13.1%), diarrhea (5.6%), leukopenia (4.7%), increased gamma-glutamyl transferase (4.7%), and fatigue (4.7%). SAEs were reported in 41% of pts. Interim efficacy analyses (ORR and PFS) for C2 are ongoing and will be presented. **Conclusions:** Administration of P + T in a single IV infusion followed by V had an acceptable AE and SAE profile with no unexpected safety signals in this interim analysis. This approach is therefore feasible from a safety standpoint and may offer greater convenience for pts. Clinical trial information: NCT01565083.

587 Poster Session (Board #76), Sat, 8:00 AM-11:30 AM

Associations of HER2-specific immunity with survival during treatment with trastuzumab and chemotherapy in breast cancer. *First Author: Keith L. Knutson, Vaccine and Gene Thrpy Inst of Florida, Port St Lucie, FL*

Background: The addition of trastuzumab to chemotherapy improves response to therapy and extends survival among patients with HER2-positive (HER2+) breast cancer. Prior work showed that trastuzumab and chemotherapy also induces HER2 extracellular domain (ECD)-specific antibodies which correlate with tumor shrinkage. The present study investigates whether combination therapy induced immune responses to other tumor antigens and whether immune responses are associated with survival. **Methods:** Pretreatment and posttreatment sera were obtained from 54 women with metastatic HER2+ breast cancer on NCCTG (now Alliance for Clinical Trials in Oncology) studies N0337 and N983252. IgG to HER2, p53, IGFBP2, CEA and tetanus toxoid were examined using ELISAs. Sera from an age-matched group (25 patients) of controls and 26 HER2+ adjuvant patients were also examined. **Results:** Prior to therapy, some patients with metastatic disease had elevated IgG levels to IGFBP2, p53, HER2-ICD, HER2-ECD, and CEA, but not to tetanus toxin, relative to controls and adjuvant patients. Elevated preexisting immunity to HER2 was associated with significantly worse outcome ($p < 0.003$). Following therapy, increases in levels of IgG to IGFBP2, HER2-ICD, HER2-ECD, and p53 were observed in metastatic patients who did not have elevated preexisting immunity. Increased immunity to HER2 was associated with improved progression-free ($p < 0.003$) and overall survival ($p < 0.04$). **Conclusions:** Combination treatment results in induction of adaptive immunity to multiple antigens that contribute to disease outcome. If these results are validated, this could provide the basis for the development of biomarkers predictive of therapeutic benefit and the development of new therapeutic approaches with monoclonal antibodies.

588 Poster Session (Board #77), Sat, 8:00 AM-11:30 AM

Neoadjuvant chemotherapy in the real world: A study of 22,819 patients from the Japanese National Clinical Database-Breast Cancer Registry. *First Author: Naoki Niikura, Tokai School of Medicine, Isehara Kanagawa, Japan*

Background: Recently, neoadjuvant chemotherapy has become a treatment of choice in clinics. Estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor 2 (HER2) expressions may convert from positive to negative and vice versa after neoadjuvant chemotherapy. We investigate the pathological complete response (pCR) rate in each subtype and the discordance rate of ER, PgR, and HER2 before and after neoadjuvant chemotherapy using Japanese breast cancer registry data. **Methods:** Records for > 300,000 cases from 741 hospitals from 2004 onwards were retrieved from the Japanese National Clinical Database-Breast Cancer Registry. After data cleanup, 22,819 cases without distant metastases, where neoadjuvant chemotherapy was administered between January 1, 2004 and December 31, 2011, were selected. pCR was defined as no invasive tumor in the surgical specimen after neoadjuvant chemotherapy. HER2 overexpression was evaluated (i.e., immunohistochemically 3+ and/or fluorescence in situ hybridization-positive). **Results:** pCR was achieved in 6.2% of luminal-type (8,995 patients), 26.0% of HER2-type (4,654 patients), and 19.9% of triple-negative (3,786 patients) breast cancer cases. Among the HER2-type cases, pCR was achieved in 33.2% of ER-negative, 18.0% of ER-positive, 32.2% of trastuzumab-treated (as neoadjuvant chemotherapy), and 18.4% of trastuzumab-untreated cases. After neoadjuvant chemotherapy, HER2-negative tumors were found in 626 (21.5%) of the 2,913 patients with HER2-positive pretreatment tumors, and HER2-positive tumors were found in 343 (3.4%) of the 10,178 patients with HER2-negative pretreatment tumors. Furthermore, 536 (4.7%) of the 11,382 patients with ER-positive tumors had ER-negative tumors and 619 (9.6%) of the 5,870 patients with ER-negative tumors had ER-positive tumors after neoadjuvant chemotherapy. **Conclusions:** We confirmed that in the real world, pCR rates for each subtype follow the same trend in clinical trials. We confirmed that a loss of HER2-positive status in primary tumors could occur after neoadjuvant treatment in patients with primary HER2-positive breast cancer.

589 Poster Session (Board #78), Sat, 8:00 AM-11:30 AM

Graded prognostic assessment (GPA) of HER2 positive breast cancer patients with brain metastases. *First Author: Ming Chi, Cleveland Clinic, Cleveland, OH*

Background: Brain metastasis (BM) is a serious complication of HER2+ breast cancer (BC). We evaluated prognostic factors for overall survival (OS) in a contemporary cohort of patients (pts) with HER2+ BCBM treated at a tertiary care institution. **Methods:** The Cleveland Clinic's IRB approved BM database was used to identify HER2+ BCBM pts treated between 2000 and 2013. OS from the diagnosis of BM was the primary endpoint. Breast-specific GPA (Sperduto et al, 2012), based on age at BM (< 60 vs >60), KPS (90-100 vs 70-80 vs 60 vs < 60), and BC subtype (luminal B versus Her2), was correlated with OS. Cox proportional hazards models with and without stepwise variable selection were used for data analysis. Recursive partitioning was used to identify cut points. **Results:** Data from 205 pts were analyzed. Median age was 52 (23-86); 51% of pts had KPS 90-100, 23% KPS < 80; 52% of pts were ER and/or PR+, and 82% had extracranial metastases at BM diagnosis. BM were initially treated with WBRT +/- surgery (62%), or WBRT + stereotatctic radiosurgery + /-surgery (17%). Median OS was 16.9 months (95% C.I. 13.0-22.5). Using breast specific GPA, 63% of pts had the most favorable profile (scores of 3.5-4), 37% had the second most favorable profile (scores 2.5-3) while a single patient scored 1.5-2. In univariate analysis, breast GPA was associated with OS ($p = .004$) as were 2 of its components, KPS ($p < .0001$) and age ($p = .01$); breast subtype was marginally significant ($p = .09$). Multivariable analysis again identified KPS ($p < .0001$) and age ($p = .003$), as independent predictors (with difference categorizations). Bone/lung metastases ($p = .007$) rather than BC subtype were predictive of OS. An updated HER2+-specific GPA was thus defined by assigning "points" to each factor: KPS > 70 = 2 points; 1 point each for age < 50 and no lung or bone metastases. Based on the cumulative number of points, 3 prognostic groups were identified: favorable (3-4 points, 49% pts), intermediate (2 points, 30% pts) and unfavorable (0-1 point, 21% pts) with median OS of 25.7, 13.7 and 5.4 months, respectively. **Conclusions:** This study confirms the prognostic value of the breast GPA, and proposes a modified HER2+ specific version.

590 Poster Session (Board #79), Sat, 8:00 AM-11:30 AM

Phase I study of LJM716, BYL719, and trastuzumab in patients (pts) with HER2-amplified (HER2+) metastatic breast cancer (MBC). *First Author: Payal Deepak Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HER2+ breast cancer is driven by HER2/HER3/PI3K signaling. Single agent targeted therapy (tx) is limited by redundant mechanisms of pathway activation and feedback loops; preclinical models support combinatorial tx. This phase I trial examined HER2, HER3 and PI3K inhibition in pts with HER2+ MBC (NCT02167854). **Methods:** Pts received weekly intravenous (IV) trastuzumab (T) at 2 mg/kg, LJM716 (L, HER3 inhibitor) at 20 mg/kg, and escalating dose cohorts of daily oral BYL719 (B, PI3Kα inhibitor) starting at 250 mg. Eligible pts had HER2+ MBC with a *PIK3CA* mutation and prior ado-trastuzumab emtansine and pertuzumab. Endpoints were: to define MTD (toxicity based on CTCAE 4.0) using the Continual Reassessment Method, to assess efficacy (RECIST v1.1), to evaluate genomics and proteomics of pre- and on-tx tumor biopsies, and to quantify cell-free DNA and *PIK3CA* mutant allele fraction (MAF). **Results:** 8 pts have been treated with a median (M) age 56y (range (R): 46-68), M ECOG of 1 (R: 0-1), and M of 6 (R: 3-10) prior tx. M duration on study was 10 weeks (R: 2-21.9). 7 pts were treated with B 250 mg. 1 pt was treated at 300 mg and had a DLT of supraventricular tachycardia in the setting of hypokalemia. A second pt had a DLT of G3 transaminitis at B 250 mg. Significant toxicities (and worst grades) included diarrhea (G3: 5 pts; G1/2: 2 pts); hyperglycemia (G3: 2 pts; G1/2: 6 pts); hypokalemia (G3: 2 pts; G1: 4 pts); mucositis: (G3: 1 patient; G1/2: 4 pts); and transaminitis: (G3: 2 pts), with no G4 toxicity. Despite prophylactic antidiarrheals, diarrhea led to dose reduction in 1 (13%) and tx interruptions in 5 (63%) pts. Overall, toxicities limited drug delivery, with only 72%/83% of total planned B/L doses given. In addition, B was dose-reduced in 2 (25%) and L in 4 (50%) of pts. Best response was SD in 5 of 6 evaluable pts. Pre-tx genomics and *PIK3CA* MAF will be correlated with response. **Conclusions:** The combination of T, L, and B has antitumor activity in these pre-treated HER2+ pts with MBC with *PIK3CA* mutations. Clinically significant gastrointestinal and metabolic toxicities limit drug delivery and dose escalation of B/L. Based on preclinical modeling, exploration of intermittent dosing schedules is warranted. Clinical trial information: NCT02167854.

591 Poster Session (Board #80), Sat, 8:00 AM-11:30 AM

Effectiveness of targeting HER2 in heavily pretreated patients with occult HER2-positive (tissue-negative, serum-positive and/or HER2-positive circulating tumor cells) metastatic breast cancer in the clinical routine. *First Author: Christian M. Kurbacher, Gynecologic Center Bonn-Friedensplatz, Bonn, Germany*

Background: A considerable proportion of patients (pts) with HER2-negative (HER2-) metastatic breast cancer (MBC) present with elevated serum levels of the HER2 extracellular domain (sHER2) and/or HER2-overexpressing circulating tumor cells (CTCs) during their further clinical course. These "occult" HER2-positive (HER2+) pts may be candidates for anti-HER2 therapy (Tx) albeit normally not subjected to such treatment. This retrospective study was undertaken to gain more insights into the feasibility of HER2-directed Tx in occult HER2+ MBC pts in the clinical routine. **Methods:** From our database, we identified 26 pts with heavily pretreated HER2- MBC (ER+, 21 pts) showing sHER2 values > 15 ng/mL (6 pts), HER2+ CTCs (6 pts), or both (14 pts) having failed 2-16 prior systemic treatments (median: 7) who did not qualify for recruitment onto a prospective clinical trial. All pts received anti-HER2 Tx with trastuzumab (H: 14 pts), lapatinib (L: 4 pts), H+L (2 pts), or H+pertuzumab (H+P: 6 pts). HER2-targeting Tx was given alone (4 pts), or in combination with endocrine agents (4 pts), cytotoxics (16 pts), or other targeted drugs (2 pts). Responses were scored according to RECIST 1.1, OS was calculated from the start of HER2-directed Ctx until death from any reason or loss to follow-up by using Kaplan-Meier statistics. **Results:** Anti-HER2 Tx was generally well tolerated. Median treatment duration was 16.1 wks (range 1.0-56.1 wks). In 2 pts with L and 1 pt with H+L, Tx was prematurely stopped due to toxicity (diarrhea, fatigue). 10 PR, 10 SD, 5 PD, and 1 non-evaluable (NE) pt accounted for an objective response rate (ORR) of 38.5% and a clinical benefit rate (CBR) of 76.9%. Median OS was 62.9 wks. **Conclusions:** Our findings indicate that anti-HER2 Tx may be a valid option in pts with heavily pretreated HER2- MBC with pathological sHER2 values and/or HER2+ CTCs in the clinical routine. Thus, results of ongoing randomized trials in this setting are eagerly awaited.

592 Poster Session (Board #81), Sat, 8:00 AM-11:30 AM

Implications of high tumor infiltrating lymphocytes (TIL) in HER2-positive and triple-negative breast cancer (TNBC). *First Author: Vassiliki Kotoula, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

Background: High TIL may confer better prognosis to TNBC patients and may interfere with trastuzumab (T) benefit in HER2-positive breast cancer (BC) patients. Here, we investigated the effect of TIL on BC patient outcome with respect to immunohistochemical subtypes and treatment. **Methods:** Intratumoral mononuclear infiltrates were assessed as % of stromal area under low magnification on whole routine sections of 2613 breast carcinomas. Three different cut-offs (c/o) for high/low TIL were used (50%, 35% and 25%). Subtyping revealed 948 Luminal A, 615 Luminal B, 477 Luminal-HER2, 246 HER2-enriched, and 327 TNBC tumors. Patients had been treated in the frame of 4 prospective trials with adjuvant anthracycline-based chemotherapy in the pre- and post-T era. T was administered sequentially for 1 year. **Results:** High TILs were present in 3.5%, 6.5% and 11.5% of all tumors, using the 50%, 35% and 25% c/o, respectively, and were subtype specific. Using the 35% c/o, high TIL were significantly more frequent in TNBC (13.8%), HER2-enriched (11.8%) and Luminal-HER2 (9.2%) than in Luminal B (5.7%) and Luminal A (1.8%) tumors ($p < 0.0001$). No significant TIL effect was observed on the outcome of patients with Luminal A and B tumors. High TIL, at all c/o, conferred decreased risk for relapse in patients with TNBC (e.g. 35% c/o, HR = 0.37, 95% CI 0.15-0.90, Wald's $p = 0.030$) and Luminal-HER2 (e.g. 25% c/o, HR = 0.41, 95% CI 0.21-0.82, $p = 0.011$), but not with HER2-enriched tumors. Among all HER2-positive patients, a significant T benefit was noticed for those with low TIL (35% c/o, HR = 0.61, 95% CI 0.44-0.85, $p = 0.003$), but not for those with high TIL tumors; non-T treated patients with high TIL performed better than those with low TIL (HR = 0.56, 95% CI 0.36-0.87, $p = 0.009$), but this effect was insignificant among T treated patients. No interaction between T and TIL was found. Similar results were obtained for all TIL c/o, in distinct test and validation sets within the entire cohort. **Conclusions:** In the context of operable BC, high TIL is a favorable prognosticator in patients with TNBC and HER2-positive tumors. In the latter, high TIL does not seem to specifically predict for T benefit upon sequential T administration.

593 Poster Session (Board #82), Sat, 8:00 AM-11:30 AM

Correlation of trastuzumab treatment benefit with quantitative HER2 expression levels in HER2 positive metastatic breast cancer. *First Author: Beatrice Bachmeier, Institute of laboratory medicine, Ludwig-Maximilians-University, Munich, Germany*

Background: The HERmark Breast Cancer Assay (Monogram Biosciences) is used as an adjunct to HER2 immunohistochemistry (IHC) and HER2 fluorescence in-situ hybridization (FISH) to determine the HER2 status of breast cancer (BC). Based on the high degree of concordance of HERmark with centrally determined HER2 status by IHC/FISH, it is expected that HERmark positive BC patients would realize greater benefit from trastuzumab treatment than HERmark negative BC patients. In the current study, this hypothesis was confirmed using a cohort comprised of: (1) HER2 positive BC patients treated before the availability of trastuzumab, (2) trastuzumab-treated HER2 positive BC patients and (3) HER2 negative BC patients. **Methods:** HERmark was performed retrospectively on formalin-fixed, paraffin-embedded tumors derived from 305 metastatic breast cancer patients in the Munich Cancer Registry with a median follow up of 10 years. Cases were evenly divided between trastuzumab-untreated HER2 positive (n = 91), trastuzumab-treated HER2 positive (n = 115) and HER2 negative (n = 99) tumors. Cutoffs for HERmark positive and negative status were pre-specified (Huang, Am J Clin Pathol, 134:303 2010). **Results:** HER2 positive patients treated with trastuzumab had longer overall survival (OS) than those not treated with trastuzumab, as expected (HR = 0.35; p < 0.0001). As reassessed by HERmark, HER2 positive patients treated with trastuzumab experienced longer OS (HR = 0.33; p = 0.0005). In contrast, the benefit of trastuzumab treatment in HERmark negative patients was not statistically significant (HR = 0.55; p = 0.13). Additionally, there was a statistically significant interaction between the degree of trastuzumab benefit and quantitative levels of HER2 expression within the HERmark positive subset (interaction p = 0.032). Potential correlations between additional markers, including p95HER2 and HER3, and treatment outcome are currently being assessed. **Conclusions:** The HERmark assay identified breast cancer patients who benefited from trastuzumab treatment. Within this group, increased levels of quantitative HER2 expression correlated with increased degree of benefit from trastuzumab therapy.

594 Poster Session (Board #83), Sat, 8:00 AM-11:30 AM

Prognostic impact of HER2 overexpression/amplification in women with pT1a N0 M0 breast cancer with known screening status: First results from a multicenter population-based cancer registry study. *First Author: Antonino Musolino, Medical Oncology Unit, University Hospital of Parma, Parma, Italy*

Background: Outcomes for women with pT1aN0M0 breast cancers (BC) may vary by biologic subtype. A higher proportion of HER2-positive BCs diagnosed in the interval between scheduled screening rounds has been proposed to account for the more aggressive behaviour of interval cancers (IC) compared with screen-detected (SD) tumors. No data are available on the prognostic role of HER2-positive status in a general population of pT1aN0M0 breast tumors with known screening status. **Methods:** All incident pT1aN0M0 BCs (n = 874), systematically collected by the Cancer Registries of Emilia Romagna Region (northern Italy) and diagnosed in women aged 50-69 from 2003 to 2009 were evaluated. Screening status was ascertained by reference to the Emilia Romagna Breast Cancer Screening Program (ERBSP) database. Patients unexposed to screening, with HER2 unknownprimary tumor and/or who received adjuvant chemotherapy or trastuzumab were excluded from analysis. **Results:** Twelve percent of patients had HER2-positive tumors. Fifty-three percent of the entire study population were SD cancers, while 18% were ICs. Tumors with high histologic grade, high proliferative rate, negative estrogen receptor status, or HER2-positive status were more likely to be diagnosed in the interval between screening. At a median follow-up of 84 months, there were 39 recurrences. The 5-year disease-free survival (DFS) rates were 89% and 95% in patients with HER2-positive and HER2-negative tumors, respectively ($P = 0.025$). In multivariate analysis, patients with HER2-positive tumors had higher risks of recurrence (hazard ratio [HR], 2.58; 95% CI, 1.38 to 5.3; $P = 0.01$) than those with HER2-negative tumors. **Conclusions:** In a general population of pT1aN0M0early BCs with known screening status, HER2-positive tumors account for a substantial proportion of screening failure and have a significant risk of relapse. Final analysis of this study will evaluate if IC detection may identify patients with HER2-positive pT1aN0M0 tumors in whom the rate of recurrence justifies consideration for systemic, anti-HER2, adjuvant therapy.

595 Poster Session (Board #84), Sat, 8:00 AM-11:30 AM

Evaluation of the Breast Cancer Index in patients with HER2+/HR+ breast cancer for risk of late recurrence and potential extended endocrine benefit. *First Author: Ruth O'Regan, Emory Univ, Atlanta, GA*

Background: Hormone-receptor positive (HR+), early stage breast cancer patients (pts) are at risk for late (> 5 year) distant recurrence (DR) and are now considered for extended (10 year) endocrine therapy (EET) to prevent late disease relapse. Approximately 50% of all HER2+ breast cancer pts are also HR+. Clinical trials investigating the benefit of EET to reduce late DR have included HER2+/HR+ pts, but subset analyses in comparison to HER2-/HR+ have been limited. Breast Cancer Index (BCI) is a gene expression based assay validated to 1) assess risk of late DR, and 2) predict benefit from EET using the endocrine response biomarker HoxB13/IL17BR (H/I). This study compared BCI results and clinicopathologic factors in HER2+/HR+ vs HER2-/HR+ breast cancer. **Methods:** Consecutive cases with known HER2 status (N = 1182) submitted for BCI clinical testing were analyzed for pt characteristics and BCI reporting rates according to HER2 status. Fisher's test was used to compare results between subgroups. **Results:** 12% of BCI testing was conducted on HER2+/HR+ pts. Tumor size distribution was similar for HER2+ and HER2- cohorts (P = 0.9). In converse, the HER2+ cohort was comprised of a higher proportion of grade 3 (51% vs 17%; P < 0.001) and ER+/PR- tumors (24% vs 7%; P < 0.001). In regards to risk of late DR, 3 times more tumors were classified as BCI High-Risk in the HER2+ cohort compared to the HER2- cohort (59% vs 19%, P < 0.001; Table 1). Twice as many HER2+ were predicted to benefit from EET compared to the HER2- cohort (High H/I; 69% vs 38%, P < 0.001; Table 1). **Conclusions:** BCI classifies a higher proportion of HER2+/HR+ tumors into a high-risk group compared to those that are HER2-/HR+, yet a subset of HER2+ tumors are classified as low-risk. Additionally, a significant proportion of the HER2+ cohort was predicted to benefit from ETT. Further studies to validate the ability of BCI to predict benefit of EET in HER2+/HR+ pts are warranted.

BCI and H/I categorizations by HER2 status.

BCI Risk Classification	HER2+ Cohort (N=140)	HER2- Cohort (N=1042)
Low	18 (13%)	564 (54%)
Intermediate	40 (29%)	283 (27%)
High	82 (59%)	195 (19%)
H/I Categorization		
Low	45 (32%)	646 (62%)
High	95 (69%)	396 (38%)

596 Poster Session (Board #85), Sat, 8:00 AM-11:30 AM

Determining whether functional subtyping with BluePrint 80-gene profile could potentially identify two distinct triple positive subtypes with and without trastuzumab/chemo-sensitivity. *First Author: Pat W. Whitworth, NRG Oncology/NSABP, ALLIANCE/ACOSOG, and Nashville Breast Center, Nashville, TN*

Background: Classification by molecular subtype can aid in the selection of therapy for patients with breast cancer. However at present, the methodology for molecular subtyping is not standardized. The aim of the prospective NBRST study is to compare chemosensitivity as defined by pathological Complete Response (pCR) using the 80-gene BluePrint (BP) functional subtype profile vs. conventional IHC/FISH subtyping. **Methods:** The study includes women aged 18–90 with histologically proven breast cancer, written informed consent, no excision biopsy or axillary dissection, and no prior therapy for breast cancer. Neo-adjuvant Chemotherapy (NCT) was at the discretion of the physician adhering to NCCN approved or other peer-reviewed regimens. BP in combination with MammaPrint classifies patients into 4 molecular subgroups: Luminal A, Luminal B, HER2 and Basal. **Results:** 721 patients had definitive surgery. 58/335 (17%) IHC/FISH HR+/HER2- patients were re-classified by BP as Basal (57) or HER2 (1). 92/222 (41%) IHC/FISH HER2+ patients were re-classified as BP Luminal (67) or BP Basal (25). 7/164 (4%) IHC/FISH triple negative (TN) patients were re-classified as BP Luminal (5) or BP HER2 (2). NCT pCR rates were 3% in Luminal A and 9% in Luminal B patients versus 10% pCR in IHC/FISH luminal patients. The NCT pCR rate was 54% in BP HER2 patients. This is significantly superior (p = 0.02) to the pCR rate in IHC/FISH HER2+ patients (40%). BP Basal and IHC/FISH TN had a pCR rate of 35%. Functional BP subtyping divided the 137 IHC/FISH triple positive patients into two major subgroups: BP Luminal (n = 66, pCR = 11%) and BP HER2 (n = 60, pCR = 45%).11 patients were re-classified as BP Basal with pCR = 45%. **Conclusions:** Molecular subtyping using BP leads to a reclassification of 23% of tumors. The re-classification is most prominent in classically assessed triple positive patients where 48% of patients are re-assigned to the less responsive BP Luminal-type group vs. 44% of patients assigned to the responsive BP HER2-type group. These findings confirm the more accurate identification of molecular subgroups for treatment decision by BluePrint functional subtype classifier. Clinical trial information: NCT01479101.

597 Poster Session (Board #86), Sat, 8:00 AM-11:30 AM

Effect of ranolazine administered after trastuzumab treatment on cardiotoxicity in mice. *First Author: Nicola Maurea, Istituto Nazionale per lo Studio e la Cura dei Tumori Fondazione Giovanni Pascale- IRCCS, Naples, Division of Cardiology, Naples, Italy*

Background: Trastuzumab (T), a monoclonal antibody against ErbB2, has improved the prognosis of breast cancer patients, but ErbB2 blockade in cardiomyocytes can produce asymptomatic left ventricular dysfunction and heart failure, whose mechanism has not been elucidated and can include changes in Ca2+ regulation. We aim at assessing whether Ranolazine (R), an inhibitor of the late sodium current, administered after T treatment, blunts T cardiotoxicity in vivo and in vitro. **Methods:** In vitro, rat H9C2 cardiomyoblasts were treated with T (0.2μM) for 3 days and then treated in the absence or presence of R (1μM or 10μM) for 3 days. In vivo, fractional shortening (FS) and ejection fraction (EF) were measured by M-mode echocardiography and radial and longitudinal strain (RS and LS) were measured using 2D speckle-tracking, in C57/BL6 mice, at 0, 2 and after 7 days of daily administration of T (2.25 mg/kg/day). These measurements were repeated after 5 days of R treatment (305 mg/Kg/day) initiated at the end of T treatment. We have divided mice in 4 groups. The first group (G1) was treated with T for 7 days. The second group (G2) was treated with T for 7 days and then treated with R for 5 days. The other 2 were control groups: CG1 (sham) and CG2 (no R). We have evaluated tissue expression of BNP (brain natriuretic peptide) by PCR analysis on heart tissue. **Results:** R reduced T toxicity in H9C2 cardiomyoblasts as evidenced by higher percentage of viable cells treated with T+ R with respect to cells treated with T alone ($p< 0.01$). In vivo, after 7 days with T, FS decreased to 48.7 $\pm$ 4.1%, $p< 0.01$ vs 62.3 $\pm$ 0.8% (sham), EF to 81.8 $\pm$ 3.5%, $p < 0.01$ versus 91.7 $\pm$ 0.5% (sham), RS to 21 $\pm$ 8.1%, $p < 0.01$ versus 43.2 $\pm$ 4% (sham), and LS to -11 $\pm$ 3.7%, $p < 0.01$ versus -38.8 $\pm$ 6% (sham). In mice treated with R for 5 days after T treatment, the indices of cardiac function recovered: FS was 61 $\pm$ 1.2%, EF was 91 $\pm$ 0.7%, $p < 0.01$; RS was 35$\pm$1.8%, $p < 0.05$ versus T. However the alteration of LS persisted after treatment with R (-15.4 $\pm$ 5.1%, $p = 0.3$ vs. T). R prevents the increased expression of BNP ($p < 0.05$) on heart tissue **Conclusions:** R post-treatment blunts cardiotoxic effects due to T both in vitro and in vivo in a mouse model, as demonstrated by the normalization of the values of FS, EF and RS. LS is the first to impair and may be the last to recover.

598 Poster Session (Board #87), Sat, 8:00 AM-11:30 AM

Skin and subcutaneous tissue disorders (SSTDs) in patients (pts) with HER2-positive metastatic breast cancer (MBC) in the phase III trial CLEOPATRA of pertuzumab or placebo with trastuzumab and docetaxel. *First Author: David Miles, Mt Vernon Cancer Centre, London, United Kingdom*

Background: CLEOPATRA established pertuzumab (P), trastuzumab (T), and docetaxel (D) as the first-line standard of care for pts with HER2-positive MBC. SSTDs were often observed in CLEOPATRA. We report detailed analyses of SSTDs from this phase III study. **Methods:** The safety population in this analysis included 396 pts in the placebo (Pla) arm (Pla+T+D) and 408 pts in the pertuzumab arm (P+T+D). SSTDs included rash (group term), pruritus, dry skin, alopecia, and nail disorders; incidence, severity (NCI-CTCAE v3.0), management, and outcome were analyzed in both treatment (tx) arms. **Results:** See table. The most common grade $\geq$ 3 SSTD in both arms of the study was rash before and after D discontinuation. Median time to onset of SSTDs was 22 days (Pla+T+D) and 20 days (P+T+D). Median duration of SSTDs was 121 days (Pla+T+D) and 96 days (P+T+D). SSTDs required medical tx in 33.8% (Pla+T+D) and 45.9% (P+T+D) of pts. Steroids were frequently used for tx of rash, antibiotics for nail disorders, and antihistamines for pruritus. Repeated episodes of any SSTD occurred in 17% (Pla+T+D) and 26% (P+T+D) of pts. SSTDs led to discontinuation of all study tx in 0.3% (Pla+T+D) and 0.2% (P+T+D) of pts; and discontinuation of D alone in 1.0% (Pla +T+D) and 3.7% (P+T+D) of pts. **Conclusions:** SSTDs were common in both Pla+T+D and P+T+D arms, although more frequent during D therapy. SSTDs were mostly low-grade, manageable, and rarely resulting in tx discontinuation. There is no specific tx for SSTDs and tx should be empirical, depending on the nature of the SSTD. These results will further inform clinicians on the nature and management of SSTDs for pts who receive P+T+D for the tx of HER2-positive MBC. Clinical trial information: NCT00567190.

Incidence of SSTDs.

All grades and most common ($\geq$ 10 or 5%) and grade $\geq$ 3 (total) SSTDs					
	Overall Exposure to Study Tx $\geq$ 10%			After D Discontinuation $\geq$ 5%	
AE n(%)	Pla+T+D n = 396	P+T+D n = 408	AE n(%)	Pla+T+D n = 267	P+T+D n = 311
Alopecia	240 (60.6)	248 (60.8)	Rash	21 (7.9)	56 (18.0)
Rash	95 (24.0)	153 (37.5)	Pruritus	15 (5.6)	42 (13.5)
Nail disorder	93 (23.5)	96 (23.5)	Nail disorder	13 (5.0)	13 (4.2)

Grade $\geq$ 3 SSTDs	8 (2.0)	18 (4.4)		1 (0.4)	2 (0.6)

599 Poster Session (Board #88), Sat, 8:00 AM-11:30 AM

Biologic characteristics of breast cancer in male compared to female: SEER analysis. *First Author: Mohammed Shaik, Michigan State University, East Lansing, MI*

Background: Male (Ma) breast cancer (BC) is a rare disease and information about tumor biomarkers(ER,PR and HER2) is lacking. Since HER2 status was not routinely collected in the population-based cancer registries for patients (pts) before 2010,in this study we aim to evaluate the expression of tumor biomarkers in MaBC compared to female (F) BC. **Methods:** Using SEER database we analyzed 917(0.84%) MaBC and 108,669 (99.16%) FBC (2010-2011). Data including age, sex, grade, stage, ER/PR status(HR), and HER2 status was used in analysis. These variables were compared between MaBC and FBC. Chi-square and t-test were used for categorical and numerical variables, respectively. **Results:** The median age for MaBC and FBC was 68 and 61, respectively. Majority were whites followed by blacks and others(81%, 14%, and 5% vs. 80%, 11% and 9%, respectively) in both MaBC and FBC. Stages(0, I, II, III and IV) in MaBC vs. FBC were 2.6%, 35.1%, 38.1% ,17.5% and 6.4% vs. 3%, 47%, 33.6%, 11.5%, and 4.7%, respectively. Tumor biomarkers in MaBC vs. FBC were HR+ 96.7%, HER2+ 12.5% and triple negative(TN) 2% vs. HR+ 83%, HER2+ 15% and TN 12%, respectively (Table). **Conclusions:** Overall prevalence of MaBC was 0.84%, diagnosed at older age and the most were of luminal subtype. Prevalence of HER2+ve in MaBC was slightly lower compared to FBC(12.5% vs 15%, $p = 0.03$). TN phenotype in MaBC was uncommon (2%). More favorable tumor biomarker profile was seen in MaBC as compared with FBC. However, HER2 +ve BC represented a significant proportion of MaBC in our study. MaBC should be included in future studies to evaluate HER2 targeted therapies.

Comparison of MaBC and FBC.

Variable	MaBC(%)	FBC(%)	p-value
Median Age (yrs)	68	61	< 0.0001*

600 Poster Session (Board #89), Sat, 8:00 AM-11:30 AM

Effect of high MMP2 and low MMP9 baseline serum levels on outcome in patients with HER2-positive inflammatory breast cancer (IBC) treated with bevacizumab (BEV)- and trastuzumab (TRA)-based neoadjuvant chemotherapy (NAC) in the BEVERLY 2 study. *First Author: Emeline Tabouret, Aix-Marseille University, AP-HM, Service de Neuro-Oncologie, CHU Timone, Marseille, France*

Background: Addition of BEV to TRA-based NAC in HER2-positive IBC has been associated with high pathological complete response (pCR) rate and favorable outcome in the BEVERLY 2 phase II trial (Pierga, Lancet Oncol, 2012; Viens, SABCS, 2013). Matrix metalloproteinase (MMP) 2 and 9 are matrix-degrading enzymes involved in tumor growth, invasion and angiogenesis. The plasma levels of which were recently associated with response to BEV in high-grade glioma (Tabouret, Neuro-Oncology, 2014). We examined the prognostic impact of MMP2 and MMP9 serum levels in Beverly 2 patients (pts). **Methods:** Serum levels of MMP2 and MMP9 were analyzed, using ELISA, in 45/52 samples from pts included in the BEVERLY 2 trial. Serums were analyzed at baseline and before surgical resection, and correlated to pCR, disease-free survival (DFS) and overall survival (OS). **Results:** Baseline (b) MMP2 and MMP9 serum levels were independent from pts characteristics including age, hormone receptor status, SBR grade, circulating tumor cells and endothelial cells, and were not correlated to pCR. As continuous variables (ROC curves), bMMP2 was significantly associated with relapse ($p = 0.002$) and death ($p = 0.049$) risks, while bMMP9 was only associated with death risks ($p = 0.035$). Using median value as cutoff, univariate analyses identified high bMMP2 as correlated to better DFS ($p = 0.001$) and OS ($p = 0.032$), while low bMMP9 was correlated to better OS ($p = 0.022$) and tended to be associated to longer DFS ($p = 0.071$). In multivariate analyses (DFS only, same cutoff), both bMMP2 ($p = 0.003$, Hazard Ratio [HR]: 10.614) and bMMP9 ($p = 0.041$, HR: 3.534) remained correlated to DFS. Between baseline and pre-surgery time points, significant increase in MMP2 and decrease in MMP9 levels ($p < 0.001$ for both) were observed in 100% and 87% of pts, respectively but did not correlate with outcome. **Conclusions:** High bMMP2 and low bMMP9 serum levels were associated with a better outcome in HER2-positive IBC pts treated with BEV- and TRA-based NAC. Their predictive value should be evaluated in randomized trial.

601 Poster Session (Board #90), Sat, 8:00 AM-11:30 AM

Expression levels of PARP1 and phospho-p65 protein in human HER2-positive breast cancers. *First Author: Jennifer Anne Stanley, University of Alabama at Birmingham, Birmingham, AL*

Background: Previous studies have shown that basal breast cancers, which may have an inherent "BRCAness" phenotype and sensitivity to inhibitors of poly (ADP-Ribose) polymerase (PARP), express elevated levels of PARP1. Our lab previously reported that HER2+ breast cancers are exquisitely sensitive to PARP inhibitors (PARPi) thru alteration of the NF-kB pathway. In this study, we assessed levels of PARP1 and phospho-p65, a marker of activated NF-kB, in human breast cancer tissues. **Methods:** PARP1 and PARP2 copy number, mRNA, and protein expression were assessed by interrogating the PAM-50 defined breast cancer patient set from the TCGA using the cBioPortal. PARP1 and phospho-p65 immunohistochemistry and correlation to clinical parameters were conducted using 307 primary breast cancer specimens (132 basal, 82 luminal, 93 HER2+) through univariate and multivariable analyses. **Results:** In the PAM50 breast cancer data set, PARP1 and 2 expression was altered in 24/58 (41%) HER2+, 32/81 (40%) basal, and 75/324 (23%) luminal A/B breast cancer patients. This correlated with a statistically significant increase in PARP1 protein levels in HER2+ and basal but not luminal breast cancers ($p = 0.003$, $p = 0.027$, $p = 0.289$, respectively). No change in PARP2 protein level was observed. Interestingly, using breast cancer specimens from 307 patients, HER2 positivity correlated with elevated PARP1 expression ($p < 0.0001$) and was three times more likely than HER2 negative breast cancers to exhibit high PARP1 levels. No significant differences were noted between race, ER status, or PR status for PARP1 expression. Additionally, we found a significant correlation between HER2 status and phospho-p65 expression ($p < 0.0001$). Lastly, a direct correlation between PARP1 and phospho-p65 ($p < 0.0001$) was noted. **Conclusions:** These results indicate a potential connection between HER2, PARP1, and phospho-p65 in human breast tumors. Additionally, these data suggest that the PARPi sensitivity we previously observed in HER2+ breast cancer cells may be due to elevated PARP1 expression. Future testing of PARPi in HER2+ breast cancer patients is warranted.

602 Poster Session (Board #91), Sat, 8:00 AM-11:30 AM

Phase 1b study of ONT-380, an oral HER2-specific inhibitor, in combination with capecitabine (C) and trastuzumab (T) in third line + treatment of HER2+ metastatic breast cancer (MBC). *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute, Brentwood, TN*

Background: ONT-380, a potent, highly selective, small molecule inhibitor of HER2, was associated with clinical benefit and minimal EGFR-type toxicities in a phase 1 single agent study in HER2+ MBC. Based on synergistic activity with chemotherapy and T in preclinical models, ONT-380 is being evaluated in combination with C and T in pts with HER2+ MBC following prior treatment with T and ado-trastuzumab emtansine (T-DM1). ONT-380 300 mg PO BID was well tolerated in combination with either C or T alone, and is now being studied in combination with both C and T as triplet therapy. **Methods:** Phase 1b 3+3 dose escalation study with expansion cohort for a total of 15 pts at a given dose. ONT-380 (300 mg PO BID), C (1000 mg/m^2 PO BID 14 days of a 21-day cycle), and T (8 mg/kg IV loading; then 6 mg/kg IV once every 21 days), are administered to HER2+ MBC pts previously treated with trastuzumab and T-DM1. Prior pertuzumab, lapatinib, or neratinib, and asymptomatic brain metastases (treated or untreated) are allowed. Assessments include safety, tumor response by RECIST 1.1, and PK. **Results:** 8 pts (# prior treatments for MBC 2-6) have completed 2–8 cycles of triplet therapy; 6 pts remain active. A dose-limiting toxicity (DLT) of reversible cerebral edema with Gr 3 dysarthria and visual field deficit was seen in a pt with known brain metastases. No additional DLTs were seen. Most toxicities have been Gr 1 or 2; the most common being nausea, vomiting, diarrhea, palmar-plantar erythrodysaesthesia, and fatigue. One additional Gr 3 treatment-related event of reversible increase in AST/ALT was reported. No Gr $\geq$ 3 diarrhea has been seen. To date, best responses in pts with at least 1 follow up scan have been: partial response (PR) n = 4, stable disease (SD) n = 2, and progressive disease n = 2. Two pts with PR and 2 pts with SD also had received prior pertuzumab. **Conclusions:** ONT-380 in combination with C and T exhibits an acceptable safety profile without Gr 3 diarrhea. The combination shows preliminary evidence of disease control in heavily pre-treated HER2+ MBC pts with prior exposure to trastuzumab, pertuzumab, and T-DM1. Enrollment in an expansion cohort is ongoing. Clinical trial information: NCT02025192.

603 Poster Session (Board #92), Sat, 8:00 AM-11:30 AM

Safety of trastuzumab emtansine (T-DM1) in 373 patients 65 years or older with HER2-positive advanced breast cancer: A subgroup analysis of the Kamilla study. *First Author: Carlos H. Barrios, PUCRS School of Medicine, Porto Alegre, Brazil*

Background: T-DM1 is approved for HER2-positive metastatic breast cancer (MBC). A pooled analysis of T-DM1 trials (N = 884) suggested a higher rate of grade $\geq$ 3 adverse events (AEs) in patients (pts) $\geq$ 65 yrs (n = 122) vs those < 65 (51.6% vs 44.0%). We report the safety profile of T-DM1 in pts $\geq$ 65 yrs from the ongoing phase IIIb global safety study Kamilla. **Methods:** Kamilla enrolled pts with HER2-positive, locally advanced or MBC with progression after chemotherapy and a HER2-directed agent for MBC or within 6 mos of completing adjuvant therapy. T-DM1 3.6 mg/kg was given q3w until unacceptable toxicity, withdrawal of consent or disease progression. **Results:** As of 20 Oct 2014, Kamilla enrolled 2001 pts; 373 pts $\geq$ 65 yrs. Pts $\geq$ 65 yrs had a longer median time since initial BC diagnosis than pts < 65 yrs (6.3 yrs vs 4.8 yrs) and a lower prevalence of brain metastases (10.2% vs 21.6%). Median exposure was 8 cycles in each group (IQR 4.0–13.0 older; 4.0–15.0 younger). AEs by age group, including known T-DM1–associated AEs, are shown. The incidence of grade $\geq$ 3 AEs and AE-related discontinuations were greater in older pts. This resulted from many small differences in AEs rather than any single AE. **Conclusions:** In this largest population of T-DM1–treated pts $\geq$ 65 yrs studied to date, while overall incidence of grade $\geq$ 3 AEs and discontinuation due to AEs was greater, the most common grade $\geq$ 3 AEs were infrequent and similar between age groups. Known T-DM1–associated AEs also occurred with a similar frequency in both groups, suggesting a similar safety profile in older and younger pts. Clinical trial information: NCT01702571.

Outcome, n (%)	≥ 65 yrs (n = 373)	< 65 yrs (n = 1628)
Discontinuation due to AEs (% based on pts who discontinued)	41 (14.3)	112 (9.5)
Fatal AEs	10 (2.7)	17 (1.0)
Grade ≥ 3 AEs	160 (42.9)	540 (33.2)
Grade ≥ 3 AEs in ≥ 2% of either group		
Thrombocytopenia*	13 (3.5)	53 (3.3)
Asthenia	12 (3.2)	18 (1.1)
Anemia	11 (2.9)	32 (2.0)

604 Poster Session (Board #93), Sat, 8:00 AM-11:30 AM

The clinical utility of *ERBB2* amplification detection in breast carcinoma using a 341 gene hybrid capture-based next generation sequencing (NGS) assay: Comparison with standard immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) assays. *First Author: Dara S. Ross, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Approximately 15-20% of invasive breast carcinomas (BCA) show HER2/*ERBB2* gene amplification which determines eligibility for treatment by targeted therapy. Traditionally, HER2 status is determined by IHC and FISH. NGS methods can be used to assess HER2 status in clinical practice but concordance with IHC/FISH is not well established. We report our experience using NGS for the assessment of HER2 amplification in conjunction with the detection of potentially targetable mutations. **Methods:** BCA samples (> 10% tumor) were analyzed in a CLIA-certified lab using a hybrid capture-based NGS assay ("MSK-IMPACT") designed to detect somatic genetic alterations in 341 genes, including copy number alterations. Tumor percentage and concurrent IHC/FISH results were recorded (using ASCO/CAP 2013 guidelines). Criteria for amplification by NGS were defined as a fold change (FC) $\geq$ 2, p-value < 0.05. **Results:** A total of 133 BCA samples (63 primaries, 70 mets) were analyzed. Compared to the combined IHC/FISH methodology, *ERBB2* amplification status by NGS had an overall concordance of 97% (129/133) (sensitivity = 82%, specificity = 100%, PPV = 100%). Discordant cases showed low tumor purity, heterogeneous IHC staining, and/or low level amplification by FISH. One sample status post trastuzumab was negative by IHC but *ERBB2* amplified by FISH (ratio 4.0) and NGS (FC 2.3). The assay also uncovered somatic alterations in 133 cancer genes including *TP53*, *PIK3CA*, *CDH1* and *ESR1*. ER and PR IHC results were available for 94 cases; 1/13 triple negative cases showed an actionable *PIK3CA* E542K mutation. Of the 22 *ERBB2* amplified cases, 6 had actionable *PIK3CA* mutations (H1047R or E545K); 4/6 were metastatic lesions in patients previously treated with trastuzumab. **Conclusions:** HER2 status can be reliably determined by hybrid capture NGS methods and allows the concurrent testing for other potentially actionable genomic alterations, particularly in limited material. Samples with low tumor content, heterogeneity and low level amplification may result in false negatives.

605 Poster Session (Board #94), Sat, 8:00 AM-11:30 AM

HER2 quantification by mass spectrometry compared to IHC or ISH in predicting clinical benefit from anti-HER2 therapy in HER2-positive breast cancer (BC). *First Author: Paolo Nuciforo, Molecular Pathology Group, Vall d'Hebron Institute of Oncology, VHIO, Barcelona, Spain*

Background: To be eligible for an anti-HER therapy, tumors have to be HER2-positive as determined by IHC or in situ hybridization (ISH) analyses. Although gene amplification is generally considered the main mechanism of HER2 protein overexpression in BC, the biologic regulation of HER2 expression is complex and gene amplification may not always correlate quantitatively with HER2 protein levels and with response to anti-HER2 therapies. **Methods:** HER2-positive (n = 123) primary BC samples were microdissected, solubilized and digested in trypsin in Liquid Tissue buffer. Absolute quantitation for HER2 protein was performed using selected reaction monitoring (SRM) mass spectrometry. ISH was centrally performed on all cases. HER2 gene copy number (GCN), HER2/Chr17 ratio, and pattern of amplification were evaluated and correlated with HER2 protein levels. The survival benefit according to protein and gene levels was calculated for patients receiving an adjuvant anti-HER2 therapy (n = 68). **Results:** HER2 SRM levels showed weak positive correlations with HER2 GCN and HER2/Chr17 ratio. Average HER2 protein levels were significantly higher in tumors amplified with homogeneous stained regions (HSR, n = 50) compared to those with double minutes (DM, n = 46). Ten amplified cases showed HER2 protein levels similar to HER2-negative tumors. Eight had a DM and 2 a mixed pattern of amplification. None was amplified in HSR. HER2 protein levels > 2,200 amol/μg predicted better disease-free survival and overall survival in patients treated with adjuvant trastuzumab. Neither HER2 GCN, HER2/Chr17 ratio nor pattern of amplification correlated with outcome. **Conclusions:** By using an objective non-antibody based method we identified a great deal of disparity of HER2 levels in BC patients that are classified as HER2-positive by ISH. Different amplification patterns resulted in significantly different protein levels; with many cases of DM amplification showing no concomitant increase in HER2 protein expression. Our findings indicate that protein abundance rather than gene status predict the clinical benefit from anti-HER2 therapy in HER2-positive BC patients.

606 Poster Session (Board #95), Sat, 8:00 AM-11:30 AM

Crosstalk between PARP-1 and NF-κB signaling pathways as a potential determinant of PARPi sensitivity in trastuzumab resistant HER2+ breast cancer cell lines. *First Author: Monicka Wielgos, Department of Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL*

Background: We have previously found that HER2+ breast cancer cells, despite being DNA repair proficient, are sensitive to poly (ADP-Ribose) polymerase inhibitors (PARPi). In this study, we investigated whether PARPi susceptibility would be retained in HER2+ breast cancer cells that are resistant to the HER2 targeted agent trastuzumab. **Methods:** Human HER2+ breast cancer cell lines BT-474, UACC812, SKBR3 and their trastuzumab resistant counterparts were used in this study. Cells were treated with vehicle or 10μM ABT-888 or transfected with scrambled or PARP-1 siRNA. We assessed cell survival by colony formation assays. Western blot analysis was used to measure protein expression. Cell cycle distribution was evaluated by propidium iodide and measured by flow cytometry. NF-κB transcriptional activity was determined via a NF-κB-driven luciferase reporter assay. The nCounter Gene Expression Assay along with qRT-PCR were used to measure the expression levels of NF-κB target genes. Tumor growth delay was assessed in mice bearing tumor xenografts. **Results:** Similar to parental cells, trastuzumab resistant HER2+ breast cancer cells retained PARPi sensitivity both *in-vitro* and *in-vivo*. The cytotoxicity in these cells was associated with greater than 40% attenuation of NF-κB transcriptional activity. Results were validated with PARP-1 siRNA. Further, re-expression of PARP-1 rescued NF-κB activity in PARP-1 knockdown cells. The expression of several NF-κB target genes, including IL-8, BRCA2, and VEGFC, was reduced with PARP inhibition or knockdown. The effects of PARP inhibition via ABT-888 or PARP-1 siRNA were independent of cell cycle redistribution. **Conclusions:** Inhibition of NF-κB signaling via pharmacological or genetic modulation of PARP-1 induces a cytotoxic response in trastuzumab resistant HER2+ tumors. This warrants the testing of PARP inhibitors as a novel therapeutic strategy for patients with HER2+ breast cancer.

607 Poster Session (Board #96), Sat, 8:00 AM-11:30 AM

Phase II study of weekly paclitaxel with trastuzumab and pertuzumab in patients with HER2-overexpressing metastatic breast cancer (MBC): Updated progression-free survival with overall survival result. *First Author: Lillian Mary Smyth, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We previously reported results of the phase II breast cancer (BC) trial of weekly paclitaxel (T), trastuzumab (H) and pertuzumab (P) with its primary endpoint of 6-month (mo) progression-free survival (PFS) of 86% (95% CI, 75% to 92%) in patients (pts) with HER2+ metastatic (M) BC treated in first- and second-line settings. At a median (med) follow-up (FU) of 21 mo, med PFS was 19.5 mo overall. Updated PFS and OS analysis from this fully accrued study is presented here. **Methods:** Pts with HER2+ MBC with 0-1 prior treatment (Rx) were eligible. Rx was weekly (w) T (80mg/m2), q3w H (loading dose 8mg/kg → 6mg/kg) and q3w P (loading dose 840mg → 420mg), all given intravenously. Primary endpoint was 6 mo-PFS. Secondary endpoints included 6-mo and median OS. Evaluable pts received at least one full dose of Rx. **Results:** From January 2011 to December 2013, 69 pts were enrolled: 51 (74%) and 18 (26%) treated in first- and second-line metastatic settings, respectively. 67 were evaluable for efficacy. As of 12-01-14, 26/67 pts (39%) remain progression-free (6 CR, 13 PR and 7 SD); 34 pts have progressed and there are 51 survivors. At a med FU of 23 mo (range, 3-40 mo), 6-mo PFS was 85% (95% CI, 74%-92%). Med PFS was 21.4 mo (95% CI, 13.8-NR) overall and 26.1 mo (95% CI, 17.0-NR) and 16.4 mo (95% CI, 8.5-NR) for pts with 0-1 prior Rx, respectively. 6-mo OS was 98% (95% CI, 90%-100%) and med OS was 37.5 mo (95% CI 31-NR). Median duration of ChemoRx was 30 weeks. Rx was well-tolerated; there were no febrile neutropenia and no symptomatic left ventricular systolic dysfunction. **Conclusions:** Updated analysis demonstrates that weekly paclitaxel, when added to H and P, is associated with prolonged PFS and OS and a favourable toxicity profile and should be considered as a therapeutic option in this patient population Clinical trial information: NCT01276041.

608 Poster Session (Board #97), Sat, 8:00 AM-11:30 AM

A phase 1b trial of blood-brain barrier (BBB)-penetrant tyrosine kinase inhibitor (TKI) tesevatinib in combination with trastuzumab for patients with HER2+ metastatic breast cancer (MBC). *First Author: Komal L. Jhaveri, New York Univ Cancer Inst, New York, NY*

Background: Patients with HER2+ breast cancer (BC) have a high incidence of brain metastases (mets). Tesevatinib (formerly KD019) is a TKI with potent activity against EGFR, HER2, and SRC. In contrast to all of the approved anti-HER2 agents in BC, tesevatinib crosses the intact BBB in mouse and rat models and achieves levels in the brain similar to plasma levels. Single-agent trials of tesevatinib in NSCLC defined the maximum tolerated dose as 300 mg daily due to QTc prolongation. **Methods:** This study was designed tofind the Recommended Phase 2 Dose for tesevatinib given daily combined with trastuzumab 6 mg/kg IV every 3 weeks. Secondary endpoints include pharmacokinetic evaluation of the combination. Eligible patients have HER2+ MBC with disease progression with or without brain mets. Three cohorts (tesevatinib 150 mg, 250 mg, and 300 mg/day) were planned. A 3 + 3 design was utilized for evaluating safety during the 21 days of Cycle (C) 1 to determine dose escalation. **Results:** 7 patients were enrolled into 2 dosing cohorts (median age 47). In Cohort 1 (150 mg) there was 1 patient with Gr 3 asymptomatic increased amylase, which resolved to Gr 1; not a DLT by protocol. There was 1 occurrence each of the following Gr 2 adverse events (AEs), all of which resolved: Gr 2 mouth sensitivity, acneiform rash, nausea, & vomiting. One patient in Cohort 1 missed doses of tesevatinib for 7/21 days (not due to AEs), and thus was not evaluable for dose escalation (but all AEs for this patient are included). The only Grade 2 or higher AE during C1 in Cohort 2 (250 mg) was a Gr 2 diarrhea that resolved to Gr 1 after 2 days with anti-diarrheal medications. Enrollment in the final dose cohort (300 mg) is ongoing. **Conclusions:** The combination of tesevatinib and trastuzumab appears to be well tolerated with no QTc prolongation so far and enrollment into the final dose cohort in Phase 1b is proceeding. Tesevatinib is a TKI with anti-HER2 activity that freely crosses the BBB and therefore has promise in the treatment of brain mets in patients with HER2+ MBC. Clinical trial information: NCT02154529.

609 Poster Session (Board #98), Sat, 8:00 AM-11:30 AM

Characterization of dominant T-cell clones by T-cell receptor (TCR) deep sequencing as a potential predictive biomarker to neoadjuvant trastuzumab (tras) in HER2-positive (HER2+) breast cancer. *First Author: David B. Page, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Because TIL quantity by H&E predicts pathologic complete response (pCR) to neoadjuvant tras in HER2+ disease, and because clinical responses to tras could be mediated by dominant T-cell clones reactive to the HER2-protein, we hypothesize that the quantity of dominant clones by TCR deep sequencing may predict tras-induced pCRs. Here, we evaluate the influence of specimen age on feasibility of TCR sequencing on breast cancer FFPE-preserved diagnostic core biopsies (bxs), and explore potential associations with pCR in a HER2+ subset. **Methods:** Two groups with pre-treatment bx's were selected and sequenced using the ImmunoSEQ platform: 12 neoadjuvant tras-treated women with "archival" HER2+ bxs (median 35mo from procurement, 12-54mo; 6 with pCRs) and 14 women treated on an immunotherapy protocol with "contemporary" bxs (median 10mo from procurement, 4-18mo). Viability was assessed by calculating the proportion of nucleotide sequences yielding productive, in-frame amino acid sequences. T-cell quantity (the proportion of T-cell to total DNA) and dominant T-cell clone quantity (# clones in top decile of reads) were measured by TCR sequencing and evaluated for associations with pCR (Wilcoxon rank sum). Accuracy of T-cell quantity was assessed by comparing with H&E TIL count. **Results:** TCR sequencing viability was lower in archival compared to contemporary bxs (median .67 v .81; $p < .0001$), and was inversely correlated with sample age (Spearman $r = -0.62$, $p = .0008$) but not input DNA amount ($r = -.05$, NS). T-cell quantity by TCR sequencing correlated with TIL quantity by H&E in contemporary ($r = 0.66$, $p = 0.03$) but not archival bxs ($r = .21$, NS). In the HER2+ group, dominant T-cell clone quantity (median # clones: pCR, 15; no-pCR, 6, $p = 0.05$) but not TIL nor T-cell quantity were associated with pCR to tras. **Conclusions:** Despite the potential influence of specimen age on accuracy of T-cell quantity by TCR sequencing, the # of dominant clones predicted for pCR in this small dataset, highlighting the possibility that dominant clones may mediate response to tras. These findings warrant further study in a larger dataset.

610 Poster Session (Board #99), Sat, 8:00 AM-11:30 AM

Efficacy and CNS progression analysis from the randomized phase 2 trial of neratinib + paclitaxel vs trastuzumab + paclitaxel as first-line treatment for HER2+ metastatic breast cancer (NEfERTT). *First Author: Ahmad Awada, Jules Bordet Institute, Bruxelles, Belgium*

Background: This large randomized open-label phase 2 trial compared the efficacy and safety of Neratinib (N), the irreversible pan-HER tyrosine kinase inhibitor, + Paclitaxel (P) vs Trastuzumab (T) + P as first-line treatment in HER2+ metastatic breast cancer (MBC). **Methods:** 479 pts were enrolled between 08/2009 and 08/2011. Women ≥18y with locally recurrent or MBC, HER2 gene amplification/HER2 overexpression, no progression within 12m (neo)adjuvant therapy, and no prior treatment for advanced disease were eligible. Pts were randomized to oral N (240mg od) + P or T+P. Dosing: T 4mg/kg iv then 2mg/kg iv weekly, P 80mg/m^2 iv weekly 3/4w. Primary endpoint: progression-free survival (PFS). Secondary endpoints: overall survival (OS); overall response rate (ORR); duration of response; clinical benefit rate; CNS progression; safety. PFS analysis was ITT by stratified log-rank test. Randomization was stratified by region, prior T, prior lapatinib, ER/PR status. 304 PFS events were required to detect 30% improvement in median PFS with 80% power (2-sided α=0.15). **Results:** 479 pts made up the ITT population (6 pts in NP arm and 12 pts in TP arm had known brain metastases at baseline; other baseline characteristics were balanced). Main efficacy findings are shown below. Most common adverse events (AEs) with NP vs TP were: diarrhea 93 vs 33% (G3 30 vs 4%; no G4; G3 median duration of 4.5d); nausea 44 vs 30% (G≥3 2 vs 1%); vomiting 36 vs 16% (G≥3 3 vs 1%); fatigue 32 vs 27% (G≥3 3 vs 3%); rash 31 vs 24% (G≥3 1 vs < 1%); cardiac disorders 2.5 vs 5.1% (G≥3 < 1 vs < 1%). **Conclusions:** NP has similar efficacy to TP; of interest, NP may be more effective than TP in reducing CNS progression. With no primary loperamide prophylaxis, diarrhea was significantly higher with NP than TP; non-GI AEs occurred at similar rates in both arms. Clinical trial information: NCT00915018.

Efficacy endpoint	N + P (n=242)	T + P (n=237)	Hazard ratio (95% CI)	P-value
Median PFS, months (95% CI)	12.9 (11.0–14.8)	12.9 (11.1–14.7)	1.03 (0.83–1.29)	0.777
ORR, n (%)	181 (75)	183 (77)	–	0.595
CNS progression[a], n (%)	19 (8)	38 (16)	–	0.0037

[a]49 events were CNS only.

611 Poster Session (Board #100), Sat, 8:00 AM-11:30 AM

Whole exome sequencing (WES) in HER2+ metastatic breast cancer (MBC) patients (pts) with extraordinary responses to trastuzumab (T). *First Author: Ines Maria Vaz Duarte Luis, Dana Farber Cancer Inst, Boston, MA*

Background: While 50-70% of pts with HER2+ MBC treated with T respond to therapy, the vast majority eventually develop resistance, after a median duration of 1 year. In rare cases, pts have exceptionally long durations of response to T. Understanding mechanisms of exceptional responses to anticancer therapies may improve patient selection and rational treatment designs. **Methods:** We conducted a retrospective screen for pts with HER2+ MBC at the Dana Farber Cancer Institute treated with T in the metastatic setting for more than 60 months. To date, we have identified 3 pts with extraordinary responses to T who provided consent for genomic studies and had sufficient tumor tissue available for study. All pts had histologic confirmation of metastatic disease and radiologic confirmation of response. Deep WES was performed on DNA extracted from pre-trastuzumab tumor biopsies and matched normal blood samples from all 3 pts, and sequencing data was analyzed for somatic point mutations, small insertions/deletions, and copy number alterations. **Results:** Clinical features are summarized in the Table. Mean target coverage for tumor samples were 181X, 178X, and 191X. Total number of somatic coding mutations were 161, 67, and 156. Somatic copy number analysis demonstrated HER2 amplification in all 3 tumors. Additional somatic genomic alterations included alterations in known breast cancer genes TP53, MAP2K4, and RB1. **Conclusions:** WES in 3 pts with HER2+ MBC treated with T in the metastatic setting for > 60 months demonstrated HER2 amplification as well as additional somatic genomic alterations. WES on tumor and germline samples from additional pts with extraordinary responses to T are underway, which may improve the power to detect underlying mechanisms of exquisite sensitivity to T.

	Receptor Status	Sites of disease	Tumor purity	Site of biopsy	Treatment	Response duration (months)
1	ER/PR negative, HER2 3+ (IHC)	Lymph nodes (LN)	60%	LN	Trastuzmab-paclitaxel*	88 (Ongoing)
2	ER/PR negative, HER2 3+ (IHC)	Skin/Chest wall, LN	40%	LN	Trastuzumab-lapatinib*	72 (Ongoing)
3	ER+(low) / PR negative, HER2 3+ (IHC)	Bone, Liver	50%	Breast	Trastuzumab-epothilone*	100 (Ongoing)

Followed by trastuzumab alone.

612 Poster Session (Board #101), Sat, 8:00 AM-11:30 AM

ONT-380 in the treatment of HER2+ breast cancer central nervous system (CNS) metastases (mets). *First Author: Cristiano Ferrario, Segal Cancer Centre, Jewish General Hospital, Montreal, QC, Canada*

Background: Up to half of pts with HER2+ metastatic breast cancer (MBC) will develop CNS mets. Surgery and/or radiation remain the mainstay of treatment for HER2+ CNS disease as systemic treatment options have limited efficacy and are often associated with significant GI and skin toxicity. ONT-380, a potent, selective small molecule inhibitor of HER2 with minimal EGFR-like side effects, has been associated with increased survival compared to lapatinib or neratinib in animal models of HER2+ CNS disease. Here we describe 9 pts with CNS mets treated with ONT-380 in combination with other systemic therapies. **Methods:** Pts with untreated asymptomatic (asx) or post-treatment progressive CNS mets were enrolled in CNS expansion cohorts of ongoing phase 1b studies of ONT-380 + ado-trastuzumab emtansine (T-DM1) or ONT-380 + trastuzumab (T) +/-capecitabine (C). All pts received treatment in 21 day cycles including ONT-380 300 mg PO BID and approved doses of either T-DM1 or T +/-C. Eligibility criteria included prior treatment with T and a taxane, and for pts receiving T+/-C, prior T-DM1. Prior lapatinib was allowed. Assessments included safety and CNS tumor response on MRI per modified RECIST 1.1 every 2 cycles. **Results:** 9 pts (4 with asx mets and 5 with progressive disease after local therapy) have received ONT-380 plus T-DM1 (n = 5), T (n = 4) or T+C (n = 1) for 1-8 cycles. 8 pts are evaluable for response (at least one follow-up MRI): 3 PR (T-DM1 n = 2; T+C n = 1) and 4 SD (T-DM1 n = 2; T n = 2). 1 pt with 15% increase in target lesion underwent resection; pathology, however, revealed only necrotic tissue. Pts with PR (1 with hx prior lapatinib) all had > 50% decrease in CNS target lesions. One non-evaluable pt (T-DM1) discontinued early due to treatment-related Gr 3 AST/ALT elevation. One other pt in T-DM1 cohort with Gr 3 ALT/AST increase remains on study following dose reduction. No other ≥ Gr 3 ONT-380 related events have been reported. **Conclusions:** ONT-380 has previously shown activity in the CNS in pre-clinical models. This case series demonstrates early clinical signs of promising activity of ONT-380 against HER2+ CNS mets in combination with other systemic agents. Further study of the CNS activity of ONT-380 is ongoing. Updated results will be reported. Clinical trial information: NCT01983501, NCT02025192.

613 Poster Session (Board #102), Sat, 8:00 AM-11:30 AM

Lack of correlation of neoantigens arising from tumor somatic mutations with tumor infiltrating lymphocytes (TILs) or survival in HER2-positive breast cancer (HER2+ BC). *First Author: Peter Stephen Savas, Peter MacCallum Cancer Centre, Thornbury, Australia*

Background: We have previously shown that TILs are positively prognostic in HER2+ BC. TILs comprise mostly CD8+ T cells but the basis for antigen recognition is unclear. Here we investigated the relationship between somatic mutations and TILs. **Methods:** Two cohorts of HER2+ early-stage BC were analysed. Cohort 1: 50 cases from the Responsify-EU project and Cohort 2: 172 cases from The Cancer Genome Atlas with whole exome sequencing, gene expression, germline SNP (inferring HLA genotype) and survival. Cohort 1 received adjuvant trastuzumab and chemotherapy. TILs were quantified from H&E slides in both cohorts using our previously defined method. We performed computational prediction of mutant peptide neoantigens binding patient specific MHC Class I. **Results:** In cohorts 1 and 2, 660/2113 (31%) and 3268/10841 (30%) non-synonymous point mutations were predicted to be immunogenic mutations (iMut), with a median of 9.5 (IQR 3 – 19), and 9 (IQR 6 – 18) per sample per cohort, respectively. The number of iMut predicted was strongly correlated with the total number of mutations (Cohort 1: $R_s = 0.9$; Cohort 2: $R_s = 0.8$, both $p < 0.00001$). TILs were strongly and significantly correlated ($R_s > 0.5$, $p < 0.001$ for all) with gene expression surrogates of immune activation (CD8A, GRZMB, PRF1) and immunosuppression (PDL1, CTLA4, IDO1). In cohorts 1&2, there was no significant correlation between TILs and total mutation count ($R_s = 0.04$; $R_s = 0.02$, respectively), iMut ($R_s = 0$ for both) nor the APOBEC mutation signature ($R_s = 0$). There was no difference in the level of TILs between lowest and highest quartiles of iMut burden in the cohorts combined ($p = 0.7$). In the trastuzumab-treated cohort 1, total mutation count (≤ 100 vs > 100) and iMut count (0 vs ≥ 1) was not associated with invasive disease-free survival (IDFS $p = 0.4$; $p = 0.9$ respectively). The presence of a recently reported melanoma neoantigen signature (Snyder, NEJM 2014) also did not significantly correlate with the presence of TILs ($R_s = 0.03$) or IDFS ($p = 0.6$). **Conclusions:** In HER2+BC, predicted tumor neoantigens did not correlate with TILs or survival. Other mechanisms seem to be eliciting the anti-tumor immune response in HER2+BC.

614 Poster Session (Board #104), Sat, 8:00 AM-11:30 AM

Neuromedin U to increase IL-6 levels and to expand cancer stem cells in HER2-positive breast cancer cells. *First Author: Vanesa Gabriela Martinez, School of Pharmacy & Pharmaceutical Sciences & Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Background: Neuromedin U (NmU) is a neuropeptide belonging to the neuromedin family. Recently, a significant association between NmU signaling and cancer has been described, particularly correlated with increased aggressiveness and resistance to chemotherapy, although the mechanism through which it exerts this effect remains unexplained. **Methods:** HER2-positive breast cancer cells were stably transfected with NmU and IL-6 levels were measured by ELISA. Migration was evaluated in the presence of anti-NMUR antibodies by wound healing assays, while drug toxicity was assessed by the acid phosphatase assay. **Results:** Overexpression of NmU increases secreted levels of IL-6 (0 vs 0.303 ± 0.12 ng/μg, $p = 0.04$), a cytokine involved in promoting migration, expansion of the cancer stem cell population and drug resistance in breast cancer cells. NmU-transfected cells also show an increased proportion of cancer stem cells (CD44+/CD24-) (52.78 ± 5.765 vs 67.42 ± 5.172 in NmU-overexpressing cells, $p = 0.07$; fold change, 1 vs 1.31 ± 0.14, $p = 0.00015$) and increased expression of the lymphocyte activation inhibitor PD-L1, as detected by flow cytometry (49.50 ± 4.213 vs 60.06 ± 1.628, $p = 0.0327$); Furthermore, NmU over-expressing cells were shown to display enhanced resistance to antibody-dependent cell cytotoxicity mediated by Trastuzumab (47.13 ± 3.31% lysis of mock-transfected cells vs 36.46 ± 4.33% lysis in NmU-overexpressing cells, $p = 0.05$). Treatment with antibodies that block NmU receptors NMUR1 and NMUR2 reduces cell migration and enhances toxicity of HER2-targeted drugs in NmU over-expressing cells, suggesting that interaction of NmU with NMUR1 and NMUR2 are necessary for its effects. **Conclusions:** Altogether, our results show a new mechanism of action of NmU in HER2-positive breast cancer cells that enhances resistance to HER2-targeted drugs and the anti-tumor immune response, and is at least partially mediated by IL-6. *Acknowledgements*: Science Foundation Ireland's funding of MTCI 08/SRC/B1410; HRB's Health Research Award [HRA-POR-2014-658]; Irish Cancer Society's Breast-Predict [CCRC13GAL]; and HEA's PRTLI Cycle 5 support of TBSI.

Effect of somatic mutations in the four genes of the HER family on occurrence in HER2-positive breast cancer, cell proliferation rates, and resistance to HER2-targeted therapies in vitro. *First Author: Naomi Elster, Medical Oncology, Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: Somatic mutations in the 4 HER family genes (EGFR, HER2, 3, 4) occur in HER2-positive breast cancer (HER2+ BC). (Cancer Genome Atlas N. Comprehensive molecular portraits of human breast tumors. Nature 2012; 490(7418): 61-70.) We investigated their frequency in a large set of HER2+ BCs and their therapeutic relevance. **Methods:** Tumors from 246 HER2+ BC patients who received adjuvant trastuzumab-based therapy after surgery were reviewed by a pathologist for tumor content. DNA from 48 matched normal and cancerous samples was sequenced using the Agilent kinome library and a MiSeq. Somatic HER gene mutations identified in this way had their frequency determined by Sequenom MassArray (n=246). HER gene mutations were correlated with patient outcomes. Constructs of 2 hotspot HER3/4 mutations were created and transfected into BT474, HCC1569 and HCC1954 cells. Doubling time, proliferation, Boyden chamber assays and RPPA were used to determine effects of mutations on cell growth, invasion, signalling and response to HER2-targeted therapies. **Results:** 12 somatic deleterious mutually exclusive mutations in the kinase and furin like domains of the 4 HER genes (3 EGFR, 2 HER2, 2 HER3, 5 HER4 mutations) were identified in 6.5 % of HER2+ BCs including 2 hotspot mutations in HER3/4. HER gene mutations did not impact OS or RFS after adjuvant trastuzumab. HER3/4 hotspot mutations increased doubling rates *in vitro* and induced resistance to anti-HER2/EGFR TKIs (Table) but not trastuzumab. Transfected cells were sensitive to the PI3K inhibitor copanlisib and copanlisib also restored sensitivity to these TKIs in these cell lines. **Conclusions:** HER family mutations occur in 6.5% of HER2+BC and affect tumour growth and response to HER2-targeted therapies.

Effects of 2 hotspot HER3/4 mutations on response to TKI's (nM) in vitro in transfected (MUT) vs. wild type (WT) cell lines. '*' indicates a p-value of < 0.05.

	HER3 MUT IC_{50}	HER3 WT IC_{50}

Trastuzumab and pertuzumab-based versus other therapy as second-line therapy in HER2-positive metastatic breast cancer: A retrospective study from single center. *First Author: Daniel Fontes Santos De Teive E Argolo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: First line treatment with dual anti-HER2 therapy (Rx) with trastuzumab plus pertuzumab (HP), and a taxane led to significant improvement in outcomes for patients (pts) with HER2+ metastatic breast cancer (MBC). In 2nd line, data on HP-based Rx are limited. We conducted a retrospective analysis of pts with HER2+ MBC who had progressive disease after 1st line treatment. **Methods:** Pts diagnosed with HER2+ MBC evaluated at MSKCC between 1-1-2011 and 6-30-2014 and who progressed on 1st line Rx were eligible. Pts who received ≥ 2 lines of Rxs were classified in two groups: pts treated with HP-based Rx (Group 1) and with other Rxs (Group 2). Primary endpoint was progression-free survival (PFS) in the 2nd line setting. **Results:** 103 pts were identified (Group 1: 24, Group 2: 79). The baseline characteristics and treatments of each group are summarized in table 1. With a median follow-up of 10.9 months (mo) (range 0.32-42.4), median PFS was 11.5 mo (95% CI, 6.5-NR) in Group 1 and 5 mo (95% CI, 3.75-7.25) in Group 2 (p=0.0027). **Conclusions:** In this retrospective analysis, HP-based Rx appeared to be associated with a longer PFS when compared with other Rx in the 2nd line setting.

Baseline characteristics and treatments.

Group 1 (n=24)

617 Poster Session (Board #107), Sat, 8:00 AM-11:30 AM

***HLA-DRB1**07:01 biomarker characterization of hepatotoxicity during lapatinib combination therapies in ALTTO.** *First Author: Colin F. Spraggs, GlaxoSmithKline, Stevenage, United Kingdom*

Background: ALTTO (NCT00490139) is a large adjuvant breast cancer (ABC) study evaluating lapatinib, alone and in combinations with trastuzumab and taxanes. Characterization of hepatic abnormalities during lapatinib treatment in ALTTO was conducted using the lapatinib hepatotoxicity risk biomarker *HLA-DRB1**07:01. **Methods:** Germline DNA collection for *HLA-DRB1* genotype determination was achieved for 76% (6323/8270) of ALTTO subjects. Association of *HLA-DRB1**07:01 allele carriage with ALT elevation during study treatments was evaluated by case-control analysis of NCI CTC AE grade 3 ALT elevation ($>$ 5x ULN, ALT). **Results:** A higher incidence of ALT elevation (2-5%, n = 6194) was observed in the three lapatinib-containing treatment arms compared with the trastuzumab monotherapy arm (1%, n = 2076; $p < 0.01$). Also, ALT was higher when lapatinib and taxane were administered concurrently. *HLA-DRB1**07:01 carriage frequency was enriched in lapatinib-treated ALT cases compared with controls (OR 6.5, 95% CI 4.6-9.3, $p = 2x10^{-26}$, n = 4568), with overall negative and positive ALT risk predictive values for the *HLA* allele of 98.6% and 8.7%, respectively. The *HLA* association was weaker when concurrent taxane was administered to lapatinib-treated patients, suggesting an ALT risk independent of *HLA-DRB1**07:01 carriage. Homozygous and heterozygous *HLA-DRB1**07:01 genotype carriers exhibited different ALT elevation risk during lapatinib treatment of 12.1% (n = 67) and 8.5% (n = 965), both higher than the risk for non-carriers (1.4%, n = 3586). Furthermore, homozygous carriers exhibited greater severity with significantly higher maximum ALT elevations. ALT elevation risk was significantly correlated with geographic differences in *HLA-DRB1**07:01 carriage frequency. **Conclusions:** Whilst efficacy of lapatinib plus trastuzumab was not sufficiently improved over trastuzumab alone to support a treatment indication for ABC, the present data provide robust lapatinib ALT risk estimates for *HLA-DRB1**07:01 allele carriage that may discriminate causality and support safety management during the use of lapatinib combinations for treatment of metastatic breast cancer globally. Funding: GlaxoSmithKline. Clinical trial information: NCT00490139.

618 Poster Session (Board #108), Sat, 8:00 AM-11:30 AM

Development of PF-05280014, a potential biosimilar to trastuzumab. *First Author: Ira A Jacobs, Pfizer Inc., New York, NY*

Background: Trastuzumab, a humanized recombinant monoclonal antibody, targets HER2 and is approved for treatment of HER2-overexpressing breast and gastric cancers. PF-05280014 is being developed as a potential biosimilar to trastuzumab. Similarity of PF-05280014 to trastuzumab sourced from the EU and US (trastuzumab-EU and -US) was assessed using structural and functional, nonclinical pharmacokinetic (PK) and tolerability, and clinical studies; the toxicity of PF-05280014 was also assessed. **Methods:** Structural similarity was determined by peptide mapping. Functional similarity was measured using an in vitro tumor cell growth inhibition assay. Comparative PK, tolerability, and anti-drug antibody (ADA) responses were evaluated in male CD-1 mice following a single dose; PK and toxicity of PF-05280014 alone were evaluated in CD-1 mice (both sexes) after 5 doses. In a phase I study, 105 healthy male volunteers received a single 6 mg/kg IV dose of PF-05280014, trastuzumab-EU, or trastuzumab-US. Drug concentration-time data were analysed by noncompartmental methods. PK similarity was considered demonstrated for a given test-to-reference comparison if the 90% CI was within 80.00%-125.00%. **Results:** Peptide mapping showed PF-05280014 was similar to trastuzumab-EU and trastuzumab-US. Dose response curves in the in vitro cell growth inhibition assay were superimposable. In vivo PK profiles were similar in mice and there were no toxicity findings for PF-05280014. In the phase I study, PK similarity was shown between PF-05280014 and trastuzumab-EU and trastuzumab-US, with 90% CI of C_{max}, AUC_T, and $AUC_{0-\infty}$ within 80.00%–125.00% for each pair-wise comparison. Adverse events were similar across groups; only 1 subject (trastuzumab-EU group) was ADA positive postdose. **Conclusions:** Evaluation of PF-05280014 thus far supports its development as a potential biosimilar to trastuzumab. An ongoing, phase III, randomized, double-blind clinical trial is comparing PF-05280014 + paclitaxel with trastuzumab-EU + paclitaxel for first-line treatment of patients with HER2+ metastatic breast cancer. A second phase III, randomized, double-blind trial evaluating PF-05280014 in the neoadjuvant setting for breast cancer is ongoing. Clinical trial information: NCT01603264, NCT02187744, and NCT01989676.

619 Poster Session (Board #109), Sat, 8:00 AM-11:30 AM

Association of tumor infiltrating lymphocytes (TILs) with pathologic response in baseline and post-brief exposure HER2+ breast cancer biopsies from BrUOG-211B. *First Author: Stefanie Avril, Department of Pathology, Case Western Reserve University School of Medicine and University Hospitals Case Medical Center, Cleveland, OH*

Background: Increased TILs are prognostic and predictive of therapy response in HER2+ breast cancer (BC). BrUOG-211B, a phase II neoadjuvant trial included early stage HER2+ BC pts treated with single-agent trastuzumab (T) or nab-paclitaxel (N) followed by 6 cycles of T, N and carboplatin combination. This correlative study evaluated TILs in both baseline and post-brief exposure biopsies in association with pathologic response. **Methods:** Stromal (sTILs) and intratumoral (iTILs) TILs were evaluated on H&E sections at baseline (n = 46) and post-brief exposure (n = 43) and scored by deciles (mean of multiple core biopsies) according to the TILs Working Group guidelines. Pathologic response was assessed by residual cancer burden (RCB) index and grouped as responders (R = pCR/RCB 0 & RCB I) or non-responders (NR = RCB II & III). **Results:** Of 60 eligible pts 49 were available for analysis (49% R). Median iTILs were 10% [range 10-40%] and 20% [10-70%], median sTILs were 30% [10-100%] and 35% [20-100%] at baseline and post-brief exposure respectively. sTILs and iTILs were highly correlated (r = 0.8). Higher iTILs ($p = 0.02$) and sTILs ($p < 0.01$) were significantly associated with ER-neg status. Median sTILs were significantly higher in R vs NR at both baseline (35% vs 25%; $p = 0.02$) and post-brief exposure (50% vs 25%; $p < 0.01$). iTILs were not significantly associated with response. Overall, each 10% increase in baseline (OR 1.4; $p = 0.03$) and post-brief exposure sTILs (OR 1.5; $p = 0.01$) was associated with higher response, independent of ER-status. Lymphocyte predominant BC ($\geq$ 50% sTILs) was seen in 22% and not significantly associated with response (70% vs 47% R; $p = 0.2$). There was no significant change in iTILs or sTILs after brief-exposure to T, and a non-significant trend for increase after N. **Conclusions:** Levels of sTILs do not change significantly in HER2+ BC following brief-exposure to single-agent T or N based on morphologic assessment; however, both baseline and post-brief exposure sTILs significantly predict for pathologic response. Further analyses are needed to determine potential changes in lymphocytic subpopulations.

620 Poster Session (Board #110), Sat, 8:00 AM-11:30 AM

Mechanisms of acquired afatinib resistance in HER2-positive breast cancer cells. *First Author: Alexandra Canonici, Molecular Therapeutics for Cancer Ireland, National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland*

Background: Afatinib is a potent irreversible ErbB family tyrosine kinase inhibitor. We have previously shown that afatinib has anti-proliferative activity in a panel of 8 HER2 positive breast cancer cell lines (IC_{50}values 5-80 nM). The aim of this study was to investigate potential mechanisms by which HER2 positive breast cancer cells may develop acquired resistance to afatinib. **Methods:** SKBR3 cells were continuously exposed to 150 nM afatinib for 6 months. Proliferation assays were performed to determine the IC_{50}values for the parental (SKBR3-P) and the afatinib conditioned cells (SKBR3-A), and to assess sensitivity to lapatinib and neratinib. The molecular profiles of the resistant cells were examined by Reverse Phase Protein Array (RPPA). **Results:** The SKBR3-A cells were more resistant to afatinib than the SKBR3-P cells ($IC_{50} > 500$ nM vs $IC_{50} = 10.9 \pm 3.4$ nM). Furthermore, the resistant cells were cross-resistant to lapatinib ($IC_{50} = 1.0\ \mu M \pm 44.0$ nM vs $IC_{50} = 25.9 \pm 3.0$ nM)and neratinib ($IC_{50} = 287.2 \pm 14.0$ nM vs $IC_{50} < 10$ nM). Of the 73 analytes tested by RPPA, 14 were significantly different in the SKBR3-A cells compared to SKBR3-P ($p < 0.05$). The level of phosphorylation of 5 proteins, including HER3 (Y1289), Akt (S473 and T308) and ERK1/2 (T202/Y204) was decreased in the afatinib resistant cells. The level of 9 proteins, including Akt2, EGFR, p38 MAPK, Bcl2 and phospho-Src (Y416) was increased. **Conclusions:** RPPA analysis of afatinib resistant cells suggests that alternative signaling pathways or alterations in apoptosis may play a role in acquired afatinib resistance. Further investigation of the proteins identified may facilitate the development of novel therapeutic strategies to overcome resistance.

621 Poster Session (Board #111), Sat, 8:00 AM-11:30 AM

HER3, PI3K, and JAK2 pathway activation on reverse phase protein microarray (RPMA) in HER2-amplified residual disease (RD) refractory to preoperative chemotherapy plus trastuzumab (H), lapatinib (L), or both (HL). *First Author: Frankie Ann Holmes, Texas Oncology, US Oncology, Houston, TX*

Background: Pretreatment (preRx) biopsies of HER2-amplified breast cancers (BCs) that did not achieve pCR with preop chemotherapy plus H vs L vs HL had PI3K pathway activation with high p-FOXO levels on RPMA (Holmes BMC Res Notes 2013). The RD obtained at surgery in these pts was enriched for co-mutations in *PIK3CA* and *TP53* (Holmes ASCO 2014, 625). Here we describe activated phosphoproteins in the HER1/2/3 pathway in the RD from these pts who did not achieve pCR with preop H vs L vs HL and in RD with *PIK3CA/TP53* co-mutations. **Methods:** 15 pts' FFPE RD BCs were acceptable for RPMA at a CLIA-certified laboratory (Theranostics Health). Immunostaining with 14 antibodies was directed against HER1/2/3 pathway proteins. Spearman correlation (ρ, p value) and Mann-Whitney U tests (p value) were performed. **Results:** 7 of 15 RD BCs had *PIK3CA/TP53* co-mutations. In the RD with co-mutant *PIK3CA/TP53,* the strongest Pearson correlations (r) were between HER3 and p-HER1 and each with p-mTOR, p-S6K, p-JAK2 and p-STAT3 (all $r > 0.9$) In preop L pts ($n = 8$), the strongest correlations in the RD were p-HER2 and HER3, p-HER2 and p-mTOR, p-HER1 and p-STAT3 , p-HER3 and p-STAT3 (all $r > 0.8$), and p-4EBP1 and p-JAK2 ($r = 0.97$). In preop H and HL pts ($n = 7$), the RD showed strong interactions between HER3 and p-HER1, p-HER2 and p-HER3, HER3 and p-S6K, p-HER1 and p-S6K and p-HER3 and p-JAK2 (all $r > 0.9$). Comparing L- vs H/HL-treated RD, L-treated RD had higher levels of p-Akt ($p = 0.08$), p-S6 ($p = 0.08$) and p-MEK1/2 ($p = 0.02$). PreRx biopsies from pts who had RD all expressed high PI3K or low PTEN ser380 levels and showed strong interactions between p-HER1 and p-IGF1R, p-HER1, PI3K, and MAPK activation, LCB3 (autophagy) and PI3K, and Musashi (stem cell regulator) and β-catenin (all $\rho > 0.8$) (all $p < 0.00006$). **Conclusions:** PreRx biopsies from HER2+ pts who had RD following preop chemotherapy + H, L or HL showed activation of HER1, PI3K and MAPK pathways. Pts' refractory RD demonstrated HER3, PI3K and JAK2 pathway activation under the selective pressure of preop H, L or HL. *PIK3CA/TP53* co-mutated RD demonstrated signaling via p-HER1/HER3 to p-mTOR/p-S6K and p-JAK2/p-STAT3.

622 Poster Session (Board #112), Sat, 8:00 AM-11:30 AM

Final pre-specified analysis of the phase II trial of the AE37+GM-CSF vaccine in high risk breast cancer patients to prevent recurrence. *First Author: Julia M. Greene, San Antonio Military Medical Center, San Antonio, TX*

Background: We are conducting a Phase II clinical trial of the AE37+GM-CSF vaccine for the prevention of breast cancer recurrence in disease-free, node-positive or high-risk node negative patients (pts). AE37, is an MHC Class II epitope capable of stimulating CD4+ helper T cells. Here, we present the final pre-specified analysis of the primary endpoint of disease free survival (DFS) at one year from last enrolled pt. **Methods:** After completion of standard of care therapy, pts with any level of HER2 expression (IHC1-3+) were randomized to the vaccine group (VG) to receive 6 monthly intradermal inoculations of AE37+GM-CSF followed by 4 booster vaccinations every 6 months, or to receive GM-CSF alone on the same schedule as a control group(CG). Demographic, safety, immunologic, and clinical recurrence data are being collected. DFS is compared using Kaplan-Meir methods (5 yr DFS rates and logrank test) and Cox proportional hazards models (HR estimates with 95% CI). Continuous variables are compared using analysis of variance techniques and proportions compared with Fisher's exact test. **Results:** Of 301 enrolled pts, 154 were randomized to the VG and 147 to the CG. There were no differences in age, grade, receptor status, tumor size or nodal status between groups (all $p \geq 0.1$). Five-year DFS rates were not different with 82% (VG) vs 79.9% (CG), HR = 0.96, p = 0.9. There were trends in several subgroups. In HER2 1-2+ pts (77 VG vs 80 CG), 5 yr DFS was 79% (VG) vs 75% (CG), HR 0.76, p = 0.48. In ER/PR- pts (59 VG vs 56 CG), 5 yr DFS was 83% (VG) vs 77% (CG), HR 0.67, p = 0.36. In TNBC pts (25 VG vs 26 CG), 5 yr DFS was 67% (VG) vs 62% (CG), HR 0.65, p = 0.42. **Conclusions:** Overall, the final timed analysis of this phase II trial shows no statistical differences between treatment arms; however, it does identify particular pt populations where the vaccine may have efficacy. The ER/PR negative and triple negative pts appear to derive greatest benefit from AE37 vaccination with reductions in relative risk of recurrence of 33% and 35%, respectively. Further studies are required to confirm these findings and investigate the link between hormone receptor status and induction of clinically beneficial anti-tumor immunity by the AE37 vaccine. Clinical trial information: NCT00524277.

TPS623 Poster Session (Board #113a), Sat, 8:00 AM-11:30 AM

MIRACLE study (CBCSG016): A randomized phase II study of letrozole versus letrozole plus everolimus for hormone receptor positive premenopausal women with recurrent or metastatic breast cancer on goserelin treatment after progession on tamoxifen. *First Author: Binghe Xu, Cancer Hosp Chinese Academy of Medcl Sciences, Beijing, China*

Background: In premenopausal women with HR-positive advanced breast cancer, ovarian function suppression combined with aromatase inhibitors is a standard first-line choice of hormone treatment, especially patients progressed after tamoxifen. An emerging mechanism of endocrine resistance arose from aberrant signaling through the phosphatidylinositol 3-kinase (PI3K)-Akt-mammalian target of rapamycin (mTOR) signaling pathway. The BOLERO-2 study showed that the addition of everolimus, an mTOR inhibitor, to exemestane significantly improved PFS in postmenopausal HR+/HER2- advanced breast cancer patients progressed on NSAIs. However, different from western countries, the majority (50-55%) of patients are premenopausal women in Asia, including China. The benefits of everolimus plus endocrine therapy in premenopausal women have not yet been well delineated. In addition, the feasibility of patients progressed on the endocrine continue to receive the same endocrine agent plus everolimus is unclear. **Methods:** Two hundred premenopausal HR+/HER2- advanced breast cancer women refractory to tamoxifen (progressed after previous treatment with tamoxifen for at least 6 months during adjuvant treatment and recurred during or within 24 months after the end of adjuvant treatment completion, or progressed during tamoxifen treatment for advanced disease) will be treated by goserelin and randomized at a 1:1 ratio to everolimus plus letrozole arm or letrozole alone arm, with stratification according to presence of visceral metastasis. Treatment will be continued until disease progression, the development of unacceptable toxicity, or withdrawl of consent. After progression in letrozole alone arm, the patients will be treated by everolimus plus letrozole. The primary endpoint is PFS, the secondary endpoints are ORR, CBR, OS and safety profile of each treatment arm. Clinical trial information: NCT02313051.

TPS624 Poster Session (Board #113b), Sat, 8:00 AM-11:30 AM

MONARCH 3: A randomized phase III study of anastrozole or letrozole plus abemaciclib, a CDK4/6 inhibitor, or placebo in first-line treatment of women with HR+, HER2-locoregionally recurrent or metastatic breast cancer (MBC). *First Author: Matthew P. Goetz, Mayo Clinic, Rochester, MN*

Background: Abemaciclib (LY2835219), a cell cycle inhibitor of CDK4/CDK6, demonstrated a clinically manageable safety profile and single-agent anti-tumor activity in MBC; all tumor responses were observed in hormone receptor positive (HR+) disease (Tolaney SM, Rosen LS, Beeram M, et al. San Antonio Breast Cancer Symposium, 2014, Abstract P5-19-13). Non-steroidal aromatase inhibitors (NSAI, letrozole and anastrazole), approved in the first-line setting for postmenopausal women with HR+ MBC, are being evaluated in combination with abemaciclib for safety and tolerability in a phase Ib study (NCT02057133) and in the present study (NCT02246621) to assess clinical efficacy. **Methods:** MONARCH 3 is a randomized, double-blind, placebo-controlled, phase III study of abemaciclib + NSAI vs placebo + NSAI in locoregionally recurrent (not amenable to curative treatment) breast cancer or MBC, with no prior systemic therapy in this disease setting. Patients will be randomized 2:1, and stratified by nature of disease (visceral vs bone-only metastases vs other) and prior (neo)adjuvant endocrine therapy (aromatase inhibitor vs other vs none). Abemaciclib 150 mg or placebo will be given continuously PO every 12 hours until progression, along with anastrozole 1 mg or letrozole 2.5 mg once daily at the investigator's discretion, and assessments will occur every 28 days. Postmenopausal women with HR+, HER2- disease, a disease-free interval > 12 mos after completion of (neo)adjuvant endocrine therapy, ECOG PS ≤ 1, adequate organ function, and measurable disease or nonmeasurable bone-only disease (RECIST v1.1) are eligible. The primary endpoint is progression-free survival (PFS); a key secondary endpoint is overall survival (OS). The study has 80% power to detect an increase in PFS of approximately 40% (hazard ratio = 0.714). Assuming a median PFS of 10 mos in the control arm, this corresponds to a 4-mo increase in the median PFS. PFS and OS will be hierarchically tested to maintain an overall type I error rate of 2.5%. Enrollment began November 2014; planned enrollment is 450 patients. Clinical trial information: NCT02246621.

TPS625 **Poster Session (Board #114a), Sat, 8:00 AM-11:30 AM**

Phase III, randomized, double-blind, placebo-controlled study of ribociclib (LEE011) in combination with either tamoxifen and goserelin or a non-steroidal aromatase inhibitor (NSAI) and goserelin for the treatment of premenopausal women with HR+, HER2– advanced breast cancer (aBC): MONALEESA-7. *First Author: Debu Tripathy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tamoxifen or NSAIs with ovarian function suppression are standard first-line endocrine therapy (ET) options for premenopausal women with HR+, HER2– aBC; however resistance eventually occurs. The cyclin D–cyclin dependent kinase (CDK)4/6–INK4–Rb pathway is frequently dysregulated in HR+ BC; preclinical data suggest that CDK4/6 inhibition may abrogate endocrine-resistant cell proliferation in BC subsets. Adding ribociclib, a highly selective CDK4/6 inhibitor, to standard ET may provide therapeutic benefit vs ET alone in HR+, HER2– aBC. **Methods:** A Ph III, randomized, double-blind, placebo-controlled study of continuous tamoxifen (20 mg once daily [QD]) or NSAI (letrozole [2.5 mg QD] or anastrozole [1 mg QD]), with subcutaneous goserelin implant (3.6 mg D1 of each 28-day cycle) and ribociclib (600 mg QD, D1–21 of each 28-day cycle) or matching placebo (MONALEESA-7; NCT02278120). Key inclusion criteria: pre- or perimenopausal women with ER+ and/or PR+, HER2– aBC; ECOG PS $\leq$ 1. Patients that have received $\leq$ 1 line of chemotherapy and/or $\leq$ 14 days of tamoxifen or NSAI (letrozole or anastrozole) with/without goserelin for aBC are eligible, but prior treatment with CDK4/6 inhibitors is prohibited. Patients are randomized (1:1) to receive either ribociclib (Arm 1) or placebo (Arm 2) in combination with tamoxifen + goserelin or NSAI + goserelin. Stratification is based on presence of lung and/or liver metastases; prior chemotherapy for aBC; endocrine combination partner (tamoxifen + goserelin vs NSAI + goserelin). Primary endpoint: PFS (RECIST 1.1); key secondary endpoint: overall survival. Other secondary endpoints include safety, tolerability, response rate, clinical benefit rate, time to response, duration of response. Tumor and blood samples will be collected for biomarker and PK assessments. Approximately 660 patients will be randomized. Global recruitment is ongoing. To our knowledge this is the first Ph III trial investigating a CDK4/6 inhibitor in only pre- or perimenopausal women with aBC. Clinical trial information: NCT02278120.

TPS626 **Poster Session (Board #114b), Sat, 8:00 AM-11:30 AM**

BELLE-3: A Phase III study of the pan-phosphatidylinositol 3-kinase (PI3K) inhibitor buparlisib (BKM120) with fulvestrant in postmenopausal women with HR+/HER2– locally advanced/metastatic breast cancer (BC) pretreated with aromatase inhibitors (AIs) and refractory to mTOR inhibitor (mTORi)-based treatment. *First Author: Angelo Di Leo, Ospedale Misericordia e Dolce, Prato, Italy*

Background: PI3K pathway activation is the most frequent alteration in BC and confers resistance to endocrine and mTORi treatment. The oral pan-PI3K inhibitor buparlisib has shown preliminary activity and a manageable safety profile in patients with HR+/HER2– BC in combination with letrozole or fulvestrant. Buparlisib + fulvestrant exhibits antitumor activity in mTORi-resistant ER+ xenograft models, suggesting that buparlisib may potentially bypass mTORi resistance by blocking upstream PI3K pathway signaling. **Methods:** BELLE-3 (NCT01633060) is a randomized, double-blind, placebo-controlled, Phase III study of fulvestrant $\pm$ buparlisib in postmenopausal women with HR+/HER2– locally advanced/metastatic BC. Key inclusion criteria: prior treatment with AIs, disease progression on or within 30 days of endocrine + mTORi therapy given as the last therapy before study entry, and $\leq$ 1 prior chemotherapy regimen for advanced disease. Approximately 420 women will be randomized (2:1) to receive buparlisib (100 mg/day) or placebo with fulvestrant (500 mg on C1D1, C1D15, D1 of subsequent cycles). Randomization will be stratified by visceral disease status. Tumor assessments will be performed at 6-weekly intervals until disease progression per RECIST v1.1. Primary endpoint: progression-free survival (PFS) per local investigator assessment (per RECIST v1.1). Key secondary endpoint: overall survival (OS). Other secondary endpoints: overall response rate (ORR), clinical benefit rate (CBR), safety, pharmacokinetics of buparlisib + fulvestrant, quality of life, and time to deterioration of ECOG performance status. Statistical methods: PFS and OS will be analyzed by Kaplan–Meier methods using a stratified log-rank test at 1-sided 2.5% level of significance. Hazard ratios will be estimated by stratified Cox regression with 2-sided 95% confidence intervals (CI). ORR and CBR will be calculated with exact 2-sided 95% CI. Recruitment onto the BELLE-3 study is ongoing. Clinical trial information: NCT01633060.

TPS627 **Poster Session (Board #115a), Sat, 8:00 AM-11:30 AM**

LORELEI: A phase II randomized, double-blind study of neoadjuvant letrozole plus taselisib (GDC-0032) versus letrozole plus placebo in postmenopausal women with ER-positive/HER2-negative, early-stage breast cancer. *First Author: Evandro De Azambuja, Jules Bordet Inst, Brussels, Belgium*

Background: Taselisib is an orally bioavailable, potent, selective inhibitor of Class I PI3-kinase (PI3K) alpha, gamma, and delta isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the alpha isoform showing enhanced activity against *PIK3CA* mutant cancer cell lines. Clinical data have demonstrated confirmed partial responses in patients with *PIK3CA* mutant breast cancer (BC) treated with single-agent taselisib. Enhanced antitumor activity has been noted when taselisib is combined with either letrozole or fulvestrant in preclinical and Phase Ib clinical studies. **Methods:** LORELEI is a Phase II, two-arm, randomized, double-blind, multicenter, study of neoadjuvant letrozole and taselisib versus letrozole and placebo in postmenopausal women with newly diagnosed ER+/HER2-, untreated, Stage I-III operable BC. Other eligibility criteria include tumor size ^{3} 2 cm by magnetic resonance imaging (MRI), ECOG PS 0-1, and evaluable tumor tissue for *PIK3CA* genotyping. Patients treated with anti-diabetic drugs are not eligible. Patients are randomized (1:1) to receive continuous letrozole (2.5 mg) with either taselisib (4 mg on a 5 days on/ 2 days off schedule) or placebo for 16 weeks, followed by surgery. Stratification is based on tumor size and nodal status. The co-primary endpoints are overall objective response rate (ORR) by centrally assessed breast MRI via modified RECIST criteria and pathologic complete response (pCR) rate in breast and axilla at time of surgery in all randomized patients and *PIK3CA* mutant patients. Secondary endpoints include ORR by centrally-assessed MRI and pCR rate in *PIK3CA* wild-type patients. The sample size was calculated to detect an absolute percentage increase of 24% in ORR with 80% power and an absolute percentage increase of 18% in pCR rate. An interim safety analysis will be conducted by an Independent Data Monitoring Committee. As of 28 Jan 2015, 15 of the 330 patients have been enrolled, and global enrollment is ongoing (clinicaltrials.gov NCT02273973). Clinical trial information: NCT02273973.

TPS628 **Poster Session (Board #115b), Sat, 8:00 AM-11:30 AM**

A phase 2, randomized, open-label study of lucitanib in patients with FGF aberrant metastatic breast cancer. *First Author: Maysa M. Abu-Khalaf, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Lucitanib is a potent, oral inhibitor of the tyrosine kinase activity of Fibroblast Growth Factor Receptors 1-3 (FGFR1-3), Vascular Endothelial Growth Factor Receptors 1-3 (VEGFR1-3) and Platelet-Derived Growth Factor Receptors α/β (PDGFRα/β). FGF aberrancy is a hallmark genomic alteration observed in up to 25% of patients with breast cancer and is defined by amplification of *FGFR1, and* or *11q* (containing FGF ligands 3, 4, 19, and CyclinD1). In a recent phase 1/2 clinical trial of lucitanib at daily doses of 5 to 20 mg, heavily pretreated patients with advanced breast cancer patients and FGF aberrancy experienced an objective response rate (ORR) of 50% and a median progression-free survival (PFS) of over 9 months (Soria et al, 2014). This compelling clinical activity has led to the initiation of a global clinical development program for lucitanib in breast cancer. **Methods:** The current phase 2 study was designed to evaluate the efficacy and safety of 2 different doses (10 and 15 mg) of lucitanib monotherapy in patients with metastatic breast cancer. Patient enrollment initiated in Sep 2014 at 32 sites in the United States. Key inclusion criteria are metastatic breast cancer, relapsed or refractory to approved standard treatment, ECOG 0 or 1, and normal organ function. Patients with uncontrolled hypertension are excluded. One hundred sixty patients with FGF-aberrant metastatic breast cancer, as determined by local testing, will be randomized 1:1 to the 10 and 15 mg daily dosing groups. An additional cohort of up to forty patients without evidence of FGF aberrancy will be enrolled to receive 15 mg of lucitanib daily in a Simon 2-stage design. FGF aberrancy will be confirmed centrally by fluorescent *in situ* hybridization testing. The primary objectives are PFS in patients who are FGF-aberrant and ORR in patients without evidence of FGF aberrancy. Secondary objectives are ORR (PFS for FGF non-aberrant cohort), duration of response, disease control rate, overall survival, patient-reported outcomes, safety, and population PK. Exploratory endpoints include analysis of tissue and blood-based biomarkers that may be predictive of response and primary resistance to treatment with lucitanib. Clinical trial information: NCT02202746.

TPS629 Poster Session (Board #116a), Sat, 8:00 AM-11:30 AM

SANDPIPER: Phase III study of the PI3-kinase (PI3K) inhibitor taselisib (GDC-0032) plus fulvestrant in patients (pts) with estrogen receptor (ER)-positive, HER2-negative locally advanced or metastatic breast cancer (BC) enriched for pts with *PIK3CA* mutant tumors. *First Author: Jose Baselga, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *PIK3CA* mutations are one of the most frequent genomic alterations in BC, being present in ~40% of ER-positive, HER2-negative breast tumors. *PIK3CA* mutations promote growth and proliferation of tumors and mediate resistance to endocrine therapies in BC. Taselisib is a potent and selective PI3K inhibitor of the alpha, gamma, and delta isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the alpha isoform. Taselisib has enhanced activity against *PIK3CA*-mutant BC cell lines, and clinical data include confirmed partial responses in pts with *PIK3CA*-mutant BC treated with taselisib either as a single agent or in combination with fulvestrant. SANDPIPER, a double-blind, placebo-controlled, randomized, phase III study, is designed to evaluate efficacy and safety of taselisib plus fulvestrant in postmenopausal pts with ER-positive, HER2-negative, *PIK3CA*-mutant locally advanced or metastatic BC. **Methods:** Pts with disease recurrence or progression during or after aromatase inhibitor treatment will be randomized 2:1 to receive either taselisib (4 mg qd) or placebo in combination with fulvestrant (500 mg intramuscular on Days 1 and 15 of Cycle 1, and on Day 1 of each subsequent 28-day cycle). Randomization will be stratified by visceral disease, endocrine sensitivity, and geographical region. Pts with *PIK3CA*-mutant tumors (n = 480) will be randomized separately from pts with non-mutant tumors (n = 120); a valid *PIK3CA*-mutation result via central assessment is required prior to enrollment. Primary efficacy endpoint is investigator-assessed progression-free survival in pts with *PIK3CA*-mutant tumors. Other endpoints include overall survival, objective response rate, clinical benefit rate, duration of objective response, safety, pharmacokinetics, and patient-reported outcomes. Target enrollment is 600 pts from ~165 sites and ~23 countries. The study is active as of February 2015. NCT02340221. Clinical trial information: NCT02340221.

TPS630 Poster Session (Board #116b), Sat, 8:00 AM-11:30 AM

A phase II trial of neoadjuvant aromatase inhibitor therapy and the mTOR inhibitor everolimus in postmenopausal women with hormone receptor positive/HER2 negative breast cancer and a low/intermediate risk Oncotype Dx Recurrence Score (≤ 25). *First Author: Maysa M. Abu-Khalaf, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Breast cancer (BC) patients (pts) with low/intermediate Oncotype Dx recurrence scores (RS) ≤ 25 represent a large fraction of BC cases, and a substantial number of distant recurrences occur in this group despite their low to moderate risk and high sensitivity to endocrine therapy. These pts are also the least likely to be sensitive to or benefit from adjuvant chemotherapy. Anatomical risk factors (nodal status, tumor size) continue to define a higher risk group among these endocrine sensitive and molecularly low risk BC pts. The goal of this study is to assess tumor response to a combination of the mTOR inhibitor everolimus and an aromatase inhibitor (AI) in this patient population, utilizing the preoperative endocrine prognostic index (PEPI). Our hypothesis is that everolimus will improve the efficacy of AI in this setting. **Methods:** This is a phase II study evaluating the efficacy and safety of neoadjuvant AI and everolimus in postmenopausal pts with hormone receptor positive (HR+)/HER2 negative clinical stage II-III BC with low/intermediate risk RS (≤ 25). Patient enrollment initiated in November 2014 at the Yale Cancer Center/Smilow Cancer Hospital and Care Centers. The study will enroll up to 66 pts. Key inclusion criteria are ECOG 0-2, adequate organ function, a fasting cholesterol ≤ 300 mg/dl and triglycerides ≤ 2.5 x IULN. Pts who had prior surgical resection of their BC, uncontrolled diabetes mellitus (HbA1c > 7%), and a prior exposure to mTOR inhibitors are excluded. Eligible pts will receive daily AI therapy (anastrozole 1 mg, letrozole 2.5 mg or exemestane 25 mg) and everolimus 10 mg daily for a total of 26 weeks. The primary objective of the study is to determine the percent of postmenopausal pts with clinical stage II-III HR+ BC and a RS ≤ 25 who achieve a PEPI score of 0 following neoadjuvant AI and everolimus. The secondary objectives are to assess the tolerability and side effect profile and to identify biologic markers predictive of a pathologic response (PEPI 0) to neoadjuvant AI and everolimus in this patient population. Clinical trial information: NCT02236572.

TPS631 Poster Session (Board #117a), Sat, 8:00 AM-11:30 AM

Phase III study of Palbociclib in combination with Exemestane vs. Capecitabine, in Hormonal Receptor (HR) positive/HER2 negative Metastatic Breast Cancer (MBC) patients with Resistance to non-steroidal Aromatase inhibitors (NSAI): PEARL study (GEICAM/2013-02_CECOG/BC.1.3.006) *First Author: Miguel Martin, Instituto de Investigación Sanitaria Gregorio Marañón, Universidad Complutense de Madrid, Madrid, Spain*

Background: Endocrine therapy (ET) is the cornerstone treatment for HR–positive, HER2-negative breast cancer (BC) patients. AIs have become the treatment of choice in postmenopausal patients. The high efficacy with ET in these patients is partially undermined by the resistance developed by most of them over time. On early disease recurrence/progression to AIs, treatment options include other AI, estrogen-receptor antagonists or chemotherapy (being capecitabine one of the best options). Preclinical data suggest that ER+/HER2- BC are dependent on cyclin-dependent kinases 4/6 (CDK4/6) function; inhibition of this target may be effective in delaying/reverting endocrine resistance. Palbociclib is an oral novel CDK4/6 inhibitor that seems to be synergistic with ET in preclinical and clinical studies. **Methods:** Phase III, international (5 countries) study. Patients are randomized 1:1 to exemestane (25 mg daily) plus palbociclib (125 mg daily x3 weeks q4w) vs. capecitabine (1,250 mg/m^2 twice daily x2 weeks q3w). Postmenopausal patients with HR+/HER2- MBC are eligible if resistant to previous NSAI (letrozole or anastrozole) defined as: recurrence while on or within 12 months after adjuvant treatment or progression while on or within 1 month after the end of treatment for MBC. Previous chemotherapy is permitted either in the (neo)adjuvant setting and/or as first line for MBC. Patients must have *measurable disease according to RECIST 1.1 or lytic bone lesions in the absence of measurable disease*. The primary objective is Progression-Free Survival (PFS); secondary objectives are overall survival, response rate, clinical benefit rate, response duration, safety, quality of life and biomarker's defined changes. The study will recruit 348 patients to detect a difference of 2.75 months in the median PFS (from 6 to 8.75 months; hazard ratio = 0.686), with a power of 80% and a 5% two sided significance level. Recruitment started in March 2014 and 87 patients have been included so far (ClinTrials.gov reference NCT02028507). Clinical trial information: NCT0208507.

TPS632 Poster Session (Board #117b), Sat, 8:00 AM-11:30 AM

A phase I trial assessing the maximum tolerated dose (MTD) and pharmacokinetics of intrapleural bevacizumab after pleural puncture in breast cancer patients with symptomatic recurrent metastatic pleural effusion: The BEVAP trial. *First Author: Benoit Rousseau, Medical Oncology, Hopital Henri Mondor, INSERM U955, Creteil, France*

Background: Metastatic pleural effusion (MPE) is frequently observed in advanced cancer, especially in breast carcinoma. Invalidating symptoms may be associated with these effusions as shortness of breath, pain or asthenia, decreased quality of life and survival. Despite effective systemic treatment, many patient still experiment local discomfort and respiratory symptoms. Local management remains the cornerstone, not edged out by the development of new systemic agents. Surgical talc pleurodesis is indeed the main validated local management to prevent recurrence in patients with good performance status, but it is often not possible. Other techniques, as intrapleural (IP) catheter to facilitate puncture, are attractive in order to relieve symptoms, improve quality of life of patients and deliver IP agents. VEGF is a proangiogenic factor increasing endothelial permeability implicated in MPE. Bevacizumab is an anti-VEGF monoclonal antibody. Encouraging results were observed with high dose IV bevacizumab in MPE and with intraperitoneal bevacizumab in metastatic ascites. IP bevacizumab may improve puncture-free survival in breast cancer patients with symptomatic MPE. To address this question, we have designed a phase I trial aiming to determine the MTD and to investigate the pharmacokinetics of IP bevacizumab in breast cancer patients with recurrent and symptomatic MPE. **Methods:** The BEVAP trial is a 3+3 phase I trial with a single IP administration of bevacizumab and a 3 dose level escalation: 1 mg/kg, 3 mg/kg, 5 mg/kg. Main inclusion criteria are: ≥ 18 years old, PS ≤ 2, breast cancer related unilateral MPE requiring an IP catheter (at least 2 punctures in the last month), life expectancy > 2 months. Primary objective is to determine the MTD of IP bevacizumab to use for phase 2 trial. Secondary objectives include puncture-free survival, safety and bevacizumab pharmacokinetics. Up to 24 patients will be enrolled in the program. Further investigations will be performed only if IP bevacizumab proves to be safe with a median puncture-free survival > 30 days. Funded by French PHRC. Clinical trial information: NCT02250118.

TPS633 Poster Session (Board #118a), Sat, 8:00 AM-11:30 AM

A Phase II study of the safety and efficacy of alpelisib or buparlisib plus letrozole in neoadjuvant treatment of postmenopausal women with HR+/HER2–, *PIK3CA* mutant or wild-type breast cancer. *First Author: Ingrid A. Mayer, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: The PI3K/AKT/mTOR pathway is the most frequently activated signaling pathway in breast cancer (BC). *PIK3CA*-activating mutations are the most common genetic alteration observed in hormone receptor-positive (HR+) BC. In preclinical studies of HR+ BC, alpelisib (PI3Kα inhibitor) and buparlisib (pan-PI3K inhibitor) demonstrated significant antitumor effects both *in vitro* and *in vivo* when combined with hormone therapy. **Methods:** A Phase II, randomized, double-blind, placebo-controlled trial of alpelisib/placebo (300 mg once daily [QD]) or buparlisib/placebo (100 mg QD; intermittent regimen [5 days on; 2 days off]) plus letrozole (2.5 mg QD) for the neoadjuvant treatment of postmenopausal women with HR+/HER2– BC (NCT01923168). Key inclusion criteria are stage T1c–T3, any N, M0 operable BC; measurable disease; HR+/HER2– BC; known *PIK3CA*status (mutant vs wild-type [WT]) and Ki67 level; and Eastern Cooperative Oncology Group performance status ≤ 1. Key exclusion criteria are locally recurrent/metastatic disease and prior systemic therapy or radiotherapy for current BC. Patients (pts) will be assigned to 1 of 2 cohorts (*PIK3CA*mutant or WT) and randomized to 1 of 3 arms (letrozole + alpelisib, + buparlisib, or + placebo), stratified by Ki67 level ($< 14\%$ vs $\geq 14\%$) and lymph node status (positive vs negative). Pts will be treated for 24 weeks until surgery, disease progression, unacceptable toxicity, or study discontinuation for any other reason. The primary endpoint is pathologic complete response (pCR; ypT0/Tis, ypN0) at 24 weeks. The secondary endpoints are objective response rate (complete or partial; RECIST v1.1); safety and tolerability; rate of breast-conserving surgery; correlation between pCR and Ki67 changes from baseline to Day 15 and to surgery; response (central preoperative endocrine prognostic index score of 0); and pharmacokinetic profiles of alpelisib/buparlisib plus letrozole. For each cohort, pCR rates will be summarized by treatment arm with 90% confidence intervals. Proof of concept will be assessed. Global recruitment is ongoing, with planned enrollment of 360 pts. Clinical trial information: NCT01923168.

TPS634 Poster Session (Board #118b), Sat, 8:00 AM-11:30 AM

TARGIT-U.S.: A registry trial of targeted intraoperative radiation therapy following breast-conserving surgery. *First Author: Michael Alvarado, UC San Francisco, San Francisco, CA*

Background: The TARGIT-US trial is a pragmatic registry trial for women with clinically localized breast cancers who will undergo breast intraoperative radiation therapy (IORT) as sole radiation therapy post-breast conserving surgery. The TARGIT-A randomized trial of IORT versus whole breast radiation that preceded this trial has published equivalent local control outcomes for these patients (Vaidya et al. *Lancet* 2013). The objectives of this registry trial, therefore, are to establish eligibility criteria based on previously published trials and studies in order to allow women who meet these criteria to receive IORT on an IRB-approved protocol and to systematically collect and assess acute and long-term toxicity and outcomes in a larger cohort of patients. This will increase the general knowledge regarding this particular form of accelerated partial breast irradiation and allow further assessment of risk groups. **Methods:** Patients age 45 or older with small (< 3.5cm) ER+, Her2- tumors planning to undergo breast conserving surgery are eligible for this single-arm trial. All patients will receive a single dose IORT (20 Gy at the surface of the applicator) from the Zeiss Intrabeam device immediately after tumor excision. If high risk features are detected on final pathology (EIC, positive node, or invasive lobular histology) the patient will undergo additional EBRT (excluding boost). Patients enrolled in this trial will be followed for at least 5 years. The primary endpoint is in-breast local failure with secondary endpoints being toxicity and morbidity, relapse-free survival and overall survival. TARGIT-US is currently enrolling at 11 sites in the US with 11 additional sites opening in 2015. Target enrollment is 789 patients and as of January 2015, TARGIT-US has enrolled 120 patients. Clinical trial information: NCT01570998 Clinical trial information: NCT01570998.

TPS635 Poster Session (Board #119a), Sat, 8:00 AM-11:30 AM

I-SPY 2 low risk registry: An I-SPY 2 trial sub-study for women with clinically advanced, ER+, HER2- breast cancer and molecular good-prognosis gene signature. *First Author: Tufia C. Haddad, Mayo Clinic, Rochester, MN*

Background: With the increased utilization of molecular gene signatures, clinicians have identified a population of breast cancer patients that have clinically advanced disease associated with a low risk molecular profile. This discordance between tumor stage and molecular prognosis results in a dilemma for which consensus and evidence to guide treatment decisions are lacking. The I-SPY 2 Low Risk Registry (LRR) was therefore developed to capture the critical treatment data and clinicopathologic outcomes of these patients. A correlative biomarker study to characterize the biology and heterogeneity amongst these tumors is also planned. The goals of the LRR are to observe treatment patterns, determine tumor chemoendocrine sensitivity, and monitor clinical outcomes of these patients in order to inform the development of future studies aimed to optimize their management and outcomes. **Methods**: Patients with stage II or III breast cancer are recruited from the ongoing phase 2 neoadjuvant I-SPY 2 TRIAL. In this study, patients with Hormone Receptor-positive, HER2-negative disease are not eligible to be randomized to standard chemotherapy and a novel agent if their tumor has a 70-gene good-prognosis signature; instead, they are encouraged to enroll in the LRR. Treatment on the LRR is not pre-specified and at the discretion of the oncology team and patient. Data collection includes: screening MRI and tumor biospecimen, surgical pathology, menopause status, treatment administered, quality of life assessment, recurrence events and survival. Follow up for 15 years is planned. Biomarker analyses will include, but are not limited to, Ki-67, SET Index, GREB1, and HOXB13:IL17BR ratio. As of January 2015, 156 patients across 20 sites were eligible for the LRR, and 72 have enrolled to the Low Risk Registry. Clinical trial information: NCT01042379.

TPS636 Poster Session (Board #119b), Sat, 8:00 AM-11:30 AM

E2112: Randomized phase III trial of endocrine therapy plus entinostat/placebo in patients with hormone receptor-positive advanced breast cancer. *First Author: Roisin M. Connolly, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: A potential mechanism of resistance to endocrine therapy in breast cancer involves changes in gene expression secondary to epigenetic modifications, which might be modulated with the use of histone deacetylase (HDAC) inhibitors such as entinostat. ENCORE 301, a phase II study evaluating the addition of entinostat to the steroidal aromatase inhibitor (AI) exemestane in patients with hormone receptor (HR)-positive advanced breast cancer who had experienced disease progression after a non-steroidal AI (NSAI), showed a significant improvement in progression-free survival (PFS), and overall survival (OS). Entinostat has been designated a Breakthrough Therapy by the FDA. **Methods:** E2112 is a multicenter randomized double-blind placebo-controlled phase III study (NCT02115282) enrolling patients with advanced HR-positive, HER2-negative breast cancer with prior disease progression on a NSAI ($n = 600$). Patients receive exemestane 25mg po daily and entinostat/placebo 5mg po every week. Eligibility: Postmenopausal women and men, ECOG 0-1, locally advanced/metastatic invasive adenocarcinoma of the breast: ER/PR-positive, HER2-negative, measurable or non-measurable (20% cap) disease. Disease progression after NSAI use in the metastatic setting OR relapse while on or within ≤ 12 months of end of adjuvant NSAI therapy. Statistics: Both PFS (central review) and OS are primary endpoints, and the study is designed to show an improvement in either PFS or OS.Secondary endpoints include:Safety and tolerability, objective response rate, changes in lysine acetylation status in peripheral blood mononuclear cells, patient-reported symptom burden and treatment toxicities, adherence. One-sided type 1 error 0.025 split between two hypotheses tests: 0.001 for PFS test and 0.024 for OS. PFS is tested in the first 360 pts, 88.5% power to detect 42% reduction in the hazard of PFS failure (median PFS 4.1 to 7.1 months); OS is tested in all 600 pts, 80% power to detect 25% reduction in the hazard of death (median OS 22 to 29.3 months). E2112 was activated in March 2014 and accrual is anticipated to complete in 40 months. Clinical trial information: NCT02115282.

TPS637 Poster Session (Board #120a), Sat, 8:00 AM-11:30 AM

Phase III randomized, placebo-controlled clinical trial evaluating the use of adjuvant endocrine therapy +/- one year of everolimus in patients with high-risk, hormone receptor (HR) positive and HER2-negative breast cancer (BC): SWOG/NRG/Alliance S1207 (NCT01674140). *First Author: Mariana Chavez-Mac Gregor, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Abnormalities of the PI3kinase/AKT/mTOR signaling network are common in BC. This pathway is associated with resistance to endocrine therapies among HR+ tumors. Everolimus, an mTOR-inhibitor, increases the biological activity of endocrine therapy. S1207 evaluates the role of everolimus in combination with endocrine therapy in the adjuvant setting. **Methods:** Specific aims/ design: Randomized phase III double-blinded, placebo-controlled trial. Primary objective is to assess whether the addition of everolimus to standard adjuvant endocrine therapy improves invasive disease-free survival (DFS) among patients with high risk, HR+ BC. Secondary objectives include overall survival, distant recurrence-free survival, safety, adherence and QoL. Patients are randomized to receive standard adjuvant endocrine therapy in combination with one year of everolimus (10 mg PO daily) or placebo. Submission of tissue specimens/ blood samples is required for translational studies Eligibility criteria: Patients with histologically confirmed HER2-negative and HR+ invasive BC treated with surgery, adjuvant chemotherapy and radiation therapy (if indicated) are eligible if they have: node-negative disease and tumors >2cm and a recurrence score (RS) >25; 1-3 positive nodes and RS >25 or grade 3 in the absence of RS; >4 positive lymph nodes regardless of RS. Patients >1 positive lymph node after completing neoadjuvant chemotherapy are eligible. Statistics/Target accrual:Parallel randomization design with equal allocation to the two treatment groups, the study will randomize 3,500 patients. All analyses are intent-to-treat with the primary analysis conducted 3 years after the last patient is randomized. The study has 90% power (with 2-sided α=0.05) to detect an effective hazard ratio of 0.75 for everolimus versus placebo, corresponding to a gain in DFS of approximately 4.3% at 5 years. All patients will be followed for 10 years. Support: NIH/NCI NCTN Grants CA180888, 180819, 180868, 180821,180822 189867, and in part by Novartis Clinical trial information: NCT01674140.

TPS638 Poster Session (Board #120b), Sat, 8:00 AM-11:30 AM

A phase I study of RAD1901, an oral selective estrogen receptor degrader, in ER–positive, HER2–negative, postmenopausal advanced breast cancer patients. *First Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

Background: RAD1901 is a novel, non-steroidal, orally bioavailable selective estrogen receptor degrader (SERD). Preclinical studies demonstrated a favorable tissue selectivity profile, dose dependent ER degradation and potent inhibition of in vitro breast cancer cell proliferation. In an MCF7 xenograft model, significant tumor regression was consistently observed with RAD1901 treatment, compared to Tamoxifen or Fulvestrant. A phase I clinical study conducted in healthy postmenopausal female volunteers evaluated once daily doses up to 1000mg/day for 7 days. All dose levels were tolerated and pharmacokinetic analysis demonstrated good plasma exposure with dose proportional increases. 18F-estradiol positron emission tomography (FES-PET) was performed at baseline and after 6 days of treatment with RAD1901, to assess estrogen receptor engagement. Standardized uptake values (SUV) pre- and post-treatment demonstrated a complete attenuation of FES-PET signal in ER-rich tissues such as the uterus at both the 200mg/day and 500mg/day dose levels. Based on these preclinical and clinical results, RAD1901 is currently being investigated in a phase I study for the treatment of hormone driven and hormone resistant metastatic breast cancers. **Methods:** RAD1901-005 is phase I study consisting of two phases: a dose escalation phase and a safety expansion phase. The dose escalation will follow a 3+3 design to establish the maximum tolerated dose (MTD), the primary objective of the study. Once the MTD has been established, the expansion will evaluate the safety, tolerability and preliminary efficacy of the recommended phase II dose (RP2D), the secondary objectives of the study. RAD1901 will be administered orally on a continuous once daily schedule until disease progression, unacceptable toxicity or patient's choice. Key inclusion criteria include post-menopausal women aged 18 years or older, with advanced ER–positive, HER2–negative breast cancer, who have received $\leq$ 2 prior chemotherapy regimens in the metastatic setting and > 6 months of prior endocrine therapy. Patient enrollment started in early 2015. Clinical trial information: NCT02338349.

TPS639 Poster Session (Board #121a), Sat, 8:00 AM-11:30 AM

Brain Metastases in Breast Cancer Network Germany (BMBC; GBG 79): Multicentric, retro- and prospective collection of patient data and biomaterial from patients with brain metastases. *First Author: Volkmar Mueller, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The incidence of brain metastases in breast cancer patients is rising and has become a mayor clinical challenge in the last years. So far, limited therapeutic options and insights into the biology of brain metastases exist. Most reports include patients with brain metastases from different tumor entities. Few studies so far analyzed exclusively patient data and tumor samples from brain metastases of breast cancer patients. Therefore, an open, multicentric registry and biobank should be helpful for analysis of a large number of breast cancer patients with brain metastases. Therefore we initiated the Brain Metastases in Breast Cancer Network Germany (BMBC; GBG79) **Methods:** Registration of patient data is allowed retrospectively as well as prospectively. To enable an easy multicentric access, an internet-based database was chosen ("MedCodes" of the German Breast Group). Captured data include incidence, number and localization of brain metastases, histopathologic characteristics, imaging methods applied, outcome and therapy modalities. Tissue of brain metastases and primary tumors will be collected for translational research projects. Planned analyses include treatment patterns in Germany, patient outcome, as well as validation of prognostic scoring systems in a multicenter setting and in the context of new targeted therapies. Planned translational research projects include the impact of glycosylation, resistance mechanisms against HER2-targeted therapies, the role of the blood brain barrier, evaluation of markers of radioresistance and specific genomic alterations associated with brain tropism of breast cancer cells. The accrual target is 1000 patients in the database and 400 tissues of brain metastases from participating German centers. The study was opened for documentation in 2014 with 70 participating centers and more than 600 patients with started documentation as of February 2015.

TPS640 Poster Session (Board #121b), Sat, 8:00 AM-11:30 AM

A phase 2 single-arm study to assess clinical activity, efficacy and safety of enzalutamide (ENZA) with trastuzumab in HER2+ AR+ metastatic or locally advanced breast cancer. *First Author: Maureen E. Trudeau, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Androgen receptor (AR) and human epidermal growth factor receptor 2 (HER2) expression have been found to correlate, with one series of breast carcinomas demonstrating AR expression in 77% of HER2+ tumors (Barton V et al. Mol Cancer Res. 2013;11:abstr A047). In vitro, ENZA inhibits proliferation of AR+/HER2+ cell lines and enhances the activity of trastuzumab. ENZA also inhibits proliferation of trastuzumab-resistant HER2+ cells (Micello D et al. Virchows Arch. 2010;457:467-476). **Methods:** Women with metastatic or locally advanced HER2+/ER-/PR- and AR+ (local or central) breast cancer will be enrolled in a phase 2 single-arm study (NCT02091960). Patients will receive daily ENZA (160 mg) continuously and trastuzumab (6 mg/kg) administered every 21 days until disease progression. Patients must have measurable disease per RECIST v1.1 and have received 1–4 prior lines of anti-HER2 therapy in the advanced/metastatic setting. Brain imaging is required to exclude patients with CNS metastases. Patients with a seizure history are excluded. The primary endpoint is clinical benefit rate (CBR), where benefit is defined as complete or partial response or stable disease $\geq$ 24 weeks according to RECIST v1.1 criteria. Additional endpoints include safety, tolerability, and the relationship between AR expression and ENZA activity. If the CBR is $\geq$ 3 in 21 evaluable patients, the sample size will increase to 66 patients. The primary endpoint will be analyzed in patients with centrally confirmed AR expression ($\geq$ 10% nuclear staining by immunohistochemistry), who have received at least 1 dose of ENZA and have $\geq$ 1 postbaseline tumor assessment. The null hypothesis, that the true CBR is 10%, will be tested against a 1-sided alternative. This Simon's 2-stage design yields 90% power when the true response rate is 25% with a 1-sided type 1 error rate of 5%. As of the date of abstract submission, 5 patients have been enrolled; enrollment is expected to continue through 2016. Clinical trial information: NCT02091960.

TPS641 Poster Session (Board #122a), Sat, 8:00 AM-11:30 AM

HERMIONE: A Phase 2, randomized, open label trial comparing MM-302 plus trastuzumab with chemotherapy of physician's choice plus trastuzumab, in anthracycline naive HER2-positive, locally advanced/metastatic breast cancer patients previously treated with pertuzumab and ado-trastuzumab emtansine (T-DM1). *First Author: Kathy Miller, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Although HER2-targeted therapies such as pertuzumab and T-DM1 have improved patient outcomes, treatment resistance typically occurs. MM-302 is a HER2-targeted liposomal doxorubicin in development by Merrimack Pharmaceuticals. In a Phase 1 study, patients with HER2-positive metastatic breast cancer (MBC) were treated with MM-302 alone and in combination with trastuzumab with or without cyclophosphamide. MM-302 had an acceptable safety profile and promising efficacy was observed in patients not previously exposed to an anthracycline. **Methods:** *Trial design:* HERMIONE (NCT02213744) is a randomized Phase 2, two-arm, open-label trial designed to evaluate if MM-302 can address an unmet medical need in patients with anthracycline naïve, trastuzumab-, pertuzumab- and T-DM1-pretreated HER2-positive locally advanced breast cancer (LABC)/MBC. Patients are randomized 1:1 to receive MM-302 (30mg/m^2, Q3W) plus trastuzumab (6mg/kg, Q3W) or chemotherapy of physician's choice (vinorelbine, capecitabine, or gemcitabine) plus trastuzumab (6mg/kg, Q3W). *Eligibility criteria:* Centrally confirmed HER2-positive LABC/MBC, no prior anthracycline exposure, prior trastuzumab in any setting, prior pertuzumab and T-DM1 in the LABC/MBC setting, unlimited prior lines of therapy, ECOG 0-1 and LVEF $\geq$50%. CNS metastases are permitted if stable and without symptoms or steroids for 4 weeks. *Specific aims:* The primary endpoint is independently assessed progression free survival (PFS). Secondary endpoints include investigator assessed PFS, overall survival, response rate, safety and patient related outcomes. *Statistics:* 250 patients will be enrolled to observe 191 PFS events for 90% power to detect a Hazard Ratio of 0.625. The MM-302 arm will be compared to the control arm on the primary endpoint of PFS using a stratified log-rank test at one-sided 0.025 level. *Accrual status:* Recruitment began in July 2014 and is expected to be complete in late 2016. Sites will be open in the US, Canada and Western Europe. Clinical trial information: NCT02213744.

TPS642 Poster Session (Board #122b), Sat, 8:00 AM-11:30 AM

PATRICIA: A phase II study of palbociclib and trastuzumab with or without letrozole in previously treated, postmenopausal patients with HER2-positive metastatic breast cancer. *First Author: Patricia Villagrasa, SOLTI Breast Cancer Research Group, Barcelona, Spain*

Background: Despite the great efficacy of anti HER2-agents, HER2+ metastatic breast cancer remains incurable and in need of additional options. Palbociclib, a CDK4/6 inhibitor, has demonstrated unprecedented clinical activity in HER2-/ER+ disease. Its potential in HER2+ disease, however, remains to be explored. Preclinical evidence suggests a potentially complementary role with trastuzumab based on their effects on the cell cycle. Our hypothesis is that the addition of palbociclib to trastuzumab-based therapy could offer clinical benefit in this population. Moreover, given that the expression of ER dictates two biologically different HER2+ subgroups, we will explore this activity accordingly, in addition to endocrine therapy. **Methods:** This is an exploratory, prospective, open-label, multicenter trial of palbociclib plus trastuzumab. Patients must have histologically confirmed HER2+ adenocarcinoma of the breast and have received 2-4 lines of anti-HER2-containing regimens for their advanced disease. The study is based on a Simon 2-stage design comprising three cohorts: cohort A includes ER- patients and cohorts B1 and B2, ER+ patients. All patients receive trastuzumab with an 8 mg/kg loading dose, followed by 6 mg/kg every 3 weeks, and 200 mg daily palbociclib for 2 weeks, with 1 week off. Additionally, patients in cohort B2 receive 2.5 mg daily letrozole. A 2-cycle safety run-in with the first 6 patients of each regimen will be performed. The primary objective is to assess clinical efficacy measured as progression-free survival rate at 6 months (PFS6). Assuming an increase of at least 20% in PFS6 by the addition of palbociclib +/- letrozole to trastuzumab, PFS6 should be $\geq$ 50% for a cohort to be successful, and proceed to stage 2. According to this, it will be necessary to include 15 patients in each cohort in stage 1. In stage 2, each cohort may continue for up to 46 patients. A treatment regimen will be considered efficacious if $\geq$ 18 patients are progression-free at 6 months, with an 80% power and α = 0.05. Based on this, a maximum of 138 patients may be included. Translational research searching for predictive biomarkers will be implemented. Clinical trial information: 2014-005006-38.

1000 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

TITAN: Phase III study of doxorubicin/cyclophosphamide (AC) followed by ixabepilone (Ixa) or paclitaxel (Pac) in early-stage, triple-negative breast cancer (TNBC). *First Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: Ixa is a microtubule stabilizer able to target mechanisms conferring taxane resistance including high b tubulin III expression, seen in TNBC. Here, we present preliminary results of a phase III study of AC followed by Ixa or Pac in patients (pts) with early stage TNBC. **Methods:** Patients with resected TNBC (ER and PR < 10% by local IHC, HER2 IHC 0-1+ or FISH/CISH negative) and no evidence of metastatic disease were eligible. Pts were randomized 1:1 to AC (60/600mg/m^2) q3wks x4 followed by either Ixa (40mg/m^2 q 3wks x4) (AC/Ixa) or weekly Pac (80mg/m^{2}x12 weeks) (AC/Pac). Growth factor use was allowed per MD discretion. Following phase II neoadjuvant results that demonstrated no AC/Ixa efficacy advantage compared to AC/Pac (including in tumors with high b III tubulin levels), the sample size of this study was revised to 590 patients to detect a 30% reduction in risk of recurrence with AC/Ixa. **Results:** Between December 2008 and March 2011, 614 pts (median age 54, 18% African American, 32% lymph node positive, 50% T2) were randomized (AC/Ixa, 306; AC/Pac, 308). 84% AC/Ixa and 77% AC/Pac pts completed protocol treatment (tx). 23 (8%) Ixa pts and 47 (16%) Pac pts discontinued tx due to toxicity. Dose reductions/dose delays occurred in 78 (26%)/121 (39%) Ixa pts and in 99 (33%)/158 (52%) Pac pts. Neuropathy was the major reason for dose reduction and tx discontinuation. G3/4 neutropenia rates were low at 11% with Ixa vs 6% with Pac, accompanied by fever in only 4 patients. At a median follow up of 46 mo, 75 pts have relapsed (AC/Ixa, 37; AC/Pac, 38). Median time from initial diagnosis to relapse was 20.8 mo. The 3 year disease-free survival of the Ixa arm was 88% (95% CI: 0.84, 0.91) and 89% (95% CI:0.85, 0.92) for the Pac arm. The hazard ratio (Ixa arm vs Pac arm) was 0.99 (95% CI: 0.63, 1.56, p = 0.98). 51 pts (AC/Ixa, 28; AC/Pac, 23) have died, 42 due to disease. **Conclusions:** AC with Ixa or Pac performed well in this early stage TNBC population with no difference in efficacy evident. Pts receiving AC/Pac had higher rates of neuropathy and more dose modifications. Clinical trial information: NCT00789581.

1001 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Phase III trial of etirinotecan pegol (EP) versus Treatment of Physician's Choice (TPC) in patients (pts) with advanced breast cancer (aBC) whose disease has progressed following anthracycline (A), taxane (T) and capecitabine (C): The BEACON study. *First Author: Edith A. Perez, Mayo Clinic, Jacksonville, FL*

Background: EP is the first long-acting topoisomerase 1 inhibitor providing sustained levels of SN38. In Phase II, EP demonstrated a 29% ORR following a median of 2 prior regimens for aBC. BEACON study (NCT01492101) randomized (1:1) pts with aBC and progressive disease following A,T and C to EP (145 mg/m^{2}q3w over 90 minutes) or TPC (any of 7 cytotoxics). **Methods**: Eligible pts had any ER/HER2 and ECOG 0-1; stable brain metastases were allowed. 852 pts enrolled over 20 months and reached target for events in Dec2014. The choice of TPC: eribulin 40%, vinorelbine 23%, gemcitabine 18%, taxane 15%, ixabepilone 4%. Primary efficacy endpoint was overall survival (OS) by 2-sided log-rank test stratified by region, prior eribulin and receptor status; the study had 90% power to detect a target Hazard Ratio (HR) of 0.77. Circulating tumor cells (CTCs) were isolated in ~80% of pts and analyzed for target-specific pharmacodynamic biomarkers. This is the first presentation of these data. **Results**: EP provided a 2.1 month improvement in median OS over TPC (12.4 vs 10.3 months; HR 0.87, p = 0.08). In a pre-specified subgroup of 67 pts with brain metastases, EP showed an improvement of 5.2 months in median OS (10.0 vs 4.8 months; HR 0.51, p < 0.01); the proportion of pts with brain metastases alive at 12-mo survival was higher with EP (44.4% vs 19.4%). Similarly, in pts with liver metastases (n = 456) median OS improved with EP (10.9 vs 8.3 months; HR 0.73, p = 0.002). Grade (G) ≥ 3 AEs were lower with EP (48%) than TPC (63%). Common G ≥ 3 AE with EP: diarrhea (9.6%), neutropenia (9.6%), anemia (4.7%) and fatigue (4.5%); TPC: neutropenia (30.5%), anemia (4.7%) and dyspnea (4.4%). Severe neuropathy: 3.7% of pts (TPC) vs 0.5% (EP). Alopecia was less with EP (10% vs 23%). Data on efficacy in CTC biomarker defined sub-groups (TOP1, TOP2) will be presented. **Conclusions**: EP provided a clinically meaningful benefit to pts with late-stage aBC, although this did not reach statistical significance. In pts with brain metastases, median OS doubled; improved survival was also seen in other pt subsets. Toxicity with EP was less than with TPC. Clinical trial information: NCT01492101.

1002 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Low-dose oral cyclophosphamide-methotrexate maintenance (CMM) for receptor-negative early breast cancer (BC). *First Author: Marco Colleoni, European Institute of Oncology, Milano, MI, Italy*

Background: IBCSG Trial 22-00 was designed to test the efficacy of the CMM regimen, hypothesized to have anti-angiogenic activity, administered following standard chemotherapy in patients (pts) whose tumors are hormone receptor negative. **Methods:** 1,086 women (ITT 1081) with hormone receptor-negative (< 10% positive cells by IHC) early BC, any nodal and HER-2 status were randomized to CMM (C, cyclophosphamide 50 mg/day orally continuously and M, methotrexate 2.5 mg twice/day orally days 1 and 2 of every week for 1 year) vs no further treatment (no CMM). 814 (75%) had triple-negative (TN) BC and 350 (43%) of them had node positive (N+) disease. The primary end point was disease free survival (DFS), and 307 DFS events were required for 80% power. **Results**: At 82.6 months' median follow-up, 271 DFS events had been observed. Overall, 71 (13%) of 527 pts randomized to CMM did not receive CMM therapy and only 177 (39%) of the 456 pts who started received 75% or more of the scheduled doses. Nevertheless, pts assigned to CMM had a reduced risk of a DFS event compared with no CMM, which was not statistically significant (p = 0.14; table). The magnitude of effect appeared to be greater for those with TNBC, especially for those with N+ disease. Multivariable allowance for baseline prognostic factors suggested a greater treatment effect within those with TN and N+ BC. A total of 64 pts, 13.5% of those receiving at least one dose of CMM, had a grade 3 or 4 treatment-related AE. Elevated SGPT was most frequently reported, followed by leukopenia. **Conclusions**: Adding CMM to adjuvant chemotherapy showed a non-significant 16% reduction in risk of a DFS event in the overall population of hormone receptor-negative early BC. Women with TN disease at higher risk of recurrence, for whom no maintenance regimen is currently available, had a greater benefit. Clinical trial information: NCT00022516.

Group	Treatment	No. of Patients	DFS events	5-year DFS %	Univariate HR (95% CI)	Multivariable HR (95% CI)
All pts	CMM	542	124	78.1%	0.84 (0.66,1.06)	0.82 (0.65,1.05)
	No CMM	539	147	74.7%		
TN	CMM	408	89	78.7%	0.80 (0.60,1.06)	0.79 (0.60,1.04)
	No CMM	406	110	74.6%		
TN & N+	CMM	175	48	71.9%	0.71 (0.49,1.03)	0.68 (0.47,0.99)
	No CMM	175	64	64.2%		

1003 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Results from a phase 2 study of enzalutamide (ENZA), an androgen receptor (AR) inhibitor, in advanced AR+ triple-negative breast cancer (TNBC). *First Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The AR may be a therapeutic target for pts with androgen-driven TNBC. ENZA, a potent AR inhibitor, is approved in men with metastatic castration-resistant prostate cancer (mCRPC) and improves median PFS compared to bicalutamide in men with mCRPC (15.7 vs 5.8 mos; HR 0.44; p<0.0001). **Methods:** MDV3100-11 was an open-label, Simon 2-stage study evaluating single agent ENZA in advanced AR+ TNBC (AR >0% by IHC; NCT01889238). Pts could be prescreened for AR, and have non-measurable bone disease and unlimited prior regimens; CNS metastases or seizure history were exclusionary. The primary endpoint was clinical benefit (CR, PR or SD) at 16 wks (CBR16) in 'Evaluable' pts defined as having both AR IHC ≥10% *and* a response assessment. CBR24, PFS, response rate, and safety were assessed. An androgen-driven gene signature (Dx) was created from gene profiling and outcomes were assessed accordingly. Stage 2 enrolled if CBR16 was ≥3 of 26 Evaluable pts; H_0 was rejected if CBR16 was ≥9 in 62 yielding 85% power at 5% significance to test against a 1-sided alternative (CBR16 ≥20%). **Results:** As of 16 JAN 2015, 404 samples were tested for AR IHC: 79% had AR >0%; 55% had AR ≥10%. 118 pts were treated with ENZA; 43 pts were not Evaluable (29 AR <10%; 14 AR ≥10% but no response assessment). Key outcomes in the defined populations are below as shown in the Table. Over 50% received ENZA as 1st or 2nd line; mPFS in these pts was 32 wks in Dx+ and 9 wks in Dx-. Two CRs and 5 PRs have been observed. Related AEs in ≥10% of 118 pts were fatigue (34%), nausea (25%), decreased appetite (13%), diarrhea and hot flush (10%). Fatigue (5%) was the only AE ≥ Grade 3 in ≥5%. **Conclusions:** This is the largest study of an AR inhibitor in TNBC. IHC results suggest AR prevalence is higher than previously reported. 47% of pts had an androgen-related gene signature (Dx+) and clinical outcomes appeared superior in this group. AEs from ENZA were consistent with its known profile. ENZA may represent a novel therapeutic option in pts with TNBC who would otherwise receive cytotoxic chemotherapy. Clinical trial information: NCT01889238.

	Evaluable n=75	Dx+ n=56	Dx- n=62
CBR16, % (95% CI)	35 (24-46)	39 (27-53)	11 (5-21)

1004 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Prediction of pathological complete response (pCR) by Homologous Recombination Deficiency (HRD) after carboplatin-containing neoadjuvant chemotherapy in patients with TNBC: Results from GeparSixto. *First Author: Gunter Von Minckwitz, German Breast Group, Neu-Isenburg, Germany*

Background: We previously showed that adding carboplatin to paclitaxel/liposomal doxorubicin (PM) can improve pCR rates in patients with TNBC at the cost of added toxicity (von Minckwitz, Lancet Oncology 2014). In this study we examine whether HRD, together with BRCA mutation in the primary tumor (tmBRCA), can predict pCR (ypT0/is ypN0). **Methods:** In GeparSixto, patients were randomized to receive PM or PM plus carboplatin stratified by subtype (TNBC, HER2+/HR-, HER2+/HR+) and Ki67 level. FFPE tumor samples with sufficient DNA were available in 193 (61.3%) out of 315 participants of GeparSixto with TNBC. TmBRCA and HRD scores (defined as the unweighted sum of LOH (Abkevich, 2012), TAI (Birkbak, 2012), and LST (Popova, 2012) scores) were determined. HR deficiency was defined as either a high HRD score (predefined with ≥ 42) or tmBRCA (HRD Positive). **Results:** Patients included in this analysis did not differ clinically from all study patients with TNBC in GeparSixto, except for Ki67 levels which were higher for patients included in the current analysis. HR deficiency was found in 136 (70.5%) tumors; 82 (60.3%) of them showed high HRD score without tmBRCA. HR deficient tumors were more likely to respond with a pCR (55.9%) than HR non-deficient tumors (29.8%; $p = 0.001$). Adding carboplatin to PM increased the pCR rate from 45.2% to 64.9% in HR deficient tumors ($p = 0.025$). The response rate in HR non-deficient patients was 20% and 40.7% in the PM vs PM plus carboplatin respectively and was not significant ($p = 0.146$). In patients with non-tmBRCA a high HRD score was associated with a higher pCR rate (49.4%) than a low HRD score (30.9%; $p = 0.050$) irrespective of the use of carboplatin. **Conclusions:** HR deficiency in TNBC as well as HRD score in non-tmBRCA TNBC are predictors of response to neoadjuvant anthracycline and taxane containing chemotherapy irrespective of the use of carboplatin with the highest response rate being in the HR-deficient group treated with carboplatin (pCR rate of 64.9%). HR deficiency may be used to identify patients likely to have a high response to DNA-damaging agents. Clinical trial information: NCT01426880.

1005 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Prevalence and predictors of androgen receptor (AR) and programmed death-ligand 1 (PD-L1) expression in *BRCA1*-associated and sporadic triple negative breast cancer (TNBC). *First Author: Nadine M. Tung, Beth Israel Deaconess Medical Center, Boston, MA*

Background: TNBC comprise 15% of breast cancers and are more common in women with germline *BRCA1* mutations. However, considerable heterogeneity exists among TNBC. While most have basal cell gene expression signatures, others resemble luminal tumors with expression of AR-related genes. In addition, a subset of TNBC expresses the immunoinhibitory protein PD-L1. Given the availability of clinical trials evaluating AR-targeted and immune therapies in TNBC, determining predictors of AR and PD-L1 expression and whether expression differs by *BRCA1* status is of interest. **Methods:** We studied 197 TNBC: 78 (39.6%) from women with germline *BRCA1* mutations (*BRCA1*+) and 119 (60.4%) from women without a *BRCA1* mutation (sporadic). Histologic type, grade, lymphovascular invasion (LVI), and lymphocytic infiltrates (LI) were evaluated on H and E sections. Tissue microarrays were constructed (three 0.6mm cores/tumor) and sections were immunostained for AR, PD-L1, CK5/6, CK14 and EGFR (to define basal features). Adjusted odds ratio (OR) are presented. **Results:** Among 194 TNBC with AR results, 18.0% were AR-positive (AR+; $\geq 1\%$ nuclei staining) and 11.3% strongly AR+ ($\geq 10\%$ nuclei staining). Among 193 TNBC with PD-L1 results, 26% were PD-L1+ ($\geq 1\%$ cancer cells staining). *BRCA1*+ TNBC were less often AR+ than sporadic TNBC (9.2% vs 23.7%; $p = 0.01$). There was no significant difference in PD-L1 positivity between BRCA1+ and sporadic TNBC ($p = 0.35$). LI were more common in BRCA1+ than sporadic TNBC (OR, 3.0; 95% CI, 1.1-8.0). PD-L1+ TNBC were more likely to be AR+ (OR, 2.6; 95% CI, 1.1-6.1). Grade 1 or 2 TNBC (OR, 4.6; 95% CI, 1.1-19.7) and TNBC in older women (OR, 1.3; 95% CI 1.03-1.7 for each 5 years of age) were more likely to be strongly AR+. Both LI (OR, 3.3; 95% CI, 1.1-10.4) and AR positivity (OR, 3.2; 95% CI, 1.4-7.5) were associated with PD-L1 positivity, while TNBC with LVI (OR, 0.41; 95% CI, 0.18-0.92) were less likely to be PD-L1+. **Conclusions:** *BRCA1*+ TNBC are significantly less often AR+ than sporadic TNBC. The frequency of PD-L1+ TNBC does not differ by BRCA1 status. These results confirm the heterogeneity of TNBC and highlight differences between *BRCA1*+ and sporadic TNBC.

1006 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

The survival benefit offered by the surgical management of low-grade ductal carcinoma in situ of the breast. *First Author: Yasuaki Sagara, Department of Surgery, Brigham and Women's Hospital, Boston, MA*

Background: The current management of ductal carcinoma in situ (DCIS) of the breast includes lumpectomy with/without whole breast radiation or mastectomy, however the magnitude of benefit for surgery has not been well established. We sought to identify the survival benefit conferred by surgical resection over non-operative management in patients with low-grade DCIS. **Methods:** We performed a retrospective longitudinal cohort study using the Surveillance Epidemiology and End Results database. Between 1988 and 2011, 57,222 eligible cases of DCIS were identified. Patients (pts) were divided into a surgery and a non-surgery group; propensity score weighting was used to balance clinico-pathologic factors between groups. Breast cancer specific and overall survival (BCSS/OS) were assessed using a log-rank test and Cox proportional hazards model. **Results:** Of 57,222 cases of DCIS, 56,053 cases (98.0%) received definitive surgery (lumpectomy: 34,439 pts, mastectomy: 16,334 pts) and 1,169 cases (2.0%) were managed non-operatively. The proportion of the following clinico-pathologic factors was higher in the non-surgery group compared to the surgery group: age > 60, diagnosis after year 2000, black race, low-grade DCIS and absence of radiation therapy. There were 576 breast cancer-specific deaths over the 72-month median follow-up period. The weighted ten-year BCSS for the surgery group was 98.5%, compared to 93.5% ($p < 0.001$) for the non-surgery group. Survival benefit for the surgery group differed by nuclear grade ($p = 0.003$). The weighted ten-year BCSS of low-grade DCIS was similar between patients managed with and without surgery (98.8% and 98.6%, respectively; $p = 0.93$). **Conclusions:** The survival benefit offered by surgery for DCIS varies by nuclear grade. In contrast to high/intermediate grade DCIS, definitive local therapy of low-grade DCIS does not offer a significant survival advantage over non-operative management.

Hazard ratio (HR) comparison between DCIS patients managed surgically versus non-operatively as adjusted by clinico-pathologic factors.

Grade	BCSS Weighted HR	95% CI	OS Weighted HR	95% CI
I	0.88	0.21 - 3.71	0.86	0.53 - 1.40
II	0.25	0.15 - 0.42	0.70	0.52 - 0.94
III	0.16	0.11 - 0.23	0.40	0.32 - 0.51

Impact of neoadjuvant therapy on breast conservation rates in triple-negative and HER2-positive breast cancer: Combined results of CALGB 40603 and 40601 (Alliance). *First Author: Mehra Golshan, Department of Surgery, Brigham and Women's Hospital, Boston, MA*

Background: Neoadjuvant therapy (NAT) improves breast conserving therapy (BCT) rates, but the extent by tumor subtype is unknown. To quantify this effect for triple-negative breast cancer (TNBC) and HER2-positive breast cancer (HER2+ BC), we reviewed surgical outcomes from CALGB 40603, a randomized phase II trial of weekly paclitaxel (P) +/- carboplatin (Cb) followed by doxorubicin + cyclophosphamide (AC) +/- bevacizumab (B) for stage (stg) II-III TNBC, and CALGB 40601, a randomized phase III trial of paclitaxel (P)+ HER2 blockade with trastuzumab (P+H), lapatinib (P+L) or both (P+H+L) for stg II-III HER2+ BC, by requiring surgeons to prospectively evaluate BCT eligibility before and after NAT. **Methods:** Patients (pts) with stg II-III TNBC (n = 404) were randomized in CALGB 40603. Pts with stg II-III HER2+ BC (n = 292) were randomized in CALGB 40601. The treating surgeon assessed BCT candidacy based on clinico-radiographic criteria before and after NAT. Subsequent surgical management was at surgeon and patient discretion. We determined (1) conversion rate from BCT-ineligible to BCT-eligible and vice-versa, and (2) rate of successful BCT, as defined by tumor-free surgical margins. **Results:** Pre- and post-treatment surgical assessments were received for 94% of 742 pts treated in the two trials. Of 696 evaluable pts, 340 (49%) were considered BCT candidates prior to NAT. Of these, 310 (91%) remained BCT eligible after NAT; BCT was successful in 209/232 (90%) in whom it was attempted. Of 356 pts (51%) considered BCT ineligible prior to NAT, 151(42%) converted to BCT eligible; BCT was successful in 87/102(85%) in whom it was attempted. The rates were similar across the two studies. Results will be broken down by treatment arm. Of 461 pts judged BCT candidates post NAT, 127(28%) chose mastectomy with no attempt at BCT. **Conclusions:** We present the largest combined prospective analysis of NAT trials showing a BCT-ineligible to BCT-eligible conversion rate of 42% in both TNBC and HER2+ BC subtypes. BCT was successful in approximately 88% of pts who chose this approach; however, a substantial fraction of BCT-eligible pts opted for mastectomy. Clinical trial information: NCT00861705.

1008 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Relationship of omission of adjuvant radiotherapy to outcomes of locoregional control and disease-free survival in patients with or without pCR after neoadjuvant chemotherapy for breast cancer: A meta-analysis on 3481 patients from the Gepar-trials. *First Author: David Krug, University Hospital Heidelberg, Heidelberg, Germany*

Background: There is controversy whether the response to neoadjuvant chemotherapy should be incorporated into the decision-making process for adjuvant radiotherapy in breast cancer. **Methods:** We presenta pooled analysis of the randomized neoadjuvant trials GeparTrio, GeparQuattro and GeparQuinto including 3,481 patients with operable and non-operable breast cancer for which information on the use of radiotherapy (RT) was available. 94% received any RT. Locoregional recurrence was defined as a recurrence in the breast, at the chest wall or in the regional lymph nodes. **Results:** Patients in the RT-group were older and received more mastectomies. Their tumors were more likely to be HER2-positive and there was a higher rate of pathologic complete response (pCR, ypT0 ypN0). The overall risk of locoregional recurrence (LR) was 8.3% after a median follow-up of 55.9 months. RT conferred a significant benefit in terms of 5-year LR-free survival (LRFS, 90% vs. 81.5% without RT, logrank $p < 0.001$) and 5-year disease-free survival (DFS, 75.4% vs. 67.4%, logrank $p < 0.001$). The absolute advantage of RT regarding both LRFS and DFS was highest among patients with clinically positive lymph nodes at first diagnosis (HR 2.32, 95% CI 1.54-3.50; $p < 0.001$; HR 1.97, 95% CI 1.48-2.62; $p < 0.001$ respectively). In patients with pCR, the 5-yr LRFS was 95.7%% with RT vs 86.6% without RT (HR 3.32, 95% CI 1.00-11.08; $p = 0.051$) and 5-yr DFS was 86.9% and 56.1% (HR 3.52, 95% CI 1.82-6.83; $p < 0.001$). In patients without pCR, the LRFS was 88.6% with RT vs 80.7% without RT (HR 1.86, 95% CI 1.29-2.67; $p < 0.001$) and 5-yr DFS was 72.6% vs 65.7%; HR 1.39, 95% CI 1.07-1.81; $p = 0.014$). Multivariate analyses with adjustment for baseline parameters as well as for pathologic tumor stage and pCR confirmed RT as an independent prognostic factor for LRFS (HR 0.54, 95% CI 0.35-0.82; $p = 0.004$) and DFS (HR 0.69, 95% CI 0.51-0.93; $p = 0.016$). **Conclusions:** This retrospective analysis suggests thatpatients managed withoutRT after neoadjuvant chemotherapy for breast cancer have a significantly worse outcome even if they achieved a pCR.

Outcomes of adjuvant ACT vs. TC chemotherapy in older women with breast cancer. *First Author: Sarah Schellhorn Mougalian, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Chemotherapy with both anthracyclines and taxanes sequentially or concurrently (ACT) has improved survival in breast cancer. A regimen containing docetaxel and cyclophosphamide (TC) was developed to avoid cardiac side effects, which are of particular concern in older women. The efficacy of ACT vs. TC is under investigation in NSABP B-49, but results are not yet available. We examined temporal trends and clinical associations with ACT vs. TC use in clinical practice in older women and compared the overall survival of patients receiving adjuvant ACT vs. TC. **Methods:** We used the SEER-Medicare database for women over 65 diagnosed 2004-2009. Women were classified by regimen received: ACT, TC, and other (including anthracycline without taxane and cyclophosphamide, methotrexate, and 5-fluorouracil). We excluded women who received trastuzumab. We used chi-square and logistic regression to identify factors associated with ACT vs. TC receipt and Cox proportional hazards models to assess survival differences by treatment. **Results:** We identified a total of 4391 patients: 1577 (36%) received ACT, 1174 (22%) received TC, and 1640 received other regimens. Use of ACT decreased from 26% in 2004 to 21% in 2009, whereas use of TC increased from 1% to 43% in the same period. Receipt of ACT vs. TC was associated with younger age; fewer comorbidities; lack of history of coronary artery disease, diabetes, or atrial fibrillation; higher stage and lymph node involvement; and living in the Northeast United States (as compared to the West or South). Five-year overall survival (OS) estimates were 81% for patients receiving ACT and 86% for patients receiving TC ($p = .21$); 3-year unadjusted survival for stage III patients was 87% for ACT and 79% for TC (0.002). The adjusted Cox proportional hazard ratio for all patients, adjusted for stage, comorbidities, and other significant associations, was 1.10 (95% CI 0.64-1.91). The hazard ratio for ACT vs. TC was not significant for stage I/II patients, but for stage III patients was 0.59 (95% CI 0.40-0.89). **Conclusions:** TC has become a common choice for adjuvant chemotherapy among older patients. In all patients, 5-year OS was similar between groups, but OS may be higher for patients with stage III disease receiving ACT.

Absence of disease-specific survival improvement over time among breast cancer patients age 70 and older: 1990-2007. *First Author: Henry G. Kaplan, Swedish Cancer Inst, Seattle, WA*

Background: 5 year disease specific survival (DSS) improvement among breast cancer (BC) patients has been observed over the past two decades. It is not known if this improvement extends to elderly women. **Methods:** Retrospective cohort study of BC patients from a dedicated BC registry database, years 1990-2007 (N = 1889). Chi square tests for bivariate proportional differences and Kaplan Meier survival analysis were used. The disease specific survival (DSS) endpoint was death from breast cancer. **Results:** Invasive breast cancer in patients age 65 and older was 62% mammography detected between 1990 and 2007 with no difference in detection method or stage by age (61% stage I, 27% stage II, 12% stage III). As age increased, patients were more often treated with surgery and radiation only [65-69 = 60%, 70-74 = 72%, 75-79 = 79%, 80+ = 82%, ($p < .001$)], and less often with chemotherapy [65-69 = 32%, 70-74 = 19%, 75-79 = 12%, 80+ = 82% ($p < .001$)] or hormonal therapy [65-69 = 74%, 70-74 = 71%, 75-79 = 66%, 80+ = 63% ($p < .001$)]. Patients 70 and older (n = 1302) had higher overall death rates [65-69 = 31%, 70-74 = 48%, 75-79 = 57%, 80+ = 62%] but an equal likelihood of breast cancer death [65-69 = 8%, 70-74 = 10%, 75-79 = 11%, 80+ = 7%]. Five year DSS improved significantly from 1990 to 2007 for patients age 65-69 from 93% to 98% but no improvement over time was observed among 70 and older patients (survival distribution equality test: $p = .004$). 5 year DSS did not improve over time for stage I breast cancer patients at any age. For stage II/III BC patients 5 year DSS only improved significantly over time for 65-69 year old patients [65-69: 1990-94 = 86%, 1995-99 = 94%, 2000-07 = 98% ($p = .031$) ; 70+: 1990-94 = 85%, 1995-99 = 90%, 2000-07 = 86% ($p = .178$)]. **Conclusions:** Breast cancer specific survival did not improve for higher stage breast cancer patients age 70 and older from 1990-2007, a time period in which both early detection and treatment improved. To improve survival in elderly women, consultation with oncologists regarding hormonal therapy options for estrogen receptor positive patients, early diagnosis by screening and development of tolerable treatment options for later stage disease are important priorities.

Contralateral prophylactic mastectomy decision-making in the population-based iCanCare study of early-stage breast cancer patients: Knowledge and physician influence. *First Author: Reshma Jagsi, University of Michigan Health System, Ann Arbor, MI*

Background: Contralateral prophylactic mastectomy (CPM) use is increasing in women who are not at increased risk of contralateral cancer development and will experience no survival benefit from the more morbid procedure. Little is known about treatment decision-making or provider interactions. **Methods:** We surveyed patients newly diagnosed with breast cancer in 2013-14, identified through the population-based SEER registries of Los Angeles and Georgia, about 6 months after diagnosis, to determine receipt of diagnostic tests and factors related to the decision about surgery (including knowledge and perceived physician recommendation). Survey return is ongoing with an expected final response rate > 70%; current response rate 68%. **Results:** Nearly half of 1949 respondents with unilateral cancer considered CPM (20% very strongly, 6% strongly, 9% moderately, 10% weakly). Only 37% of those who considered CPM knew that it does not improve survival for all women with breast cancer (23% believed it does, 49% didn't know). Among women receiving CPM, 36% believed it generally improves survival. Ultimately, 1138 (58%) received BCS and 811 (42%) mastectomy (387, or 20% overall, with CPM). On multivariable analysis, pts who received CPM were younger, more likely to be white, and more likely to have a family history, private rather than Medicaid insurance, and received MRI. Even among pts without a deleterious genetic mutation or family history in multiple relatives (1,849), 354 (19%) received CPM; CPM was uncommon among pts who reported that their surgeons recommended against it (3.7% [13/649]) but much higher (22.7% [197/869]) among those who reported no surgeon recommendation regarding CPM and (58.7% [138/235]) among those who perceived their surgeons to have recommended it. **Conclusions:** Many patients consider CPM, but knowledge is low and discussions with surgeons appear incomplete. Use of CPM is substantial among patients without clinical indications but is low when patients report their surgeon recommended against it. More effective discussion and navigation about CPM is needed to reduce potential overtreatment. Funding: P01-CA-163233.

1012 Poster Discussion Session; Displayed in Poster Session (Board #126), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Can routine cavity shave margins (CSM) improve local control in breast cancer? Initial results of the SHAVE trial, a prospective randomized controlled trial of routine CSM vs. standard partial mastectomy (SPM). *First Author: Anees B. Chagpar, Yale School of Medicine, New Haven, CT*

Background: Considerable controversy exists regarding the utility of routine CSM in patients undergoing partial mastectomy for breast cancer. We performed a prospective RCT to determine whether this practice results in a lower positive (+) margin rate. **Methods:** 251 patients with preoperative Stage 0-3 breast cancer undergoing partial mastectomy were randomized 1:1 to SPM or CSM (80% power to detect a reduction in (+) margin rate from 30% to 15%). Prior to intraoperative randomization, surgeons performed SPM per their usual practice. The sealed randomization envelope was then opened and surgeons were instructed either to take circumferential CSM or close. (+) margins were defined as tumor at ink for invasive cancer, and < 1 mm for DCIS. **Results:** The median patient age was 61 (range; 33-94). 61 (24.3%) had invasive cancer only, 50 (19.9%) had DCIS alone, and 129 (51.4%) had a combination of both. The median invasive tumor size was 1 cm (range; 0-6.5), and median DCIS size was 0.9 cm (range; 0-9.3). The groups were well-matched in terms of baseline characteristics (see table below). Margin status prior to randomization was not significantly different between the two groups (34.9% vs. 33.6%, p = 0.894). After randomization, those randomized to CSM had a significantly lower (+) margin rate than SPM (18.3% vs. 33.6%, p = 0.006). This was the primary endpoint of the study. Not all (+) margins were re-excised due to anatomic considerations; however, CSM resulted in a significantly lower re-excision rate than SPM (9.5% vs. 20.8%, p = 0.014). **Conclusions:** This is the first RCT to conclusively demonstrate that CSM halves the (+) margin and re-excision rate of SPM. Use of routine CSM may significantly reduce morbidity and cost of reoperation for margin clearance. Clinical trial information: NCT01452399.

Risk after local excision alone for DCIS patients. *First Author: Eileen Rakovitch, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: The DCIS Score (DS) was validated as a predictor of ipsilateral breast recurrence (IBR; DCIS or invasive) in E5194 pts tx by breast-conserving surgery (BCS) w/o RT. The Ontario population-based study of 3,320 pts w/ DCIS from 1994 to 2003 (Rakovitch, 2013) tested the DS as a predictor of IBR risk in a broader, more contemporary population of pts tx w/ BCS alone - w/ & w/o clear margins (CM). **Methods:** DS was obtained per E5194. The pre-specified 1º objective was to determine the relationship (HR/50 units) between the risk of an IBR and the continuous DS (using Cox models) in pts tx w/ BCS alone w/ ER+ DCIS and CM (no ink on tumor). The association between the continuous DS in all pts with BCS alone w/ & w/o CM was explored. **Results:** 1,751 pt blocks were collected; 718 had BCS alone (571 w/ CM). Median f/u was 9.4 yrs. Among 718 pts w/ BCS alone, 136 had an IBR (DCIS, N=57; invasive, N=80). Among 571 pts w/ CM, 100 had IBR (DCIS, N=44; invasive, N=57). In the 1ºanalysis, among pts tx by BCS alone w/ CM the continuous DS was significantly associated with IBR in ER+ pts (HR 2.26; 95%CI 1.41,3.59; P=0.001) and in all pts (HR 2.15; 95%CI 1.43,3.22;P=<0.001). DS was associated w/ invasive IBR (HR 1.78; 95%CI 1.03,3.05;P=0.04). In multivariable analysis for IBR, the HR/50 units for the DS among pts tx w/BCS alone w/ CM was 1.68 (95%CI 1.08,2.62; P=0.022) adjusting for multifocality, tumor size, subtype, and age. Among all 718 pts tx by BCS alone w/ and w/o CM, the DS was associated w/ IBR, and the HR/50 units for the DS was 2.04 (95%CI 1.39,2.98; P=<0.001) adjusting for multifocality, size, subtype, and age. **Conclusions:** The DS quantifies IBR risk for DCIS pts tx by BCS w/ or w/o CM. Integrating the DS with established risk factors can more accurately identify DCIS pts tx with BCS alone with low (<10%) or high (>25%) 10yr average IBR risk.

10 yr KM IBR rate (95%CI).

A phase II, open-label, neoadjuvant, randomized study of LCL161 with paclitaxel in patients with triple-negative breast cancer (TNBC). *First Author: Marina Parton, The Royal Marsden Hospital, London, United Kingdom*

Background: LCL161 is a small molecule that induces apoptosis by inactivating inhibitor of apoptosis proteins (IAPs). LCL161 preferentially synergizes with paclitaxel in TNBC models with a defined gene expression signature (GS) that reflects the biology of IAP antagonists. Here we present preliminary safety and efficacy data from a completed Phase II study of neoadjuvant LCL161 with paclitaxel in patients with GS+ and GS– TNBC (NCT01617668). **Methods:** Women with operable, newly diagnosed TNBC (T2, N0–N2, M0) were stratified into GS+ and GS– groups upfront, then randomized to receive paclitaxel (80 mg/m^2/week) ± LCL161 (1800 mg/week) for 12 weeks. Patients then received surgery to assess pathological complete response (pCR), followed by investigator's choice of adjuvant therapy. Primary objective: To assess whether LCL161 enhances the efficacy of paclitaxel in patients with GS+ or GS– TNBC, defined by a ≥ 7.5% increase in pCR rate after 12 weeks of combination treatment vs paclitaxel alone. **Results:** All 209 treated patients completed the study; 17/106 patients (16.0%) in the combination arm and 17/103 patients (16.5%) in the control arm achieved pCR. In the GS+ group (30.1% of patients), 13/34 patients (38.2%) in the combination arm and 5/29 patients (17.2%) in the control arm achieved pCR; the posterior probability of a ≥7.5% increase in pCR rate was 88.8%. In the GS– group, 4/72 patients (5.6%) in the combination arm and 12/73 patients (16.4%) in the control arm achieved pCR. The most frequent adverse events (AEs; ≥ 30% of patients, all grades) are shown in the table below. Serious AEs of pyrexia (combination 17.9%; control 1.0%), pneumonia (10.4%; 1.9%), and pneumonitis (9.4%; 0%) were significantly increased in the combination arm. **Conclusions:** Neoadjuvant LCL161 with paclitaxel shows promising signs of efficacy in a GS+ subset of TNBC (~30% of patients), but with notable toxicity at the 1800 mg/week dose. Clinical trial information: NCT01617668.

A phase I study of veliparib (ABT-888) in combination with weekly carboplatin and paclitaxel in advanced solid malignancies and enriched for triple-negative breast cancer (TNBC). *First Author: Shalu Pahuja, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Veliparib (ABT-888) is an oral, potent small molecule inhibitor of poly-ADP-ribose polymerase (PARP). The combination of veliparib (V) with carboplatin (C) and paclitaxel (P) dosed every 3 weeks has been shown to be safe with early signs of efficacy in a phase I study conducted by our group. In breast cancer patients (pts), weekly P improves disease-free and overall survival vs. every three week P with comparable safety (ECOG 1199), thus supporting the exploration of weekly C and P in combination with V. This study is designed to determine the recommended phase 2 dose (RP2D), maximum tolerated dose (MTD), dose-limiting toxicities (DLTs), adverse events (AEs), anti-tumor activity, and pharmacokinetic (PK) parameters of this combination. **Methods:** A standard 3+3 design was used with 4 escalating V dose levels ranging from 50-200 mg bid. C (AUC 2) and P (80 mg/m^2) were administered on a weekly basis over a 21-day cycle on all dose levels. Dose escalation was followed by dose expansion in pts with TNBC with mandatory tumor biopsies. **Results:** A total of 30 pts were enrolled (median age 52 yr [range 33-83]; 27 female; median prior treatments 3 [range 0-8]; 24 breast [22 TNBC], 2 lung, 1 cervix, 1 ovarian, 1 prostate, 1 gastric). DLTs occurred at the following dose levels: prolonged gr 2 thrombocytopenia at 150 mg bid, and gr 4 neutropenia at 200 mg bid. The RP2D of veliparib was established to be 150 mg bid. The most common all-grade and grade 3/4 AEs included: neutropenia (gr 3/4 in 18 pts [60%]), anemia (gr 3/4 in 5 pts [17%]), and thrombocytopenia (gr 3/4 in 3 pts [10%]). PK parameters of V in this trial were comparable to historical single-agent V. Of the 27 evaluable pts, 13 (48%) responded (1 CR, 12 PR), 10 (37%) had SD, and 4 (15%) had PD. Objective response rate in TNBC was 52%. Among 21 evaluable TNBC pts, response was 60% in *BRCA1/2*+ pts (3/5 PR), 67% in non-*BRCA1/2* pts (1/9 CR; 5/9 PR) and 29% in unknown status pts (2/7 PR). The only ovarian cancer pt was *BRCA2*+ and had PR. **Conclusions:** V in combination with weekly C and P was well tolerated with acceptable safety profile. Promising anti-tumor activity was observed, particularly in TNBC. Clinical trial information: NCT01281150.

Therapy of refractory/relapsed metastatic triple-negative breast cancer (TNBC) with an anti-Trop-2-SN-38 antibody-drug conjugate (ADC), sacituzumab govitecan (IMMU-132): Phase I/II clinical experience. *First Author: Aditya Bardia, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Background: Patients with metastatic TNBC have an aggressive disease with limited therapy options. The duration of response with standard chemotherapy is usually short, with median PFS of about 3-4 months, and there is an unmet need for better therapies. Trop-2 is highly expressed in most epithelial cancers, including TNBC (> 90%). IMMU-132 is a conjugate of a humanized anti-Trop-2 (trophoblast cell-surface antigen) mAb coupled site-specifically to SN-38 (7.6 moles SN-38/IgG), the active metabolite of irinotecan, using a proprietary linker. **Methods:** In an ongoing Phase I/II clinical trial (ClinicalTrials.gov, NCT01631552), patients with metastatic TNBC patients refractory or relapsing to prior therapies, including topoisomerase inhibitors, received IMMU-132 i.v. on days 1 and 8 of 21-day treatment cycles. Treatment was continued based on tolerance or until progression, with safety and response assessments (RECIST1.1) made every week and at 8-12 weeks, respectively. Dose reductions/delays allowed most patients to continue treatment until progression. **Results:** As of Feb 2, 2015, a total of 174 pts with relapsed/refractory diverse epithelial tumors have been treated with IMMU-132. Forty-eight pts with TNBC were treated: median age = 51 ys (range, 33-81), median of 4 prior chemotherapies (range, 1-11). In TNBC, Grade 3/4 toxicities included neutropenia (G3, 24%; G4, 6%) and febrile neutropenia (G4, 3%). Other G3 toxicities included diarrhea (3%), anemia (3%), leucopenia (3%), lymphopenia (3%), caecitis (3%). No pt developed antibodies to the conjugate; no one discontinued due to toxicity. Thirty-four TNBC pts had at least 1 response assessment, with an objective response rate (ORR) of 21% (including one complete response), a disease stabilization rate (CR+PR+SD) of 74%, and a clinical benefit ratio with CR+PR+SD ≥ 6 mo = 37% (7 of 15 pt with SD are still on treatment). **Conclusions:** IMMU-132 therapy is associated with encouraging clinical activity and limited toxicity in patients with metastatic TNBC s/p multiple prior lines of therapy. It warrants further evaluation for this refractory disease. Clinical trial information: NCT01631552.

Phase II neoadjuvant clinical trial of carboplatin and eribulin in women with triple negative early stage breast cancer (NCT01372579). *First Author: Virginia G. Kaklamani, Northwestern University Division of Hematology/Oncology, Chicago, IL*

Background: Platinum-based chemotherapy has been reported to have efficacy in patients with Triple Negative Breast Cancer (TNBC). Germline *BRCA1/2* mutation status has been shown to be predictive of platinum response in patients with metastatic TNBC. In the neoadjuvant setting some, but not all patients with sporadic TNBC also achieve a pathologic complete response (pCR). This study evaluated the efficacy and toxicity of neoadjuvant treatment with carboplatin and eribulin in patients with early stage TNBC, and assessed the role of a HRD (homologous recombination deficiency) test to predict response. **Methods:** Patients with histologically confirmed early stage TNBC received carboplatin AUC 6 iv every 21 days and eribulin 1.4 mg/m^2 day1 and day 8 every 21 days for four cycles. The primary endpoint of the study was pCR, with secondary endpoints including clinical response rate and safety of the combination. Tumor specimens were evaluated for *BRCA1/BRCA2* mutations, *BRCA1* promoter methylation, and HRD status. **Results:** A total of 30 patients enrolled in the study. 13 (43.3%) achieved pCR. The combination was safe with mostly grade 1 and 2 toxicities. 28 pre-treatment samples were available for HR deficiency assessment and 26 obtained passing HRD scores. HR deficiency (HRD positive with HRD score ≥ 42), significantly predicted pCR in the full cohort ($P = 0.0012$) and in the subset of *BRCA1/2* wild type patients ($P = 0.0018$). **Conclusions:** The combination of carboplatin and eribulin is safe and efficacious in the treatment of early stage TNBC. The use of an HRD test can predict pCR after carboplatin and eribulin treatment in this patient population and with further validation can be used to identify patients beyond those with a germline BRCA mutation who will respond to a platinum-containing regimen. Clinical trial information: NCT01372579.

Combined Homologous Recombination Deficiency (HRD) scores and response to neoadjuvant platinum-based chemotherapy in triple-negative and/or *BRCA1/2* mutation-associated breast cancer. *First Author: Melinda L. Telli, Stanford University School of Medicine, Stanford, CA*

Background: The HRD-LOH (loss of heterozygosity) score is significantly associated with favorable response to neoadjuvant platinum-based therapy in PrECOG 0105. We set out here to assess the combined HRD score, an unweighted sum of LOH, telomeric allelic imbalance (TAI) and large-scale state transitions (LST) scores. In combination, these measures are a more robust predictor of HR deficiency than the individual components. **Methods:** The HRD threshold was previously established by analyzing scores in a training cohort of 497 breast and 561 ovarian chemotherapy naive tumors with known defects in HR, and defining a cut-off with 95% sensitivity to detect those HR deficient tumors. This threshold, along with *BRCA1/2* tumor mutation data, was used to predefine tumors from the PrECOG 0105 cohort (N = 93; 72 with molecular data) as either HR deficient (HRD score ≥ the threshold OR a tumor *BRCA1/2* mutation) or HR non-deficient (HRD score < the threshold and no tumor *BRCA1/2* mutation). **Results:** In univariate analysis, a HRD score ≥ 42 was significantly associated with both RCB 0/1 and pCR (p = 0.0086; p = 0.010). In addition, HR deficiency was significantly associated with both RCB 0/1 and pCR (OR = 5.00 [1.65, 15.2], p = 0.0029; OR = 6.65 [1.40, 31.6], p = 0.0050), and identified responders lacking a deleterious *BRCA1/2* mutation. When the analysis was confined to tumors with intact *BRCA1/2,* HR deficiency was no longer significantly associated with RCB 0/1 or pCR; however power to detect this association was limited. HR deficiency remained a significant predictor of RCB 0/1 when the score was adjusted by clinical variables including grade, stage, cycles of chemotherapy, and age at diagnosis (p = 0.0075). **Conclusions:** In this study, HRD status provides significant improvement over clinical variables, or *BRCA1/2* status, in identifying tumors with an increased likelihood of response to platinum-based neoadjuvant therapy among patients with TNBC. Clinical use of the HRD test has the potential to identify TNBC patients likely to respond beyond those currently identified by germline *BRCA1/2* mutation screening. Prospective evaluation is warranted. Clinical trial information: NCT00540358.

Concordance of intrinsic subtyping and risk of recurrence (ROR) scores between matched primary and metastatic tissue from Triple Negative Breast Cancer Trial (TNT). *First Author: Maggie Chon U Cheang, Institute of Cancer Research Clinical Trials & Statistics Unit (ICR-CTSU), London, United Kingdom*

Background: The majority of triple negative breast cancers are of basal-like subtype (BLBC). There is uncertainty about concordance of intrinsic subtypes and ROR scores by PAM50 between matched primary and metastasis samples. We sought to examine agreement of intrinsic subtypes and ROR groups using tissue in the TNT trial. **Methods:** TNT is a phase III, multicentre, randomized trial of carboplatin vs docetaxel in women with ER- PgR-HER2- metastatic/recurrent locally advanced breast cancer. Using Prosigna test on Nanostring nCounter, intrinsic subtyping was performed in a central laboratory on primary tumour (PT) from 216 patients, 66 positive lymph nodes (PLN) and 13 recurrent tissue samples (RC). The ROR-S (ROR based on subtype contents) and ROR-P (ROR based on subtype contents and proliferation index) were calculated using research-based PAM50 classifier (Parker JCO 2009). Agreement on classification was assessed by kappa statistics (k). **Results:** Of 216 PT, 175 (81%) were BLBC, 23 (11%) HER2enriched (HER2E), 13 (6%) Luminal A (LumA), 5 (2%) Luminal B (LumB). Of 66 PLN, 49 (74%) were BLBC, 12 (18%) HER2E, 2 (3%) LumA, 3 (5%) LumB. Of RC, majority were BLBC (12/13, 92%) with 1 HER2E. There were 63 matched PT and PLN pairs, with substantial agreement between subtype calls (k = 0.74 (95% CI 0.56-0.92), p < 0.0001; Table 1). 1 BLBC PT was classified HER2E in PLN. Of the 8 LumA PT, 5 (63%) were HER2E, 1 (13%) LumB, 2 (25%) LumA in their matched PLN. Comparing ROR risk groups, all high risk cases remained high risk (Table 1), while low/med switched to med/high risk groups. **Conclusions:** Our study confirms that BLBC and high risk ROR assignments in PT were substantially conserved with matched PLN and RC. None of the PT/non-BLBC was classified as BLBC in matched PLN or RC. LumA appeared to switch to aggressive subtypes or higher ROR-defined risk groups in matched PLN and RC. Gene expression profiles of matched samples will be presented.

RespondR: A genomic score to predict the responsiveness of triple-negative breast cancer patients to chemotherapy. *First Author: Steven Buechler, Notre Dame University, South Bend, IN*

Background: A significant number of triple-negative breast cancer (TNBC) patients achieve pathological complete response (pCR) and improved relapse free survival from neoadjuvant taxane-anthracycline (AT) based chemotherapy. However, the 3-year distant relapse free survival (DRFS) probability for AT-treated TNBC patients is only about 0.50. A test is needed that identifies the AT-insensitive patients who are candidates for an alternative therapy. **Methods:** Gene expression measurements of 242 AT-treated TNBC patients were divided into training and validation sets balanced for clinical traits and pCR. An innovative multistate gene methodology was used to identify predictors of pCR in the training set and confirmed in validation set, along with higher DRFS in the predicted TF-sensitive group. **Results:** Analysis of the training set (n = 129; 38 pCR) identified 15 genes that were most predictive of pCR. RespondR Score was developed using these genes to continuously stratify patients by probability of pCR. In the validation set (n = 133; 60 pCR), RespondR stratifies patients into groups of low (RR-low, 55%), moderate (RR-moderate, 21%) and high (RR-high, 24%) sensitivity with rate of pCR 0.24 (RR-low), 0.29 (RR-moderate), 0.62 (RR-high) and 5-year DRFS probability 0.49 (RR-low), 0.61 (RR-moderate) and 0.80 (RR-high). In the RR-high group mitosis-related genes are up-regulated and genes involved in extracellular matrix organization and cell adhesion are down-regulated. **Conclusions:** The RespondR Score accurately predicts those TNBC patients likely to achieve pCR and improved survival using AT neoadjuvant chemotherapy. RespondR can provide critical information to patients and physicians deciding between AT and an alternative therapy.

1021 Poster Session (Board #135), Sat, 8:00 AM-11:30 AM

Role of β blocker and angiotensin antagonist for the prophylaxis of early onset anthracycline-induced ventricular dysfunction: A meta-analysis of five randomized controlled trials. *First Author: Nicole Vincelette, Mayo Clinic, Rochseter, MN*

Background: Anthracycline is one of the most effective and commonly used chemotherapeutic agents in patients with breast cancer, Hodgkin and non-Hodgkin lymphomas. However, it is associated with cardiomyopathy that is accumulative dose related and irreversible. We performed a meta-analysis to determine the efficacy of β blocker or angiotensin antagonist to prevent early onset anthracycline-induced ventricular dysfunction and cardiac events. **Methods:** Relevant articles were searched in PubMed, EMBASE and Cochrane database. Eligible studies were limited to randomized controlled trials comparing cardioprotective agents (β blocker and angiotensin antagonist) to control in adult patients treated with anthracycline based regimens. Relative risks and 95% CI were calculated using random effect model and statistical analysis was performed by using RevMan 5.3 software. **Results:** The combined estimate demonstrated an association of β blocker and angiotensin antagonist treatment with higher post-chemotherapy LVEF with 63.61% vs. 56.19% (MD 7.15, 95% CI, 0.47 to 13.84, $p = 0.04$). Cardiac events rate in experimental group was non-significantly lower than control with 9.7% vs. 27.4% (RD -0.15, 95% CI, -0.38 to 0.08, $p = 0.2$). In a subgroup analysis, the benefit of experimental agents on LVEF preservation was significant in patients treated with higher anthracycline accumulative dose (MD 14.61, 95% CI, 12.26 to 16.97, $p < 0.00001$), however not in lower dose (MD 1.79, 95% CI, -3.11 to 6.70, $p = 0.47$). **Conclusions:** In a meta-analysis of randomized controlled trials in patients treated with anthracycline, β blocker and angitensin antagonist treatment was associated with significantly better LVEF preservation, and the benefit was prominent in patients with higher anthracycline accumulative dose. Collectively, these results suggest that routine use of β blocker or angiotensin antagonist should be encouraged in patients undergoing anthracycline based chemotherapy, especially when higher accumulative dose is expected.

1022 Poster Session (Board #136), Sat, 8:00 AM-11:30 AM

Standard chemotherapy versus capcitabine for older women with early stage breast cancer: An update of CALGB/CTSU/Alliance 49907. *First Author: Hyman B. Muss, UNC Chapel Hill, Chapel Hill, NC*

Background: CALGB 49907 compared capecitabine (X) with standard (S) chemotherapy in BC patients (pts) 65 yrs and older. Initial results: inferiority of X for both RFS and OS at 2.4 yrs median follow-up (NEJM 2009;360:2055). Current median 9 yrs. **Methods:** Pts $\geq$ 65 years with Stage I-IIIB BC. Randomization: Xx6 vs S (physician choice: CMFx6 or ACx4 (q3wk)). Endocrine therapy recommended for hormone receptor (HmR) positive. Endpoints: relapse-free (RFS) and overall survival (OS). We now include recurrence-free interval (RFI) and BC-specific survival (BCSS) to separate competing risk from other-cause mortality. All endpoints defined by the STEEP. Primary analysis: Bayesian probability of X inferiority in RFS for early stopping and final. **Results:** At first interim analysis, after 633 pts (9/2001–12/2006), met the criterion for early stopping. Final Bayesian probability of inferiority of X to S was > 99% for both RFS and OS. Accrual closed (2006) and results published (2009). At 7-yrs for S vs X: RFS 60% vs 52%; RFI 83% vs 75%; OS 79% vs 68%; BCSS 91% vs 83% - all $p < .05$. Table shows hazard ratios (HR) of X:S and 95% confidence intervals (CI). The magnitude of S effect and its interaction with HmR status has decreased; its benefit in HmR-neg tumors remains. There are 45 new primary cancers (S: 29; X: 16): breast 13 (S:5, X:8), AML/MDS 6 (CMF: 2; AC: 3; X:1). **Conclusions:** Long-term follow-up shows X inferior to S. Competing risks are important contributors to mortality in this population. Clinical trial information: NCT00024102.

HR of X:S (95% CI) by time of analysis and HmR status.

Association of disregulated neuronal and peripheral BDNF with vulnerability to paclitaxel-induced peripheral neuropathy. *First Author: David Azoulay, Galilee Medical Center, Naharia, Israel*

Background: Brain Derived Neurotrophic Factor (BDNF) is important for neuronal survival and repair. We hypothesized that a disregulated neuronal and peripheral BDNF may enhance vulnerability to Paclitaxel-Induced Peripheral Neuropathy (PIPN). **Methods:** 21 women with breast cancer were examined for peripheral neuropathy at baseline and during paclitaxel treatment, using the Total Neuropathy Score (TNSr) and the neurotoxicity subscale; Fact/GOG-NTx. Allelic discrimination of val66met BDNF polymorphism, which is reported to cause a deficit in the cellular distribution and regulated secretion of neuronal BDNF, was done by PCR and DNA sequencing. Peripheral BDNF was studied by analyzing the delta between the BDNF protein levels at baseline and after 8 weeks of treatment in each patient as was measured by ELISA. **Results:** Seven of the patients (33.3%) had TNSr $\geq$ 2 at baseline and identified to have pre-existing peripheral neuropathy (PEX-PN). The remaining 14 patients (66.7%) were identified as non-pre-existing peripheral neuropathy (NPEX-PN). The frequency of BDNF-SNP in the study population was Val/Val in 13 patients (62%) and Val/Met in 8 patients (38%). None of the patients were Met/Met (0%). We found a significantly higher incidence of the Val/Met genotype in the PEX-PN group than in NPEX-PN (5 out of 7 (71.4%) vs. 3 out of 14 (21.4%) respectively). Correspondingly, patients carrying the Val/Met genotype reached higher maximal TNSr and Fact-GOG scores in response to paclitaxel compared to Val/Val patients (4.69 ± 0.74 vs. 8.87 ± 2, respectively, prob > t 0.02; and 8.69 ± 1.96 vs. 20.37 ± 3.24, respectively, prob > t 0.002). As regards peripheral BDNF we found that BDNF decreased in patients with PEX-PN along their treatment with paclitaxel while it increased in NPEX-PN (-1.58 ± 2.80 ng/ml vs. $+6.16 \pm 2.58$ ng/ml, respectively, prob > $t = 0.03$). **Conclusions:** BDNF may play a protective role in PIPN, and exhaustion of its peripheral resources may lead to the exacerbation of PIPN. The genetic data presented here suggests that dysfunctional neuronal BDNF-induced repair mechanism due to BDNF-SNP may be a predisposing condition that exacerbates PIPN.

1024 Poster Session (Board #138), Sat, 8:00 AM-11:30 AM

Hippocampal memory impairment in breast cancer survivors after chemotherapy measurement using covert testing. *First Author: Anthony J. Ryals, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Cognitive impairments are frequently reported following adjuvant chemotherapy, yet potential neuropathological substrates remain uncertain. Chemotherapy and anti-estrogen therapy have neurotoxic effects in rodent models, with disproportionate impairment of the structure and function of the hippocampus, a critical structure for long-term declarative and relational memory. To date, there have been no detailed assessments of human hippocampal function following adjuvant chemotherapy. **Methods:** We used a specialized test of covert long-term memory processing sensitive to hippocampal impairment, involving eye-movement tracking coupled with functional MRI (fMRI). We compared 13 premenopausal breast cancer survivors on tamoxifen who were within 18 months of completing adjuvant chemotherapy to 14 healthy controls. **Results:** Relative to controls, patients were not impaired on standard delayed overt recognition memory testing or on neuropsychological tests. In contrast, patients were impaired in eye-movement-based discrimination of repeated visual scenes matched on configural similarity. Impairments were associated with less recruitment of hippocampal activity during covert memory testing. The location of hippocampal relative hypoactivity co-localized with regions of hippocampus that showed significant local volume reductions in survivors, demonstrating concurrence of structural and functional measures of hippocampal impairment. **Conclusions:** We identified hippocampal and memory abnormalities in breast cancer survivors that were not evident using standard testing. These deficits mapped onto structural measurements of hippocampal atrophy, possibly indicating a neurologic basis of self-reported cognitive difficulties frequently experienced by cancer survivors.

1025 Poster Session (Board #139), Sat, 8:00 AM-11:30 AM

Randomized study of tailored neoadjuvant chemotherapy according to the expression of tau, topo II α, and ERCC1 versus standard chemotherapy in HER2-negative breast cancer. *First Author: Yen-Shen Lu, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

Background: We hypothesized that selecting chemotherapy (CT) agents according to the expressions of drug sensitivity predictive biomarkers from tumor sample may improve the treatment efficacy for breast cancer (BC). **Methods:** Patients (pts) with stage II/III HER2 negative BC were eligible. Tumor biopsy samples were tested with immunohistochemistry study for the expression of tau, topo II α, and ERCC1. Four cycles of neoadjuvant CT were given after randomization, followed by operation. For control arm, Docetaxel (T)/ epirubicin (E) was given. For tailored arm, 1 of the 7 different CT regimens that containing 2 drugs among T, E, cisplatin, vinorelbine, and weekly high dose 5FU/leucovorin were given according to the expression of tumor biomarkers. After operation, 2-4 cycles of adjuvant CT were given and the choice of regimens were at investigators discretion. The primary endpoint was the primary tumor (T) pathological complete response (pCR) rate, and 268 pts were planned to be recruited. In the pre-planned interim analysis after recruitment of 60% of pts, the independent data monitoring committee decided to stop the recruitment because the difference between the two arms was too small to continue this study. **Results:** From April 2009 to March 2014, a total of 161 pts were enrolled, 78 and 83 of them were randomized to control arm and tailored arm, respectively. Median age was 49, 111 (68.9%) pts were ER positive, 65 (40.4%) pts were stage III. Among the tailored arm, 58 (69.9%), 41 (49.4%), and 64 (77.1%) of pts were positive for tau, topo II α, and ERCC1, respectively. The results of efficacy were listed in table. There were significantly higher incidence of grade 3/4 leukopenia (11.7% vs. 4.4%) and febrile neutropenia (2.9% vs. 0.3%) in control arm. **Conclusions:** Using the strategy of tailored CT according to the expression of tau, topo II α, and ERCC1 did not increase the efficacy neoadjuvant CT in BC. Clinical trial information: NCT00776724.

The utility of bi-weekly eribulin therapy for metastatic breast cancer: A Japanese multicenter phase II study (JUST-STUDY). *First Author: Tetsuhiro Yoshinami, Osaka Medical Center for Cancer and Cardiovascular Disease, Osaka, Japan*

Background: The EMBRACE study established eribulin as a standard treatment for metastatic breast cancer (MBC). However, eribulin at the standard dose and schedule (1.4 mg/m^2 on days 1 and 8 every 3 weeks) frequently leads to adverse events. The aim of this study was to investigate a new approach to control eribulin toxicity by schedule modification rather than dose modification. **Methods:** We conducted a multicenter phase 2 study to evaluate the efficacy and safety of bi-weekly eribulin. Eligibility criteria included MBC treated with both anthracycline and taxane, and up to three prior regimens of chemotherapy for MBC. Eribulin was started at the standard dose and schedule, but the schedule was changed to bi-weekly without dose reduction, if any of administration criteria were not satisfied by day 8 of the 1st cycle or day 1 of the 2nd cycle, or remained unchanged if all administration criteria were met at both time points. The primary endpoint was clinical benefit rate (CBR) of bi-weekly therapy based on RECIST v. 1.1. Secondary endpoints included time to treatment failure (TTF), OS, and safety. **Results:** From July 2012 to April 2014, 86 patients were enrolled, and 42 and 38 patients were placed in bi-weekly and standard therapy, respectively. The remaining 6 patients did not continue eribulin mainly due to disease progression just after first administration. Both treatment groups had a median of 2 prior chemotherapy regimens for MBC and similar characteristics. In the bi-weekly and standard therapy groups, the median dose intensity was 60.4% and 94.8% and the CBR was 31.0% and 21.1%, respectively. The median TTF was 81.5 days, and the median OS was 486 days in the bi-weekly group. No severe adverse event was reported in both groups. **Conclusions:** Bi-weekly eribulin therapy is effective and safe for patients unable to continue on the standard schedule of eribulin. This is the first report to show the utility of bi-weekly scheduling about eribulin. A phase 3 standard-of care trial of bi-weekly eribulin is needed.Clinical trial information: UMIN000008491.

1027 Poster Session (Board #141), Sat, 8:00 AM-11:30 AM

Utilization of neoadjuvant systemic therapy (NST) for breast cancer. *First Author: Jahan J. Mohiuddin, UNC Chapel Hill School of Medicine, Chapel Hill, NC*

Background: Multiple clinical trials demonstrated the efficacy of NST to downstage cancers and increase breast conservation. NCCN guidelines recommend NST for clinical stage IIA-IIIA patients who desire breast conservation. Understanding the national patterns of NST use is especially important in light of increasing mastectomy rates. **Methods:** Women diagnosed 2006-12 were included from the National Cancer Data Base, which contains 70% of incident cancers across the US. Logistic regression was used to examine factors associated with NST use. **Results:** Among 474,333 women, NST use increased by clinical stage: IIA (15%), IIB (39%), IIIA (52%), and IIIB (77%). Use for inflammatory breast cancer was 89%. NST use also varied by age and receptor status (Table). Mastectomy rates in patients who did not receive NST were: stage IIA (50%), IIB (69%), and IIIA (75%). On multivariable analysis, age, stage and receptor status remained significantly associated with NST. Compared to hormone receptor (HR)+/HER2- patients, adjusted odds ratios (aOR) for other groups were: HR+/HER2+ (1.91, 95% CI 1.83-2.00), HR-/HER2+ (2.56, 2.41-2.72), triple negative (2.62, 2.51-2.74). There was lower use of NST in the community (vs academic centers, aOR 0.58, 0.55-0.61) and in patients with higher vs lower Charlson comorbidity score (aOR 0.77, 0.74-0.81). There was higher use in Black vs White patients (aOR 1.11, 1.06-1.16). Medicaid and uninsured patients did not have lower NST use compared to private insurance. NST use increased over time (2012 vs 2010, aOR 1.20, 1.15-1.24). **Conclusions:** NST is an increasingly common approach, particularly for high risk clinical and biologic subtypes. However, many stage IIA-IIIA patients undergo mastectomy without attempting NST to downstage their cancers.

Percentage of patients receiving NST by stage 2010-2012.

IIA					
Age	<50	50-59	60-69	70-79	80+
HR+/HER2-	16	12	9	7	7
HR+/HER2+	31	23	19	11	9
HR-/HER2+	35	28	24	16	12

1028 Poster Session (Board #142), Sat, 8:00 AM-11:30 AM

A comparison of toxicity profiles between standard and lower dose capecitabine (CAP) in breast cancer (BC): a meta-analysis. *First Author: Tomohiro Funakoshi, The Univ of North Carolina, Chapel Hill, NC*

Background: CAP 1,250 mg/m2 BID x 14 days every 21 days (14/21) as monotherapy is the FDA approved dose and schedule for metastatic breast cancer (MBC). In trials of CAP 1,250 mg/m2 BID (14/21), 26%–65% of patients required a dose reduction due to toxicities. A more favorable toxicity profile has been reported in trials of CAP 1,000 mg/m2 BID (14/21). We performed a systematic review and meta-analysis to compare a safety profile between CAP starting dose of 1,250 and 1,000 mg/m2. **Methods:** Studies were identified using PubMed, and ASCO and San Antonio Breast Cancer Symposium abstract databases from 1966 to November 2014. Eligible studies included phase II and III trials of CAP monotherapy at 1,250 or 1,000 mg/m2 BID (14/21) for BC patients that reported adequate safety data for grade 1-4 or 3-4 adverse events (hand foot syndrome (HFS), diarrhea, fatigue, nausea, vomiting, stomatitis, neutropenia, thrombocytopenia, or anemia), dose reduction or treatment discontinuation. The summary incidence was calculated from CAP monotherapy arms of the included studies using random- effects models (comprehensive meta-analysis program Ver. 2, Englewood, NJ). **Results:** A total of 4,283 patients from 32 trials (12 phase III and 20 phase II) of CAP monotherapy were included. 29 trials were in the locally advanced or MBC setting, 2 trials were neoadjuvant, and 1 trial was adjuvant. 3,065 and 1,218 patients were treated with CAP 1,250 and 1,000 mg/m2, respectively. A significantly lower incidence of dose reductions, high grade HFS, diarrhea, neutropenia and anemia as well as all grade neutropenia was seen in CAP 1,000 mg/m2 compared to 1,250 mg/m2. (Table) **Conclusions:** CAP monotherapy at 1,000 mg/m2 BID (14/21) has a clinically meaningful and significantly better toxicity profile compared to 1,250 mg/m2 BID (14/21).

	CAP 1,250 mg/m2 Incidence % (95% CI)	CAP 1,000 mg/m2 Incidence % (95% CI)	P value
Dose reduction	39.0 (32.4-45.9)	15.9 (7.5-30.5)	0.0007
HFS (G3-4)	18.6 (14.9-22.9)	12.0 (9.0-15.7)	0.0122
Diarrhea (G3-4)	10.0 (7.4-13.2)	5.3 (3.9-7.0)	0.0050
Neutropenia (G3-4)	7.0 (5.4-9.1)	1.8 (1.1-2.9)	0.0001
Anemia (G3-4)	3.4 (2.7-4.2)	1.9 (1.0-3.5)	0.0465
Neutropenia (G1-4)	25.4 (17.3-35.7)	5.8 (1.8-17.5)	0.0015

1029 Poster Session (Board #143), Sat, 8:00 AM-11:30 AM

Phase II randomized study of nab-paclitaxel versus conventional paclitaxel as first-line therapy of metastatic HER2-negative breast cancer for neurotoxicity characterization: An Oncosur Study Group study. *First Author: Eva Ciruelos, Hospital Universitario 12 De Octubre, Madrid, Spain*

Background: Nab-paclitaxel (Nab-P) is a nanoparticle albumin-bound form of paclitaxel commonly used in various tumor types. Its main toxicity is neuropathy; however, it has not been clinically and physiologically characterized properly. **Methods:** 1st-line patients (pt) with confirmed HER2-negative metastatic breast cancer were treated with: A) conventional P 80 mg/m2 on days 1, 8 and 15; B) Nab-P 100 mg/m2 on days 1, 8 and 15; C) Nab-P 150 mg/m2 on days 1, 8 and 15; D) Nab-P 150 mg/m2 on days 1 and 15, in 28-day cycles. Primary objective: characterize neurotoxicity according to Total Neuropathy Score (TNS) and electromyographic changes. Secondary objectives: rate of induced NP, pharmacogenetic study for NP, activity, toxicity profile and QoL. **Results:** Sixty pt included from Jan 2013 until Jul 2014 in 7 centers. Median age: 59 (37-84); main sites of mets: liver (60%), bone (42%), and lung (23%). Sixteen (27%) pt stage IV at diagnosis; 52 (87%) received prior adjuvant CT (52% anthracyclines, 35% taxanes). Twelve pt remain on therapy (median 6 cycles), while 48 pt stopped treatment mainly due to disease progression (20 pt) or toxicity (17 pt, 13 NP). Most common AEs (all grades) per pt: asthenia (62%), NP (75%), alopecia (30%), neutropenia (23%) and nail toxicity (28%). Forty five pt had NP: 20 G1 (4 pt A, 6 pt B, 3 pt C, 7 pt D), 18 G2 (4 pt A, 6 pt B, 4 pt C, 4 pt D) and 7 G3 (1 pt A, 6 pt C). Median time to develop grade > 1 NP was 8.8 months (4 months in arm C; NR arms A and D). TNS scores showed a rapid deterioration in first assessments followed by a plateau. At current follow up, changes in TNS and toxicity were not statistically different between arms. Concerning genetic variants, the strongest association to NP risk corresponded to *EPHA5*-rs7349683. **Conclusions:** Median time to development of significant NP was longer than expected, except for higher Nab-P doses (arm C). No stat. differences in NP rates were observed (small simple size); numerically arm C had higher risk of G3 NP. EPHA-rs7349683 SNP is associated with higher NP risk. Detailed genomic data and EMG results will be presented. Clinical trial information: NCT01763710.

1031 Poster Session (Board #145), Sat, 8:00 AM-11:30 AM

A randomized phase III study of vinflunine versus an alkylating agent of physician's choice in metastatic breast cancer (MBC) previously treated with or resistant to an anthracycline, a taxane, an antimetabolite and a vinca-alkaloid. *First Author: Javier Cortes, Vall D'Hebron University Hospital, Barcelona, Spain*

Background: There is currently no consensus on the efficacy of chemotherapy (CT) beyond 3rd line in MBC and only eribulin (which has been recently approved) has shown to improve survival. No proven treatment options are available. VFL was tested in comparison with an AA of physician's choice in MBC treated in $> 3^{rd}$line. **Methods:** This open-label phase 3 study enrolled 594 MBC pts who have received at least 2 prior CT regimens for MBC including an anthracycline (A), a taxane (T), an antimetabolite (AM) and a vinca-alkaloid (VA). Pts were no longer candidate for those CT because of resistance and/or intolerance. Pts were randomised to VFL 280 mg/m^2 every 3 w (N=298) or to an AA used as a single agent every 3 w (N=296). Randomization was stratified by performance status (PS), number of prior CT lines for MBC and disease measurability. Primary endpoint was OS population assuming a median OS of 6.5 m for AA and a 2 m difference between arms. **Results:** Pts had a median age of 58 y [range: 28-79]; visceral metastases for 81.5% them; and had received a median of 4 prior CT regimens for MBC. Resistance was the main reason for no retreatment with A (59.9%), T (82.5%), AM (93.3%) and VA (87.4%). In the AA arm, the most frequently used agents were cyclophosphamide (33.4% of pts), carboplatin (31.4%) and cisplatin (15.5%). Median OS did not differ between arms: 9.1 m for VFL and 9.3 m for AA. Response rates were similar for VFL (6.4%) and for AA (4.4%); disease control rate was higher for VFL than for AA (43.6% vs 35.5%, P=0.0424). Median PFS was 2.4 m for VFL and 1.9 m for AA (P=0.4927). For VFL, the main grade 3-4 drug related adverse events were neutropenia (19.2% of pts vs 10.8% for AA) rarely complicated (0.7% of febrile neutropenia and 2% of neutropenic infection) and asthenia/fatigue (10.8% with grade 3; no grade 4). For AA, they were thrombocytopenia (7.7% of pts vs 3% for VFL) and asthenia/fatigue (3.1% of grade 3 only). **Conclusions:** VFL 280 mg/m^2 every 3 w did not improve OS compared to an AA of physician's choice in MBC pts treated in $> 3^{rd}$ line. The safety profile of VFL was acceptable and allows to consider testing VFL at 320 mg/m^2. Clinical trial information: NCT01091168.

1032 Poster Session (Board #146), Sat, 8:00 AM-11:30 AM

Efficacy of 12 weeks neoadjuvant nab-paclitaxel combined with carboplatinum vs. gemcitabine in triple-negative breast cancer: WSG-ADAPT TN randomized phase II trial. *First Author: Oleg Gluz, West German Study Group, Moenchengladbach, Germany*

Background: Pathological complete response (pCR) is associated with improved prognosis in TNBC, but optimal chemotherapy remains unclear. Neoadjuvant weekly nab-paclitaxel (Nab-Pac) has higher efficacy than conventional paclitaxel, with maximum benefit in TNBC. Both gemcitabine (Gem) and carboplatinum (Carbo) are interesting partners for taxane combinations, as metastastic BC data reveal. **Methods:** ADAPT TN compares 12-week neoadjuvant regimens: Carbo vs. Gem combined with Nab-Pac and aims to identify early-response markers for pCR (yPN0 and ypT0/is). TNBC patients (ER/PR $< 1\%$, centrally HER2 neg.), cT1c-cT4c, cN0/+ were randomized to arm A (Nab-Pac 125/Gem 1000 d1,8 q3w) vs. B (Nab-Pac 125/Carbo AUC2 d1,8 q3w). The trial is powered for pCR comparison by therapy arm and by presence vs. absence of early response. Pre-planned interim analysis aimed to identify a dynamic biomarker, e.g. drop of 3-week Ki-67, and to validate trial assumptions. **Results:** The first 130 randomized patients were assessed for interim analysis: 69 in arm A, 61 in arm B; 84% vs. 93% completed study therapy ($p = 0.1$), respectively. Median age was 50y. At baseline, 93% had G3 tumors, median Ki-67 was 65%; 64% had cT2-4c tumors, 23% cN+. SAE analysis: 20 SAEs in 10 patients (A) vs. 5 SAEs in 5 patients (B) were reported ($p = 0.3$). pCR occurred in 36% of patients overall; A: 25%, B: 49.2% ($p = .006$). In contrast to a strong association of baseline Ki-67 with pCR, no significant association between pCR and dynamic Ki-67 change was detected among patients with at least 500 tumor cells in the 3-week biopsy; however, 49% of patients had less than 500 tumor cells, and this condition appeared to be positively associated with pCR. **Conclusions:** Early results suggest rather intriguing high efficacy and favorable toxicity of short-term therapy with Nab-Pac + Carbo vs. Gem in unselected TNBC. Identification of early-proliferation responders by prespecified protocol for Ki-67 drop failed, possibly due to substantial tumor necrosis already after first therapy cycle. 336 pts were enrolled at 45 sites by 01/2015. The study will be completed in April, 2015. Clinical trial information: NCT01815242.

1033 Poster Session (Board #147), Sat, 8:00 AM-11:30 AM

Clinical predictors of failure of granulocyte colony stimulating factor (G-CSF) prophylaxis in patients with breast cancer treated with dose dense epirubicin (E), cyclophosphomide (C) + paclitaxel (T) Adjuvant chemotherapy: Subgroup analysis of the NCIC CTG MA.21 study (NCT00014222). *First Author: Ravi Ramjeesingh, NCIC Clinical Trials Group, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

Background: Administration of prophylactic GCSF is recommended for curative chemotherapy regimens with an estimated incidence of febrile neutropenia of ≥ 20% (Smith *et al.*,JCO 24:3187-3205, 2006). Clinical predictors of failure of prophylaxis are poorly understood. **Methods:** We retrospectively analyzed data pertaining to patients treated with dose dense EC-T chemotherapy (E: 120 mg/m^2 IV Day 1 + C: 830 mg/m^2 IV Day 1, q14days x 6 cycles followed by T: 175 mg/m^2 IV q21days x 4 cycles) and primary prophylaxis with GCSF (5 μg/kg subcutaneously, days 2-13) on the NCIC CTG MA21 phase III study which compared 3 different anthracycline based chemotherapy regimens. An interim analysis has been published (Burnell *et al.,* JCO, 2010). **Results:** 695 patients were randomized to the EC-T arm and received at least one dose of protocol therapy and primary GCSF prophylaxis. 139 (20.0%) patients experienced a febrile neutropenic event; of which 46 (33.1%) were hospitalized. There were no deaths secondary to febrile neutropenia. In a multivariate analysis, no significantly detrimental role of the covariates, including the ones listed, were identified. **Conclusions:** In the context of the MA.21 study, the failure rate of primary prophylaxis with GCSF therapy for prevention of febrile neutropenia in patients treated with dose dense EC-T therapy was 20% with an associated hospitalization rate of 30%. In multivariate analysis, none of the patient variables analyzed was significantly associated with failure of GCSF prophylaxis.

Selected Covariates	OR	95% CI	P-Value
Age	0.997	0.958 - 1.038	0.883
BMI	0.995	0.966 - 1.025	0.741
Diabetes	1.597	0.42 - 6.07	0.492
Liver Disease	1.335	0.149 - 11.94	0.796
Menopausal Status	1.152	0.559 - 2.215	0.672
Performance Status	1.21	0.661 - 2.214	0.537

1034 Poster Session (Board #148), Sat, 8:00 AM-11:30 AM

A nomogram to predict axillary response to neoadjuvant chemotherapy in clinically node positive breast patients. *First Author: Jose Vila, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Many clinically node positive breast cancer patients receive neoadjuvant chemotherapy (NAC), with 40% converting to node negative. Recent trials suggest a potential role for limiting axillary surgery in these patients. This study was undertaken to develop a nomogram predicting the likelihood of axillary pathologic complete response (pCR) in biopsy-proven cN1 patients receiving NAC. **Methods:** Patients with cT1-4N1M0 disease who received NAC and underwent axillary lymph node dissection were identified. Patients received anthracycline- and/or taxane-based therapy with trastuzumab in HER2+ patients. Estrogen receptor (ER) was recorded as the percentage of cells staining positive. Univariate and multivariate logistic regression analyses were performed to determine factors predictive of nodal conversion. A nomogram to predict the likelihood of nodal pCR was constructed. **Results:** A total of 614 cN1 patients were included: 93 (15%) cT1, 367 (60%) cT2, 107 (17%) cT3, and 47 (8%) cT4. Imaging showed multifocal disease in 24% (146/614). Receptor status was ER+ in 75% (458/614), PR+ in 64% (394/612), and HER2+ in 20% (124/614). Axillary pCR was achieved in 37% (228/614). On univariate analysis, nuclear grade (OR 13.67 grade 3 vs. 1, p = < .001) and HER2+ status (OR 4.6, p < .0001) were predictive of nodal pCR. Significant negative factors included multifocality on imaging (OR 0.67, p = 0.045), lobular histology (OR 0.53, p < .0001), PR+ (OR 0.24, p < .0001), ER percentage as a continuous variable (OR 0.98, p < .0001) as well as ER+ categorized as > 1% staining (OR 0.29, p < .0001). Nomograms to predict nodal pCR were created using these variables in addition to the clinically significant factors of T stage and number of abnormal nodes on US (< 4 vs. ≥ 4). The discrimination of the nomogram using ER positive (> 1% staining) versus negative (AUC = 0.775) was improved using the percentage of ER staining (AUC = 0.789). **Conclusions:** Multifocality, histology, nuclear grade, ER, PR, and HER2 status predict the ability to achieve nodal pCR with NAC. A nomogram incorporating these factors predicts the likelihood of nodal pCR with NAC which may help guide decisions regarding surgical management of the axilla in these patients.

1035 Poster Session (Board #149), Sat, 8:00 AM-11:30 AM

Direct effects on bone metabolism induced by perioperative anthracycline- and/or taxane-based chemotherapy depend on the menopausal status of patients with primary breast cancer. *First Author: Nadine Rauschenbach, Gynecologic Center Bonn-Friedensplatz, Bonn, Germany*

Background: Whereas cancer therapy-induced bone loss (CTIBL) is among the well-known sequelae of adjuvant endocrine therapy in patients (pts) with primary breast cancer (PBC), the knowledge about direct effects of modern perioperative Ctx protocols on bone metabolism is limited. This translational project was initiated to gain detailed insights into the influence of anthracycline (A)- and/or taxane (T)-based Ctx on bone turnover of both pre- and postmenopausal PBC pts in the clinical routine. **Methods:** Data of 109 pts (premenopausal: 49; postmenopausal: 60) receiving A- and/or-T-based neoadjuvant or adjuvant Ctx were included. Serum bone markers including the C-telopeptide of type I collagen (ICTP) indicating osteoclast activity, the N-propeptide of type I collagen (P1NP) measuring osteoblast activity, and bone alkaline phosphatase (BALP) were determined at baseline and prior to each subsequent Ctx cycle (C) up to C6. Changes of ICTP, P1NP, and BALP over time were analyzed by repeated-measure ANOVA. **Results:** 600 Ctx cycles were analyzed. Baseline levels of ICTP (p = 0.0027), P1NP (p = 0.0063), and BALP (p = 0.0007) were significantly higher in post- versus premenopausal pts. BALP levels remained largely unchanged during Ctx. Trends showing an increase of ICTP from baseline until C6 in premenopausal pts and a decrease in postmenopausal pts did not reach statistical significance. In contrast, P1NP significantly declined in postmenopausal pts from baseline to C6 (p = 0.0152). In premenopausal pts, P1NP declined from baseline to C3 and thereafter increased to C6. These changes were highly significant (p = 0.0024). **Conclusions:** Our study represents one of the first systematic evaluations of bone turnover in pts exposed to A- and/or T-based Ctx for PBC in the clinical routine. In postmenopausal pts, Ctx was associated with a sustained suppression of osteoblast activity whereas osteoblast suppression recovered until the end of Ctx in premenopausal pts. Whether these effects will translate into an increased risk of CTIBL remains a matter of further investigations which should clearly focus on the individual menopausal status.

1036 Poster Session (Board #150), Sat, 8:00 AM-11:30 AM

Death during study treatment: An evaluation of events in 31 German clinical trials. *First Author: Jenny Furlanetto, German Breast Group, Neu-Isenburg, Germany*

Background: Information on deaths occurring during oncological clinical trials has never been systematically assessed to describe patient, tumor, and treatment characteristics. **Methods:** Information on patients´ deaths during German Breast Group (GBG) led breast cancer (BC) trials was prospectively captured. In addition to the trial databases, data were derived from death narratives that included autopsy results if performed. All deaths were evaluated for possible causes, underlying conditions, treatment relatedness, time point and rate of autopsies. **Results:** From 12/1996 to 12/2014 23,570 patients were treated within 31 trials. Of those 75 (0.3%) died on therapy within 14 trials. 29/12,956 patients died in neoadjuvant (0.2%), 35/9,851 in adjuvant (0.3%) and 11/763 in metastatic studies (1.4%). Median age was 64 yrs (range 35-84), 63.5% of patients had an abnormal BMI (25.7% underweight, 32.4% overweight, 5.4% obese); 60% had 1-3 and 13.3% ≥ 4 comorbidities; 56% had 1-2 cardiovascular risk factors (CRFs); 45.3% took ≥ 3 drugs; 80% had an ECOG 0. Over 50% of patients had a stage III tumor at baseline with a luminal B-like BC subtype (HR+/Her2-/G3). More patients with advanced disease had a high BMI (p = 0.024), ≥ 3 comorbidities (p = 0.013) and CRFs (p = 0.001) compared to early stage patients. Main causes of death were infections (34.7%; febrile neutropenia 4%), cardiac (14.7%) and respiratory disorders (12%). 13% of patients (4 in metastatic BC, 6 in early BC) had a disease progression. 42.5% of patients received taxane (T)-based chemotherapy (CT) and the event mostly occurred in the first 4 cycles. Relatedness to chemotherapy was declared in 55% of patients, mainly when a T-based CT was given (51.2% for T-based CT, 14.6% for anthracycline (A)-based CT, 22% for A-T-based CT, 12.2% for other regimens (capecitabine, bevacizumab, lapatinib, CMF, celecoxib), none for hormone therapy); p = 0.001). An autopsy was performed in 13% of patients. **Conclusions:** Death during study treatment was mainly related to infections, and patients with advanced disease, high BMI, underlying comorbidities and CRFs. If considered for study participation these patients need careful monitoring due to their higher risk for death on study.

1037 Poster Session (Board #151), Sat, 8:00 AM-11:30 AM

Tumor infiltrating lymphocytes (TILs) in HER2 positive breast cancer: Evaluation according to the new recommendations by the international TILs working group 2014. *First Author: Houman Nafisi, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Assessment of TILS has gained interest in oncologic pathology especially as a predictor of outcome in HER2+ and triple negative breast cancer (BC). Recently, a standardized approach to assess TILs on routine histopathology slides as a biomarker in BC was recommended by an international panel of experts. Using this approach, we assessed the inter rater reliability and predictive value of TILs in HER2+ locally advanced BC cases. **Methods:** Core biopsies from52 HER2+ BC patients obtained prior to neoadjuvant (NAT) chemotherapy with or without trastuzumab (T) were identified. Two pathologists independently quantified stromal TILs, intratumoral heterogeneity (ITH), presence of lymphocyte predominant (LPBC, ≥ 60%) BC and tertiary lymphoid structure (TLS) using H&E-stained slides following 2014 international guidelines. Discordant results were resolved by reviewing on a double headed microscope. The association of TILs as continous and categorical (LPBC) variables with complete pathological response (pCR) rates was determined by Mann-Whitney WIlcox test. Inter rater reliability was measured using Cohen's Kappa coefficient. **Results:** An average of 4 cores per case were assessed. 8/52 (15%) cases had LPBC. Heterogeneity was mild in 30, moderate in 16 and severe in 6 cases. The pathologists agreed on 90%, 96% and 88% of the cases for quantitative TILs, LPBC(≥ 60%) and ITH, inter rater reliability was excellent (Cohen's Kappa 0.89, 0.85 and 0.81 respectively). On univariate analysis, high levels of TILs and LPBC were associated with greater pCR rates for the cohort of patients who received NAT with T (p= 0.004, p = 0.05 respectively). **Conclusions:** Our results show that the levels of TILs can be reliably assessed on breast core biopsies. High levels of TILs as a continous variable and LPBC are candidate predictors of pCR in Her2+ BC patients receiving NAT T.

1038 Poster Session (Board #152), Sat, 8:00 AM-11:30 AM

A phase I/II trial of olaparib in combination with eribulin in patients with advanced or metastatic triple negative breast cancer (TNBC) previously treated with anthracyclines and taxanes: First results from phase I. *First Author: Hiroyuki Yasojima, National Hospital Organization Osaka National Hospital, Osaka, Japan*

Background: Olaparib is a PARP inhibitor which has been reported to be effective against some solid tumors and the recommended dose is 300 mg bid as monotherapy. Eribulin is currently a global standard drug after treatment with anthracyclines and taxanes in advanced TNBC; however, olaparib has also shown promising efficacy in breast cancer with BRCA mutations, which are associated particularly with TNBC. Therefore, we designed this phase I/II trial (UMIN000009498) with an expectation of synergistic effects. **Methods:** By the traditional 3+3 design, 1.4 mg/m^2 of eribulin was administered intravenously on days 1 and 8. Olaparib tablet was orally administered twice daily according to dose escalation method from level 1: 25 mg bid to level 7: 300 mg bid. Dose-limiting toxicities (DLTs) consist of neutropenia G4 over seven days, thrombocytopenia G4, febrile neutropenia, non-hematotoxicity G3/4, administration of eribulin deferred on both days 8 and 15 due to adverse events, and onset of cycle 2 delayed over 14 days. **Results:** Twenty-four patients were enrolled from February 2013 to April 2014. The median age was 52 years old (range: 36 to 77). The median number of prior chemotherapy regimens was 3 (range: 2 to 7). Significant adverse events (G3 or higher) were neutropenia (87.5%), febrile neutropenia (20.8%) and anemia (16.7%). Nausea (54.2%) of any grade was also observed, for which most subjects required antiemetic. There was only one DLT observed through phase I part; a subject in level 7 could not be administered eribulin on both day8 and 15 due to neutropenia. In respect to efficacy, PR in 4 patients and SD in 12 patients were observed. The response rate was 18.2% [n = 4/22], while the disease control rate (PR and SD) was 72.7% [n = 16/22]. C_{max} and AUC of olaparib were correlated with its dose. PK parameters of both eribulin and olaparib were not influenced by each other. **Conclusions:** RD of olaparib was estimated to 300 mg bid because MTD was not attained. Now we are conducting phase II part. Enrollment has already completed and the final results will be available reported in the third quarter of 2015. Clinical trial information: 000009498.

1039 Poster Session (Board #153), Sat, 8:00 AM-11:30 AM

Neoadjuvant chemotherapy plus trastuzumab in stage II/III breast cancer with low HER2 expression. *First Author: Qamar J. Khan, University of Kansas Medical Center, Kansas City, MO*

Background: Adjuvant trials have demonstrated that addition of trastuzumab (T) to chemotherapy reduces risk of recurrence and death in women with HER2 overexpressed or gene amplified early breast cancer (BC). Central testing of specimens from patients in NSABP B-31 demonstrated that ~ 10% of patients without overexpression/gene amplification of HER2 had similar benefit from adjuvant T. Aim of this study was to assess pathologic complete response (pCR) when T is added to neo-adjuvant (NA) chemotherapy in women not exhibiting HER2 FISH amplification but had low level of protein (IHC) expression (1+ or 2+). **Methods:** Single arm phase II trial of clinical stage II/III operable BC with HER2 expression of 1+ or 2+ by IHC and FISH negative (Ratio < 2). All clinically suspicious axillary nodes were biopsied. Eligible women received 12 weeks of weekly nab-paclitaxel (100mg/m2) + weekly T (4mg/kg LD then 2mg/kg) followed by 4 cycles of dose dense AC (60/600), followed by surgery. Women with + axillary nodes at diagnosis had ALND. **Results:** 32 subjects were enrolled between 7/2009-9/2013. Median age was 53. 59% were postmenopausal. 6% had grade 1, 41% grade 2 and 53% had grade 3 tumor. All but 1 were ER + (97%) with average ER expression of 85% (range 50-99%). 22 tumors (70%) were 1+ by IHC; 10 (30%) were 2+. Median tumor size was 4.1 cm (range 1.5 to 8cm). 17 (53%) had biopsy proven + axillary nodes. 14 subjects had clinical CR after 12 weeks of nab-paclitaxel/trastuzumab. 18 had cCR at completion of AC. 8 (25%) patients had pCR in breast. 7 (22%) had pCR in breast + axilla. Of 17 biopsy proven node + patients at diagnosis, 9 (53%) were rendered node negative at surgery. 14 (44%) had one or more grade 3 toxicity. Neuropathy was noted in 23 (72%) subjects (53% grade 1, 19% grade 2). No cardiac events observed. 29/32 women completed all therapy. **Conclusions:** Neo-adjuvant T/nab-paclitaxel followed by AC in HER2 negative, ER + BC resulted in pCR rates higher than expected for this population. Among patients with positive axillary nodes, a very high (53%) complete response rate was noted in axilla. Correlative studies are underway to identify biomarkers of response. Benefit of T in BC with low HER2 expression should be studied in a randomized neo-adjuvant trial. Clinical trial information: NCT00944047.

1040 Poster Session (Board #154), Sat, 8:00 AM-11:30 AM

Mechanistic and clinical analysis of Sperm associated antigen 5 (SPAG5) as a novel prognostic, predictive, actionable gene in Breast Cancer (BC). *First Author: Tarek M. A. Abdel-Fatah, Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom*

Background: Clinicopathological implications of SPAG5 were investigated in BC. **Methods:** *SPAG5* copy number changes and gene expression were investigated in 1980 cases of BC (METABRIC cohort) and validated in multicentre databases (n = 3500). SPAG5 protein expression was evaluated in three primary BC cohorts (n = 2250) with 20-year-median follow-up. The response to chemotherapy (CT) was investigated in two cohorts in whom pathological complete response (pCR) was the primary endpoint: a) Multicentre phase II trial (NCT00455533; n = 295) received doxorubicin/cyclophosphamide followed by 1:1 randomisation to ixabepilone or paclitaxel and b) 250 BC treated with neoadjuvant-anthracycline (AC). BC cell lines with high (+) and low (-) SPAG5 expressions were tested for CT sensitivity. **Results:** 10-20% of BC showed gain/amplification of SPAG5 locus at Ch17q11.2. *SPAG5* gain/amplification and mRNA+ were significantly associated with: TP53 mutation; PAM50 Her2; PAM50 Basal; PAM50 LumB and integrative molecular clusters 1, 5, 9 and 10 ($p < 0.0001$). *SPAG5* gain/amplification, mRNA+ and protein+ were associated with poor survival and were independent prognostic factor ($p < 0.0001$). In the clinical trial, *SPAG5* mRNA+ was associated with higher pCR (OR = 2.3, 95% CI = 1.2-4.2, p = 0.008), especially among ER- BC (OR = 2.8, 95% CI = 1.3-5.9, p = 0.007). Patients with *SPAG5*-mRNA+ in the ixapeblone arm achieved higher pCR in all patients (OR = 3.0, 95% CI = 1.3-7.1, p = 0.01) and ER- cases (OR = 4.2, 95% CI = 1.3-13.0, p = 0.01). In the paclitaxel arm there was no statistical association between pCR and SPAG5 mRNA level. SPAG5-protien+ was shown to be an independent predictor for pCR (OR; 2.4; 95% CI = 1.6-3.9, $p < 0.001$). In *in vitro* cell line models, SPAG5+ expression was linked to cell response to CT drugs, irrespective of ER and TP53 status. For instance, T47D and BT549 cell lines with SPAG5+ expression were sensitive to Doxorubicin and knocking-down of SPAG5 made cells resistant to CT agents. **Conclusions:** SPAG5 is a novel amplified gene on ch17.q11 and is an independent prognostic factor. SPAG5 could help in the selection of patients who will benefit from AC-CT. and its interaction with TP53 need to be explored.

1041 Poster Session (Board #155), Sat, 8:00 AM-11:30 AM

A model-based approach to dose optimization of neurotoxic chemotherapy for metastatic breast cancer (MBC). *First Author: Manish Sharma, The University of Chicago Medicine, Chicago, IL*

Background: CALGB 40502 (Alliance) randomized patients (pts) with MBC to paclitaxel 90 mg/m^2, nab-paclitaxel 150 mg/m^2, or ixabepilone 16 mg/m^2 on days 1, 8 and 15 every 28 days, with or without bevacizumab. The aims of this analysis were to develop a model of chemotherapy-induced peripheral neuropathy (CIPN) using dosing data and patient-reported symptoms, and to use this model to inform a dose adjustment algorithm to reduce CIPN. **Methods:** FGSUM4 is the sum of scores from 4 questions of the FACT/GOG Neurotoxicity subscale, which are scored 0-4 on a Likert scale and inquire about numbness/tingling and discomfort in the hands and feet. Of 799 pts, data from 655 with baseline FGSUM4 $\leq$ 4 were used to develop a kinetic-pharmacodynamic model of CIPN. Baseline height, weight, age, race and prior taxane therapy were evaluated as covariates. The model was evaluated by standard diagnostic plots and bootstrapping. Simulations evaluated the model's ability to predict later CIPN from early CIPN data. Simulations were also used to explore dose adjustments to minimize later CIPN. **Results:** The model identified paclitaxel as the least neurotoxic drug in the study: for paclitaxel, the median average dose per day divided by SDK_{50} (a parameter that reflects clearance and intrinsic toxicity) was 0.56, compared to 0.95 for nab-paclitaxel and 1.02 for ixabepilone. Using the first 3 cycles of data, the model predicts mean FGSUM4 $\geq$ 5 at later time points with 73% sensitivity and 73% specificity. Simulations support a dose adjustment algorithm in which pts with 4 $\leq$ FGSUM4 $<$ 8 after 3 cycles skip the day 8 dose in subsequent cycles, while pts with FGSUM4 $\geq$ 8 skip the day 8 dose and reduce the day 1 and 15 doses by 50%. This algorithm reduces the number of pts with FGSUM4 $\geq$ 8 after 6 cycles by 33% compared to no dose adjustment. **Conclusions:** A model of CIPN in pts with MBC treated with neurotoxic chemotherapy was developed using patient-reported symptoms from CALGB 40502. The model can use early CIPN assessments to predict later CIPN with good sensitivity and specificity. Simulations support a dose adjustment algorithm after the first 3 cycles of therapy that reduces later CIPN. Validation of the model with an independent data set is necessary before clinical use.

1042 Poster Session (Board #156), Sat, 8:00 AM-11:30 AM

Association of non-disruptive P53 mutations with poor progression-free survival (PFS) in resected breast cancer treated with neoadjuvant chemotherapy. *First Author: Alejandro Martinez-Bueno, Instituto Oncológico Dr Rosell, Hospital Universitario Quirón Dexeus, Barcelona, Spain*

Background: Neoadjuvant chemotherapy is generally used for treatment of both early stage and locally advanced breast cancer. However, robust prognostic or predictive biomarkers are needed in this setting. *TP53* is mutated in 23% of breast cancers, although this frequency varies widely among different histologies. HER-2 amplified and basal-like tumors show the higher rates of mutation: 37% and 45%, respectively. We tested whether *TP53* mutations influence disease free-survival (DFS) in breast cancer patients treated with neoadjuvant chemotherapy (NACT). **Methods:** We assessed *TP53* status in pretreatment paraffin-embedded tumor samples from a cohort of 79 breast cancer patients (p) treated homogenously with NACT. Of these, 26 were HER2+ and 53 HER2 negative. *TP53* mutations were classified as "disruptive" (D) and "non disruptive" (ND) according to the degree of disturbance of p53 protein function and structure. **Results:** Mutations in exons 5-8 of *TP53* were detected in 16 patients (20%). Of those, 6 harbored disruptive and 10 non-disruptive mutations. As previously reported, *TP53* mutations were more common in non-luminal subgroups. After 40 months of follow-up, no recurrences had occurred among *TP53* D patients (0%), compared with 7 in the *TP53* WT group (11.1%) and 5 in *TP53* ND (50%). No deaths were registered in *TP53* D group, compared with 4 (6.3%) in TP53 WT and 2 (20%) in *TP53* ND. Median progression-free survival (PFS) in patients with ND mutations was 24.5 months (CI 95% 15.2-41.7) while it was not reached in patients *TP53*-wt or carrying D mutations ($P < 0.0001$ in a Log Rank test). The association of ND mutations with shorter PFS was maintained when patients were divided according to HER2 status. **Conclusions:** Non-disruptive mutations in the *TP53* gene areassociated with shorter PFS in resected breast cancer treated treated with neoadjuvant chemotherapy. Further studies are warranted to determine whether *TP53* ND mutations can be a prognostic marker of poor outcome in this setting.

1043 Poster Session (Board #157), Sat, 8:00 AM-11:30 AM

A single institution experience of salvage therapy for locally advanced breast cancer: Treatments and trends. *First Author: Jacques Raphael, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada*

Background: Progression during neoadjuvant therapy (NAT) for LABC is uncommon. However, these patients often do poorly, and salvage treatment (ST) options are varied. Predictors of resistance or response to ST are not well defined. The goal of this study was to establish the characteristics of LABC patients requiring ST and potential predictors of response or progression after ST. **Methods:** A retrospective review was conducted using our LABC database. Survival outcomes were estimated using Kaplan-Meier. Fisher's exact test was used to estimate the probability of progression after ST. PFS1 represents the time between diagnosis and first progression (on NAT) and PFS2 the time between the first progression and the second progression (after ST), or the date of last follow up. **Results:** Eighteen patients out of 232 (8%) progressed on primary NAT. Median follow up was 23 months and the median age 51. The majority (72%) of these patients had T3/T4 disease and 56% were also N1. Tumors were mainly ductal carcinoma (89%), grade 3 (78%) and 72% had triple negative receptor phenotype (TN). Most patients (94%) had local tumor progression alone; the most commonly used ST (56%) was concurrent radiation and cisplatin (RT/CT); 69% of the TN patients had RT/CT. 93% of the patients had a clinical response to ST and 72% had mastectomy. One patient (TN) had a complete pathologic response (pCR) on surgery after RT/CT, and 10 patients (56%) had a recurrence after ST. PFS1 and PFS2 were 4.2 and 29 months respectively. Median overall survival for all patients was 37.3 months. Initial tumor size was the only variable predictive of progression after ST (p= 0.03). Patients who received concurrent RT/CT had a trend towards better PFS2 (p= 0.08). **Conclusions:** In this patient cohort, progression on NAT was comparable to the literature. Most tumors were TN and of these almost 70% received RT/CT as ST. These patients had a trend towards improved progression free survival after ST; one patient had a pCR. Ongoing work in this area is imperative; effective ST can have a significant impact on delaying disease progression. ST with RT/CT should especially be investigated further for TN LABC progressing on NAT.

1044 Poster Session (Board #158), Sat, 8:00 AM-11:30 AM

Gene expression of metastatic biopsies for prediction of response to palliative chemotherapy in breast cancer. *First Author: Theodoros Foukakis, Karolinska University Hospital, Stockholm, Sweden*

Background: To date, no clinically useful predictive tests for chemotherapy in breast cancer (BC) are available. Several studies have tried to identify predictive gene expression signatures in the neoadjuvant setting, but no data are available for metastatic BC. **Methods:** Patients with advanced breast cancer were treated with epirubicin and paclitaxel with or without capecitabine as first-line treatment in the Swedish Phase 3 TEX trial. For 111 patients, a metastatic biopsy was obtained at baseline for gene expression profiling (Affymetrix array GPL10379). PAM50 molecular subtypes and published gene modules related to immune response or proliferation were investigated as predictors of objective response to chemotherapy (by RECIST 1.0) and progression-free survival (PFS). **Results:** 102 patients were evaluated and 58 had an objective response. Table shows the PAM50 classification and the response within each subtype. Nine patients achieved a complete response, 6 of them were classified as basal-like and 3 as luminal B. Median PFS was significantly higher in luminal tumors than in non-luminal (16.5 vs. 8 months, hazard ratio = 2.2, 95% confidence interval (CI) = 1.4-3.4, $p < 0.001$ by log-rank test). A high immune response module was predictive of response to chemotherapy for the whole cohort (Odds ratio (OR) = 1.61, 95% CI 1.02-2.64) and for luminal tumors (OR = 2.91, 95% CI 1.32-7.75), but not for basal-like tumors (OR = 0.87, 95% CI 0.34-2.25). The PAM50 proliferation index was positively associated with response in patients with estrogen receptor (ER) negative tumors (OR = 2.58, 95% CI 1.06-7.83). **Conclusions:** A high immune gene module was predictive of chemotherapy response in metastatic breast cancer, but this was restricted to the subgroup of luminal tumors. ER negative tumors with high proliferation rate had a higher probability to respond to chemotherapy. Clinical trial information: nct01433614.

Objective responses within PAM50 molecular subtypes.

	Objective Response			
PAM50 subtype	**non-responders**		**responders**	
Basal-like	10	(40.0%)	15	(60.0%)
Her2 enriched	15	(51.7%)	14	(48.3%)
Luminal A	6	(60.0%)	4	(40.0%)
Luminal B	11	(34.4%)	21	(65.6%)
Normal-like	2	(33.3%)	4	(66.7%)

1045 Poster Session (Board #159), Sat, 8:00 AM-11:30 AM

Proteomic analysis of primary and metastatic breast cancers and expression of the folate receptor as a potential drug target. *First Author: Todd A. Hembrough, OncoPlex Diagnostics, Rockville, MD*

Background: The folate pathway is a critical nucleotide biosynthetic pathway in many tumor cells, and blockade of this pathway with antifolates has demonstrated clinical utility in NSCLC and mesothelioma. The folate receptor alpha (FRa) is reported to be highly expressed in triple negative breast cancer (TNBC). However, targeting this pathway with pemetrexed in metastatic breast cancer (MBC) has been a modest success (~20% response rate in unselected patients). We used multiplexed mass spectrometry (MS) to assess the expression of the FRa and other biomarkers in TNBC to identify patients who may be responsive to antifolate therapy. **Methods:** In our clinical lab, primary and metastatic BC tissues were microdissected, solubilized and enzymatically digested following CAP/CLIA guidelines. Archival BC tissues (n = 270) were analyzed following GLP protocols. Absolute quantitation of protein targets was performed using selected reaction monitoring (SRM) mass spectrometry **Results:** Using quantitative proteomic analysis, we found that ~40% of TNBC tumors express high levels of FRa. In contrast, among 247 hormone receptor-positive and HER2-positive tumors, only 8% expressed FRa. FRa showed a 10-fold range of expression in both sample sets; a range that is most likely indiscernible by IHC. Correlation analysis between FRa and several other markers of chemotherapy sensitivity in the TNBCs showed only weak correlations suggesting that the FRa pathway is not influenced by other known pathways. **Conclusions:** Multiplex MS data confirm that FRa expression is more common in TNBC than other BC subtypes, and demonstrate that there is a wide dynamic range of FRa expression Further analyses are warranted to identify a cutoff which predicts for antitumor activity of antifolate drugs. Proteomic screening should be performed to identify TNBCs which highly overexpress FRa to enrich for a population most likely to benefit from antifolate therapy. Prospective evaluation of pemetrexed and other FRa-targeted agents is warranted in metastatic TNBC pts whose cancers express high levels of FRa.

1046 Poster Session (Board #160), Sat, 8:00 AM-11:30 AM

Impact of systemic therapy on the outcomes of patients with metastatic breast cancer to brain: MD Anderson Cancer Center (MDACC) experience 1999-2012. *First Author: Diogo Bugano Diniz Gomes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Management of metastatic breast cancer to the brain (MBC-B) is mainly surgery and/or radiation. The efficacy of systemic therapy remains controversial. **Methods:** Out of 1514 consecutive patients (pts) with MBC-B treated at MDACC October 1999-December 2012, 882 had complete data and were included in this retrospective study. We used a Cox multivariate model to identify the effect of any systemic therapy on time-to-progression in the brain (TTP-B) and overall survival (OS). **Results:** Disease subtypes: ER+/HER2- (26%) ER+/HER2+ (17%); ER-/HER2+ (20%); ER-/HER2- (33%), missing (4%). Number of brain metastasis (BM): 1 (24%), > 1 (67%), concurrent LMD (8%), missing (1%). Local treatment: metastasectomy (S) (5%), stereotactic radio-surgery (SRS) (14%), whole-brain radiation (WBRT) (58%), combination S/SRS with WBRT (12%); no treatment (11%). Subsequent systemic therapy was given to 679 pts (77%). Median OS was 9.7 months (m) (4.0-21.9). Systemic therapy prolonged OS (HR 0.44 CI 0.36-0.52 p < 0.001) for all subgroups: HER2+ (17.8 vs 3.3m); ER+/HER2- (10.7 vs 2.3m); ER-/HER2- (8.4 vs 2.4m). Other factors associated with OS: ER+, HER2+, age < 60, ECOG 0-1, single BM, controlled extra-cranial disease, local therapy to the brain, less than 3 lines of therapy prior to diagnosis of BM. Disease progression in the brain was documented in 359 pts (40.7%). Median TTP-B was 6.8m (3.7-12.1). Systemic therapy prolonged TTP-B (7 vs 4.5m; HR 0.58 CI 0.40-0.84 p = 0.005). Other factors associated with TTP-B: ER+, HER2+, single BM, and local therapy to the brain. In pts receiving anti-HER2 based therapy at diagnosis of BM, continuation of anti-HER2 agents prolonged TTP-B (HR 0.41 CI 0.23-0.72, p < 0.001) and OS (HR 0.41 CI 0.28-0.59, p < 0.001). Lapatinib-based was not superior to trastuzumab-based therapy and capecitabine was not superior to other cytotoxic agents. Pts who were on systemic therapy at diagnosis of BM and had controlled extra-cranial disease did not benefit from switching to non-cross-resistant agents. **Conclusions:** In patients with breast cancer metastatic to the brain, systemic chemotherapy was associated with better control in the brain and longer survival.

1047 Poster Session (Board #161), Sat, 8:00 AM-11:30 AM

Pre-treatment Near-Infrared Spectral Tomography (NIRST) to predict pathologic complete response to neoadjuvant chemotherapy (NAC) in women with locally advanced breast cancer (LABC). *First Author: Peter Kaufman, Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: NIRST has a potential role for easily integrated monitoring and prediction of therapeutic response in women with LABC undergoing NAC. It captures biophysical changes in tissue occurring in the vascular as well as intra- and extra-cellular matrix compartments. **Methods:** 42 Women with LABC receiving NAC were enrolled in this pilot study to evaluate the role of NIRST, undergoing NIRST before, during, and after NAC. The NIRST imaging technology uses low intensity NIR light at 6 wavelengths (658-849nm) to assess total hemoglobin concentration (HbT), blood oxygen saturation (StO2), and water, at different time points. To normalize subject-specific variations of absolute HbT, StO2, and water in the tumor region, the ratios of these parameters to that of the baseline contralateral breast were used, to test the ability to differentiate patients having a pathologic complete response (pCR) versus lack of pCR. Additionally, whether the pre-treatment Dynamic Contrast MRI (CE-MRI) will improve the pre-treatment predication power was tested. A two-sample t-test was used to determine p-values for difference in mean between pCR and non pCR groups and Area Under the Receiver Operating Characteristic curve (AUC) was obtained to illustrate graphically. **Results:** The best NIRST predictor was tumor Hb_T change during the first cycle of NAC. The p-value and AUC were 0.001 and 1.0 between subjects with pCR and non pCR, respectively. A statistically-significant separation of *Pre-TX* Hb_Tbetween subjects with pCR and non pCR (p-value < 0.01, AUC = 0.92) was also found, suggesting that NIRST has the potential to differentiate between groups before NAC has begun. Additionally, by adding the delayed signal intensity enhancement of breast in pretreatment staging CE-MRI (relative to the contralateral breast), the AUC of differentiating pCR from non pCR can be raised to 0.94. **Conclusions:** Hb_T change subsequent to the first cycle of NAC and Pre-TX Hb_T correlate to response to NAC and may be predictive of pCR. These biomarker data could lead to image-based surrogates for pCR, and thus accelerate the validation of optimal NAC regimens.

1048 Poster Session (Board #162), Sat, 8:00 AM-11:30 AM

Impact of sequencing weekly paclitaxel (T) and dose-dense doxorubicin/cyclophosphamide (DDAC) on tolerability and relative dose intensity (RDI) in breast cancer (BC) patients (pts) receiving neoadjuvant chemotherapy (NAC). *First Author: Nicholas Martin LeCroy, Memorial Regional Hospital - Department of Pharmacy, Hollywood, FL*

Background: A preferred NAC regimen for HER2-negative BC is DDAC for 4 cycles followed by 12 weeks of T. RDI of 1 indicates that all intended doses are given at the scheduled interval. While large randomized studies are lacking, few studies indicated improved pCR and/or RDI when taxanes are given first. We hypothesize that tolerability and RDI are improved when T is given before DDAC. To our knowledge, this is the first study evaluating the impact of sequence on tolerability and RDI when using DDAC/weekly T. **Methods:** This IRB-approved, retrospective chart review included pts with stage II-III HER2-negative BC who received DDAC/weekly T NAC at our institution between August 2012 and May 2014. The sequence was based on physician preference. Conventional sequence group (CS) included pts who received weekly T after DDAC; reverse sequence group (RS) received T before DDAC. Our primary outcomes were rate of pCR and tolerability/RDI. **Results:** We identified 27 pts in CS and 29 pts in RS. No statistical differences between groups with respect to age, ethnicity or tumor characteristics (ER, PR, Ki67) were found. The RS had numerically more pts with stage III ($p = 0.054$). The table lists results relevant to the primary objectives. **Conclusions:** T before DDAC was associated with more pts tolerating the T maximum dose intensity (T-RDI = 1) without compromising DDAC-RDI or pCR. More pts experienced a T dose reduction (T-DR) in CS. The difference in tolerability of T cannot be explained by a specific toxicity but rather by a multitude of complications observed in CS. The most common reason for decreased T-RDI was peripheral neuropathy (PN) in both groups. Interestingly, significantly more pts in CS required pharmacologic intervention (Rx) for PN. Our study confirms the findings of others with respect to administering taxanes before antracyclines and provides specific evidence to support sequencing weekly T before DDAC.

Outcome, # (%)	CS (N = 27)	RS (N = 29)	p
T-RDI = 1	11 (40.7)	20 (69)	0.034
DDAC-RDI = 1	22 (81.5)	21 (72.4)	0.422
T-DR	11 (40.7)	5 (17.2)	0.049
pCR	5 (18.5)	5 (17.2)	0.587
Rx for PN	16 (59.3)	9 (31)	0.034

1049 Poster Session (Board #163), Sat, 8:00 AM-11:30 AM

Clinical evaluation of germline polymorphisms (SNPs) associated with capecitabine (C) toxicity (tox) in metastatic breast cancer (MBC). *First Author: Peter H. O'Donnell, The University of Chicago, Chicago, IL*

Background: C is associated with sometimes severe tox affecting patient (pt) adherence and quality of life, which can result in dose disruption/reduction potentially attenuating effectiveness. We sought to identify pharmacogenomic (PGx) markers of C tox using a novel prospective tox assessment method in a large, multi-institutional study of women with MBC. **Methods:** Pts were prospectively identified prior to C monotherapy initiation at 2000 mg/m^2/d, 14 d on/7 off. Pts completed in-person tox questionnaires (q) on d1 of each cycle (cy) and automated phone-in q on d8, d15 for 4 cy, but met study endpoint earlier if C was dose-reduced or suspended. Genetic analysis of 50 prespecified markers and a separate genome-wide association study (GWAS) were conducted with phenotypes immediate (cy 1) and overall diarrhea or hand-foot syndrome (HFS). **Results:** N = 259 pts enrolled from 14 institutions (median age 57 yrs, range 25-85). Pt adherence with tox reporting was robust, with 86% (cy 1) and 71% (cy 4) of q completed. Rates of any-grade diarrhea and HFS were 52% and 69%, respectively, including 17% reporting grade 3 diarrhea and 9% grade 3 HFS. Worst tox was identified solely via at-home phone reporting in 39% of pts. Only 29% of pts completed 4 cy without C interruption, dose change, or early discontinuation. In candidate PGx analysis, 3 SNPs associated with development of diarrhea: *DPYD*5* (OR 4.9; P = 0.0005, significant after multiple test correction), missense SNP in *MTHFR* (OR 3.3; P = 0.02), and upstream SNP of *MTRR* (OR 3.0; P = 0.03). For HFS, GWAS elucidated a novel SNP (OR 3.0; P = 0.0007) upstream of *TNFSF4*, a gene implicated in systemic sclerosis and graft-versus-host disease of skin, never before implicated in HFS. **Conclusions:** To our knowledge, this is the first PGx study to use phone-in pt self-reporting, permitting increased accuracy of tox-phenotype characterization. Three germline SNPs previously associated with fluorouracil sensitivity in preclinical/clinical models were identified, and a novel SNP having strong functional relevance was discovered. If further replicated, these markers could improve prediction of pts at highest risk for C tox, reducing morbidity and enhancing outcomes. Clinical trial information: NCT00977119.

1050 Poster Session (Board #164), Sat, 8:00 AM-11:30 AM

The role of LHRH agonists in ovarian function preservation in premenopausal women undergoing chemotherapy for early stage breast cancer: A systematic review and meta-analysis. *First Author: Rodrigo Ramella Munhoz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The risks of chemotherapy-induced ovarian dysfunction and fertility impairment remain a clinical challenge in the management of premenopausal women diagnosed with early breast cancer (EBC). For this subgroup of patients (pts) undergoing treatment with curative intent, careful consideration of techniques to minimize these risks should be given. In this setting, the role of gonadotropin-releasing hormone agonists (GnRHa) for protection of ovarian function is not fully resolved. **Methods:** We searchedPubMed, SCOPUS and Cochrane Central Register of Controlled Trials databases, as well as ASCO Annual Meeting and San Antonio Breast Cancer Symposium abstracts. Prospective, randomized trials investigating the effect of GnRHa administered concurrently with chemotherapy (CT) for ovarian function preservation were selected for data extraction. **Results:** Six placebo-controlled studies were included in the analysis, totaling 827 randomized pts (673 evaluable pts). GnRHa used for ovarian suppression included either goserelin or triptorelin. Anthracycline and cyclophosphamide-based regimens were administered to over 90% of the pts in the neo- or adjuvant setting; a smaller proportion received taxanes. The use of GnRHa was associated with statistically significant improvement in the rate of recovery of regular menses after 6 months (OR = 2.53; 95% CI 1.23-5.22; p = 0, 01) and at least 12 months (OR 1.76; 95% CI 1.17-2.64; p = 0,007) following last CT cycle among evaluable pts. A higher number of pregnancies occurred among pts treated with GnRHa in comparison to the control arms, however, the total number of attempted pregnancies was not uniformly reported and this was not statistically significant (OR 1.79; 95% IC 0.97-3.31). Additional analyzes addressing mean time to recovery of menses and changes in hormonal levels were hampered by incomplete data. **Conclusions:** This meta-analysis provides evidence to support the use of GnRHa as a tool to prevent chemotherapy-induced amenorrhea in young women undergoing treatment for EBC. Additional outcomes related to ovarian function and fertility need to be further investigated.

1051 Poster Session (Board #165), Sat, 8:00 AM-11:30 AM

FDG-PET/CT versus contrast enhanced CT for prediction of progression-free and disease-specific survival in stage IV breast cancer patients. *First Author: Christopher Riedl, Memorial Sloan-Kettering Cancer Center, Molecular Imaging and Therapy Service, New York, NY*

Background: To compare FDG PET/CT to contrast-enhanced CT (CECT) for the prediction of progression-free and disease-specific survival in stage IV breast cancer patients undergoing systemic therapy. **Methods:** The hospital database was searched for patients with stage IV breast cancer, who received first or second line systemic therapy in clinical trials from 2007-2012 and had received a (CECT)and a FDG PET/CT at baseline and within 3 months after therapy initiation. In the 71 evaluable patients identfied, response to treatment was evaluated by RECIST 1.1 for CT. For FDG PET/CT SUVmax of up to 5 FDG avid target lesions (SUVmax ≧4) was summed and response categorized by PERCIST criteria. If there was no FDG avid lesion (5 patients) response was assessed by RECIST 1.1. Response to treatment was correlated with progression-free (PFS) and disease-specific (DSS) survival. **Results:** All responders by RECIST (n = 24) were responders by PERCIST, but 43% (20/47) of the non-responders by RECIST were responders by PERCIST (Tab. 1). 2-year-PFS of responders and non-responders by RECIST was 39% and 19%, whereas 2-year PFS by PERCIST was 41% and 0%. 4-year-DSS of responders and non-responders by RECIST was 58% and 40%, whereas 4 year-DSS by PERCIST was 64% and 6% (Fig. 1). 4-year DSS of patients classified as non-responders by RECIST but as responders by PERCIST, was 72%. **Conclusions:** FDG PET/CT seems to improve prediction of PFS and DSS in stage IV breast cancer patients. Additional information gained with PET/CT, can change treatment in up 22% of patients. Prospective evaluation of FDG PET/CT for response assessment in randomized clinical trials is warranted.

The early effect of breast density legislation on mammogram reporting. *First Author: Esther Jieun Lee, Loma Linda University School of Medicine, Loma Linda, CA*

Background: Federal legislation mandating mammographic breast density reporting to patients has been introduced to Congress. California enacted breast density notification legislation (SB1538) on April 1, 2013. What, if any, effect legislation has on mammogram reporting is unknown. We sought to determine the impact of legislation on mammographic density reporting. **Methods:** A retrospective review of consecutive patients undergoing mammography at a tertiary-care institution in California between March 1, 2013 and May 31, 2013 was conducted. Demographic variables and pre- and post- legislation mammogram results were analyzed. **Results:** Of 2,020 mammograms performed during the study period, 5.4% did not report breast density, leaving 1,911 cases for study. Median patient age was 58 (26-92). Dense breast tissue was reported in 72.3% of cases in the month prior to legislation, compared with 50.1% and 41.3% in the first and second months post-legislation respectively (p < 0.0001). On multivariable logistic regression analysis, dense breast tissue was independently associated with age < 50 (OR 2.42, 95%CI 1.82-3.20 vs ³50), Asian (OR 2.36, 95%CI 1.49-3.72) and Hispanic (OR 1.39, 95%CI 1.04-1.86) vs. white race/ethnicity, and lower BMI (< 25 OR 2.88, 95%CI 1.66-4.99, vs. ³30). Dense breast tissue was reported less frequently in the first month (April 2013, OR 0.65, 95%CI 0.42-1.00) and second month (May 2013, OR 0.30, 95%CI 0.17-0.52) post-legislation than pre-legislation (March 2013). **Conclusions:** Differences in breast density reporting pre- and post-legislation demonstrate the need for an objective measure of breast density. Breast density legislation has the potential to disproportionately target young, Asian, and Hispanic women. Health care providers, as well as legislators, should realize the full effects of this law on women undergoing mammograms who may have concerns regarding their results.

1053 Poster Session (Board #167), Sat, 8:00 AM-11:30 AM

Breast cancer with extensive regional lymph node involvement: Toward optimizing local management. *First Author: Lior Zvi Braunstein, Harvard Rad Onc Prog, Boston, MA*

Background: Extensive lymph node (LN) involvement portends significant risk for distant metastasis (DM) among breast cancer patients. As a result, local management may be of secondary import to systemic control in this population. We analyzed patients with ≥ 10 involved LNs (N3) to evaluate the outcomes of breast conserving surgery (BCS) vs modified radical mastectomy (MRM) in this high-risk cohort. **Methods**: From 1973-2011, 98 women with N3 disease were treated at our institution. Of these, 46 (46.9%) underwent BCS and 52 (53.1%) received MRM. Adjuvant chemotherapy was administered in 79 (80.1%) cases, and hormonal therapy in 56 (57.1%). Nearly all patients (92%) received comprehensive radiotherapy including axillary and supraclavicular fields. The Kaplan-Meier method was used to estimate local regional control (LRC), disease-free survival (DFS) and overall survival (OS). **Results:** At a median age of 51.5 years (range 26-82), 54% of patients had disease in 10-14 nodes, 26% in 15-19, and 20% had > 19 involved nodes. Median follow-up was 76 months, with a 5-year DFS of 64.9% and OS of 71.9% among the cohort. Multivariate Cox regression revealed that age < 50 years was unfavorable with regard to LRC ($p = 0.02$), although young age did not influence DFS ($p = 0.12$) or OS ($p = 0.31$). However, poorly differentiated ($p = 0.007$), ER-negative tumors (0.015) heralded adverse DFS outcomes. 10-year LRC was 91.4% following MRM and 89.3% following BCS ($p = 0.15$). Notably, treatment groups did not differ with regard to 10-year DFS (45.4% for MRM vs 57.6% for BCS; $p = 0.31$), or OS (61.4% vs 63.7%; $p = 0.79$). Though only 12 local regional recurrences were observed, 47 patients developed DM with a DM-free survival of 48.9% following MRM and 60.6% following BCS ($p = 0.19$). The use of contemporary chemotherapy improved 5-year OS (82.0% following doxorubicin, cyclophosphamide and taxol vs 61.3% for other regimens; $p = 0.04$). **Conclusions**: Patients with ≥ 10 involved LNs have similar outcomes following BCS or MRM, suggesting that radiotherapy may obviate the need for more-extensive surgery. While local regional control is comparably-favorable regardless of surgical approach, systemic control remains a challenge in this population.

1054 Poster Session (Board #168), Sat, 8:00 AM-11:30 AM

Risk of axillary node metastasis in Paget disease with invasive ductal carcinoma. *First Author: Stephanie M. Wong, Harvard School of Public Health, Boston, MA*

Background: Paget disease of the nipple is a rare manifestation of breast cancer that is associated with underlying invasive ductal carcinoma in approximately 60% of cases. The underlying pathology of patients with Paget disease and IDC is typically aggressive, with a tendency towards larger, high grade, hormone receptor-negative and HER2-positive tumors. Using population-based data, we sought to examine whether the presence of Paget disease was associated with increased risk of axillary node metastases in patients with underlying IDC. **Methods:** We identified women diagnosed with Paget disease and IDC (PD-IDC) or IDC alone and managed surgically from 2000 to 2011 using the Surveillance, Epidemiology and End Results database. We compared baseline patient demographic and tumor characteristics between the PD-IDC and IDC alone groups. We used multivariate logistic regression to examine the potential association of PD-IDC and axillary lymph node metastasis. **Results:** The study cohort consisted of 1,102 patients with PD-IDC, and 302,242 controls with IDC alone. The groups were similar with respect to patient demographics such as age (mean age 58.9 years PD-IDC vs. 58.6 years IDC, $p = 0.46$) and race distribution ($p = 0.12$). On analysis comparing characteristics of PD-IDC to IDC alone, tumors were more likely to be centrally located (26.9 vs. 5.5%, $p < 0.001$), high grade (63.5 vs. 40.3%, $p < 0.001$), larger than 2 cm (47.1 vs. 35.7%, $p < 0.001$), and estrogen/progesterone receptor-negative (45.2 vs. 22.1%, $p < 0.001$). In adjusted analysis controlling for patient age, tumor size, location, histologic grade, and hormone receptor status, PD-IDC had higher odds of axillary node metastasis (OR 1.83, $p < 0.001$) than IDC alone patients. **Conclusions:** In the context of invasive ductal carcinoma, the presence of Paget disease is independently associated with an increased risk of axillary lymph node metastasis compared with IDC alone.

1055 Poster Session (Board #169), Sat, 8:00 AM-11:30 AM

The efficacy and efficiency of half frozen section assessment of breast cancer sentinel lymph nodes: A retrospective analysis of 1116 cases. *First Author: Houpu Yang, Peking University People's Hospital, Beijing, China*

Background: Sentinel lymph node (SLN) biopsy became the standard of care for the staging of clinically negative axillary lymph node in patients with invasive breast cancer. Surgeons often request intra-operative frozen section assessment of SLN to guide treatment decision during the operation. This study was to assess whether this protocol was accurate and efficient. **Methods:** We retrospectively reviewed pathology records for consecutive breast cancer patients with frozen section of SLNB examined from 2012 to 2014. We defined paraffin section diagnosis as gold standard. Sensitivity, specificity, false negative rate, and false positive rate were calculated. The waiting time for frozen section analysis was record. **Results:** In total, 1116 cases involved frozen section evaluation of sentinel lymph nodes. The sensitivity, specificity of frozen section was 79.9%, 99.6% respectively. In 49 cases (20.1% of positive patients), the SLN was called negative during the intra-operative evaluation but positive on final examination (false negative). Furthermore, in another 3 patients, malignancy was only detected on frozen but not on paraffin sections (false positive). The waiting time for frozen diagnosis, unnecessary for true negative patients (77.8%), was 51±17 minutes, which is approximately 1.5 times the duration of a secondary axillary dissection (33±15). Only 17.4% patients from intra-operative half frozen section assessment. **Conclusions:** We do not recommend intra-operative frozen section to guide further axillary surgery, as the protocol of freezing half of SLN is not an accurate or an efficient method, with a relatively high false negative rate and some false positive cases which might make the axillary staging complicated.

1056 Poster Session (Board #170), Sat, 8:00 AM-11:30 AM

Cosmetic outcome after breast conserving surgery and either external beam or intraoperative radiotherapy for early breast cancer: Objective assessment of patients from a randomized controlled trial in Lublin, Poland. *First Author: Norman R. Williams, University College London, London, United Kingdom*

Background: The international randomised controlled TARGeted Intraoperative radioTherapy (TARGIT A) trial demonstrated non-inferiority between the technique of TARGIT (Intra-Operative RadioTherapy (IORT) with Intrabeam) and whole-breast external beam radiotherapy (EBRT) in women with early breast cancer. The aim of this study was to determine if the single high dose of TARGIT leads to impaired cosmesis in a group of patients in Lublin, Poland. **Methods:** Frontal digital photographs were taken of women participating in the TARGIT Trial at the Medical University in Lublin and analysed, blinded to treatment received, by BCCT.core software which produced overall Harris scores, and scores for various measures of symmetry, colour and scar. **Results:** 29 women (16 EBRT, 13 IORT), median age 56 years (range 49 to 79) had photographs taken at baseline (up to 2 days prior to surgery), then at 12m (median 364d). There were no differences in overall classification or measures of symmetry apparent between treatment groups. At 12m there was a significant difference in cEMDL, cEMDb and cX2b (see Table); these differences indicate more "redness" in the EBRT group compared with the IORT group. **Conclusions:** This objective assessment of aesthetic outcome in patients from a randomised trial demonstrates that "redness", a surrogate for radiation induced erythema grade I or II, is significantly worse in patients receiving EBRT compared with those receiving IORT. This study provides further evidence that the objective scoring of cosmesis using BCCT.core is feasible and may be an approach for standardisation, and confirms an early beneficial effect of TARGIT on cosmesis.

Median (first – third quartiles) of three measures of colour.

Measure	EBRT	IORT	p*
cEMDL	2.15 (1.54 - 3.48)	0.69 (0.43 - 1.10)	0.002
cEMDb	0.62 (0.37 - 0.92)	0.45 (0.15 - 0.57)	0.017
cX2b	0.22 (0.12 - 0.35)	0.13 (0.03 - 0.20)	0.037

* Wilcoxon Two-Sample test, 2-sided.

1057 Poster Session (Board #171), Sat, 8:00 AM-11:30 AM

Phase I dose escalation trial using stereotactic body radiation therapy (SBRT) for partial breast irradiation (PBI). *First Author: Asal Shoushtari Rahimi, Moncrief Rad Onc, Irving, TX*

Background: To evaluate tolerability of escalating doses of 5 fraction SBRT PBI in treating early stage breast cancer after partial mastectomy on a phase I dose escalation trial. The primary objective was to escalate the PBI dose utilizing a robotic stereotactic radiation system treating the lumpectomy cavity without exceeding the maximum tolerated dose (MTD). **Methods:** Eligible patients included DCIS or invasive ductal histologies, AJCC stage 0-II with tumor size $<$ 3cm, and margins $\geq$ 2mm. Prior to simulation 3-4 four gold fiducials were placed around the lumpectomy cavity for real-time respiratory tracking. Dose limiting toxicity (DLT) equaled grade $\geq$ 3 toxicity by CTCAE deemed definitely related to treatment for: skin, bone (fracture), pulmonary, neurological (intercostal or brachial plexus nerves) or any grade 4/ 5 toxicity definitely attributed to therapy. Both patients and physicians completed baseline and subsequent cosmesis questionnaires using a four point scale – excellent, good, fair, poor. Starting dose was 30 Gy in 5 fractions. Dose was escalated by 2.5 Gy total, provided 4 or fewer of 15 patients experienced a DLT within 90 days of treatment within each dose group. If more patients had DLT in a given dose cohort, the MTD would be exceeded. **Results:** 68 patients (15 per dose cohort (cohort 5 -8 patients)) enrolled with median age 62 years. Median follow-up for cohorts 1,2,3,4, and 5 were - 36.3, 26.4, 16, 8.8, and 2.3 months. The first 3 dose cohorts completed 90 day follow-up without DLTs. There was 1 focal grade 3 dermatitis DLT at 37.5 Gy. DLT follow-up is still ongoing in cohort 5. There were 72 grade 1 toxicity events, 2 grade 2 toxicities (rib fracture and breast pain), and 2 grade 3 radiation dermatitis toxicities. Physicians scored cosmesis as excellent or good in 94.9%, 100%, 97.7%, and 100% respectively ($p = 0.28$), at baseline, 6, 12, and 24 months post SBRT, while patients scored the same periods 82.7%, 96.2%, 95.4%, and 92.8% ($p = 0.04$). **Conclusions:** Dose is escalated to 37.5 Gy in 5 fractions without MTD thus far. Soon we are completing dose escalation for 40Gy in 5 fractions PBI, hoping to increase the likelihood of long term tumor control while evaluating toxicity and cosmesis of this innovative therapy. Clinical trial information: NCT01162200.

1058 Poster Session (Board #172), Sat, 8:00 AM-11:30 AM

Evaluation of the new Commission on Cancer Quality measure for post-mastectomy radiation treatment for breast cancer. *First Author: Christina Ahn Minami, Center for Healthcare Studies, Chicago, IL*

Background: Current National Comprehensive Cancer Network (NCCN) guidelines recommend post-mastectomy radiation therapy (PMRT) for patients with $\geq$ 4 positive lymph nodes and suggests strong consideration of PMRT in women with 1-3 positive nodes. These recommendations have been developed into a new Commission on Cancer (CoC) quality measure. Our aim was to describe the trends in the use of PMRT in breast cancer patients. **Methods:** From the National Cancer Data Base (NCDB), 268,557 mastectomies at 1123 hospitals were identified from 1998-2011. Changes in PMRT use over time were examined using random effects logistic regression analysis, adjusting for patient, tumor, and hospital characteristics. Analyses were stratified by having $\geq$ 4 nodes positive, 1-3 nodes positive, or node negative. **Results:** Overall, the proportion of patients receiving XRT increased from 1998 to 2011 ($\geq$ 4 positive nodes: 55.9% to 66.0%; 1-3 positive nodes: 25.9% to 38.0%; negative nodes: 7.9% to 8.9%, $p < 0.001$ for all), even after adjusting for differences in patient characteristics and tumor factors. When patients with T3 and T4 tumors were excluded, the proportion of patients receiving XRT similarly increased ($\geq$ 4 positive nodes: 55.1% to 66.6%; 1-3 positive nodes: 22.3% to 34.9%; negative nodes: 6.3% to 7.3%, $p < 0.001$ for all). In adjusted analyses, patients with $\geq$ 4 positive nodes were more likely to received PMRT if they had grade 3 or T3 tumors. Patients with 1-3 positive nodes were more likely to receive PMRT if they had higher grade or larger tumors. Irrespective of patients' nodal status, PMRT utilization rates decreased as age increased. **Conclusions:** Though PMRT rates increased over time in patients with $>$ 4 positive nodes and with 1-3 positive nodes, guideline-recommended use of PMRT in breast cancer patients with $\geq$ 4 positive nodes remains underutilized. Feedback to hospitals through the new CoC measure for patients with $\geq$ 4 positive nodes should help to improve adherence rates.

1059 Poster Session (Board #173), Sat, 8:00 AM-11:30 AM

Breast cancer brain metastases: Comprehensive review of tumor extent, histology and treatment on survival. *First Author: Jennifer A. Crozier, Mayo Clinic, Ponte Vedra Beach, FL*

Background: Breast cancer brain metastases (BCBM) are associated with poor overall survival (OS) and no treatment guidelines exist. Localized treatments include neurosurgery (ns), stereotactic radiosurgery (SRS) and whole brain radiation therapy (WBRT). We studied the association of OS with tumor and patient (pt) characteristics, ns and radiation (rad). **Methods:** 196BCBM pts who received brain rad from 2009-2013 at three Mayo Clinic sites were retrospectively studied. Data included primary tumor histological subtype: ER+, HER2+, and triple negative (TN). ECOG status at BCBM diagnosis, number of brain lesions, ns and rad treatments were also studied. **Results:** In single variable analysis (Table), TN status had 1.8 fold ($p = 0.004$) increased hazard of death compared to ER+, while HER2+ had improved OS (HR 0.6, $p = 0.008$). Hazard of death in pts with leptomeningeal disease was 2.5 fold higher ($p = 0.003$) than pts with 1-3 brain lesions. Poor ECOG status was associated with poor OS. Pts who received WBRT and SRS had an improved OS (HR 0.37, $p < 0.001$) compared to WBRT alone. Combining ns, WBRT and SRS had better OS (HR 0.26, $p < 0.001$) than WBRT alone. **Conclusions:** In this large dataset,pts with the best OS had an ECOG score of 0, HER2+ disease, 1-3 brain lesions, and the combination of ns and rad.

1060 Poster Session (Board #174), Sat, 8:00 AM-11:30 AM

Effect of the use of immediate reconstruction on the rates of bilateral mastectomy and adjuvant radiation therapy use in women with node-positive breast cancer treated with neoadjuvant chemotherapy on ACOSOG Z1071 (Alliance). *First Author: Judy Caroline Boughey, Mayo Clinic, Rochester, MN*

Background: Each treatment decision can impact other multidisciplinary treatment recommendations. Herein we evaluate the interaction of surgery, reconstruction and radiation in node-positive breast cancer treated with neoadjuvant chemotherapy in a contemporary clinical trial. **Methods:** ACOSOG Z1071 (Alliance) was a prospective study evaluating sentinel node surgery after chemotherapy in patients with initial node-positive disease. We reviewed breast operation, use of immediate reconstruction and radiation on all patients who underwent mastectomy. Differences in proportions/rates were assessed with a chi-square test. **Results:** Of 686 eligible patients with data available, 409 underwent mastectomy (47% bilateral). Bilateral mastectomy rate was higher at 67% (117/176) in women undergoing immediate reconstruction compared to 33% (75/233) in women without reconstruction ($p < 0.0001$). Use of immediate reconstruction varied by clinical tumor stage at presentation, with reconstruction rates being higher in cT0-1 tumors, similar in T2 tumors and lower in cT3-4 disease ($p < 0.0001$) compared to no reconstruction. Immediate reconstruction did not vary by approximated tumor subtype, pathological tumor stage or nodal stage after chemotherapy. Adjuvant radiation was used less often in patients with immediate reconstruction (76% vs 88%, $p = 0.0002$) and those patients with pathologic complete response (72% vs 86%, $p = 0.002$). On multivariable analysis, use of immediate reconstruction was significantly associated with absence of adjuvant radiation ($p = 0.009$). **Conclusions:** A majority of node-positive patients treated with neoadjuvant chemotherapy undergoing mastectomy receive adjuvant radiation. Bilateral mastectomy rates are higher in women electing immediate reconstruction. We found that radiation therapy was less commonly used in patients with immediate reconstruction. Since radiation therapy in node-positive breast cancer may impact local control and survival, multidisciplinary input in surgical and reconstructive planning decisions is recommended. Clinical trial information: NCT00881361.

1061 Poster Session (Board #175), Sat, 8:00 AM-11:30 AM

Residual breast tissue after mastectomy in non high risk and BRCA mutated patients. *First Author: Georg Pfeiler, Med Univ of Vienna, Vienna, Austria*

Background: Skin sparing mastectomy (SSM) and nipple sparing mastectomy (NSM) and immediate reconstruction by an implant are widely used in patients with breast cancer and in high risk patients for prophylaxis. Surgical procedure is guided by oncological aspects on the one hand – meaning cutaneous/subcutaneous envelope as thin as possible – and by cosmetic aspects on the other hand – meaning envelope as thick as possible. Pre-operative MRI might help the surgeon to choose the right thickness of this envelope. In this retrospective analysis we investigated the presence of residual breast tissue and the thickness of the envelope after SSM and NSM. **Methods:** Patients treated with SSM or NSM for prophylaxis or after breast cancer at a single university hospital, who had at least one post-operative MRI, were included. MRI's were retrospectively analysed by two independent radiologists. Analyses included (a) the detection of residual breast tissue (yes/no) and (b) the maximum thickness of the envelope directly above the implant. **Results:** 39 patients of which 19 had bilateral SSM/NSM were included. 14 patients with BRCA 1/2 mutation had prophylactic bilateral SSM/NSM. Residual breast tissue could be detected in all 58 reconstructed breasts. The medium thickness of the envelope was 11.2mm (1-35mm). In patients with bilateral SSM/NSM, a strong correlation between the thickness of left and right breast envelope could be observed ($r = 0.79$, $p < 0.05$). **Conclusions:** Thickness of the envelope of the reconstructed breast does not appear to be the major determining factor of residual breast tissue.

Detrimental effect of blood-product transfusion on survival for patients with breast cancer in Florida (1996-2007). *First Author: Hattan Alghamdi, University of Miami Hospital, Miami, FL*

Background: There has been a large body of evidence discussing the immunological effects of blood transfusion on survival in patients with a number of different types of cancers. However, few studies have examined the effect of blood transfusion on survival in breast cancer patients and these have had inconsistent results. **Methods:** Data from Florida Cancer Data System, Agency for Health Care Administration (AHCA), and the US Census were linked for female breast cancer patients in Florida (1996-2007) to understand the association of blood transfusion with female breast cancer patients' survival. Multivariate regression analyses for overall survival were adjusted for potential confounders related to blood transfusions, including age, gender, race, treatment received, and co-morbidities. **Results:** Among 120,940 patients identified, 17,686 (14.6%) received blood transfusion during the course of their treatment. The majority of patients were White (90.4%) and non-Hispanics (90.2%); most live in neighborhoods with middle-high (37.9%) and middle-low (29.2%) SES. Patients who had transfusion were older (mean = 66 years), with more advanced SEER stages (24.6% metastasis vs. 20% regional, direct extension±lymph nodes). Transfusion rates were higher in Blacks (18.8%) than in Whites (14.3%) and other races (8.2%). Medicare patients (18.1%) received more blood transfusion compared to private insurance and non-insured population (12%, both). Patients who received chemotherapy (16.8%) had higher rates of blood transfusion compared to the non-chemotherapy group (13.8%). Transfused patients had a shorter overall median survival time (7.7 years) compared to non-transfusion group (12.7 years). Among patients who received transfusion, Blacks, non-Hispanics, and patients with lower SES categories had lower overall median survival. Multivariate analysis indicated that blood transfusion is a significant independent predictor for survival (HR = 1.08;95%CI:1.03,1.13; $p < 0.001$) after adjusting demographic, clinical, and comorbid factors. **Conclusions:** Our study concludes that blood transfusion is a significant independent risk factor for survival in female breast cancer patients.

1063 Poster Session (Board #177), Sat, 8:00 AM-11:30 AM

Impact of neoadjuvant chemotherapy to surgery interval on survival outcomes in breast cancer patients. *First Author: Rachel Ann Sanford, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Retrospective analyses have sought to identify the optimal interval between surgery and initiation of adjuvant chemotherapy in breast cancer, with conflicting results. No studies have examined the impact of the interval from conclusion of neoadjuvant chemotherapy to surgery. We evaluated the relationship between survival outcomes and the time interval between neoadjuvant therapy and surgery. **Methods:** Retrospective review of the prospectively maintained Breast Medical Oncology Institutional database at The University of Texas MD Anderson Cancer Center identified 1101 women diagnosed with stage I-III breast cancer between June 1995 and April 2007 who received any neoadjuvant chemotherapy. We examined the effect of the interval from completion of neoadjuvant chemotherapy to surgery, defined as < 4 weeks, 4-6 weeks, or > 6 weeks, on survival outcomes. Descriptive statistics and Cox proportional hazards models were used. **Results:** Three hundred thirty five of 1101 patients (30.4%) had surgery within 4 weeks of their last dose of neoadjuvant chemotherapy, 524 (47.6%) within 4-6 weeks, and 242 (22%) after more than 6 weeks. Median age was 50 years, median time to surgery was 33 days (range 8-159 days) and median follow-up was 94 months (range 3-178 months). Patients whose interval was < 4 weeks were more likely to have more advanced stage ($p = 0.003$) and higher grade ($p = 0.04$) disease. The 5-year overall survival (OS) estimate was 79%, 87%, and 81% in patients who received surgery in 0-4, 4-6, and > 6 weeks after neoadjuvant chemotherapy, respectively ($p = 0.04$). The three groups did not differ in five-year locoregional recurrence-free survival (LRFS) or recurrence-free survival (RFS). In multivariate analysis adjusting for important clinical and pathologic characteristics, compared with an interval of < 4 weeks, patients who underwent surgery at 4-6 weeks or at > 6 weeks had equivalent OS (4-6 weeks HR = 0.88, 95% CI 0.68 – 1.16; > 6 weeks HR = 1.12, 95% CI 0.83 – 1.53), LRFS and RFS. **Conclusions:** Our results suggest no relationship between the neoadjuvant chemotherapy to surgery interval and overall survival, LRFS, or RFS. This data should prove reassuring to clinicians coping with ever-increasing patient volumes.

1064 Poster Session (Board #178), Sat, 8:00 AM-11:30 AM

Influence of marital status on tumor characteristics and survival in male breast cancer. *First Author: Shourya Tadisina, McLaren Flint, Flint, MI*

Background: The effect of marital status (MS) on survival varies according to cancer type and gender. To our knowledge there has been no report on the impact of MS on survival in male breast cancer (MBC). This study aims to determine the influence of MS on tumor characteristics at diagnosis and 5-year cancer specific survival (CSS) in MBC using the SEER database. **Methods**: We included patients (pts) with MBC ≥ 18 years of age in the SEER database from 1990 to 2011. Pts with unknown MS or survival data were excluded. Marital status was classified as married and unmarried (including single, divorced, separated, widowed and domestic partners). Kaplan-Meier method was used to estimate the 5-year CSS. Multivariate regression models were used to determine the independent covariates of cancer specific mortality and metastatic disease (stage IV) at diagnosis (Cox and logistic respectively). **Results**: We included 3,761 pts; 2,647 (70.4%) were married. Mean age was 64.9 years with no significant difference between the married and unmarried. Unmarried pts were more often diagnosed with advanced MBC (Stage III & IV) compared to married pts (33.3% vs. 22.1%, $p<0.0001$) but there was no significant difference in hormone receptor status, histologic grade or subtype. Unmarried pts were significantly less likely to undergo surgery compared to married pts (92.4% vs. 96.7%, $p<0.0001$). Overall unmarried pts with stage II, III & IV MBC have significantly worse 5-year CSS compared to married (Table). The survival difference between the two groups was significant only in MBC diagnosed after the year 1999. On multivariate analysis being unmarried was associated with increased hazard of death (HR=1.44, $p<0.0001$) and increased likelihood of metastatic disease at diagnosis (OR=1.95, $p<0.0001$). **Conclusions**: It is known that males with breast cancer (BC) have worse survival compared to females. Our study showed that unmarried males with BC are at an even greater risk for advanced disease at diagnosis and poorer outcomes compared to married males.

5-year cancer specific survival.

Stage	Married	Unmarried	p-value*
I	98%	96%	0.685
II	91%	86%	0.049
III	76%	71%	0.038
IV	31%	12%	0.002
Overall	88%	77%	< 0.0001

*Log rank test.

1065 Poster Session (Board #179), Sat, 8:00 AM-11:30 AM

Phase II study of panitumumab, nab-paclitaxel, and carboplatin followed by FEC neoadjuvant chemotherapy for patients with primary HER-2 negative inflammatory breast cancer. *First Author: Naoko Matsuda, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EGFR overexpression is an independent poor prognostic factor in patients with inflammatory breast cancer (IBC). Our IBC animal model indicates that EGFR targeted therapy inhibited IBC tumor growth. It will reverse epithelial mesenchymal transition. Historically, the pathological complete response (pCR) rate in IBC has been 15%. We determined the effect of an anti-EGFR monoclonal antibody (panitumumab) of neoadjuvant chemotherapy by determining the pCR rate. **Methods:** In this single-arm, phase II prospective study, the patients received 4 cycles of combination panitumumab (2.5 mg/kg), nab-paclitaxel (100 mg/m^2), and carboplatin (AUC 2) on a weekly schedule (PNC). After the PNC regimen was completed, 4 cycles of FEC (5-fluorouracil, 500 mg/m^2; epirubicin, 100 mg/m^2; cyclophosphamide, 500 mg/m^2) was administered followed by surgical resection, radiation and hormonal therapy (ER+). The primary end point was the pCR rate. The secondary objectives were disease-free survival, safety and to identification of biomarkers. **Results:** We analyzed 25 IBC patients. Median age was 57 years (range 23-68 years). 15 were HR+/HER2- and 10 were HR-/HER2- (TNBC). The median follow-up time was 11.7 months (range, 8.7-33.9 months). The pCR rate was 36% (95% CI: 0.18-0.58). Six (60%) TNBC patients and 3 (20%) HR+/HER2- patients achieved pCR. Five patients experienced disease recurrence, and 4 died. The frequency of grade 3 or 4 hematological events was 18 (72%), grade 3 nonhematological adverse events were seen in 9 (36%) patients, (rash, n = 5; fatigue, n = 2; infection, n = 1; anorexia, n = 1; stomatitis, n = 1; pleuritic pain, n = 1) and grade 4 was 0 during the PNC regimen.The association between pCR and subtype has trending for significance (p = 0.087). There was no correlation between pCR and biomarker expression (EGFR, COX2, Nodal, E-Cadherin, Vimentin, ALDH1 expression) in 14 samples. **Conclusions:** Our data show that this novel treatment, based on the biological characteristics of IBC, produced unprecedentedly high pCR rates in TNBC. We plan to conduct a randomized study to determine the role of this regimen compared with standard regimens. Clinical trial information: NCT01036087.

1066 Poster Session (Board #180), Sat, 8:00 AM-11:30 AM

MHC II antigen presentation pathway expression in triple-negative breast cancer. *First Author: Andres Forero-Torres, University of Alabama at Birmingham, Birmingham, AL*

Background: The purpose of this study was to identify gene expression differences between triple negative breast cancer (TNBC) tumors from patients who did or did not have disease relapse. **Methods:** 47 snap frozen macro-dissected primary TNBC tumors from treatment-naïve patients, with an adequate follow up (greater than 24 months), were analyzed using RNA-seq to identify gene expression differences between patients with disease relapse and patients who did not relapse. In addition, archived de-identified primary TNBC tumors underwent standard immunohistochemical analysis with anti-CD74 and anti-HLA-DPB1 antibodies. **Results:** Database included 22 patients with disease relapse and 25 who did not relapse. 24 genes had significantly higher expression in tumor tissue from patients who did not relapse and 11 of these genes were integral members of the MHC II antigen presentation pathway. The 24 gene signature was significantly associated with progression free survival (PFS) (HR = 0.24; log rank p = 0.00016). Individually expression of CIITA and CD74, key components of the MHC II pathway, were significantly associated with PFS (HR values of 0.17 and 0.35; log rank p = 0.0002 and 0.0164. A large meta-analysis of microarray data from 199 patients with TNBC (Breast Cancer Res 2013; 140: 219) validated that 10 of the 24 genes (including 6 MHC II genes) were prognostic for PFS with a HR = 0.31; log rank p = 0.0000009 and CD74 alone was similarly prognostic with a HR = 0.31; log rank p = 0.0000019. Immunohistochemical analysis of patient primary tumors detected CD74 and HLA-DPB1 protein in TNBC tumor cells (greater than 20% of the cells), suggesting the MHC II pathway may be aberrantly expressed in tumor cells. The expression MHC II pathway genes correlated strongly with a tumor infiltrating lymphocyte gene signature. **Conclusions:** Tumor MHC II antigen presentation pathway is likely an important component of the anti-tumor immunity associated with good prognosis TNBC.

1067 Poster Session (Board #181), Sat, 8:00 AM-11:30 AM

A study of triple-negative breast cancer patients tested with a 25-gene panel of hereditary cancer genes. *First Author: John F. Sandbach, Texas Oncology Central Austin, Austin, TX*

Background: Although triple-negative breast cancer (TNBC) accounts for 15% to 20% of all breast cancers diagnosed in the US, its epidemiology is not well understood. Previous studies have shown a high incidence of *BRCA1* and, more recently, *BRCA2* mutations in patients with TNBC. As panel testing becomes more prevalent, these studies can be extended to other genes with a known breast cancer risk and improve understanding of the genetic origin of TNBC. Here we examined the gene distribution of mutations identified with a 25-gene hereditary cancer panel in patients with TNBC. **Methods:** We queried a commercial laboratory database for patients affected with breast cancer who were tested with a 25-gene panel of hereditary cancer genes from September 2013 through December 2014. Patients affected with TNBC were analyzed separately. All patient data was obtained by health care provider report on test requisition forms. **Results:** We identified 2,535 patients with a personal history of TNBC and 17,304 patients with a personal history of other breast cancers. Of the TNBC patients, 14.5% (367) were identified as having a pathogenic mutation, compared to only 8.8% (1,522) among patients with a personal history of other breast cancers. As previously reported, the TNBC mutation carriers were found to a have a higher occurrence of *BRCA1* mutations than patients with other breast cancers (47.5% and 18.1%, respectively). In line with more recent studies, we also found that 19.7% (74) of mutations in TNBC patients were in *BRCA2*. Additionally, patients with TNBC showed a marked shift in the mutation distribution in several genes relative to patients with other breast cancers. This included an enrichment in *RAD51C* (3.5%) and *PALB2* (10.9%) mutations, but a depletion in *ATM* (1.9%) and *CHEK2* (1.1%) mutations. **Conclusions:** This data confirms previous findings that patients with TNBC have a high incidence of *BRCA1* mutations. This study also shows that patients with TNBC have a different distribution of mutations compared to patients with other breast cancers. This data offers insight into the underlying genetic mutations that may drive the development of TNBC, which may allow affected patients to receive more appropriate medical management.

1068 Poster Session (Board #182), Sat, 8:00 AM-11:30 AM

Phase I dose-finding study of the gamma secretase inhibitor PF-03084014 (PF-4014) in combination with docetaxel in patients (pts) with advanced triple-negative breast cancer (TNBC). *First Author: Giuseppe Curigliano, Istituto Europeo di Oncologia, Milan, Italy*

Background: Gamma secretase is a key component of the Notch signaling pathway, which is involved in cancer cell biology and survival in various tumor types including breast cancer. PF-4014 demonstrated synergistic anti-tumor activity with docetaxel in preclinical models, supporting clinical development of this combination. **Methods:** Pts received PF-4014 orally, twice daily (BID) in combination with docetaxel Q3W, following a matrix design with the modified toxicity probability interval method. The purpose was to estimate the maximum tolerated dose (MTD); the primary endpoint was first-cycle dose-limiting toxicity (DLT). The MTD was defined as the highest, tested dose with a first-cycle DLT rate < 0.33. **Results:** In all, 22 female pts received treatment; mean age 50 yrs (27-76 yrs). The most common treatment-related adverse events (AEs) were neutropenia (91%), fatigue (77%), leukopenia (68%), nausea (64%), alopecia (59%), diarrhea (59%), and anemia (50%), which were generally mild to moderate in severity. We also noted G3 leukopenia (41%), hypophosphatemia (14%), and pneumonia (14%); and G4 neutropenia (82%), leukopenia (23%) and febrile neutropenia (FN) (18%). One G5 treatment-related AE, septic shock, occurred. DLTs are listed in the table, by treatment cohort. One pt, previously treated with paclitaxel, had a confirmed partial response in first-line treatment for advanced TNBC. Six pts had stable disease. PK and pharmacodynamic evaluations of pathway modulation in surrogate (blood) and tumor tissues are ongoing. Co-administration with PF-4014 did not affect exposure to docetaxel. **Conclusions:** The MTD estimated for the combination in pts with advanced TNBC was PF-4014 100 mg BID/docetaxel 75 mg/m^2. Antitumor activity will be assessed in an expansion cohort of pts with advanced TNBC (first-line setting). Clinical trial information: NCT01876251.

Cohort	PF-4014 100 mg BID/docetaxel 75 mg/m^2	PF-4014 150 mg BID/docetaxel 75 mg/m^2	PF-4014 100 mg BID/docetaxel 100 mg/m^2
Evaluable pts, n	8	11	3
DLT events, n (%)	1 (13) G3 diarrhea	4 (36) G3 dehydration, G3 nausea, G4 FN, G5 septic shock	1 (33) G3 diarrhea and G4 FN

1069 Poster Session (Board #183), Sat, 8:00 AM-11:30 AM

Lymphopenia after adjuvant radiotherapy (RT) to predict poor survival in triple-negative breast cancer (TNBC). *First Author: Anosheh Afghahi, Stanford Univ Med Ctr, Stanford, CA*

Background: The immune system is increasingly recognized as critical in cancer development, progression, and treatment response. Intense lymphocytic infiltration in pre-treatment biopsies predicts improved survival in TNBC; lymphopenia after RT correlates with poor prognosis in other solid tumors. We investigated the prognostic impact of RT-associated lymphopenia in early-stage TNBC. **Methods:** Diagnostic and treatment data from electronic medical records of Stanford University Hospital (SU) and Palo Alto Medical Foundation (PAMF), a nearby community practice, were linked at an individual patient level with demographic, staging and survival data from the California Cancer Registry. A Cox proportional hazards model (adjusted for patient age, race, insurance, marital and neighborhood socioeconomic status, and for tumor stage, grade, and chemotherapy receipt) was used to analyze the relationship between immunologic measures obtainable from complete blood counts (CBC) treated as continuous variables (minimum absolute lymphocyte count [ALC], absolute neutrophil count [ANC], and white blood cell count [WBC]) and overall survival (OS). **Results:** 1211 TNBC patients (pts) seen at SU and/or PAMF were identified from 2000-2011; 218 pts with stage I-III TNBC received adjuvant RT and CBC within 12 months of starting radiation. 190 of these 218 pts (87.2%) received neoadjuvant or adjuvant chemotherapy. 58.3% of treated pts were lymphopenic (ALC $<$ 1.0 K/uL) with median ALC of 0.9 (interquartile range: 0.66-1.23). On multivariable analysis, lower ALC immediately after RT was strongly associated with worse OS (hazard ratio [HR] for death with an increase of 0.1 K/uL in ALC = 0.70, 95% confidence interval [CI]: 0.55–0.91); lower ANC (HR = 0.98, 95% CI: 0.95–1.01) and WBC (HR = 0.99, 95% CI: 0.97–1.00) were not associated with OS. **Conclusions:** Among curable TNBC pts, a low ALC after RT was independently associated with a substantial increase in the risk of death; no such effect was observed with other blood counts. These results build on tumor-based studies implicating lymphocyte function as a key determinant of treatment response and survival, and may guide development of targeted immunotherapies for TNBC.

1070 Poster Session (Board #184), Sat, 8:00 AM-11:30 AM

Masitinib plus carboplatin and gemcitabine for treatment of patients with advanced triple negative breast cancer: An open label phase Ib/II trial. *First Author: Mario Campone, Cancer Institute of the West (ICO), Nantes, France*

Background: Masitinib (MAS) is a selective inhibitor of c-Kit and mast cell function, both of which have been linked to disease progression and poor prognosis in triple negative breast cancer (TNBC). This trial evaluated MAS in combination with either carboplatin (C) and/or gemcitabine (G) as a treatment of advanced TNBC. We report here findings from the cohort receiving MAS plus CG. **Methods:** This dose-escalating phase I study assessed the safety and maximum tolerated dose of MAS plus C (AUC5) and G (1000 mg/m^{2}on days 1 and 8) over a 3 week cycle in patients (pts) with metastatic or locally advanced TNBC. Dose Limiting Toxicity (DLT) was defined as grade 3 for non-hematological adverse event (AE) or any grade 4 AE related to MAS. Phase II evaluated efficacy of the combination. **Results:** Twenty-one pts received MAS combined with CG. Reduction of dose was performed for MAS (from 9 to 6 mg/kg/day) and G (-25%) due to occurrence of DLT. In this cohort (n=13), 10/13 pts (77%) reported grade 3-4 AE (including neutropenia, 38% and thrombocytopenia, 38%); and 5/13 pts (38%) reported serious AE (including neutropenia, 15%). No treatment related deaths were reported. Overall, median OS was 10.2 months (95%CI [9.2;16.4]) and median PFS was 4.7 months (95%CI [2.1;10.8]). Objective response rate was 43%. **Conclusions:** The safety profile of MAS (6 mg/kg/day) plus C (AUC5) and G (750 mg/m^2) was acceptable, thereby defining the combination's MTD and recommended dose for further study. Efficacy findings seem to compare favorably against historic benchmarks (see table). MAS may therefore potentially offer patients a new active compound for treatment of metastatic or locally advanced TNBC. A confirmatory phase III trial evaluating MAS (6 mg/kg/day) in combination with C (AUC5) and G (750 mg/m^2) has been initiated.

	MAS + CG (n = 21)	*Benchmark CG (n = 62)
OS (months)	10.2	7.7
PFS (months)	4.7	3.6
Objective Response Rate	43%	32%
Complete	0%	2%
Partial	43%	31%

1071 Poster Session (Board #185), Sat, 8:00 AM-11:30 AM

Enzalutamide: A new hormonal treatment for triple-negative breast cancer? *First Author: Francesco Caiazza, Education and Research Centre, St.Vincent's University Hospital and School of Medicine and Medical Science, University College Dublin, Dublin, Ireland*

Background: Like the estrogen receptor (ER), the androgen receptor (AR) is present in approximately 80% of invasive breast cancer. However, in contrast to the ER which is never expressed in triple-negative breast cancer (TNBC), the AR can be present in up to 30% of patients with this molecular subtype of breast cancer. The aim of this study was therefore to investigate the targeting of AR with the second generation anti-androgen enzalutamide as a possible new hormonal approach for the treatment of breast cancer. **Methods:** IC_{50}values for enzalutamide were determined for 14 breast cancer cell lines (8 TN; 6 non-TN), using the colony formation assay. AR was measured using both Western blotting and ELISA. Cell motility was determined using Boyden chamber assays in 4 TN cell lines. **Results:** enzalutamide IC_{50}values across 14 breast cancer cell lines varied from 4 μM to $>$ 50 μM. Response to the anti-growth activity of enzalutamide was similar in TN and non-TN cell lines but depended on the presence of AR. In addition to blocking cell growth, enzalutamide also inhibited cell migration and invasion in 3 out of 4 TN cell lines, again in an AR-dependent manner. Similar to enzalutamide, the first generation anti-androgen flutamide also blocked cell growth, migration and invasion in TNBC cell lines. The addition of doxorubicin to enzalutamide enhanced growth inhibition in 4 of 5 breast cancer cell lines investigated, including 2 TN cell lines. In contrast to doxorubicin, no enhancement of growth inhibition was found with cisplatin, carboplatin or 5-FU. **Conclusions:** We conclude that targeting AR with enzalutamide may represent a new approach to breast cancer treatment, especially for patients with AR-positive TN disease. The current availability of anti-androgens for the treatment of metastatic prostate cancer should facilitate their clinical investigation in TNBC. Finally, since the AR is expressed in several different types of cancer, targeting with enzalutamide may have wide application in cancer treatment.

1072 Poster Session (Board #186), Sat, 8:00 AM-11:30 AM

Prognostic significance of tumor subtypes in male breast cancer: A population-based study. *First Author: Jose Pablo Leone, University of Iowa, Iowa City, IA*

Background: Male breast cancer (MaBC) is an uncommon disease, information about prognostic factors is controversial and few reports have studied the role of tumor subtypes. The aim of this study was to analyze the characteristics of each tumor subtype in MaBC and its association with prognosis compared with other factors. **Methods:** We evaluated men with microscopically confirmed invasive breast cancer between 2010 and 2011 with known estrogen receptor (ER) and progesterone receptor (PR) (together hormone receptor [HR]) status and human epidermal growth factor receptor 2 (HER2) status reported to the Surveillance, Epidemiology, and End Results (SEER) program, which registers HER2 status since 2010. Patients (pts) with other primary either before or after breast cancer were excluded. Tumor subtypes were classified as: HR+/HER2-, HR+/HER2+, HR-/HER2+ and triple negative (TN). Pt characteristics were compared between tumor subtypes. Univariate and multivariate analyses were performed to determine the effect of each variable on overall survival (OS). **Results:** We included 657 pts. Median age was 65 years (range 29-97). Median follow-up was 10 months (range 0-23). At diagnosis 82.6% were ductal, 46.4% T1, 56.1% N0, 7.6% M1, 14% had breast conservation and 22% adjuvant radiotherapy. Tumor subtype distribution was: 84% HR+/HER2-, 12.2% HR+/HER2+, 1.2% HR-/HER2+ and 2.6% TN. Pts with TN tumors were younger (p = 0.007), had higher grade (p = 0.0001), presented with more advanced stage (p = 0.01), more likely to have mastectomy (p = 0.001) and to die from breast cancer (p = 0.0003). Univariate analysis showed that HER2+ was associated with shorter OS (p = 0.04) and TN pts had worse prognosis (p $<$ 0.0001). In multivariate analysis, pts who had no surgery, those with stage IV and those with TN tumors had significantly worse OS (table). **Conclusions:** In this cohort, we observed significant differences in pt characteristics according to tumor subtype. HER2+ and TN represented a small proportion of cases. In addition to stage and surgery, tumor subtype has clear influence on OS in MaBC.

Neoadjuvant chemotherapy with dose-dense doxorubicin, cisplatin, and paclitaxel in patients with early triple-negative breast cancer (TNBC). *First Author: Mona Frolova, N.N. Blokhin Russian Cancer Research Center, Moscow, Russia*

Background: TNBC is characterized by aggressive behavior and poor prognosis. It has been shown that achievement of pathological complete regression (pCR) after neoadjuvant chemotherapy improved survival of patients (pts) with TNBC. Rates of pCR with standard antracycline- and taxanebased chemotherapy regimens don't exceed 20-27%. There are strong phenotypic and molecular similarities between BRCA1-related breast cancers and triple-negative sporadic tumors. Markers of BRCA1-dysfunction may predispose sensitivity to specific agents such as platinum salts. We performed a prospective trial to evaluate efficacy of dose-dense schedule of doxorubicin, cisplatin and paclitaxel in correlation with BRCA1-dysfunction in pts with early TNBC (NCT01672671). **Methods:** Pts with early TNBC (cT1-2N0-1M0) were treated with doxorubicin 25 mg/m2 iv weekly, cisplatin 30 mg/m2 iv weekly and paclitaxel 100 mg/m2 iv weekly for planned 8 weeks with G-CSF 300 mcg 2-4 days followed by surgery. Pathologic response was assessed in correlation with BRCA1-dysfunction in 17 pts. **Results:** Forty one pts were included in the study. Median agewas 44 years (23-72), 45% of pts had tumor Grade 3, Ki67 was $>$ 20% in 95% of cases. Forty pts completed chemotherapy (median treatment duration 8,9 weeks) and underwent surgery. Twenty-six pts (65%) achieved pCR. With median follow-up of 19,7 months, 3 pts had a disease progression and 2 pt died (one from disease progression and one from pulmonary embolism after 6 injections of chemotherapy). 1-year DFS was 95,1% and OS was 97,5%. The dose-limiting toxicities were neutropenia (53.7% grade 3-4) and mucositis (19.5% grade 3). In 8 pts treatment was discontinued early due to toxicity. Somatic BRCA1 5382insC mutation correlated with achievement of pCR ($p = 0.004$). All pts with somatic 185delAG and C61G mutations had residual disease ($p = 0,2$ and 0,2, accordingly). **Conclusions:** Dose-dense doxorubicin, cisplatin and paclitaxel regimen shows high activity as neoadjuvant treatment of early TNBC with acceptable toxicity. Somatic BRCA1 mutations may determine different responses to platinum-based chemotherapy. Clinical trial information: NCT01672671.

1075 Poster Session (Board #189), Sat, 8:00 AM-11:30 AM

Rampant centrosome amplification and aggressive disease course of triple-negative breast cancers. *First Author: Vaishali Pannu, Georgia State University, Atlanta, GA*

Background: Centrosome amplification (CA), a cell-biological trait characteristic of pre-neoplastic and pre-invasive lesions has empirically been associated with tumor aggressiveness suggesting an early and causal role of excess centrosomes in driving tumor progression. Recent studies provide convincing evidence that CA leads to malignant transformation and promotes invasion in mammary epithelial cells. Given that supernumerary centrosomes occur in ~80% of breast cancers, we hypothesize that CA can serve as a predictor of breast cancer aggressiveness. Triple (ER/PR/Her2) negative (TN) breast cancer, a histologically-aggressive breast cancer subtype, commonly afflicts African-American (AA) women and is characterized by high recurrence, metastases, and mortality rates. TN and non-TN breast tumors follow variable kinetics of metastatic progression, and thus constitute a test bed to explore if the severity and nature of CA can distinguish the two subtypes. **Methods:** Utilizing formalin-fixed paraffin-embedded and fresh-frozen breast cancer tissues, we quantitatively assessed extent of structural and numerical centrosomal aberrations for each patient sample in a large-cohort of grade-matched TNBC ($n = 30$) and non-TNBC ($n = 98$) cases employing multi-color immunofluorescence confocal imaging and immunoblotting. **Results:** Our data establish previously unrecognized differences in incidence and severity of CA between TNBC and non-TNBC cell lines and clinical specimens. We found strong correlation between CA and markers of aggressiveness associated with breast cancer metastasis in 20 pairs of grade-matched TNBC and non-TNBC clinical specimens ($p < 0.02$). Time-lapse imaging of MDA-MB-231 cells stably-transfected with GFP-tagged centrin harboring amplified centrosomes demonstrated that CA confers enhanced migratory ability. **Conclusions:** Our study reveals a causative link between CA and breast cancer aggressiveness. Organellar disparity between breast cancer subtypes harboring different metastatic potential has immense translational value as it may allow early-risk prediction and explain higher tumor aggressiveness in TNBC patients.

1076 Poster Session (Board #190), Sat, 8:00 AM-11:30 AM

Prognostic role of androgen receptor expression in triple-negative breast cancer. *First Author: Yanru Wang, Jinling Hospital, Southern Medical University, Nanjing, China*

Background: Expression of androgen receptor (AR) was reported to be associated with estrogen receptor (ER) expression and predict better disease-free survival (DFS) and overall survival (OS) in early breast cancer. The prognostic role of AR expression in triple-negative breast cancer (TNBC) is unclear. We performed a meta-analysis of published clinical studies to date. The Cancer Genome Atlas (TCGA) data was used to evaluate the association of AR expression with survival outcomes in TNBC. **Methods:** PubMed was searched for eligible clinical studies that investigated the association of AR expression with clinical outcomes (DFS and/or OS) of TNBC. Pooled hazards ratios (HRs) for survival outcomes with 95% confidence interval (CI) were calculated using Comprehensive MetaAnalysis (v2). AR mRNA expression, clinical information and survival data of breast cancer patients were extracted from the TCGA Data Portal. OS of TNBC patients with different levels of AR expression was compared using Cox-proportional hazards model and Kaplan-Meier method in Statistical Analysis System (SAS. v9.3). **Results:** Ten retrospective studies including 2463 patients were included in the meta-analysis. AR was expressed in 590 (24.1%) patients. Expression of AR was associated with significantly better DFS (HR = 0.70, 95% CI = 0.54-0.89, $P = 0.005$) in TNBC. Although there was a trend toward longer OS in TNBC patients with AR expression, it was not statistically significant (HR = 0.76, 95% CI = 0.56-1.04, $P = 0.083$). In the TCGA dataset, mRNA expression, clinical information and survival data were available for 971 female breast cancer patients. There were 149 TNBC cases for further analysis. AR expression was significantly lower in TNBC than adjacent normal tissue ($P = 0.001$). Again although there was a trend toward longer OS in cases with higher AR expression, the difference was not statistically significant (HR = 0.71 for $>$ 10% vs $\leq$ 10% AR expression, $P = 0.583$; HR = 0.66 for $>$ 15% vs $\leq$ 15% AR expression, $P = 0.470$; and HR = 0.70 for $>$ 50% vs $\leq$ 50% AR expression, $P = 0.452$). **Conclusions:** Expression of AR in TNBC is associated with better DFS. Though there is a trend for better OS in patients with high levels of AR expression, this requires validations by additional large studies.

1077 Poster Session (Board #191), Sat, 8:00 AM-11:30 AM

Measurement of nucleotide excision repair activity and correlation with cisplatin sensitivity. *First Author: Anne Calkins, University of Tennessee College of Medicine, Memphis, TN*

Background: Nucleotide excision repair (NER) of DNA is necessary for removal of crosslinks and other damage produced by UV light, genotoxins and chemotherapies. Germline NER deficiency causes Xeroderma Pigmentosum (XP) and inevitably leads to cancer. We explored the relationships between NER, breast cancer (BC), and cisplatin, a platinum-based chemotherapy. NER removes platinum-induced DNA crosslinks. Ergo, NER deficits may contribute to sensitivity to cisplatin-based chemotherapies. **Methods:** We assessed NER deficiency and sensitivity to cisplatin and UV in 40+ BC cell lines, including various subtypes as presented by published sources (COSMIC database from Forbes et al, 2014, and Neve et al Cancer Subtype Study, 2006). To monitor NER we measured removal of [6-4] photoproducts from UV-irradiated cells using a DDB2 proteo-probe (Dreze et al. 2014). Data analysis was based in Prism with t-tests and correlation studies. **Results:** The vast majority of tested cell lines, both cancerous and non-cancerous, exhibited more than 90% removal of [6-4] photoproducts 2 hours after UV damage. In general, UV damage persisted in triple negative (TN) cell lines compared to other BC, though not statistically significant (8% damage remaining vs 2%, $p > 0.05$). NER deficiency did not correlate with either cisplatin or UV sensitivity, while cisplatin and UV sensitivities correlated with each other. Fundamentally, intermediate steps exist between DNA deficiency and cell death in the majority of cell lines. However, one TN cell line, MDA-MB-468, showed extreme NER deficiency equivalent to XP cells (89% damage remaining). We did not identify mutations in NER genes but found reduced XP group F protein (XPF). Complementation with wildtype XPF cDNA rescued NER activity. This cell line may represent a new subtype of DNA repair-deficient breast cancer. In addition, BRCA1 and BRCA2 gene mutation status did not correlate with NER activity. **Conclusions:** We propose NER deficiency is present in DNA repair-deficient breast cancer, specifically in the TN subtype. NER deficiency is oncogenic and may be a driver of cancer. Measurement of NER in breast tumors may identify patients who benefit from platinum-based therapies.

1078 Poster Session (Board #192), Sat, 8:00 AM-11:30 AM

Nuclear HSET as a negative prognostic indicator and racial disparity biomarker in breast cancer patients. *First Author: Angela Ogden, Georgia State University, Atlanta, GA*

Background: The kinesin HSET (human spleen, embryo, and testes) is a negative prognostic indicator in cancer. Specifically, increased expression levels are associated with brain metastases in lung cancer, and increased nuclear levels are associated with worse overall and progression-free survival in breast cancer. HSET is overexpressed in triple-negative breast cancer, which is associated with African American (AA) race; however, a definitive role for HSET in health disparity has not been established. **Methods:** To probe associations between HSET levels, race, and prognosis, formalin-fixed paraffin-embedded breast tumor biopsies from 149 AA and 109 European American (EA) patients were immunostained for HSET. Staining intensity (0-3) and extent (0-100%) in nuclei and cytoplasms were determined by blinded pathologists. Weighted indices were calculated as the products of the staining intensity and extent and were stratified into low, moderate, and high groups. Associations of these groups with negative prognostic indicators and overall and progression-free survival were determined using Cox proportional hazards and Kaplan-Meier analyses. **Results:** High nuclear HSET was associated with more advanced grade and a higher percentage of Ki67-positive cells than low nuclear HSET regardless of race ($P < 0.05$ for all). However, high nuclear HSET was only associated with triple-negative receptor status ($P < 0.001$) and worse overall survival ($P = 0.02$) in AAs. In multivariate analysis, AA breast cancer patients with high nuclear HSET had a 5.05-fold increased risk of worse overall survival after adjusting for grade, stage, and triple-negative receptor status (95% CI = 1.77-14.40). They also had a 2.72-fold increased risk of worse progression-free survival in multivariate analysis (95% CI = 1.00-7.39). Cytoplasmic HSET was not significantly associated with survival in either race. **Conclusions:** These data suggest that nuclear HSET is a valuable negative prognostic biomarker in AA breast cancer patients. Determination of nuclear HSET levels may help to risk-stratify AAs with breast cancer, who suffer disproportionate disease-specific morbidity and mortality relative to their EA counterparts.

1079 Poster Session (Board #193), Sat, 8:00 AM-11:30 AM

DNA methylation signature to identify treatment response in triple negative breast cancer. *First Author: Begona Pineda, INCLIVA, Valencia, Spain*

Background: The triple negative breast cancer (TNBC) subtype is an aggressive phenotype with scarce treatment alternatives. Chemotherapy (CT) is only effective in about 40% of patients. DNA methylation could play a role in this differential response between TNBC. The objective of our work was to define a DNA methylation profile with potential to predict response to CT in TNBC patients. **Methods:** Tumor samples from patients diagnosed with a TNBC stage I to III and considered candidate for neoadjuvant CT with anthracycline and taxane were identified. DNA was extracted from FFPA samples obtained by pre-surgery biopsy. Patients were classified according to residual cancer burden (RCB) index in responders (RCB = 0, n = 10) *vs.* non-responders (RCB > 0, n = 14). DNA methylation was performed by the Infinium HumanMethylation450 array (Illumina) that allows interrogating more than 485,000 methylation CpG sites per sample. The selection criteria were: $p < 0.05$ and mean difference between methylation groups of $\geq 20\%$. The functions associated to genes were analyzed using the Gene Ontology FDR. **Results:** We identified 24 samples from TNBC patients. Median age was 58.4 (48.5-69.0) years. Most patients presented T1-2 tumors (72%), no axillar lymph involvement (53%). Proliferative scores were high with 53% of patients with ki67 > 60% and 88% of grade 3 tumors. We have detected 133 differentially methylated CpGs allowing clearly separate the responders from the non-responders. Thirty five were located at CpG islands (CGIs) or CGI shores at promoter regions. We selected 11 CpGs corresponding to 11 genes with the less variation intragroup (standard deviation $\leq 20\%$). Nine of them showed a consistent DNA methylation profile of consecutive CpGs. Of these, 5 genes (genes 1 to 5) increased and 4 genes (genes 6 to 9) decreased methylation in non-responding patients compared to those who responded to treatment. The increase ratio varies between 0.20 and 0.27, and the decrease ranges between -0.21 and -0.22. Some of these genes were related to Wnt and Hedgehog pathways, epithelial-mesenchymal transition and cell migration. **Conclusions:** DNA methylation profile is an interesting predictive tool for response to neoadjuvant CT in TNBC.

1080 Poster Session (Board #194), Sat, 8:00 AM-11:30 AM

A Phase II study of cabozantinib for metastatic triple-negative breast cancer (TNBC). *First Author: Sara M. Tolaney, Dana Farber Cancer Institute, Boston, MA*

Background: Data suggests that MET expression and activation are important for initiation and progression of TNBC. We evaluated the efficacy of cabozantinib (XL184), a novel inhibitor of multiple receptor tyrosine kinases, including MET and VEGFR2, in patients with metastatic TNBC. **Methods:** In this single-arm, two-stage Phase 2 study, patients with metastatic TNBC with measurable disease by RECIST v1.1 and up to 3 lines of prior chemotherapy in the metastatic setting received cabozantinib 60 mg daily on a 21-day cycle. Patients were restaged 6 weeks following treatment initiation and every 9 weeks thereafter. The primary endpoint was objective response rate (ORR). If $\geq 1/13$ pts responded at stage 1, 22 more will be enrolled. If $\geq 4/35$ responded, the null rate (5%) would be rejected in favor of a 20% rate of activity. Predefined secondary endpoints included progression free survival (PFS) and toxicity. **Results:** Thirty-five patients (median age 50 years, range 31-78) initiated protocol therapy and were included in this analysis. Patients had 0 (n = 6, 17%), 1 (n = 18, 51%), 2 (n = 4, 11%), or 3 (n = 7, 20%) prior lines of chemotherapy for metastatic disease. Two patients achieved confirmed PR (ORR 9% [95% CI 1-25%]) and 3 achieved unconfirmed PR; 18 patients (51%, 95% CI: 34-69%) had SD as their best response. The clinical benefit rate at 15 weeks was 31% (95% CI 17-49%) and the median PFS was 1.9 months (95% CI 1.3-3.3). The most common toxicities (all grades) were fatigue (77%), diarrhea (40%), mucositis (37%), and palmar-plantar erthrodysesthesia (PPE) (37%). There were no grade 4 toxicities. Twelve (34%) patients required dose reduction, 4 due to PPE and 8 due to other toxicities. Ongoing studies are exploring MET expression and amplification in archival tumor samples, MET amplification in circulating tumor cells, and plasma biomarkers of response to cabozantinib. **Conclusions:** In patients with metastatic TNBC, cabozantinib monotherapy showed evidence of antitumor activity. Adverse events requiring dose reduction occurred in about one-third of patients. Biomarker changes and their association with outcome will be presented at the meeting. Clinical trial information: NCT02260531.

1081 Poster Session (Board #195), Sat, 8:00 AM-11:30 AM

Contribution of immune system and tumor-related interferon signaling to epirubicin response in triple-negative (TN) breast cancers. *First Author: Giampaolo Bianchini, San Raffaele Scientific Institute, Milan, Italy*

Background: In HER2+ patients treated with HER2-targeted monoclonal antibodies in the NeoSphere trial, multivariate analysis showed a complex interplay between immune system and response (Gianni L SABCS 2012). High STAT1 and IGG metagens were associated with pCR, whereas high MHC1 and Interferon-inducible (IF.I) metagenes were associated with resistance. We sought to assess in TN tumors if there is a similar relationship between immune system and response to anthracyclines, which leads to immunogenic cell death **Methods:** We selected Affymetrix GEPs for 87 TN breast cancers (BCs) treated with neoadjuvant epirubicin monotherapy in the TOP trial (Desmedt C JCO 2011). Association between four previously define immune metagenes (IGG, STAT1, IF.I and MHC1), pCR and distant metastasis free survival (DMFS) were assessed. We assessed in 51 BC cell lines (25 TN) if isolated cells themselves also express those immune-related genes. **Results:** In TOP trial, immune metagenes were not associated with pCR in univariate analysis. In multivariate analysis, high STAT1 (OR 5.17 (1.66-16.1); $p = 0.004$) and low MHC1 (OR 0.19 (0.07-0.51); $p = 0.001$) were associated with pCR. Significance was retained when clinical variables and TOP2A amplification/deletion were included. In univariate analysis for DMFS, only high STAT1 was associated with lower risk of relapse (HR 0.62 (0.43-0.90); $p = 0.012$). In multivariate, high STAT1 (HR 0.26 (0.12-0.59); $p = 0.001$) and low IF.I (HR 2.75 (1.26-6.00); $p = 0.01$) were associated with lower risk of recurrence. Results were similar when only patients with residual disease were considered in the analysis. In BC cell lines, expression of MHC1-related genes was very heterogeneous from low to very high. A group of cell lines, TN and HER2+ in particular, expressed also some IF.I/STAT1 related genes. **Conclusions:** Multivariate analysis is needed to uncover the contribution of immune components to the response and prognosis of TN tumors treated with anthracyclines, which was similar to the involvement with response of HER2+ tumors to monoclonals. Interferon signaling, defined by STAT1 and IF.I metagenes, and MHC1 expression are related to both the immune system status and tumor cells.

1082 Poster Session (Board #196), Sat, 8:00 AM-11:30 AM

Cisplatin with or without rucaparib after preoperative chemotherapy in patients with triple negative breast cancer: Final efficacy results of Hoosier Oncology Group BRE09-146. *First Author: Kathy Miller, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Patients (pts) with triple negative breast cancer (TNBC) with residual disease after neoadjuvant therapy have a high risk of recurrence. **Methods:** Pts with BRCA mutations and/or TNBC with lymph node (LN) or > 2 cm of invasive disease after anthracycline (A) and/or taxane (T) neoadjuvant therapy were assigned 1:1 to cisplatin (C: 75 mg/m^{2}D1 q3 wks x 4) +/- rucaparib (R: 24-30 mg IV D1,2,3 q3 wks x 4 followed by R 30 mg IV or 100 mg orally wkly for 24 wks). BROCA analysis identified deleterious germline mutations. Pharmacokinetic sampling to assess R exposure was obtained during IV and oral dosing. The primary objective was 2-yr DFS. **Results:** From Feb 2010 to May 2013, 128 pts were enrolled. Median tumor size at surgery was 1.9 cm (0-11.5) with median LN involvement 1 (0-38); median Residual Cancer Burden (RCB) score was 2.6. Neoadjuvant therapy included A in 57% and T in 91%. 86.7% of pts received radiation therapy prior to entry. BROCA identified deleterious mutations (8 BRCA 1, 12 BRCA 2, 2 BRIP1) in 22/101 (22%) pts. 8 pts randomized to C and 1 to CR did not start therapy. Toxicity was similar in both arms. Despite frequent dose reductions (21% of pts.) and delays (43.8% of pts), 73% of pts completed planned C. R dose reduction was uncommon (6%). 11 pts (17.5%) assigned to CR did not begin R monotherapy; 51% of pts completed the planned 24 wks. Rucaparib exposure was limited with median(min,max) concentration 275(82,4694) ng/mL post-infusion on Day 3. Exposure was less during oral maintenance (median concentration 47(19,185) ng/mL two hours post-treatment). 2-yr DFS was similar in both arms (C-58.3%, CR-63.1%; p = 0.43). In an exploratory analysis of patients receiving A-containing neoadjuvant therapy, 2-year DFS was significantly improved with CR (55.9% vs. 69.9%; p = 0.04). Mutation status did not impact DFS. **Conclusions:** The addition of low dose R did not impact the toxicity of cisplatin or improve 2-yr DFS. The dose of R used in this study was substantially less than the current phase II monotherapy dose (600 mg orally twice daily) and may not have been sufficient to inhibit PARP activity. Clinical trial information: NCT01074970.

1083 Poster Session (Board #197), Sat, 8:00 AM-11:30 AM

A novel biomarker to predict sensitivity to enzalutamide (ENZA) in TNBC. *First Author: Joel S. Parker, UNC Chapel Hill, Chapel Hill, NC*

Background: TNBC is a heterogeneous disease with multiple subtypes and drivers. ENZA, a potent inhibitor of AR signaling, is being tested in patients (pts) whose TNBC expresses AR (> 0%) by IHC (NCT01889238). However, AR expression may not confer ENZA sensitivity. Gene profiling was therefore explored to determine whether this could be superior to IHC in predicting benefit from ENZA. **Methods:** Consent and tissue for AR testing was collected from 404 pts. Next-Gen RNA-sequencing analysis was performed on 175 tissue samples: 122 samples came from pts treated with ENZA (118 unique pts) (ITT); 55 were from untreated pts. A Training Set (TrS, n = 122); and a Validation Set (VS; n = 55) were created. TrS consisted of 80 samples from ENZA treated pts (77 unique pts) + 42 from untreated pts (29 AR = 0%; 13 AR > 0 %). VS consisted of 42 samples from ENZA treated pts (41 unique pts) + 13 from untreated pts (10 AR = 0%; 3 AR > 0 %). A gene expression model of biological subtype (GES) was built directly from the response data in the TrS. Model development utilized the elastic-net algorithm in the context of 500 rounds of Monte-Carlo cross-validation. Tuned parameters were used to validate the gene-expression model in the VS, outcomes were blinded during model validation. **Results:** The selected GES achieved 80% sensitivity and 65% specificity in prediction of 16 week clinical benefit (CBR16). Utilization of this model to define Diagnostic positive (Dx+) and Dx- populations showed the following results in pts treated with ENZA are shown in the Table. Highest accuracy was demonstrated in pts receiving ENZA as their 1st or 2nd line of therapy. **Conclusions:** A genomic signature, associated with androgen biology, has been identified that demonstrates the potential to predict clinical response to ENZA in pts with TNBC. Nearly half of the pts enrolled in the phase 2 were classified as Dx+, suggesting a reasonable prevalence of pts who may benefit from this hormonal therapy. This assay may be useful to select TNBC pts for future studies evaluating ENZA. Clinical trial information: NCT01889238.

	Training Set		Validation Set		ITT (both sets)	
	Dx+ (n=39)	Dx- (n=38)	Dx+ (n=17)	Dx- (n=24)	Dx+ (n=56)	Dx- (n=62)
CBR16 (% pts; 95% CI)	44 (29-60)	13 (5-27)	29 (12-54)	8 (2-26)	39 (27-53)	11 (5-21)
CBR24 (% pts; 95% CI)	39 (24-55)	10 (4-24)	29 (12-54)	0 (0-13)	36 (24-49)	6 (2-16)

1084 Poster Session (Board #198), Sat, 8:00 AM-11:30 AM

Rac1 inhibition to sensitize triple negative breast cancer to EGFR inhibition. *First Author: Georges Azzi, University Of Miami/Sylvester Cancer Ctr, Miami, FL*

Background: Triple Negative Breast Cancer (TNBC) a subtype of breast cancer with the poorest prognosis lacks expression of estrogen progesterone receptors and does not overexpress HER2. Currently, there are no effective targeted therapies. TNBC frequently overexpresses EGFR, a member of the ErbB family of transmembrane receptor tyrosine kinases. Although EGFR targeted therapies are approved and used widely in lung cancer and head and neck cancer, their use in breast cancer has not revealed significant activity. Previous studies in lung cancer have shown that Rac1 overexpression results in resistance to EGFR inhibition. Rac1, a Rho GTPase, is frequently overexpressed in breast cancer. We have previously reported that Rac inhibition may be an effective therapeutic strategy in breast cancer. Furthermore, we have previously shown that EGFR over-expression results in resistance to Rac inhibition in breast cancer. The aim of the current study was to assess the activity of gefitinib (an EGFR tyrosine kinase inhibitor) and a Rac inhibitor (EHT1864) alone or in combination in TNBC. **Methods:** Using proliferation and clonogenic assays we assessed the activity of gefitinib (2.5 μM) and EHT1864 (25 μM), and their use in combination on the growth of TNBC breast cancer cell lines (MDA 231, MDA 468, MDA 436, HS578T). We also confirmed the pharmacological effect of gefinitib on EGFR with molecular knockdown of EGFR in HS578T cells. **Results:** All 4 cell lines tested did not show any significant growth reduction or difference in colony formation with either agent alone but the combination was effective in significantly reducing both growth and colony formation potential in 2 of the TNBC cell lines (HS578T and MDA468). The combination of shEGFR knockdown and Rac inhibition phenocopied the results of pharmacological inhibition with gefitinib plus EHT1864. **Conclusions:** Our results suggest that Rac inhibition sensitizes a subset of TNBC to EGFR inhibition and the combination of Rac and EGFR inhibition is a promising therapeutic strategy for a subset of TNBC that warrants further studies.

1085 Poster Session (Board #199), Sat, 8:00 AM-11:30 AM

Protein activation mapping and exploratory predictive markers for pCR in triple-negative breast cancer patients treated with neratinib in the I-SPY 2 TRIAL. *First Author: Julia Dianne Wulfkuhle, George Mason Univ, Columbia, MD*

Background: In the I-SPY 2 trial, the pan-ERBB inhibitor, neratinib (N) arm was open to all HR/HER2 subtypes but graduated in the HR-/HER2+ signature. Exploratory analysis of protein signaling was performed to identify biomarker candidates correlated with pCR in the TN population. We evaluated 110 key signaling proteins using reverse phase protein microarray (RPPA) data from pre-treatment LCM purified tumor epithelium. **Methods:** Of 59 TN patients, 49 (N: 30, concurrent controls: 19) had RPPA and pCR data. RPPA data was correlated to pCR in both the treated and untreated patients using parametric (t-test) or non-parametric (Wilcoxon) statistical analysis, depending on data distribution. Only analytes whose levels were associated with response in the N but not the control arm were selected for further analysis. Markers are analyzed individually; p-values are descriptive and were not corrected for multiple comparisons. ROC analysis identified an optimal cut point and pCR rates of biomarker positive patients were assessed using that cut point. **Results:** Out of 110 analytes analyzed, only activation of HER2 Y1248, p = 0.03; EGFR Y1173, p = 0.009; were found to be positive predictors of pCR, and 3 proteins, TIE2 Y992, p = 0.02; LC3B, p = 0.02, and A-RAF S299, p = 0.0008, were found to be negative predictors of pCR. pCR rates in the biomarker positive group of 62.5% (10/16), 66% (11/16), 55%(10,/18), 67% (12/17). 61% (11/18) were determined for phospho- HER2, EGFR, TIE2, A-RAF and total LC3B, respectively, compared to a pCR rate of 40% ffor the IHC/FISH-based TN subgroup where RPPA data were available. **Conclusions:** Our sample size is too small to draw definitive conclusions. However, activation of HER2-EGFR in HER2- tumors may identify patients who respond to N. Low levels of activated A-RAF and LC3B also correlated with response. The results imply that there is a subset TN patients that paradoxically exhibit HER family signaling activation and may achieve clinical benefit with N. These findings merit future consideration as we develop trials for patients with suboptimal response to neoadjuvant therapy where biomarkers could be used as the basis for treatment reassignment. Clinical trial information: NCT01042379.

1086 Poster Session (Board #200), Sat, 8:00 AM-11:30 AM

Characterization of KCNK9 in The Cancer Genome Atlas breast cancer dataset. *First Author: Keith A. Dookeran, Division of Epidemiology and Biostatistics, School of Public Health, University of Illinois at Chicago, Chicago, IL*

Background: Background: KCNK9 is a maternally imprinted and functionally mono-allelic 2-pore domain K+ channel proto-oncogene. It has been posited that loss of KCNK9 methylation (LOM) is associated with more aggressive triple negative (TN) phenotype breast cancer. Epidemiologic data characterizing KCNK9 is sparse and was the rationale for this study. **Methods:** Publically available breast cancer data from The Cancer Genome Atlas on clinical factors and KCNK9 gene methylation (HM450 beta values), amplification (putative copy-number alterations (CNA) from GISTIC), and mRNA expression Z-scores (RSEM) was examined in 818 women. Multivariable (MV) logistic regression models with model-based standardization were used to estimate risk ratios (RRs) with 95% confidence intervals (CIs). **Results:** Overall, KCNK9 gene amplification was more common than deletion (58% vs. 6%, respectively). Bivariate results for KCNK9 LOM (highest tertile loss vs. others), gene amplification (CNA gain vs. normal), and mRNA expression (highest tertile vs. others) are provided in the table below. Median overall survival for women with gain was 103 vs. 140 months (log-rank test, p= 0.011), and 96 vs. 130 months for higher vs. lower expression (p=0.014), but was not different for LOM. **Conclusions:** KCNK9 gene LOM, amplification and higher mRNA expression occur more frequently in black women, and ER/PR-negative and TN disease, and amplification and expression are associated with worse survival outcome.

KCNK9	LOM			Amplification			mRNA expression		
Characteristic	RR	95% CI	p	RR	95% CI	p	RR	95% CI	P

1087 Poster Session (Board #201), Sat, 8:00 AM-11:30 AM

Expression and significance of the co-regulatory ligands B7-H4 and PD-L1 in triple negative breast cancer. *First Author: Mehmet Altan, Yale Cancer Center/Yale School of Medicine, New Haven, CT*

Background: B7-H4 is a member of the CD28/B7 family of immune co-inhibitory molecules and is upregulated in various tumors. It has been postulated that it functions as a negative regulator of effector T-cells. Here, we measured the levels of B7-H4 and PD-L1 protein in triple negative breast cancers (TNBC) using objective methods and determined their relationship with tumor infiltrating lymphocytes (TILs) and patient outcome. **Methods:** We used automated quantitative immunofluorescence (QIF) to assess the levels of B7-H4 (clone D1M8I, CST) and PD-L1 (clone E1L3N, CST) in 96 stages I-IV TNBC represented in tissue microarray format [YTMA149]. B7-H4 and PD-L1 were measured in the tumor and stromal compartments by simultaneous staining of pancytokeratin (Dako) and DAPI. The proportion of stromal TILs was assessed in H&E stained preparations by a pathologist using 10% increments, as recently reported. Cases with more than 50% stromal TIL content were considered as lymphocyte predominant breast carcinomas (LPBC). **Results:** B7-H4 expression was detected in 83 % of cases (80/96) and PD-L1 in 9% (9/96). In samples with high B7-H4 levels, the signal was predominantly located in the tumor compartment. Elevated PD-L1 was seen both in tumor and stromal cells. LPBC corresponded to 28% of cases (26/96) and were significantly associated with tumor and stromal PD-L1 expression (Table). Expression of B7-H4 was not associated with LPBC or PD-L1 positivity. Regression analysis of PD-L1 and B7H4 is suggestive of an inverse relationship. In univariable survival analysis expression of B7-H4 and PD-L1 were not significantly associated with overall survival. **Conclusions:** B7-H4 is expressed in the majority (~80%) of TNBC, but is not associated with the lymphocyte infiltrates. PD-L1 expression occurs in a lower proportion of TNBC (~10%) and shows strong association with LPBC. Most cases that are high for B7H4 are low for PD-L1, suggesting that expression of these checkpoints may be specific to tumor regions or types. Futures studies are required to better understand the relationship between these two immune checkpoints.

Protein Expression	High TILs	Low TILs	P value
Tumor stroma PD-L1	194 ± 18	324 ± 28	<0.0005
Tumor PD-L1	219 ± 15	299 ± 30	<0.012

1088 Poster Session (Board #202), Sat, 8:00 AM-11:30 AM

Clinical utility of in depth RNA sequencing for non-metastatic triple negative breast cancers. *First Author: Benoit Thouvenot, GENCLIS, Vandoeuvre-Les-Nancy, France*

Background: Triple negative breast cancers (TNBC), that represent the most severe form of the disease, are not amenable to current targeted therapies. RNA DNA divergences (RDD) reflect changes in RNA sequences not present at the DNA level. **Methods:** DNA and RNA from fresh frozen samples collected from 65 patients diagnosed with non metastatic TNBC before the age of 65 Y were sequenced with Illumina. The cohort was divided in a training set (n = 20) -9 alive after 2500 days of follow up and 11 dead within 1000 days following diagnosis- and a blind replication set (n = 45). **Results:** On the training set, sparse PLS discriminant analysis identified 5 transcripts with statistically significant different RDD rate that, when combined, separated patients with good and poor outcome with greater than 90 % accuracy after cross validation. Kaplan-Meier analysis showed that application of the RDD based algorithm to 45 unknown samples was highly predictive of clinical outcome ($p < 10^{-4}$). Most importantly, RDD algorithm accurately predicted outcome of patients with in situ, stage I and II TNBC (n = 53), 36 were predicted with good outcome and all are alive at the last follow-up irrespective of chemotherapy (n = 10 received no post-surgery treatment). RDD algorithm performances were not affected by patients ethnic origin, recruitment centers (n = 11), BRAC mutation, nor menopausal status. Neither positive lymph node (p = 0.09), nor tumor size (p = 0.89), nor Ki67 (p = 0.84), nor an expression-based model (p = 0.82) were statistically significant predictors of TNBC clinical outcome. **Conclusions:** RDD are previously unsuspected molecular events strongly associated with TNBC severity. The most immediate clinical application of the finding is to eliminate the need for conventional and potentially harmful chemotherapy for patients with predicted good outcome. Patients included in the current analysis were mostly from the USA. Therefore, a larger retrospective study based on an european cohort (Patients and Methods of the PATH Biobank – A Resource for Breast Cancer research; Waldmann A et al. Geburtshilfe Frauenheilkd. 2014 Apr;74(4):361-369) and powered to statistically ascertain the accuracy of the test, is currently undergoing in depth RNA sequencing.

1089 Poster Session (Board #203), Sat, 8:00 AM-11:30 AM

Prognostic markers in triple-negative breast cancer (TNBC): The role of androgen receptor, e-cadherin, and Ki67. *First Author: Giuseppina Rosaria Rita Ricciardi, Medical Oncology Unit AOOR Papardo-Piemonte, Department of Human Pathology, University of Messina, Messina, Italy*

Background: TNBC represents a group of tumors with poor prognosis owing to aggressive tumor biology and lack of targeted therapies. However, TNBC is clinically and biologically heterogeneous and no clear prognostic biomarker has been identified. We evaluated the prognostic value of various clinical-pathological variables, including androgen receptor (AR), E-cadherin (CDH1) and Ki67. **Methods:** This is an observational, retrospective study of 99 patients (pts) with TNBC diagnosed during 2000-2010 in two Italian hospitals. All pts received neo/adjuvant chemotherapy (mostly anthracycline/taxane-based). Immunohistochemistry (IHC) of the primary tumors was performed in formalin-fixed paraffin-embedded primary tumor samples. CDH1 expression was considered positive as ≥ 30% of the membrane cells staining. AR positivity was defined as > 10% of positive tumor cells. High Ki67 was defined as > 14% positive tumor cells. Cox proportional hazard univariate and multivariable models were used to evaluate the associations of each variable with relapse-free survival (RFS) and overall survival (OS). Distribution of samples within groups was compared using a Chi-square test. **Results:** Median age was 61 years (range 33-83). The majority of tumors were ductal (n = 85, 85.8%), node-negative (n = 49, 58.3%), grade 3 (n = 66, 66.7%) and showed high Ki67 (n = 74, 74.7%). The distribution of tumor stage was I (n = 32, 32.3%), II (n = 37, 37.4%), III (n = 30, 30.3%). AR, CDH1 expression was found in 17.1% and 50.5% of the cases. Only 26.6% of AR-positive cases were grade 3 compared with 68.2% of grade 3 in AR-negative cases (p =0.01). At median follow-up of 62.0 months (range 3.0-118.0), 95 pts were evaluable for RFS and OS. Univariate analyses showed that lack of expression of CDH1, tumor size and nodal status were significantly associated with worse RFS and OS (p< 0.05). AR expression and low Ki67 showed a trend towards better RFS and OS. Multivariate analysis showed an independent association between CDH1 expression and better RFS and OS (p< 0.05) beyond tumor size, nodal status and grade. **Conclusions:** Our findings support the potential prognostic value of molecular biomarkers such as CDH1 that might be useful to classify subgroups of TNBC.

1090 Poster Session (Board #204), Sat, 8:00 AM-11:30 AM

Programmed cell death 1 (PD-1) receptor and programmed death ligand 1 (PD-L1) expression in primary breast cancer (BC); correlations with clinical characteristics and patient outcomes. *First Author: Neelima Vidula, UC San Francisco, San Francisco, CA*

Background: The interaction of the PD-1 receptor on tumor infiltrating lymphocytes and PD-L1 on tumor cells dampens antitumor immunity. Two phase I trials suggested efficacy of anti-PD-1/PD-L1 antibodies in triple negative (TN) BC. This study investigated associations between primary BC PD-1 and PD-L1 expression, clinical characteristics, and patient outcomes in publically available databases. **Methods:** We evaluated PD-1 and PD-L1 expression using microarray data from the neoadjuvant I-SPY 1 study (n = 149). Associations with clinical features and chemotherapy response were assessed by Kruskal-Wallis and Wilcoxon rank sum tests, respectively. Recurrence free survival (RFS) associations were assessed by the Cox proportional hazard model. Pearson correlations between PD-1 and expression of PD-L1, HAVCR2, STAT5A, FOXP3, MYC, and ESR1 were determined in I-SPY 1 and 2 other datasets: METABRIC (n = 1992) and TCGA (n = 817). **Results:** In I-SPY 1, PD-1 expression was significantly higher in HER2+ and TNBC (p = 0.003), and in grade 2/3 tumors (p = 0.043); this association was also seen in METABRIC. PD-1 expression was associated with pathologic complete response (p = 0.006) but not with tumor stage, nodal status, lymphovascular invasion or RFS. While PD-L1 did not correlate with tumor features, patients with PD-L1 expression in the lowest quintile had worse RFS, even after subtype adjustment (HR 2.33, p = 0.01). In all 3 datasets, PD-1 significantly correlated with PD-L1, HAVCR2, and STAT5A, and inversely with ESR1. In the TN subset of TCGA and METABRIC, PD-1 significantly correlated with PD-L1, HAVCR2, and STAT5A. In TCGA and METABRIC, PD-L1 significantly correlated with HAVCR2 and STAT5A, and this was also seen in the TN subset. In TCGA alone, PD-1 and PD-L1 significantly correlated with FOXP3, and PD-1 with MYC. **Conclusions:** PD-1 expression is higher in TN and other aggressive BC subtypes. PD-1 and PD-L1 correlate with immune related genes HAVCR2 and STAT5A. Low PD-L1 expression may be an adverse prognostic factor. Trials are underway to investigate the activity of anti-PD-1/PD-L1 antibodies in TNBC and to elucidate markers of response.

1091 Poster Session (Board #205), Sat, 8:00 AM-11:30 AM

Reproducibility of homologous recombination deficiency (HRD) scores in biopsies of triple negative breast cancer (TNBC) tumors. *First Author: Kirsten Timms, Myriad Genetics, Inc., Salt Lake City, UT*

Background: The HRD score is the sum of three previously described (Abkevich et al, Birkbak et al, Popova et al) metrics that quantitate genomic rearrangements. The HRD score is significantly associated with both tumor *BRCA1/2* mutations (tmBRCA) and response to DNA damaging agents in TNBC. This study assesses the consistency of the HRD score in multiple biopsies obtained from the same cancer to examine the impact of spatial heterogeneity and sampling on the results. **Methods:** HRD scores, tmBRCA, and *BRCA1* promoter methylation were assessed in 96 samples from 32 surgically resected, stage II-III breast cancers; each cancer was biopsied in three distinct areas. HR deficiency was defined as having either high HRD score ($\geq$ 42) or tmBRCA positive. **Results:** A total of 81 samples (31 tumors) yielded DNA for sequencing and generated 81 tmBRCA calls and 76 BRCA1 methylation values passing QC metrics. HRD scores were obtained for 70 (86%) samples, leaving 16 triplets and 7 duplicates available for reproducibility analysis, and 8 singles. High HRD scores were observed in all biopsies that were tmBRCA positive (3 triplets; 1 single) or *BRCA1* methylation positive (2 triplets). *BRCA1/2* mutation and *BRCA1* methylation were consistent within all replicates. *BRCA1/2* wild type tumors without *BRCA1*methylation had high HRD scores in 4 tumor sets (1 triplet; 3 pairs). The average standard deviation (SD) within replicates was 2.6 with a coefficient of variation (CV) of 9%. SD was slightly higher in samples with higher scores but the difference between low and high HRD scores was not significant (Wilcoxon p = 0.18). HR deficiency status was the same in different biopsies from each of the 31 tumors; however, observable differences were apparent between the genomic profiles. **Conclusions:** All HRD metrics examined were consistent across the multiple repeat biopsies from different regions of the same cancer. While observable changes in the genomic profiles of matched samples were noted indicating subtle within-tumor spatial genomic heterogeneity, the HRD scores were highly conserved.

1092 Poster Session (Board #206), Sat, 8:00 AM-11:30 AM

Outcomes with neoadjuvant versus adjuvant chemotherapy for T1-2 node negative triple negative breast cancer. *First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

Background: Randomized studies have demonstrated that Neoadjuvant Chemotherapy (NAC) is equivalent to adjuvant chemotherapy (AdjC) in operable breast cancer (BC). However, the differential impact of NAC vs AdjC on outcomes in various BS subtypes is not known. Specifically, the impact of AdjC vs NAC BC outcomes in small (T1-2) clinically node negative (NN) triple negative breast cancer (TNBC) is not known. Aim: To evaluate the impact of NAC vs. AdjC on BC recurrence and RFS in NN T1-2 TNBC utilizing data from a prospective registry. **Methods:** 316 stage I-III TNBC patients enrolled in a multisite IRB approved registry between 2011 and 2014. Clinical, demographic, chemotherapy and recurrence information was collected. This study was restricted to analysis of registry participants with T1-2, NN disease. RFS was estimated according to the Kaplan-Meier method and compared among groups with log-rank statistic. **Results:** 146 patients with NN T1-2 TNBC enrolled on the registry since 2011. Patients underwent either NAC (67/146, 46%) or AdjC (79/146, 54%) at the discretion of treating physician. For the 146 eligible patients, median age was 55 yrs (range 24-80), 14%: African American, 49% had T1 and 51% had T2 disease. Almost all patients received Anthracyline and/or taxane containing chemotherapy (AdjC: 95%, NAC: 100%). Compared to AdjC patients, NAC patients were younger (median age 52 vs 58 yrs, p = 0.015), more likely to have T2 tumors (76% vs 29%, p < 0.001), more likely to be treated at academic center (91% vs 24%; p < 0.001) and more likely to have received > 4 cycles of chemotherapy (85% vs 53%; p = 0.001). PCR was observed in 55% of NAC cohort (37/67). Overall, at a median follow of 37 months (6-89) there have been 8 (5%) recurrences (1/67 in NAC group & 7/79 in AdjC group). RFS in NAC group was 98% vs. 91% in AdjC group (p = 0.07). On multivariate Cox regression analysis, AdjC (compared to NAC) was the only factor demonstrating a trend towards worse RFS (p = 0.080). **Conclusions:** Patients with NN, T1-2 TNBC demonstrate excellent outcome when treated with NAC (98% RFS). Compared to AdjC, NAC was associated with a trend towards better RFS in NN T1-2 TNBC. In patients with clinically node negative TNBC, NAC should be compared to AdjC prospectively.

1093 Poster Session (Board #207), Sat, 8:00 AM-11:30 AM

Transcriptomic and protein expression analysis of helicase antigen (HAGE) in triple negative breast cancer (TNBC) as a novel prognostic and predictive biomarker. *First Author: Tarek M. A. Abdel-Fatah, Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom*

Background: We recently provided evidences that HAGE is immunogenic. In current study, the expression of HAGE as a prognostic and predictive tool was assessed in 1079 TNBC patients. **Methods:** HAGE protein and mRNA expressions were investigated in two cohorts of BC who received adjuvant chemotherapy (CT) with 10 year median follow up: (1) early primary TNBC (EP TNBC; n = 520) and (2) the METABRIC TNBC (n = 317) cohorts, respectively. The relationship between HAGE protein and mRNA expressions and response to CT was explored in two TNBC cohorts in whom pathological complete response (pCR) was the endpoint: (3) the multicentre phase II clinical trial cohort (NCT00455533; n = 132) received doxorubicin/cyclophosphamide neoadjuvant-CT (Neo-ACT), followed by 1:1 randomisation to ixabepilone (n = 68) or paclitaxel (n = 64) and (4) a locally advanced primary TNBC cohort (LAP TNBC, n = 110) received anthracycline-based Neo-ACT (AC-Neo-ACT), respectively. To investigate HAGE interactome in TNBC, a non-linear, artificial neural network (ANN) modelling based, data mining approach was applied. **Results:** In CT naïve EP TNBC, high (+) HAGE protein expression had a higher risk of death compared to low (-) HAGE expression (HR (95% CI) = 1.4 (1.2-1.7, p = 0.0000004). While in EP TNBC patients who received adjuvant CT, HAGE mRNA+ level exhibited lower risk of death compared to HAGE mRNA- (HR (95% CI) = 0.56 (0.36-0.86), p = 0.0.008). In LAP TNBC received AC-Neo-ACT, pre CT HAGE+ expression was: linked to tumour infiltration lymphocytes (TILs, p < 0.001), found to be independent predictor for pCR [OR (95%CI) = 5.1 (1.2-22.4), p = 0.03] and significantly associated with prolonged survival (HR (95% CI) = 0.54 (0.41-0.85), p = 0.0.005). Following AC-Neo-ACT, loss of HAGE protein expression was found (p = 0.002) and patients with HAGE+ residual disease exhibited no TILs and had two fold increase in the risk of death (HR (95% CI) = 1.66 (1.10-2.52), p = 0.0.018) compared to HAGE- residual tumours. HAGE interactome included genes that involved in protein degradation and antigen presentation **Conclusions:** The expression of HAGE is a potential prognostic marker and a predictor of response to AC CT in TNBC.

1094 Poster Session (Board #208), Sat, 8:00 AM-11:30 AM

Association of tumor BRCA1 reversion mutation arising during neoadjuvant platinum-based therapy in breast cancer (BC) with therapy resistance. *First Author: Anosheh Afghahi, Stanford University School of Medicine, Stanford, CA*

Background: In germline BRCA1 or BRCA2 mutation carriers, restoration of tumor BRCA1/2 function by a secondary mutation in these genes has been recognized as a mechanism of acquired resistance to platinum and PARP inhibitors, primarily in ovarian cancer. We set out to evaluate this mechanism of resistance in newly diagnosed BRCA1/2-mutant BC patients (pts) with a poor response to platinum-based therapy. **Methods**: PrECOG 0105 was a single-arm phase II study in pts with clinical stage I-IIIA triple-negative (TN) or BRCA1/2 mutation-associated BC. Pts received neoadjuvant therapy with gemcitabine, carboplatin and iniparib every 21 days for 6 cycles (n = 80). The primary endpoint was pathologic complete response, defined as no invasive carcinoma in the breast and axilla. In addition to comprehensive germline BRCA1/2 testing, all pts underwent tumor BRCA1/2 genotyping using pre-treatment biopsies. For mutation carriers with unfavorable response (moderate or extensive residual disease at surgery), tumor BRCA1/2 status was re-sequenced in the residual surgical tissue. All testing was performed at Myriad Genetics. **Results**: 19 pts had a deleterious germline BRCA1/2 mutation, and of these 4 had moderate residual disease at surgery. BRCA1/2 sequencing of residual tissue was available in 2 of 4 pts (no consent in 1 case; inadequate DNA extraction in 1 case). These 2 pts had BRCA1 1479delAG and W1712X mutations with LOH at these loci in the pre-treatment tumor. In the first case, a new BRCA1 mutation (a 42 base pair [bp] deletion that overlapped with the original 2 bp deletion) was detected in the residual tissue. This resulted in a 14 amino acid deletion and restoration of the BRCA1 reading frame. A relapse biopsy 4 months later revealed the identical reversion mutation and the pt subsequently died of metastatic TNBC. No reversion mutation was observed in the residual tissue of the second BRCA1 carrier, who notably had ER/PR+ BC. **Conclusions**: We report a BRCA1 reversion mutation in a newly diagnosed TNBC pt that developed over the course of 18 weeks of platinum-based neoadjuvant therapy. This was associated with poor neoadjuvant therapy response, early relapse and death from metastatic BC.

1095 Poster Session (Board #209), Sat, 8:00 AM-11:30 AM

Evaluation of local and distant recurrences pattern in patients with triple negative breast cancer according to age. *First Author: Julia Caroline Radosa, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Triple negative breast cancer (TNBC) and young patient age are both associated with an increased risk of local (LR) and distant recurrence (DR). In young women with TNBC it is unclear whether age or subtype is driving prognosis. Here we examine outcomes in a large population of patients with TNBC according to age. **Methods:** Our prospectively maintained database was reviewed to identify all patients treated for primary TNBC from 1998 to 2011. Clinical data and outcomes were abstracted from medical records. Comparisons were made between patients < 40 and ≥ 40 years of age at diagnosis and multivariate models adjusted for disease stage, grade and treatment were used to identify factors independently associated with LR and DR. Cumulative incidence of LR and DR and disease free survival (DFS) were compared using competing risks methodology and log-rank tests. **Results:** Among 1930 patients with TNBC, 289 (15%) were < 40 and 1641 (85 %) were ≥ 40 years of age at diagnosis. Younger patients were more likely to have larger tumors (median 2.0 cm vs 1.7 cm, $p = 0.001$), positive nodes (47% vs 36%, $p = 0.022$), to receive mastectomy (61 % vs 42 %, $p < 0.0001$) and adjuvant chemotherapy (91 % vs 81 %, $p < 0.0001$). On univariate analysis there was no difference in LR by age (5 yr LR = 6% in both groups), although in the subset (n = 1066) treated with breast conserving therapy (BCT), patients < 40 had higher rates of LR (5 yr LR = 10% vs 6%, $p = 0.03$). Cumulative incidence of DR was higher for younger patients (5 yr DR = 20% vs 14%, $p = 0.04$). At a median followup of 74 months (0-201) there was no difference in DFS by age (6-yr DFS = 74% under 40 vs 75% ≥ 40). On multivariate analysis, BCT, nodal positivity, larger tumor size and no chemotherapy were associated with increased risk of LR. Larger tumor size, LVI and nodal positivity were associated with increased risk of DR. Age was not associated with either LR or DR. **Conclusions:** In this large population of women with TNBC treated at a single institution, younger patients were more likely to present with higher stage disease and experienced higher rates of LR when treated with BCT. However, after adjusting for stage, grade and treatment young age was not associated with an increased risk of local or distant recurrence.

1096 Poster Session (Board #210), Sat, 8:00 AM-11:30 AM

Effect of the anti-Warburg agent BPM 31510 on TAC therapy synergy and survival in a xenograft model of triple-negative breast cancer (TNBC). *First Author: Niven R. Narain, Berg, Framingham, MA*

Background: High glycolytic metabolism in breast cancer is known to support tumor progression and metastasis, and a unique glycolysis signature has been identified in ER- and triple-negative (TNBC) breast tumors. Here, the therapeutic effect of the anti-Warburg agent BPM 31510 (in clinical trials for solid tumors) was investigated alone and in combination with standard-of-care chemotherapy in a murine xenograft model of TNBC. **Methods:** Treatment cycles included TAC (5mg/kg docetaxel, 1 mg/kg doxorubicin, 35 mg/kg cyclophosphamide, 1x week) and/or BPM 31510 (75 mg/kg, IV 1x day) administered in cycles (3 weeks on, 1 week off) to MDA-MB231 tumor-bearing mice. Survival was assessed. A subset of tumors were analyzed histologically after 2 cycles of treatment. *In vitro* models were used to define mechanistic underpinnings. **Results:** BPM 31510 or chemotherapy alone improved survival; however, BPM 31510 monotherapy was associated with more than a 6 week increase in survival compared to TAC alone. BPM 31510 in combination with chemotherapy further attenuated tumor growth and enhanced survival compared to either treatment alone. Cleaved caspase 3 levels were higher in tumors from BPM 31510-treated mice, demonstrating activation of apoptosis in response to this treatment. A panel of primary, non-tumorigenic, and breast cancer cells was used to determine IC_{50} values for BPM 31510 *in vitro*. At doses comparable to circulating levels achieved *in vivo*, BPM 31510 exposure was selectively cytotoxic in cancer cells with the triple-negative MDA-MB231 cells demonstrating maximal sensitivity to cell death. Interestingly, although cellular proliferation rate was not predictive of anti-cancer responses to BPM 31510, a bioenergetic signature characterized by high glycolytic flux and low mitochondrial respiration was highly correlated with sensitivity to BPM 31510-induced cell death. **Conclusions:** These data demonstrate that BPM 31510 is effective as a single agent in breast cancer. When used in combination with chemotherapy, BPM 31510 augments survival, particularly in distinctly glycolytic TNBC, a sub-type for which prognosis is poor and few therapeutic options exist.

1097 Poster Session (Board #211), Sat, 8:00 AM-11:30 AM

A 3-gene expression score as prognostic factor in triple negative and basal breast tumors with residual disease. *First Author: Joseph A. Pinto, División de Investigación, Oncosalud, Auna, Lima, Peru*

Background: Residual disease after neoadjuvant chemotherapy (NAC) in triple negative breast cancer (TNBC) represents poor prognosis. Identification of genes involved in prognosis could lead to a better stratification of patients and better design of therapeutic strategies. Our aim was to identify gene signatures related to the recurrence free survival (RFS) in this subset of patients. **Methods:** We quantified expression for 450 genes by Nanostring in 82 triple negative residual tumors after NAC (discovery group). Levels of gene expression were normalized to spike controls then log2 transformed and median centered. The validation group consisted in 117 basal breast tumors with residual disease (from the public dataset GSE25066) profiled with the U133A microarray. Samples in this dataset were evaluated before NAC. **Results:** An univariate Cox regression identify 7 genes significantly related with the RFS (CCL5, CYBB, DDIT4, GTPBP4, KRT6B, PALMD and POLR1C). A stepwise multivariate analysis selected to CCL5, DDIT4 and POLR1C as independent factors for RFS. Using the regression coefficient for each gene we constructed a score (-0.393*CCL5 + 0.443*DDIT4 + 0.490*POLR1C). The median of score was 0.1494. The CoxPH show an HR = 2.72 per unit of change ($P < 0.001$; CI95%: 1.72-4.28). The median score in the validation set was -0.036 and the score was significant related with the RFS with an HR = 15.86 per unit of change ($P < 0.045$; CI95%: 1.06-237.11). Using the logrank test and the median scores as cutoff (for each group), it was possible identifies two subgroups with different RFS ($P < 0.001$ in the discovery group and $P < 0.003$ in the validation group). **Conclusions:** We could identify a prognostic score based in CCL5, DDIT4 and POLR1C expression related with the recurrence free survival. A deep evaluation of the molecular mechanisms of these genes in resistance to chemotherapy should be done.

1098 Poster Session (Board #212), Sat, 8:00 AM-11:30 AM

TOP2A-based prognostication in triple negative breast cancer and correlation with basal phenotype. *First Author: Benjamin C. Calhoun, Cleveland Clinic Foundation, Cleveland, OH*

Background: Patients with triple-negative breast cancer (TNBC) are ineligible for endocrine and HER2-trageted therapy and remain at high risk for relapse after treatment. Most TNBC are basal-like (BL) but recent studies identified additional subtypes of TNBC. Immunohistochemistry (IHC) for various markers has been reported to correlate with clinical outcomes, but many studies are based on relatively limited IHC panels. We applied a large IHC-based marker set in a TNBC cohort to evaluate their potential for prognostic and predictive modeling **Methods:** Archived tissue samples from a prospectively maintained registry of 145 TNBC patients (mean age 57.2 years; median follow up 3.8 years) were used to investigate associations between marker expression and time-to-progression. Progression was defined as local, regional, or distant recurrence. IHC for EGFR, HMWCK (high molecular weight cytokeratin), TOP2A, BCL2, and AR was performed. Simple data imputation was used for missing protein data as complete case analysis (no missing data) resulted in a sample size of 82. Positive was defined as $>$ 10% for AR and $>$ 0% (any staining) for EGFR and HMWCK.TOP2A and bcl2 staining was recorded in 5% increments and optimal cut-points relative to time-to-progression were used to define positivity and negativity. Cox proportional hazard models were used to examine associations between expression and progression. A random forest classification tree approach was used to identify potential co-expression between proteins **Results:** TNBC expressed HMWCK, EGFR, AR, TOP2A, and BLC2 in 76.6, 86.2, 13.1, 58.6, and 12.4% of cases, respectively. With an optimal derived cutoff of 40%, TOP2A expression was associated with shorter time to progression (HR = 2.01; p = 0.059) while the expression of BCL2 (optimal cut-off: 60%) was not (HR = 0.18; p = 0.087). Sixty-seven (46.2%) cases showed co-expression of HMWCK, EGFR, and TOP2A. TOP2A was consistently correlated with HMWCK (66% agreement in positivity) and c-MET (43% agreement in positivity) per the classification tree **Conclusions:** Results indicate a potential correlation of TOP2A with the BL phenotype of TNBC and provide a rationale for further investigation into tailored therapy for TNBC.

1099 Poster Session (Board #213), Sat, 8:00 AM-11:30 AM

Neratinib to inhibit the growth of triple-negative breast cancer cells. *First Author: Maeve Mullooly, Education and Research Centre, St.Vincent's University Hospital and School of Medicine and Medical Science, University College Dublin, Dublin, Ireland*

Background: An urgent problem in breast cancer treatment is the identification and validation of a targeted therapy for triple-negative breast cancer (TNBC), ie, breast cancer negative for ER, PR and HER2. Neratinib is a low molecular weight irreversible pan-HER inhibitor that selectively targets the tyrosine kinase activity of EGFR, HER2 and HER4. To-date, neratinib has been exclusively investigated in HER2-positive tumors. However, as neratinib also targets EGFR expression, we hypothesised that it may also have clinical efficacy in TNBC. **Methods:** The anti-proliferative effects of neratinib were investigated in 14 TNBC cell lines. To identify potential biomarkers of response, we examined the expression of baseline EGFR, HER2, HER3 and HER4 using reverse phase protein array (RPPA) analysis and flow cytometry analysis. **Results:** IC_{50} values for neratinib across the 14 TNBC cell lines ranged from 0.06 μM to 1.9 μM. However, basal A-type cells were significantly more sensitive to neratinib than basal B-type cells (p = 0.024). No relationship was observed between IC_{50} values for neratinib and levels of EGFR, phospho-EGFR, HER2 or phosphor-HER2. In contrast, a significant correlation was detected between response and HER3 levels (with flow cytometry, r = -0.612, p = 0.020; with reverse phase protein arrays, r = -0.55, p = 0.043), suggesting that levels of HER3 may identify response to neratinib in this subset. Using a larger panel of 35 breast cancer cell lines of all molecular subtype, we found a significant relationship between the IC_{50}values for neratinib and those previously reported for another pan-HER inhibitor, i.e., dacomitinib ($p < 0.001$; r = 0.65). **Conclusions:** Based on our findings *in vitro*, further studies are required to further investigate the clinical potential of neratinib treatment in TNBC. Acknowledgements: The authors wish to thank Science Foundation Ireland, Strategic Research Cluster Award (08/SRC/B1410) to MTCI and the Science Foundation Ireland Short Term Travel Fellowship Award for funding this work.

TPS1100 Poster Session (Board #214a), Sat, 8:00 AM-11:30 AM

Cardiac toxicity prevention in non-metastatic breast cancer patients treated with anthracycline-based chemotherapy: A randomized, placebo controlled, phase III trial—SAFE trial. *First Author: Icro Meattini, Florence University, Florence, Italy*

Background: Anthracyclines and trastuzumab play a key-role in preoperative and adjuvant breast cancer (BC) treatment, and showed a significant survival benefit in several trials. Although acute cardiac toxicity is infrequent and usually reversible in a dose-dependent manner, published data evidenced a clinically relevant early late cardiac toxicity, with a chronic progressive deterioration of left ventricular ejection fraction (LVEF), up to congestive heart failure (CHF). Late toxicity occurs in most cases within the first year following chemotherapy completion, but an echocardiographic monitoring is strongly recommended even after a longer time. Recent studies highlighted that the evaluation of myocardial strain could be a refined predictive marker of early cardiac dysfunction after anthracyclines exposure. The aim of our study is to find out the best approach as cardiac toxicity prevention in non-metastatic BC patients undergoing anthracycline-based chemotherapy, with or without subsequent anti-HER2 therapy. **Methods:** This is a randomized phase III, four-arm, single-blind, placebo-controlled study that aims to evaluate the effect of bisoprolol (5 mg, twice daily), ramipril (5 mg, twice daily), or both drugs, compared to placebo, on anthracycline therapy induced LVEF dysfunction for non-metastatic disease. Cardioprotection is administered for one year, or until the end of trastuzumab (if HER2 positive). All patients undergo cardiac surveillance with echocardiogram and speckle tracking strain at baseline and every three months, until 2 years. Primary endpoint is maximum change in LVEF. Assuming a cardiac toxicity incidence of 40%, with a 15% reduction in both arms to reach the outcome, a sample of 120 patients per arm provides a 90% statistical power, for a total of 480 enrolled patients. The analysis is based on intent-to-treat. Exclusion criteria are: history of CTCAE (v.4) grade $>$ 2 symptomatic CHF, previous myocardial infarction, significant symptoms (grade $>$ 2) relating to LVEF dysfunction, valvular disease, cardiac arrhythmia (grade $>$ 3). Clinical trial information: NCT2236806.

TPS1101 Poster Session (Board #214b), Sat, 8:00 AM-11:30 AM

A randomized phase III trial comparing two dose-dense, dose-intensified approaches (EPC and PM(Cb)) for neoadjuvant treatment of patients with high-risk early breast cancer (GeparOcto). *First Author: Andreas Schneeweiss, Heidelberg University, Heidelberg, Germany*

Background: The sequential use of dose-dense, dose-intensified epirubicin, paclitaxel, and cyclophosphamide (EPC) (Möbus et al. J Clin Oncol 2010) as well as weekly treatment with paclitaxel/liposomal doxorubicin (plus carboplatin in triple negative disease, TNBC) (PM(Cb)) (von Minckwitz et al. Lancet Oncol 2014), both with dual HER2 blockade in HER2+ breast cancer (BC), are considered highly efficient regimens for high-risk early stage BC patients and will be compared in the GeparOcto study. **Methods:** GeparOcto (NCT02125344) will randomize patients to 18 weeks EPC (E 150mg/m^2 q2w for 3 cycles, P 225mg/m^2 q2w for 3 cycles, C 2000mg/m^2 q2w for 3 cycles) or PM(Cb) (P 80mg/m^2 q1w concomitantly with M 20mg/m^2 q1w and, in case of TNBC, Cb AUC 1.5 q1w). Patients with HER2+ BC will receive trastuzumab 6 (8) mg/kg q3w and pertuzumab 420 (840) mg q3w concomitantly with all P, C, and PM(Cb) cycles. Patients with untreated, histologically confirmed, cT1c - cT4a-d BC and central receptor assessment can be included. Patients with HER2+ or TNBC are eligible irrespective of nodal status, luminal B-like tumors only if pN+. Primary objective is to compare pCR rates (ypT0/is ypN0). Sample size calculations assumed a pCR rate of 50% for EPC and 60% for PM(Cb), requiring 950 patients to show superiority of PM(Cb). Secondary objectives are to compare pCR rates between treatment arms within the stratified subpopulations (BC subtype [HER2+ HR+/- vs HER2- HR+ vs HER2- HR-], Ki-67 [$\leq$ 20 vs $>$ 20%], lymphocyte-predominant BC [no vs yes]), amongst others. Due to a high risk of chemotherapy induced anemia in both regimens, patients are also randomized to parenteral ferric carboxymaltose or physician's choice for treatment of iron deficient patients. **Results:** Recruitment started in 12/2014 and is planned for 18 months at 80-100 sites in Germany. 65 patients were recruited by 1st Feb 2015. **Conclusions:** GeparOcto investigates the efficacy of dose-dense dose-intensified EPC compared to weekly PM(Cb), both with dual HER2-blockade in HER2+ BC, in high-risk early stage patients and compares anemia management strategies. Clinical trial information: NCT02125344.

TPS1102 Poster Session (Board #215a), Sat, 8:00 AM-11:30 AM

Phase 3 randomized, placebo-controlled trial of carboplatin (C) and paclitaxel (P) with/without veliparib (ABT-888) in HER2-*BRCA*-associated locally advanced or metastatic breast cancer (BC). *First Author: Shannon Puhalla, Magee-Womens Hospital of UPMC, Pittsburgh, PA*

Background: *BRCA*-mutated tumors are more susceptible to platinum therapy and PARP inhibitors due to underlying defects in homologous recombination repair of DNA damage. In preclinical models the potent oral PARP1/2 inhibitor veliparib was shown to enhance sensitivity to C and to have single-agent activity in *BRCA*+ cell lines. Phase 1 trials suggest promising antitumor activity and acceptable toxicity of veliparib plus C/P in triple-negative BC (Puhalla et al. *Cancer Res* 2012;72[24 suppl]:PD09-06) and single-agent activity of veliparib in *BRCA*+ BC (Somlo et al. *J Clin Oncol* 2014;32[15 suppl]:abstr. 1021). This phase 3 trial assesses efficacy and toxicity of veliparib plus C/P vs C/P alone in patients with HER2− *BRCA*-associated locally advanced or metastatic BC (NCT02163694). **Methods:** Phase 3 randomized, double-blind, placebo-controlled, multicenter trial. Eligible patients (female or male; $\geq$ 18 years) have HER2−metastatic/locally advanced unresectable BC with (suspected) deleterious *BRCA1/2* germline mutations and received 2 or fewer prior lines of DNA-damaging chemotherapy for metastatic BC. In addition, patients must have received $\leq$ 1 prior line of platinum therapy (any setting) without progression within 12 months of completing treatment. Patients are randomized 2:1 to C/P with veliparib or C/P with placebo, stratified by estrogen and/or progesterone receptor expression, prior platinum therapy, and central nervous system metastases. Veliparib (120 mg p.o. BID) or placebo will be given on Days −2 to 5, C (AUC 6 mg/mL/min i.v.) on Day 1, and P (80 mg/m^2 i.v.) on Days 1, 8, and 15 (21-day cycles). Treatment continues until unacceptable toxicity or progressive disease (PD). Patients in the placebo arm who discontinue due to PD are eligible for crossover to veliparib monotherapy. The primary objective is to assess if the addition of veliparib to C/P increases progression-free survival; additional objectives include evaluation of overall survival, clinical benefit rate, objective response rate, quality of life, and safety. Enrollment began in July 2014 with a planned sample size of 270 patients. Clinical trial information: NCT02163694.

TPS1103 Poster Session (Board #215b), Sat, 8:00 AM-11:30 AM

POSNOC: Positive sentinel node—Adjuvant therapy alone versus adjuvant therapy plus clearance or axillary radiotherapy: A randomised trial looking at axillary treatment in early breast cancer (ISRCTN54765244). *First Author: Amit Goyal, Royal Derby Hospital, Derby, United Kingdom*

Background: Women with early breast cancer that has spread to 1 or 2 sentinel nodes (SNs) undergo axillary node clearance (ANC) or axillary radiotherapy (ART). The publication of the Z11 trial challenged this practice. There are however concerns about this trial which may limit the interpretation and generalisability of its results. These issues include the proportion of patients with micrometastases, variability in radiotherapy and applicability in patients undergoing mastectomy. Therefore further randomized trials are needed to define the role of axillary treatment in patients with 1 or 2 SNs with macrometastases. The UK-ANZ POSNOC trial is asking this question and will provide a more solid evidence base to inform clinical practice. **Methods:** Trial design: A pragmatic, randomized, multicenter, non-inferiority trial. Interventions:All participants will receive systemic adjuvant therapy according to local guidelines and radiotherapy to breast or chest wall if indicated. Women in the intervention group will receive systemic adjuvant therapy alone, whereas those receiving standard care will receive adjuvant therapy plus ANC or ART. Study population: Women with unifocal or multifocal invasive breast cancer($\leq$ 5 cm) undergoing breast conserving surgery or mastectomy, node-negative by clinical and ultrasound examination, who have 1 or 2 nodes with macrometastases at SN biopsy and no extranodal extension. The sample size is 1900 women. All participants will be followed up for 5 years. Primary outcome: axillary recurrence at 5 years. Secondary outcomes: arm morbidity, quality of life, anxiety, loco-regional recurrence, distant metastasis; time to axillary recurrence, axillary recurrence-free survival, disease-free and overall survival, contralateral breast cancer, non-breast malignancy and economic evaluation. Key differences from Z11: a) stringent radiotherapy quality assurance program, b) prospective pathology reporting, b) axillary ultrasound is mandatory, b) mastectomy patients are eligible, c) axillary treatment in the standard group may be ANC or ART. Current enrollment: 35 patients. Clinical trial information: ISRCTN54765244.

TPS1104 Poster Session (Board #216a), Sat, 8:00 AM-11:30 AM

A phase 2 randomized, double-blind, placebo-controlled trial of hormone therapy (HT) ± radium-223 dichloride (Ra-223) in HER2$^-$ hormone receptor$^+$ breast cancer patients (pts) with bone metastases (mets). *First Author: Robert E. Coleman, University of Sheffield, Weston Park Hospital, Sheffield, United Kingdom*

Background: Treatment of bone-metastatic breast cancer (MBC) is limited. Multimodality therapy may improve symptom control and survival. In a phase 2a study of advanced breast cancer pts with bone-dominant and no visceral disease, Ra-223, a first-in-class α-emitter selectively targeting bone mets, reduced baseline bone biomarker levels with favorable safety (Coleman et al. *Breast Cancer Res Treat* 2014). This study (NCT02258464) evaluates Ra-223 efficacy and safety vs placebo (pbo) in HER2$^-$ hormone receptor$^+$ breast cancer pts with bone mets receiving single-agent HT. **Methods:** Pts receive (1:1) Ra-223 50 kBq/kg IV or pbo q 4 wk (6 cycles) + concurrent single-agent HT + best supportive care. Stratification is by geographic region, prior lines of HT for MBC, and number of prior skeletal events. Pts are assessed for efficacy and safety, and followed to symptomatic skeletal event (SSE), radiologic progression, death, or withdrawal. Primary endpoint is SSE-free survival. Eligible pts are pre- or postmenopausal with estrogen receptor$^+$, HER2$^-$, bone-dominant MBC with $\geq$ 2 bone mets and $\geq$ 1 or 2 prior SSEs (external beam radiotherapy for bone pain, pathologic bone fracture, spinal cord compression, orthopedic surgery). Pts had $\geq$ 1 line of HT for MBC; are taking bisphosphonates or denosumab for $\geq$ 1 month before study; are eligible for endocrine treatment; and have evaluable disease (RECIST 1.1), asymptomatic or mildly symptomatic bone disease (Brief Pain Inventory), ECOG score 0-1, and adequate hematologic, renal, and liver function. Pts may not have had visceral or brain mets or leptomeningeal disease, need for chemotherapy for mets, and untreated spinal cord compression. Assuming a 1-sided α of 0.1, power of 90%, ~ 119 SSEs are required for the analysis. Time-to-event variable analysis will use a log-rank test, accounting for stratification. Kaplan-Meier estimates and survival curves will be given for each treatment group. Safety analyses will be descriptive. Target enrollment is 227 pts. First pt first visit is expected in early 2015. Clinical trial information: NCT02258464.

TPS1105 Poster Session (Board #216b), Sat, 8:00 AM-11:30 AM

NRG BR002: A phase IIR/III trial of standard of care therapy with or without stereotactic body radiotherapy (SBRT) and/or surgical ablation for newly oligometastatic breast cancer. *First Author: Steven J. Chmura, The University of Chicago Hospitals, Chicago, IL*

Background: This is a randomized Phase II trial to evaluate if stereotactic body radiotherapy (SBRT) and/or surgical resection (SR) of all metastatic sites in oligo-metastatic breast cancer who have received up to 6 months of first line systemic therapy without progression will significantly improve median progression free survival (PFS). If this aim is met the trial continues as a phase III to evaluate if SBRT/SR improves 5 year overall survival (OS). Secondary aims include local control in the metastatic site, distant metastatic rate, and technical quality. Translational primary endpoint is to determine whether $<$ 5 CTCs is an independent prognostic marker for improved PFS and OS. Predictive value of CTCs will be assessed. **Methods:** Women with pathologically confirmed metastatic breast cancer to $<$ / = 2 sites who have received up to 6 months of standard first line systemic therapy and the primary site disease is controlled are eligible. CNS metastases are ineligible. ER/PR and HER-2 neu is required on the primary or metastatic site. Site radiation credentialing with a facility questionnaire and a case benchmark is required. Randomization is to local radiotherapy/surgery for palliation only when necessary versus ablation of all metastases with SBRT and/or SR. Statistics: For the phase IIR portion to detect a signal for improved median PFS from 10.5 to 19 months with 95% power and accounting for ineligible/lost patients, 146 patients will be required. For the Phase III, an additional 246 patients will be required to definitively determine if ablative therapy improves 5-year OS from 28% to 42.5% (HR = 0.67), with 85% power and a one-sided type I error of 0.025. For the translational research, the number of patients accrued in Phase IIR and Phase III portions will provide sufficient power of at least 91% to detect whether $<$ 5 CTC's is a prognostic marker for improved PFS and OS. Contact Information: Protocol: CTSU member web site https://www.ctsu.org. Pt enrollment: OPEN at https://open.ctsu.orgor the OPEN tab on CTSU member web site. Support: NCI U10CA180868 and U10CA180822 Clinical trial information: Pending.

TPS1106 **Poster Session (Board #217a), Sat, 8:00 AM-11:30 AM**

Weekly *nab*-paclitaxel (*nab*-P) plus gemcitabine (gem) or carboplatin (carbo) vs gem/carbo as first-line treatment for metastatic triple-negative breast cancer (mTNBC) in a phase 2/3 trial (tnAcity). *First Author: Denise A. Yardley, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: Treatment of mTNBC is an unmet clinical need. First-line *nab*-P with gem or carbo/bevacizumab has demonstrated efficacy and safety in female patients (pts) with mTNBC. *nab*-P significantly improved pCR vs solvent based-paclitaxel in pts with early TNBC. The phase II/III tnAcity (triple-negative Albumin-bound paclitaxel combination international treatment study) trial will compare the efficacy and safety of 2 *nab*-P combination regimens (with gem or carbo) vs gem/carbo as a control as first-line treatment for mTNBC. **Methods:** 790 female pts $\geq$ 18 yrs with measurable mTNBC will be enrolled at $\approx$150 sites globally per major eligibility criteria (Table 1). In phase II, 240 pts will be randomized 1:1:1 to receive *nab*-P 125 mg/m^2 + gem 1000 mg/m^2 (arm A), *nab*-P 125 mg/m^2 + carbo area under the curve (AUC) 2 (arm B), or gem 1000 mg/m^2 + carbo AUC 2 (arm C), given D 1 and 8 q3w. Pts will be treated until disease progression. Stratification factors are disease-free interval ($\leq$ 1 yr vs $>$ 1 yr) and prior taxane exposure (phase III only). A ranking algorithm of 5 efficacy and safety parameters will be used to identify the *nab*-P combination for the phase III portion in which 550 pts will be randomized 1:1 to receive the selected *nab*-P regimen (arm A or B) or gem/carbo. Pts in phase II will not be in the phase III population. The phase III primary endpoint is PFS by independent radiological assessment. Study design provides $\approx$ 90% power to detect an HR of 0.70 for PFS with a 2-sided 5% significance level. Secondary endpoints: ORR, OS, disease control rate, duration of response, and safety. Exploratory analyses include tumor biomarkers and circulating tumor cells analyses. Current enrollment as of submission: 128 pts. Clinical trial NCT01881230. Clinical trial information: NCT01881230.

Key eligibility criteria.

ER and PgR expression both < 1% of tumor cell nuclei

HER2 IHC 0 or 1+ or FISH−, or IHC 2+ and FISH−
ECOG PS 0-1
Peripheral neuropathy grade < 2
No prior chemo for metastatic disease
Prior adjuvant/neoadjuvant anthracycline treatment required unless contraindicated
Prior taxane, gem, or platinum treatment permitted if completed ≥12 months before randomization

TPS1107 **Poster Session (Board #217b), Sat, 8:00 AM-11:30 AM**

A phase 3, open-label, randomized, parallel, 2-arm international study of the oral PARP inhibitor talazoparib (BMN 673) in BRCA mutation subjects with locally advanced and/or metastatic breast cancer (EMBRACA). *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Poly-ADP-ribose polymerase (PARP) represents a family of enzymes of which at least two (PARP1 and PARP2) play important roles in DNA repair. PARP inhibition induces synthetic lethality in tumor cells bearing deleterious mutations in the genes *BRCA1/2*. Talazoparib (BMN 673) is a novel, dual-mechanism PARP inhibitor that potently inhibits the PARP enzyme and effectively traps PARP on DNA [1]. In preclinical models, trapping PARP on DNA was more likely to induce cancer cell death than inhibition of PARP alone [1,2]. Talazoparib is the most potent preclinical PARP inhibitor described to date with the highest efficiency at trapping PARP-DNA complexes [1]. Talazoparib has shown promising single-agent anti-tumor efficacy in several solid tumor types and was generally well tolerated in a Phase 1/2 clinical study [3]. **Methods:** This international Phase 3 trial (EMBRACA) compares the safety and efficacy of talazoparib versus physician's choice (capecitabine, eribulin, gemcitabine or vinorelbine) in patients with advanced breast cancer. The primary objective is progression free survival (PFS). Secondary objectives include objective response rate (ORR), overall survival (OS), and safety. Exploratory objectives include duration of response (DOR) and health-related quality of life assessments. Subject eligibility includes $\geq$ 18 years, histologically/cytologically confirmed breast carcinoma, locally advanced and/or metastatic disease, germline *BRCA1/2* mutations, $\leq$ 2 prior chemotherapy-inclusive regimens, prior treatment with a taxane and/or anthracycline, and ECOG performance status $\leq$ 1. Subjects (n = 429) will be randomized 2:1 to receive either talazoparib oral capsules (1.0 mg/day, 21-day cycles) or physician's choice treatment. This trial is currently enrolling patients from the United States, Asia/Pacific, Europe, Israel, and South America (NCT01945775). [1] Murai J et al. *Mol Cancer Ther.* 2014;13:433-443. [2] Murai J et al. *Cancer Res.* 2012;72(21):5588-5599. [3] Wainberg ZA et al. *J Clin Oncol.* 2014;32(suppl):5; abstr 7522 Clinical trial information: NCT01945775.

TPS1108 **Poster Session (Board #218a), Sat, 8:00 AM-11:30 AM**

A phase 2 study (2-stage, 2-cohort) of the oral PARP inhibitor talazoparib (BMN 673) in patients with germline BRCA mutation and locally advanced and/or metastatic breast cancer (ABRAZO). *First Author: Nicholas C. Turner, Royal Marsden, London & Surrey, United Kingdom*

Background: Poly-ADP-ribose polymerase (PARP) represents a family of enzymes of which at least two (PARP1 and PARP2) play important roles in DNA repair. PARP inhibition induces synthetic lethality in tumor cells bearing deleterious mutations in the genes *BRCA1/2*. Talazoparib (BMN 673) is a novel, dual-mechanism PARP inhibitor that potently inhibits the PARP enzyme and effectively traps PARP on DNA [1]. In preclinical models, trapping PARP on DNA was more likely to induce cancer cell death than inhibition of PARP alone [1,2]. Talazoparib is the most potent preclinical PARP inhibitor described to date with the highest efficiency at trapping PARP-DNA complexes [1]. Talazoparib has shown promising single-agent anti-tumor efficacy in several solid tumor types and was generally well tolerated in a Phase 1/2 clinical study [3]. **Methods:** This Phase 2 trial (ABRAZO) evaluates the safety and efficacy of talazoparib in patients with locally advanced or metastatic breast cancer with a deleterious germline *BRCA 1* or *BRCA 2* mutation. Eligible subjects will be assigned to one of two cohorts: 1) Subjects (n = 70) previously responding to a platinum-containing regimen for metastatic disease (PR or CR) or 2) Subjects (n = 70) with $>$ 2 prior chemotherapy regimens in metastatic setting, no prior platinum therapy. The primary objective is objective response rate (ORR). Secondary objectives include clinical benefit rate (CBR), duration of response (DOR), progression free survival (PFS), and overall survival (OS). Health-related quality of life assessments are an exploratory objective. Patient eligibility includes $\geq$ 18 years, locally advanced and/or metastatic disease, deleterious *BRCA1/2* mutation, and ECOG performance status $\leq$ 1. Eligible patients will receive oral talazoparib (1.0 mg/day, 21-day cycles) until disease progression or unacceptable toxicity. This trial is enrolling patients in the United States, France, Germany, Spain, and the United Kingdom. (NCT02034916). [1] Murai J et al. *Cancer Res.* 2012;72(21):5588-5599. [2] Murai J et al. *Mol Cancer Ther.* 2014;13:433-443. [3] Wainberg ZA et al. *J Clin Oncol.* 2014; 32(suppl):5; abstr 7522 Clinical trial information: NCT02034916.

TPS1109 **Poster Session (Board #218b), Sat, 8:00 AM-11:30 AM**

OlympiA: A randomized phase III trial of olaparib as adjuvant therapy in patients with high-risk HER2-negative breast cancer (BC) and a germline *BRCA*1/2 mutation (g*BRCA*m). *First Author: Andrew Nicholas James Tutt, King's College London School of Medicine, London, United Kingdom*

Background: In a Phase II proof-of-concept study (NCT00494234), treatment with the PARP inhibitor olaparib (Lynparza; 400 mg twice daily [bid]; capsules) resulted in antitumor activity in patients (pts) with advanced BC harboring a gBRCAm (objective response rate: 41%; Tutt et al Lancet 2010). An AstraZeneca-sponsored Phase III trial (OlympiA; NCT02032823; coordinated by BIG, NRG Oncology, Frontier Science and AstraZeneca) of olaparib as adjuvant monotherapy has been initiated in pts with gBRCAm-associated triple negative BC (TNBC) who have completed local treatment and neoadjuvant or adjuvant chemotherapy (CT). **Methods:** OlympiA is a double-blind trial in which pts with TNBC at high risk of recurrence are currently randomized (1:1) to receive treatment with olaparib (300 mg tablets bid [2 x 150 mg]) or placebo for a maximum of 12 months. Eligible pts must have completed definitive local treatment and at least 6 cycles of either neoadjuvant CT (without a pathological complete response) or adjuvant CT. Pts must also have a known or suspected deleterious gBRCAm, which will be retrospectively confirmed by Integrated BRACAnalysis (Myriad Genetic Laboratories) before entering the trial. Stratification factors include prior neoadjuvant versus adjuvant CT, and whether pts have received prior platinum therapy for current BC. The primary objective is invasive disease-free survival (IDFS). Efficacy assessments will be made by mammograms/breast MRI scans annually for 10 years, beginning 6 months from randomization, and by medical history/physical examination from randomization every 3 months for 2 years, then every 6 months for a further 3 years and annually thereafter. Secondary objectives include overall survival, distant DFS, incidence of new cancers, HRQoL, safety and tolerability. The primary IDFS analysis will be performed after 330 IDFS events (25% maturity) using a stratified log-rank test. Patient enrollment began in April 2014. The target number for randomization is ~1320 patients across ~550 sites and ~25 countries worldwide. Support: U10CA12027,-69651,-37377,-69974,-180868,-180822,-189867; AstraZeneca Clinical trial information: NCT02032823.

TPS1110 **Poster Session (Board #219a), Sat, 8:00 AM-11:30 AM**

METRIC: A randomized international study of the antibody-drug conjugate glembatumumab vedotin (GV or CDX-011) in patients (pts) with metastatic gpNMB-overexpressing triple-negative breast cancer (TNBC). *First Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: The internalizable transmembrane glycoprotein NMB (gpNMB) is overexpressed in 20% of BC, including 40% of TNBC (Yardley JCO, in press), where it is a poor prognostic marker (Rose CCR 2010). gpNMB enhances tumor invasion and metastasis and promotes angiogenesis in preclinical models. GV is a novel antibody drug conjugate targeting the potent cytotoxin monomethylauristatin E (MMAE) to gpNMB+ tumor cells. In a Phase I/II study (Bendell JCO, 2014) and the Phase II "EMERGE" study (Yardley JCO, in press), GV demonstrated promising activity, particularly in pts with TNBC and gpNMB overexpression, and was well-tolerated (treatment related toxicities: rash, neutropenia and neuropathy). In subset analyses, for GV vs. "investigator's choice" (IC) single-agent chemotherapy, objective response rate (ORR) was 30% (7/23) vs. 9% (1/11) in pts with gpNMB overexpression (in $\geq$ 25% of tumor epithelium); 18% (5/28) vs. 0% (0/11) in TNBC; and 40% (4/10) vs. 0% (0/6) in gpNMB-overexpressing TNBC, with apparent improvements in progression-free survival (PFS; hazard ratio (HR) = 0.11) and overall survival (OS; HR = 0.14). **Methods:** The international (US, CA, Aus) "METRIC" study (NCT01997333) is recruiting up to 300 pts with metastatic, gpNMB-overexpressing TNBC. Eligibility criteria include: $\geq$ 25% of tumor epithelium gpNMB+ by central IHC prescreening of archival tissue; ER and PR $<$ 10% and HER2(-) [0-1+ IHC, or ISH copy number $<$ 4.0 / ratio $<$ 2.0] by local assessment; ECOG 0-1; taxane resistance; anthracycline exposure (if indicated); $\leq$ 2 chemotherapy regimens for advanced BC; measurable disease; no persistent Grade $\geq$ 2 toxicity; and capecitabine naive. Pts are randomized (2:1) to GV (1.88 mg/kg IV q 21 days) or capecitabine, a current standard for this population (2500 mg/m^2 daily for d1-14, q21 days) until progression or toxicity. Crossover is not permitted. Endpoints are PFS (primary), ORR, duration of response, OS, safety, PK, PD (immune dynamics) and quality of life. Imaging will be centrally assessed per RECIST 1.1. The trial has 85% power to detect a PFS HR of 0.64 with α = 0.05. Clinical trial information: NCT01997333.

TPS1111 **Poster Session (Board #219b), Sat, 8:00 AM-11:30 AM**

LOTUS: A randomized, phase II, multicenter, placebo-controlled study of ipatasertib (Ipat, GDC-0068), an inhibitor of Akt, in combination with paclitaxel (Pac) as front-line treatment for patients (pts) with metastatic triple-negative breast cancer (TNBC). *First Author: Sung-Bae Kim, Asan Medical Center, Seoul, South Korea*

Background: The PI3K/Akt pathway is often activated in TNBC through loss of PTEN expression, low INPP4B expression, and/or increased *AKT3* amplification. Activation of Akt may then lead to chemoresistance; thus, inhibition of Akt signaling may result in improved efficacy of chemotherapy in TNBC. Ipatasertib (GDC-0068) is an oral, potent ATP-competitive small molecule inhibitor of all three isoforms of Akt. In preclinical breast cancer models, the combination of Ipat with taxanes enhanced efficacy. In a Phase Ib clinical study, the combination of Ipat with Pac was well-tolerated; the most commonly reported adverse events associated with Ipat were Grade 1-2 diarrhea, nausea, fatigue, vomiting, decreased appetite, and rash. RECIST responses were seen with the combination, including pts with tumors having PI3K/Akt activation. **Methods:** LOTUS is a randomized, double-blind, placebo-controlled, global Phase II study designed to estimated the efficacy and safety profile of Pac plus Ipat versus Pac plus placebo in pts with inoperable locally advanced or metastatic TNBC not amenable to resection with curative intent. Approximately 120 pts with measurable TNBC will be randomized (1:1) and stratified by prior adjuvant/neoadjuvant treatment, disease free interval from last dose of chemotherapy, and tumor PTEN status. Pts will receive Ipat or placebo 400 mg orally once daily on Days 1 to 21 of each 28-day cycle with Pac 80 mg/m^2 on Days 1, 8, and 15 of each 28-day cycle until disease progression, intolerable toxicity, withdrawal, or study completion. Pts will then be followed every 3 months for survival. The primary efficacy outcome is progression-free survival in all pts and in pts with PTEN-low tumors. Additional endpoints include overall survival, objective response rate, duration of response, safety, pharmacokinetics, patient-reported outcomes, and correlative biomarkers. The study is open for accrual.Clinical trial information: NCT02162719.

TPS1112 **Poster Session (Board #220a), Sat, 8:00 AM-11:30 AM**

FAIRLANE: A phase II randomized, double-blind, study of the Akt inhibitor ipatasertib (Ipat, GDC-0068) in combination with paclitaxel (Pac) as neoadjuvant treatment for early stage triple-negative breast cancer (TNBC). *First Author: Mafalda Oliveira, Vall d'Hebron University Hospital / VHIO, Barcelona, Spain*

Background: TNBC often exhibits activation of PI3K/Akt signaling, associated with loss of PTEN expression, low INPP4B expression, and/or increased *AKT3* amplification. Inhibition of the PI3K/Akt pathway in diverse cancers leads to radiosensitization and/or chemosensitization. Ipat is an oral, potent ATP-competitive small molecule inhibitor of all three isoforms of Akt. The combination of ipat with taxanes in preclinical models resulted in enhanced efficacy relative to either ipat or chemotherapy alone. In a Phase Ib clinical study, the combination of Ipat with diverse chemotherapy regimens was well-tolerated and resulted in RECIST responses, particularly pts with tumors having PI3K/Akt activation. **Methods:** FAIRLANE is a randomized, double-blind, placebo-controlled, multicenter, neoadjuvant Phase II study designed to estimate the efficacy of ipat combined with pac versus placebo combined with pac in women with Stage Ia - IIIa TNBC. Approximately 150 patients (Pts) will be enrolled, randomized in a 1:1 ratio, and stratified by PTEN status, node involvement, and tumor size. Pts will receive 3 cycles of Ipat or placebo 400 mg orally once daily on Days 1 to 21 of each 28-day cycle, along with pac 80 mg/m^2 every 7 days for a total of 12 doses. All patients will undergo pretreatment and Day 8 tumor tissue acquisition to evaluate pathway biomarkers. Following three cycles of treatment, patients will undergo surgery. The primary efficacy endpoint, pCR within the breast and axilla (ypT0/Tis ypN0) in all patients and in patients with PTEN-low tumors, will be assessed by local pathology evaluation following completion of neoadjuvant therapy and surgery. Additional endpoints include objective response rate, safety, BCS rate, pharmacokinetics, and pathway biomarkers. Following surgical resection of primary tumor, patients are expected to continue post-operative treatment with a standard adjuvant chemotherapy regimen at physician's discretion. The study is open for accrual. Clinical trial information: NCT02301988.

TPS1113 **Poster Session (Board #220b), Sat, 8:00 AM-11:30 AM**

Women's triple-negative, first-line treatment: Improving outcomes in triple-negative breast cancer (TNBC) using molecular triaging and diagnostic imaging to guide neoadjuvant therapy (NACT). *First Author: Stacy L. Moulder, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In TNBC, pathologic compete response (pCR/RCB-0) or minimal residual disease (RCB-I) to NACT is associated with a good prognosis while extensive residual disease (RCB-II-III) has a ~50% chance of recurrence. It is important to predict pCR, in order to direct responsive disease (RespD) toward standard NACT and non-responsive disease (NRD) to therapy on clinical trials. **Methods:** The use of genomic signatures (JAMA, 2011; 305:1873-81) and imaging to predict response to NACT will be validated and the impact of selecting pts for targeted therapy on clinical trial in predicted NRD will be determined. Pts will have primary tumor biopsy for molecular analyses and be randomized 2:1 to know results versus not (control). Pts will receive 4 cycles anthracycline-based NACT with imaging for response. Pts with molecular/imaging criteria for NRD will be offered a clinical trial based upon molecular profiling or based upon physician/patient choice (control). Pts having RespD in either arm receive taxane based NACT. INCLUSION: tumor size $>$ 1.5 cm diameter; TNBC by standard assays; $>$ 18 years of age; LVEF $>$ 50%; adequate organ and bone marrow function. EXCLUSION: Stage IV disease; invasive cancer within 5 years; excisional biopsy of the primary; features that limit response assessment by imaging; unfit for taxane and/or antracycline regimens; prior anthracycline therapy; $>$ grade II neuropathy; Zubrod performance status of $>$ 2; history of serious cardiac events. *Primary Aim:* prospectively determine the impact of a molecular diagnostic/imaging platform in pts with localized invasive TNBC. *Secondary Aims:* compare rates of clinical trial enrollment, compare DFS, integrated biomarker analyses, identify therapeutic targets for resistant disease. A maximum of 360 pts will be randomized (2:1)using a group sequential design with one-sided O'Brien-Fleming boundaries, with two equally spaced binding interim tests for futility and superiority and one final test, having an overall Type I error .05 and power .80 to detect an improvement in pCR/RCB-I from 50% to 64%.

1500 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Final updated results of the NRG Oncology/NSABP Protocol P-2: Study of Tamoxifen and Raloxifene (STAR) in preventing breast cancer. *First Author: Donald Lawrence Wickerham, NRG Oncology/NSABP, and Allegheny Cancer Center at Allegheny General Hospital, Pittsburgh, PA*

Background: NSABP P-2 (STAR) was a randomized, double-blinded trial of tamoxifen vs raloxifene for the reduction of breast cancer incidence. The initial report from 2006 found raloxifene to be as effective as tamoxifen in preventing invasive breast cancer, but with fewer associated toxicities. In 2010 updated results indicated that raloxifene retained 76% of the effectiveness of tamoxifen in preventing invasive breast cancer and remained less toxic. **Methods:** May 31, 2012, STAR was permanently closed to followup. This current and final update is based on data through the end of followup for invasive and noninvasive breast cancer, other cancers, vascular events, and deaths. The final analysis comprises the same 19,490 women (9736 in the tamoxifen group and 9754 in the raloxifene group) as the 2010 update report. The median time of followup as of May 31, 2012, was 9.7 yrs. **Results:** Similar to the previous update, raloxifene remains less effective in preventing invasive breast cancer than tamoxifen (RR = 1.19, 95% CI = 1.04–1.37). For noninvasive breast cancer, the borderline statistically significant difference between treatment groups seen in the original findings continues to decrease (RR = 1.09, 95% CI = 0.88–1.36). Raloxifene also continues to have a better profile than tamoxifen re thromboembolic events (RR = 0.80, 95% CI = 0.66–0.96) and uterine cancer (RR = 0.56, 95% CI = 0.40–0.79). There were no statistically significant differences between treatment groups for any other site of cancer. There was, however, a borderline statistically significant all-cause mortality difference between the treatment groups. The death rates per 1000 in the raloxifene and tamoxifen groups were 4.10 and 4.73, respectively (RR = 0.87, 95% CI = 0.75–1.00). **Conclusions:** Raloxifene has retained approximately 81% of the effectiveness of tamoxifen in preventing invasive breast cancer and continued to grow closer to tamoxifen in preventing noninvasive breast cancer. Raloxifene has also maintained a better profile with respect to uterine disease, thromboembolic events, and death. Support: U10CA37377, -69974; -180868 -180822; -189867; -44066; Elli Lilly and Company; AstraZeneca Clinical trial information: NCT00003906.

1501 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Vasomotor symptoms, BMI, and adherence to tamoxifen in the National Surgical Adjuvant Breast and Bowel Project (NSABP) Breast Cancer Prevention Trial (P-1). *First Author: Farzana L Walcott, National Cancer Institute, Rockville, MD*

Background: Tamoxifen (T) is underutilized as a chemopreventive agent for breast cancer (BC), despite a 50% reduced risk of developing breast cancer in high risk women with use of T vs. placebo (P). Vasomotor symptoms (VS - hot flashes, night sweats, cold sweats) were the most frequently cited reasons for women stopping tamoxifen in the P-1 study and occurred most frequently in the T arm. BMI may modify experience of vasomotor symptoms in women, with higher BMI associated with worse symptoms. **Methods:** 13,388 women at high risk of BC were randomly assigned to T (20 mg/day) vs. P from June 1992 to September 1997. We analyzed data from 11,064 women enrolled at least 36 months before trial un-blinding in May 1998. Associations between VS and adherence to T: Stratifying on study arm (T vs. P) and 10 year age group, we used proportional hazards (Cox regression) models for time-to-first non-adherence. Covariates were VS, BMI, and breast cancer risk (Gail model). VS were coded on a 5-point scale ranging from 0 (no symptom/symptom not at all bothersome) to 4 (symptom extremely bothersome). BMI was categorized into: normal (< 25), overweight (25-30), and obese (≥ 30). Time-to-non-adherence was censored at 36 months. Associations between VS and BMI: logistic regression (LR) was used for each VS starting at month 3. Covariates were BMI, 10-year age group, and study arm. VS were coded on a 2-point scale (0 = no symptom/symptom not extremely bothersome, 1 = symptom extremely bothersome). **Results:** Time-to-non-adherence analysis: Estimated hazard ratios (HR) and 95% confidence intervals (CI): hot flashes= 1.35 (1.22, 1.50); night sweats = 1.43 (1.28, 1.60); cold sweats =1.49 (1.19, 1.87); BMI = 1.13 (1.05, 1.21) (normal vs. obese). LR: Estimated odds ratios (OR) for BMI (normal vs. obese): hot flashes = 1.57 (1.26, 1.95); night sweats = 1.50 (1.19, 1.90); cold sweats=1.64 (0.86, 3.10). **Conclusions:** Adherence to T was lower in obese women and those with severe VS. In addition, VS were more severe in obese women. In order to improve uptake and adherence to chemopreventive options such as T in healthy, high risk women, interventions targeting risk factors for non-adherence must be addressed. SUPPORT: CA180868, 180822, 189867

1502 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Estrogen alone and health outcomes in black women by African ancestry. *First Author: Rowan T. Chlebowski, Los Angeles BioMedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA*

Background: Disparities are seen in breast cancer outcome in black compared to white women. However, in black women in the Women's Health Initiative (WHI) randomized trial, estrogen alone significantly reduced breast cancer incidence, but its comprehensive influence on health outcomes in black women in this trial has not been reported. Therefore we examined, in post-hoc analyses, the risks and benefits for estrogen alone use in black women in the WHI randomized trial overall and by African ancestry. **Methods:** Of 10,729 postmenopausal women with prior hysterectomy randomized at 40 US centers, 1,616 were black, including 1,061 with % African ancestry determined using information from 656,852 single nucleotide polymorphisms. Participants received daily conjugated equine estrogen (CEE 0.625 mg) or placebo for 7.2 years (median intervention) with 13 years cumulative follow-up. Coronary heart disease (CHD) and breast cancer were primary efficacy and safety outcomes. A global index of outcomes under potential hormone influence also included stroke, colorectal cancer, hip fracture, pulmonary embolism and death. **Results:** At entry, black women had more diabetes, hypertension, and prior myocardial infarctions compared to white women. Black women in the estrogen alone compared to the placebo group had fewer breast cancers (17 vs. 40, hazard ratio [HR] 0.47 95% confidence interval [CI] 0.26-0.82) and somewhat fewer thromboembolism events (23 vs. 40, HR 0.63 95% CI 0.38-1.06, interaction p = 0.049 vs. effect in white women). All other outcomes including CHD, stroke, overall survival and the global index (HR 0.95 95% CI 0.77-1.17) were null without racial differences. In women with > 80% African ancestry, breast cancer HR was lower (0.32 95% CI 0.12-0.86, trend p = 0.04 for effect modification by ancestry). In black women, the estrogen global index effect was more favorable in younger (50-59 years) (HR 0.65 95% CI 0.43-0.98) than in older women. **Conclusions:** In black postmenopausal women with prior hysterectomy, estrogen alone significantly reduced breast cancers with no apparent adverse influence on CHD, stroke, or mortality. Favorable estrogen alone effects on the global index in younger Black women warrant further study. FUNDING: National Institutes of Health. Clinical trial information: NCT00000611.

1503 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Predisposing germline mutations in high grade ER+HER2- breast cancer (BC) patients diagnosed (Dx). *First Author: Judy Ellen Garber, Dana-Farber Cancer Institute, Boston, MA*

Background: Evaluation of women with triple negative BC for germline *BRCA1/2* mutations has become standard of care due to its impact on management and 11% mutation prevalence. Approximately 70% of *BRCA2*-associated BC is high grade ER+/HER2-, but the prevalence of *BRCA1/2* mutations has not been assessed. **Methods:** Blood samples from BC patients age <50 at the Dana-Farber Cancer Institute with grade III ER+/HER2- invasive BC who consented to research were identified in the Dana-Farber/Harvard SPORE biobank. DNA mutations in 25 cancer genes were identified using a next generation sequencing based panel. Germline sequence variations and large rearrangements were classified for pathogenicity. **Results:** 104 samples from eligible subjects were included. Mutations were found in 11 (10.6%) women [95% CI 5.4-18.1%]). *BRCA1/2* mutations were found in 6.7% [95% CI 2.7-13.4%]. Mutation frequencies were higher among Ashkenazim (p=0.02), women with PR negative tumors (p<0.01) and women who had undergone prior clinical testing (p=0.01). 3/11 mutation carriers had BC age 45-49. Family hx of BC/ovarian cancer (OC) in 1st or 2nd degree relatives (FDR/SDR) was not associated with mutation status. Among 49 women with no FDR/SDR with BC/OC, 5 (10.2%) had a mutation. Two mutations (1 *BRCA2*, 1 *PALB2*) were found in 56 women who had not undergone previous clinical testing. **Conclusions**: Approximately 10% of women with high grade BC ER+/HER2- diagnosed age <50 carry a germline mutation in a BC-associated gene. The frequency of *BRCA1* mutations is notable. Expanded testing in women with Grade III ER+/HER2- BC age <50 will find mutation carriers, which can impact management decisions. Examination of women diagnosed age >50 will be important.

Gene	Frequency	Percent	BC Dx Age	Ashkenazim	Family Hx**
BRCA1	4	3.85%	28,38,41,46	Y,Y,N,N	Y,Y,Y,Y
BRCA2	3*	2.88%	37,39*,42	Y,N,N	Y,N,N
PALB2	2	1.92%	25,43	N,N	N,N
CHEK2	1	0.96%	49	N	Y
ATM	2*	1.92%	39*,47	N,N	N,N

1504 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Uterine cancer (Ut Ca) following risk-reducing salpingo-oophorectomy (RRSO) in women with *BRCA* mutations (*BRCA*+): A multicenter, prospective study. *First Author: Catherine A. Shu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While RRSO is key in management for *BRCA*+ women, concomitant hysterectomy is not standard. Here we estimate the risk of Ut Ca in *BRCA*+ women following RRSO and examine the distribution of specific histologic subtypes. **Methods:** *BRCA*+ women from 9 centers who underwent RRSO with retention of the uterus were prospectively followed from latest of ascertainment, *BRCA* testing, or RRSO. Censoring occurred at hysterectomy, Ut Ca diagnosis, last follow-up or death. Expected cancer incidence was determined using age and race specific SEER data, adjusted for prevalence of hysterectomy. Ut Ca were categorized into endometrioid endometrial cancer (E-EC) [e.g. endometrioid, adenocarcinoma NOS], serous endometrial cancer (S-EC) [e.g. serous, undifferentiated], and sarcoma. The observed-to-expected (Obs/Exp) ratios and lower limit of 97.5% CI were analyzed using 1-sided Poisson distribution test. **Results:** 1083 *BRCA*+ women were followed for a median 5.2 years. 8 incident Ut Ca were observed [4.2 Exp; Obs/Exp = 1.9, p = 0.06]. When stratified by subtype, there was no increased risk of E-EC [2 Obs vs 3.7 Exp; p = 0.29] or sarcoma [1 Obs vs 0.14 Exp; p = 0.13]. 5 S-EC were observed 7.2 – 12.9 yrs after RRSO [0.33 Exp; Obs/Exp = 15.2, p < 0.0001]. Tumor tissue was available from 4 *BRCA1*+ women. LOH and/or IHC analyses confirmed loss of *BRCA1* function in 3 of 3 S-EC. In the sarcoma, *BRCA1* function was retained. Analyses for S-EC stratified by prior breast cancer or tamoxifen use are below. **Conclusions:** While the overall risk of Ut Ca following RRSO does not appear to be increased, there is a small absolute increased risk of more aggressive S-EC (≈ 1.1% at 10 yrs in *BRCA1*+ women). Further studies are needed to define the risk/benefit of hysterectomy at time of RRSO.

1505 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Initial results of a prospective, multicenter trial to study inherited lung cancer risk associated with germline EGFR T790M: INHERIT EGFR. *First Author: Geoffrey R. Oxnard, Dana-Farber Cancer Institute, Boston, MA*

Background: EGFR T790M is most commonly seen as a somatic mutation in NSCLC following resistance to EGFR targeted therapies. Rarely EGFR T790M can be seen as a germline mutation where, in case reports, it has been associated with inherited lung cancer risk. The INHERIT study (INvestigating HEreditary RIsk from T790M, NCT01754025) is designed to prospectively identify and study individuals with this rare germline mutation. **Methods**: Subjects were eligible if they had EGFR T790M identified on routine cancer genotyping (excluding acquired T790M after therapy), or if they or a relative had already been found to carry a germline EGFR mutation. Subjects could participate in-person at 3 ALCMI sites or remotely via phone & mail. All subjects provided consent, filled out a questionnaire, and submitted a specimen for germline testing in a CLIA lab. Those interested in learning germline results were first provided counseling, and if positive could invite relatives to participate. **Results**: 46 subjects enrolled between 12/12 and 12/14; 22 in-person and 24 remotely (from 21 US states total); including 16 probands (NSCLC, germline pos), 23 relatives, and 6 germline neg patients with T790M-positive NSCLC (1 pending). Germline T790M prevalence: 16 of 22 patients with T790M-pos NSCLC (72%), 10 of 14 1st-degree relatives (71%). Among 12 total relatives with germline T790M, 1 had previously been diagnosed with NSCLC, 1 was diagnosed with NSCLC since germline testing, 4 have sub-cm lung nodules, 0 have negative CT scans, and 6 have not undergone CT imaging. In 18 germline carriers with NSCLC: median age at diagnosis was 56 (29-76), NSCLC stage was I-II in 2, III in 4, IV in 9. Pedigrees for 14 probands show 1-2 1st-degree relatives with NSCLC in 8, no 1st-degree relatives with NSCLC in 6. **Conclusions**: Using an innovative trial design including remote participation and germline testing based upon abnormal tumor genotyping, we have assembled the first multi-centered cohort of subjects with germline EGFR mutations. Penetrance is variable, but in some individuals germline T790M is associated with lung nodules or advanced NSCLC at a young age. Clinical trial information: NCT01754025.

1506 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Statin use and all-cancer mortality: Prospective results from the Women's Health Initiative. *First Author: Ange Wang, Stanford Univ School of Medcn, South Pasadena, CA*

Background: Statin medications are widely used for lipid lowering and heart disease prevention. Retrospective studies and basic scientific evidence have suggested that statins may also reduce cancer mortality. Data fromthe Women's Health Initiative Observational Study (WHI-OS) and Clinical Trial (WHI-CT) were used to investigate the association between statin use and all-cancer mortality in a prospective cohort of postmenopausal women. **Methods:** The WHI study enrolled women aged 50-79 from 1993-1998 at 40 U.S. clinical centers. Among 146,326 participants with median 14.6 follow-up years, 23,067 incident cancers and 3,152 cancer deaths were observed. Cox proportional hazards models were used to investigate the relationship between statin use (as a time-dependent exposure) and cancer mortality. Analyses were adjusted for age, race/ethnicity, education, smoking, body mass index, physical activity, family history of cancer, current health care provider, hormone use, age at menarche, solar irradiance, and history of heart disease/diabetes. **Results:** Compared with never users, current statin use was associated with significantly decreased cancer mortality (HR 0.78; 95% CI 0.71-0.86). Use of other lipid lowering medications was associated with a similar reduction in cancer deaths compared to monotherapy statin use (p-het = 0.57). The reduction in cancer death associated with statin use was not dependent on statin potency (p-het = 0.22), lipophilicity/hydrophilicity (p-het = 0.43), type (p-het = 0.34) or duration (p-het = 0.33). Current statin use was associated with significantly decreased mortality of multiple cancer types, including breast, colorectal, ovarian, digestive, and bone/connective tissue cancer deaths, but not lung cancer. However, past statin users were not at lower risk of cancer death compared to never users (HR 1.06; 95% CI, 0.85-1.33); additionally, statin use was not associated with a reduction in cancer incidence despite its effect on mortality (HR, 0.96; 95% CI: 0.92-1.001). **Conclusions:** In a cohort of postmenopausal women, regular use of statins or other lipid-lowering medications may decrease cancer mortality, regardless of the type, duration, or potency of statin medications used. Clinical trial information: NCT00000611.

1507 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Post-diagnosis BMI and physical activity in association with triple-negative breast cancer prognosis: Results from 5 prospective cohorts. *First Author: Sarah Jean Nechuta, Vanderbilt University Medical Center, Nashville, TN*

Background: Triple negative breast cancer (TNBC), defined as ER-/PR-/HER2-, has a poor prognosis and limited targeted treatment options. Modifiable lifestyle factors, including body mass index (BMI) and physical activity (PA), have been well-studied for overall breast cancer prognosis. However, no prospective study has investigated BMI and PA in TNBC prognosis; we conducted such an analysis using data from 5 breast cancer survivor cohorts in the US, UK, and China. **Methods:** The pooling project included 12,240 stage I-III breast cancer cases with known ER/PR/HER2 status from 5 cohorts, with 1,695 TNBC cases (13.9%). Clinical characteristics including treatment, and lifestyle factors collected on average 1.8 years after diagnosis, were pooled and harmonized. Self-reported recreational PA, summarized in MET-hours/week, was available for 4 cohorts; weight and height were available in all cohorts. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using delayed-entry Cox regression models, stratified by cohort and adjusted for known prognostic factors. Outcomes were breast cancer-specific survival (BCSS) and overall survival (OS). **Results:** Among TNBCs, mean follow-up was 9.5 years (401deaths). In adjusted models, increasing PA (MET-h/w) was associated with improved BCSS; HRs (95% CIs) by tertile (reference: < 4.1) were: 0.80(0.56-1.15) for 4.1-15.9 and 0.61(0.41-0.92) for ≥ 16.0; Ptrend = 0.02. Similar results were observed for OS (HRs (95% CIs): 0.86(0.64-1.15) for 4.1-15.9 and 0.63(0.45-0.88) for ≥ 16.0; Ptrend = 0.007). In adjusted models, a U-shaped association was observed for BMI (kg/m^2) and OS (ref. = 21.5-24.9). Only the HR for BMI < 21.5 was statistically significant, HR (95% CI): 1.60(1.10-2.32), however, the HR was no longer significant after exclusion of the Chinese cohort, HR (95% CI): 1.27(0.78-2.08). **Conclusions:** In this prospective evaluation of PA and BMI in TNBC, a trend for increasing PA and improved BCSS and OS was observed, which was significant only for high levels of PA (equivalent to ≥ 4 h of moderate intensity PA/wk). A U-shaped pattern was observed for BMI; however, obesity was not significantly associated with survival.

1508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Alcohol consumption and prognosis in patients with stage III colon cancer: A correlative analysis of phase III trial NCCTG N0147 (Alliance). *First Author: Amanda I. Phipps, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Alcohol consumption is associated with a modest increased risk of colon cancer (CC). The relationship between alcohol and survival after CC, however, has not been well elucidated. Using data from N0147, a phase III randomized adjuvant trial in stage III CC, we assessed the association of alcohol consumption with CC outcomes. **Methods:** Patients completed a risk factor questionnaire before randomization to FOLFOX or FOLFOX + cetuximab (N = 1984). Information was collected on lifestyle factors, including smoking, physical activity, and the frequency and extent of alcohol consumption. Separate information was collected for different alcohol types. Multivariate Cox models assessed the association between alcohol consumption and outcomes of disease-free survival (DFS), time-to-recurrence (TTR) and overall survival (OS), adjusting for age, sex, study arm, body mass index, smoking, physical activity, and performance status. **Results:** Overall, 70% of patients had ever consumed alcohol regularly. There was no statistically significant difference in outcomes between ever and never drinkers in multivariate analyses [hazard ratio ($HR)_{DFS}$= 0.86, p = 0.11, HR_{TTR}= 0.87, p = 0.18, HR_{OS}= 0.86, p = 0.14]. However, when considering alcohol type, ever consumers of red wine (n = 639) had significantly better outcomes than never consumers (HR_{DFS}= 0.81, p = 0.01; HR_{TTR}= 0.81, p = 0.02; HR_{OS}= 0.78, p = 0.01). Favorable outcomes were confirmed in patients who consumed 1-30 glasses of red wine per month (n = 612, HR = 0.81 to 0.83, p = 0.03 to 0.048); there was a suggestion of more favorable (but not statistically significant) outcomes in patients who consumed > 30 glasses of red wine per month (n = 27, HR = 0.30 to 0.38, p = 0.05 to 0.06). For white wine, better OS was observed for patients who consumed 1-30 glasses/month (n = 538) compared to never consumers (HR = 0.75, p = 0.007), but no association was noted for other outcomes. Beer and liquor consumption were not associated with improved outcomes. **Conclusions:** Although alcohol consumption was not associated with CC outcomes overall, mild to moderate red wine consumption was suggestively associated with longer OS, DFS, and TTR in stage III CC patients.

1509 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Tumor relevant germline findings in targeted tumor sequencing using matched normal DNA of 1,570 unselected cases. *First Author: Kasmintan A Schrader, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor Sequencing (TS) can reveal presumed pathogenic germline variants (PPGV) that may be tumor-relevant (TR) and associated with tumorigenesis. Identification of PPGV may have significant implications for the individual and family. **Methods:** To estimate the burden of TR-PPGV identified in tumor-normal massively parallel sequencing, we analyzed 1,570 cases, unselected for cancer type or family history, that had undergone TS with matched normal DNA using a 341 gene panel employed at MSKCC (MSK-IMPACT). Subjects had provided IRB approved consent and anonymized analysis of the normal DNA samples was conducted under an IRB approved waiver. **Results:** Tumor phenotype was assessed for known genotype-phenotype correlations in cases harboring sequence PPGV in cancer-related genes of accepted clinical utility (ACMG gene list). Of 100 PPGV (98 cases, 2 cases had 2 PPGV each), 43 cases had expected tumor phenotypes. While 94 PPGV were retained in the tumor in 93 cases, in 24 cases we observed LOH/aberrant sequence of the other allele, suggesting possible involvement in pathogenesis. Eight out of 24 such cases were in tumors that do not typically trigger genetic evaluation for each corresponding syndrome; *BRCA1* (n = 2) in stomach adenocarcinomas; *BRCA2* (n = 2) in a neuroendocrine tumor and a pleomorphic sarcoma, *RET* (n = 1) in a colon cancer, *SDHC* (n=1) in a breast cancer and *MUTYH* (n = 2) in a breast cancer and Hurthle cell thyroid cancer. **Conclusions:** TR-PPGV can be estimated to occur in the matched normal DNA of up to 6% (93/1570) of unselected individuals undergoing TS. Correlation of the PPGV and tumor phenotype was seen in 44% (43/98) of cases, however 14% (8/56) of cases that had PPGV with non-conforming genotype-phenotypes showed evidence supportive of a role of the PPGV in tumorigenesis. These data indicate that phenotypes beyond those linked to known cancer syndromes may benefit from evaluation for TR-PPGV, which may also identify potentially aberrant pathways amenable to targeted therapeutic strategies.

1510 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Prevalence of incidental actionable germline mutations in 1,000 advanced cancer patients on a prospective somatic genomic profiling program. *First Author: Funda Meric-Bernstam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Next generation sequencing is increasingly used in cancer research and precision oncology. This practice may also reveal germline variants of potential clinical significance. We here report patient preferences for return of results as well as the prevalence of incidental deleterious germline mutations. **Methods:** Targeted exome sequencing of 202 genes was performed on tumor and normal DNA in a research laboratory. This panel included 18 genes for which return of incidental deleterious findings is recommended by The American College of Medical Genetics and Genomics. Mutations in these genes, as well as PALB2, were considered actionable. Results were confirmed with an orthogonal CLIA assay. A companion protocol determined patient preferences of return of incidental germline results. Return of results was initiated with genetic counseling and repeat CLIA testing. **Results:** Of 1,000 advanced cancer patients who underwent sequencing, 999 had at least one germline variant in one of the 19 "actionable" genes and 43 had likely pathogenic mutations: *BRCA1* (11*), BRCA2* (10), *TP53* (10), *MSH6* (4), *PALB2* (2), *PTEN* (2), *TSC2* (1), and *RB1* (1). Only 20 (49%) of 43 mutations were known based on clinical genetic testing. The ratio of somatic to pathogenic germline mutations differed by gene; for *TP53,* 375 patients had somatic mutations and 10 had pathogenic germline *TP53* mutations (38 to 1); for *BRCA1/2*, 106 patients had somatic mutations and 21 had pathogenic germline mutations (5 to 1). The 22 previously unrecognized mutations identified in the research environment were re-tested with an orthogonal CLIA platform with 100% concordance of mutation and interpretation. Of 1,167 patients who consented for a germline testing protocol, 1,157 (99%) stated they would like to be informed of incidental germline results. Initial experience with return of results will be presented. **Conclusions:** Most patients undergoing genomic testing are comfortable with germline testing and desire return of incidental results. A significant number may have unknown pathogenic mutations. Thus, genomic testing must be accompanied by a plan for return of germline results, in partnership with genetic counseling.

1511 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Characteristics of high risk breast cancer patients with mutations identified by multiplex panel testing. *First Author: Kara Noelle Maxwell, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Multiplex panel testing studies evaluating cancer susceptibility in breast cancer (BC) patients suggest that between 4-11% of *BRCA1/2* negative individuals have a deleterious mutation in a high or moderate penetrance gene. The range in mutation positivity is likely due to heterogeneity of the studied patient populations. **Methods:** We performed targeted, massively parallel sequencing of 795 *BRCA1/2* negative BC patients in a research laboratory and analyzed 18 cancer susceptibility genes.Three high risk groups were studied: multiple primary cancers (MP, n = 315), early onset breast cancer (EOBC, n = 323), and familial breast cancer (FBC, n = 415). MP was defined as at least one BC and at least one other primary malignancy excluding non-melanoma skin cancer, EOBC was defined as BC under age 40, and FBC was defined as at least three first to third degree relatives with BC under age 75. **Results:** Overall, 78 patients (10%) were found to have a deleterious mutation. Mutations were found most commonly in *CHEK2* (n = 32, 4.0%), *ATM* (n = 14, 1.8%), *TP53* (n = 10, 1.3%), and *MSH6* (n = 4, 0.5%). One to two patients each had deleterious mutations in *BARD1*, *BRIP1*, *CDKN2A*, *MRE11A*, *MSH2*, *NBN*, *PALB2*, *PTEN*, *PMS2*, and *RAD50*; no mutations were identified in *CDH1*, *MLH1*, or *STK11*. Deleterious mutations were more common in MP patients versus FBC patients without MP (12% versus 7%, p = 0.04) but not EOBC patients without MP (10%, p = NS). *CHEK2* and *MSH6* mutations were more common in MP versus non-MP patients (6% vs 3% and 1.3% vs none, respectively, p = 0.05) whereas *ATM* mutations were more common in non-MP patients (0.6% vs 2.5%, p = 0.05). The most common cancers in mutation carriers were a second primary breast cancer, sarcoma, melanoma, hematological malignancies, ovarian, thyroid and uterine cancer. There was a similar distribution of malignancies in MP mutation carriers versus non-mutation carriers. Sequencing is ongoing for 276 additional MP patients to validate these findings. **Conclusions:** Our results indicate that multiplex panel testing may find a higher rate of mutations in patients with MP malignancies as compared to patients with FBC alone; however, the type of second primary malignancy may not be predictive of mutation status.

Identification of ERCC2 as novel susceptibility gene for hereditary breast and ovarian cancer. *First Author: Pauline Wimberger, University Hospital Carl Gustav Carus, Dresden, Germany*

Background: Breast and ovarian cancer (BC/OC) predisposition has been associated with several high-, moderate-, and low-penetrance susceptibility genes. Despite comprehensive testing by next-generation sequencing (NGS), there is still a large portion of high risk cases with absence of mutations in any of the known susceptibility loci. Therefore, it is essential to extend the diagnostic spectrum by screening novel candidate genes. **Methods:** Inclusion criteria for study patients (n = 717, German and Lithuanian) were defined by the German Consortium for Breast and Ovarian Cancer. NGS was performed on the Illumina MiSeq sequencer and with the TruSight cancer panel including 94 genes cancer associated genes. **Results:** In 19.7 % of the patients, BRCA1 or BRCA2 variations were found. These were either pathogenic loss-of-function mutations (43%) or rare unclassified missense variations with high probability of a deleterious effect (57%). In 17.9% of the patients we found null-mutations and rare unclassified missense variants in the acknowledged BC/OC susceptibility genes ATM, CDH1, CHEK2, NBN, PALB2, RAD51C/D and TP53. Analysis of the non-BC/OC genes on the NGS panel identified the "excision repair cross-complementing rodent repair deficiency, complementation group 2" gene (ERCC2 or XPD) as promising BC/OC predisposition candidate: we found 3 frame-shift mutations and 1 splice-site mutation in four independent BC/OC families. In all individuals tested so far, ERCC2 mutations co-segregate with the occurrence of BC and/or OC. Additionally, we found 20 rare unclassified ERCC2 sequence variations with a cumulative allele frequency of 2.9%, which is 14.5-fold overrepresented compared to the "exome aggregation consortium" (ExAC) cohort (61486 exomes). Functional testing of ERCC2 variants is still ongoing. Preliminary results show that at least some of the protein variants (e.g. NM_000400.3:p.Asp513Tyr) have lost their DNA repair ability. **Conclusions:** Our data suggest ERCC2 as a novel BC/OC susceptibility gene and provide clinical rationale for ERCC2-mutational analysis in high risk patients with confirmed absence of mutations in known BC/OC predisposition genes.

Clinical impact of multi-gene panel testing for hereditary breast and ovarian cancer risk assessment. *First Author: Leif W. Ellisen, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Genetic testing for hereditary breast and ovarian cancer is evolving with the recent introduction of multi-gene panels, although the clinical impact of such panels is as yet poorly defined. For patients without BRCA1/2 mutations management is guided by personal and family history, although additional (non-BRCA) mutations can contribute additional information regarding risk for both the patient and their family members. It is unknown how often finding such mutations, including those that lack gene-specific guidelines, will potentially alter clinical management. **Methods:** We used similar 25 or 29 gene panels to test 1112 patients enrolled prospectively as appropriate candidates for HBOC evaluation at three academic medical centers. We applied uniform criteria to analyze the clinical impact of the non-BRCA1/2 mutations observed in these patients and also in comparable patients at these centers. Primary outcome measures included the frequency and types of potential management changes based on each patient's gene-associated cancer risks given personal/family history and established risk-based practice standards. **Results:** The prevalence of BRCA (9.0%, CI 7.1-11.3%) and non-BRCA (3.9%, CI 2.7-5.6%) mutations was in line with previous studies and suggests that this was a representative population. The most common non-BRCA findings involved known breast/ovarian cancer genes (PALB2, ATM, and CHEK2) and Lynch syndrome genes. Among 61 patients in all groups with non-BRCA findings, the majority would result in consideration of additional disease-specific screening and/or prevention measures for the patient (56%, 34/61) or mutation-positive first-degree relatives (76%, 42/55). **Conclusions:** In appropriately-referred patients, multi-gene panel testing yields clinically relevant findings with potential management impact for substantially more patients than does BRCA1/2 testing alone. Thus, this approach may improve care for many mutation-affected individuals in the short term, and in the long term should lead to the development of additional evidence-based guidelines for at-risk individuals.

1514 Poster Discussion Session; Displayed in Poster Session (Board #337), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Assessment of the clinical presentation of patients with at least two deleterious mutations on multi-gene panel testing. *First Author: Jeffrey N. Weitzel, City of Hope, Duarte, CA*

Background: Technical advances have upended the established paradigm of testing high penetrance cancer predisposition genes based on syndromic features. National guidelines now include discussion of multi-gene panels. However, significant gaps in our knowledge of gene-specific phenotypes have been identified, and the effects of various gene combinations are unknown. **Methods:** We examined results from patients tested with a 25-hereditary cancer gene panel in a CLIA approved laboratory. Clinical history was obtained from test requisition forms. **Results:** Of 55,803 patients tested, 3,953 (7.1%) had a single deleterious mutation, and 106 (0.19%) had mutations in at least two genes. Breast or colon cancer was the most common diagnosis among the probands (42.8-46.8% and 10.4-12.9%, respectively for single and dual mutation carriers). There were 19 different genes among the dual mutation carriers; both were high penetrance in 47 cases, 42 were combinations of high with moderate and 17 were a combination of 2 moderate penetrance genes. The most common second mutations were in *MUTYH*, *ATM* and *CHEK2*. Of 20 patients with 2 *MUTYH* mutations, 4 did not report either CRC or a polyp history. Common combinations included 6 *BRCA2/PMS2,* and 5 each for *BRCA1/ATM*, *BRCA2/ATM* and *CHEK2/PALB2*. Of 27 patients with mutations in two high penetrance genes (*APC, BRCA1, BRCA2, CDH1, MLH1, MSH2, MSH6, p16, PMS2, TP53*), 11/27 showed a mixed phenotype, consistent with both; 16/27 only reflected the phenotype of one of the two. There was no significant difference in age at cancer onset (< or > age 50 years) or probability of being unaffected; 23/89 (25.8%) dual mutation carriers vs.1205/3953 (30.5%) single mutation carriers (Chi-Square = 1.1941, p = .2745). **Conclusions:** Discovery of more than one deleterious mutation by multi-gene panel testing confounds accurate prediction of the phenotype or magnitude of risk. Despite a trend for more dual mutation carriers to be affected with cancer, the sample size was inadequate to reach statistical significance. Some cases with two high penetrance gene mutations only manifested one's phenotype. There is no obvious effect of low penetrance genes (e.g., *ATM*) on high penetrance gene phenotypes.

Outcomes of clinical testing for 50,000 patients utilizing a panel of 25 genes associated with increased risk for breast, ovarian, colorectal, endometrial, gastric, pancreatic, melanoma, and prostate cancers. *First Author: Eric T. Rosenthal, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

Background: Genetic assessment for inherited risk is a key tool for cancer prevention. Genetic testing strategies are evolving in response to expanding information about gene associations and available technologies for the cost-effective simultaneous screening of large numbers of genes. Here we provide outcomes data from clinical testing of a large, diverse cohort of US patients using a panel of 25 genes known to be associated with an increased risk for 8 common cancers with known genetic associations. **Methods:** Results are included from the first 50,000 patients tested with the 25-gene panel in a CLIA approved laboratory. All clinical information was obtained from test requisition forms completed by ordering healthcare providers. **Results:** 3750 (7.5 %) of tested patients were found to carry one or more pathogenic variants linked to an increased risk for cancer, distributed as shown in the table below. Clinical history review demonstrates that many patients had pathogenic variants in genes for which they most likely would not have been tested based on the reported personal/family history. Pathogenic variants in most genes were found in patients of all ancestries, indicating that the panel testing strategy can increase the sensitivity of testing in all populations. **Conclusions:** Testing with a 25 gene panel targeted at 8 common cancers significantly increases the number of patients identified as being at an increased cancer risk compared with testing targeted to a single gene or syndrome. This potentially benefits patients carrying pathogenic variants in genes for which testing was not widely available previously, and/or whose personal/family histories do not fit unambiguously with a single gene or syndrome.

Distribution of pathogenic variants detected.

Gene	Pathogenic Variants Detected

Sarcoma: A Lynch syndrome (LS)-associated malignancy? *First Author: John M. Kaczmar, Temple Univ/Fox Chase Cancer Ctr, Philadelphia, PA*

Background: Lynch syndrome (LS) is a well characterized hereditary cancer syndrome caused by mismatch repair (MMR) deficiency of epithelial tumors. Uncertainty remains as to whether several less common non-epithelial cancers such as sarcomas may also be associated with LS. We sought to describe the incidence and characteristics of sarcomas within a sample of LS families assembled through a multi-institutional collaboration. **Methods:** Participating sites (n = 7) queried their databases for molecularly proven and clinical LS families with sarcoma reported in a close relative (1st, 2nd, 3rd-deg). Information on the familial underlying MMR gene mutation (*MLH1*, *MSH2*, *MSH6*, *PMS2*, or *EPCAM*) was collected, as was age, sex, and tumor histology of all familial cancers from LS-sarcoma pedigrees (if available). Vague sarcoma diagnoses ("bone") were considered possible, while a documented category/histology ("rhabdosarcoma") was considered likely. **Results:** In total, from 958 LS families, 55 LS-sarcoma families (5.7%) contained 58 individuals with possible (n = 16) or likely (n = 42) sarcomas. Mean age of sarcoma diagnosis was 47.1 years (age range 4-87 years), with a 1:1 male to female ratio. Nearly two-thirds (62%, 36/58) of sarcomas were in *MSH2*+/*EPCAM*+ families, in contrast to the ~40% of all LS that are *MSH2*+. Other LS-sarcoma families were: *MLH1*+ (n = 12), *MSH6*+ (N = 3), *PMS2*+ (n = 3) and unknown (n = 4). Sarcoma histologies were diverse and included pleomorphic, synovial, myxofibroid, DFSP, liposarcoma, rhabdomyosarcoma, and osteosarcoma. Recurrent *MSH2* mutations in presumed unrelated LS-sarcoma families included 2 known founder mutations del exon 1-6 and c.942+3A > T as well as c.1216C > T, c.2135insT and c.1906G > C. Other pedigree findings included: Muir-Torre variant LS in 14/38 (37%) evaluable families, 7 thyroid cancers (2 early-onset, 29 and 31 yrs), an adult retinoblastoma, and an MSI-H thymoma in a 55 year-old woman with 2 soft tissue sarcomas. **Conclusions:** From a large sample of nearly 1000 LS families, our findings suggest sarcomas may be a rare manifestation of LS, especially *MSH2*+ LS. More research of genotype-phenotype correlations in LS is needed.

1517 Poster Discussion Session; Displayed in Poster Session (Board #340), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

A comparison of ascertainment of Lynch syndrome in colorectal cancer patients via reflex testing vs. hereditary guideline-based testing. *First Author: Setareh Samimi, BCCA VC, Vancouver, BC, Canada*

Background: In accordance with The American College of Medical Genetics and Genomics (ACMG), many institutions including The Hereditary Cancer Program (HCP) of the B.C. Cancer Agency recommend initiating testing for Lynch Syndrome (LS) based on the Bethesda criteria and/or on an age threshold of less than 50 years. Reflex immunohistochemical (IHC) testing independent of family history to infer deficient Mismatch Repair (dMMR) status combined with mutant BRAF 600E (mBRAF) IHC assessment provides an alternative means of screening for LS. Although many centers have adapted a reflex approach to screening for LS, this approach is still not standard. This study compares the efficacy of the two methods. **Methods:** From January 2012 to July 2013, reflex IHC testing to detect dMMR and mBRAF was performed in all cases of resected CRC across different jurisdictions in the greater Vancouver catchment area. Additional characteristics such as age at diagnosis, personal history of cancer, family history of cancer, and status of referral to HCP were reviewed. **Results:** In total, 1458 CRC patients were analysed, of which 194 (13%) were dMMR. The dMMR subset comprised abnormal staining of hMLH1 (n = 162), hMSH2 (n = 18), hPMS2 (n = 7) and hMSH6 (n = 7). Of these 194 patients, 103 (53%) were mBRAF, 60 (31%) were BRAF Wt and in 31 (16%), results are unknown. Using dMMR and BRAF Wt combined testing results to initiate referral to the HCP, only 60 patients would require further genetic evaluation, obviating the need for assessment of 103 potentially unnecessary referrals if only dMMR IHC was considered. Of the 60 dMMR and BRAF Wt patients, 54 (90%) were older than 50 years of age and 35 (65%) did not meet Bethesda criteria on chart review. **Conclusions:** A significant number of potential cases of LS would not be identified using established guidelines. Conversely, using only MMR testing would lead to unnecessary referrals. The combination of MMR and BRAF IHC testing may serve as a simple cost efficient and time saving tool to identify patients at highest risk for LS, supporting the role of reflex IHC testing of MMR and BRAF in CRC.

Usefulness of the patient self-administered cancer family history questionnaire in identification of gynecological cancer patients suspected of Lynch syndrome: KCOG-G1302 study. *First Author: Ryutaro Nishikawa, Nagoya City University, Nagoya, Japan*

Background: Detailed family history collection is necessary to detect gynecological cancer patients suspected of Lynch syndrome (LS). However, clinicians have little time for family history interviews. In addition, there is a lack of genetic counselors in Japan. Therefore, information from medical records on the first visit (MR) is insufficient to determine if a patient may be at risk of LS. We showed that using the self-administered cancer family history questionnaire (SACFHQ) improves identification of patients suspected of LS. **Methods:** We recruited endometrial or ovarian cancer patients already diagnosed or newly diagnosed from research participating institutions. After consent was obtained, participants completed the questionnaire. By referring to the cancer family history obtained from MR and SACFHQ, we referred to cases that met the Amsterdam criteria II(AMSII), the SGO20-25% criteria (SGO20-25%), ACOG's clinical bulletin 2014 criteria (ACOG2014). **Results:** There was a total of 493 participants. 38 patients were excluded by exclusion criteria. Finally, 455 were eligible. Median age at diagnosis was 56 (range21-84). 243 participants were endometrial cancer patients, and 213 were ovarian cancer, including peritoneal and tubal cancer. 12 cases had either synchronous/metachronous endometrial and colorectal cancer. 4 cases had either synchronous/metachronous ovarian and colorectal cancer. Among these 16 cases, endometrial or ovarian cancer was sentinel in 8 cases. By using MR, 0/455 (0%), 4/455 (0.9%), and 170/455 (37%) cases met AMSII, SGO20-25%, ACOG2014 criteria, respectively. By using SACFHQ, 6/455 (1.3%), 9/455 (2.0%), and 217/455 (48%) cases met AMSII, SGO20-25%, ACOG2014 criteria, respectively. All 6 cases that met AMSII were endometrial cancer patients. 8 of 9 patients who met SGO20-25% were endometrial cancer patients, and one patient was ovarian cancer. **Conclusions:** Family cancer history obtained from MR was shown to be insufficient to identify individuals at risk of LS. SACFHQ improves identification of gynecological cancer patients suspected of LS. Clinical trial information: 000013192.

Recreational activity and sedentary behavior in relation to lung cancer incidence and mortality in the Women's Health Initiative. *First Author: Ange Wang, Stanford Univ School of Medcn, South Pasadena, CA*

Background: Studies have suggested that physical activity may decrease cancer incidence and mortality. Data fromthe Women's Health Initiative Observational Study (WHI-OS) and Clinical Trial (WHI-CT) were used to investigate this relationship in a prospective cohort of postmenopausal women. **Methods:** The WHI study enrolled women aged 50-79 years from 1993-1998 at 40 U.S. clinical centers. Among 134,058 participants, Cox proportional hazards models were used to assess the association between lung cancer incidence/mortality and physical activity levels at study baseline [MET-minutes/week: inactive < 100 (reference), low 100- < 500, medium 500- < 1200, high 1200+] and sedentary behavior (sitting time/day in WHI-OS). **Results:** Over 11.8 mean follow-up years, 2,229 total incident lung cancer cases and 1,427 lung cancer deaths were identified. Increased total physical activity at study entry was associated with significant decreases in both lung cancer incidence [p = 0.004; physical activity levels: low HR 0.86 (95% CI: 0.77-0.96), medium HR 0.81 (0.72-0.91), high HR 0.89 (0.78-1.01)] and mortality [p < 0.0001, low HR 0.80 (0.70-0.92), medium HR 0.68 (0.58-0.79), high HR 0.77 (0.65-0.91)]. BMI was found to be an effect modifier of the relationship between total physical activity and lung cancer incidence (p = 0.008), with reduced HRs found for increasing physical activity levels for BMI < 30. While smoking status was not a statistically significant effect modifier, former smokers > 10 pack-years and current smokers were estimated to have reduced lung cancer incidence and mortality HRs for increasing physical activity levels, when compared to inactive women with the same smoking status. In the subtype analysis, decreased lung cancer mortality was associated with increased total physical activity levels for both overall NSCLC and adenocarcinoma. No association was found for sedentary behavior and lung cancer incidence or mortality. **Conclusions:** In a cohort of postmenopausal women, physical activity prior to diagnosis may decrease lung cancer incidence and mortality. Physical activity may be particularly protective for women with BMIs under 30, and for current and heavy former smokers. Clinical trial information: NCT00000611.

Modifiable metabolic markers c-peptide (C-PEP), highly sensitive c-reactive protein (hsCRP), leptin (LEP)] and lung cancer (LC) risk: A matched case-control study nested in the prostate, lung, colorectal and ovarian (PLCO) cancer screening study. *First Author: Pamela Jean Goodwin, Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada*

Background: LC is not associated with obesity; however, metabolic factors have been inconsistently associated with LC risk or death in previous small studies (involving < 100 LC cases). We investigated pre-diagnosis C-PEP, hsCRP and LEP and LC risk in EVER and NEVER smoking PLCO participants. **Methods:** 986 LC cases and 2054 controls [matched for age, gender, race/ethnicity, study center, duration in study, smoking status (never, former and current smoker)] provided non-fasting blood ≥ 2 years pre-diagnosis (≥ 3 yrs in 75%). After storage at -80°C, C-PEP, hsCRP and LEP were assayed using Luminex xMAP Multiplex immunoassays. Log transformed continuous blood markers were analyzed using multivariable conditional logistic regression [that included family history LC (FH), COPD, and smoking intensity, duration and quit-time]. 2-tail P ≤ 0.05 was considered significant. **Results:** Cases [854 NSCLC, 132 SCLC] and controls had similar age (64 yr) and ethnicity (90% white); cases had more smoking pack years (57.4 vs 39.6, p < 0.001). In EVER smokers (89.2% of total), LC cases (vs controls) had higher mean C-PEP (976.9 vs 939.4 pmol/L, p_{trend} = 0.02), hsCRP (22.6 vs 18.3 mg/L, p_{trend} < 0.001) and lower LEP (7.7 vs 8.1 ng/ml, p_{trend} < 0.001). Multivariably, higher C-PEP (p = 0.049) and hsCRP (p = 0.001) but lower LEP (p = 0.001) were associated with LC [Odds Ratios (OR) for upper vs lower quartiles 1.23, 1.54, 0.60 respectively]. FH (OR 1.75, p < 0.001), COPD (OR 1.38, p = 0.04), and extent of smoking were also associated with LC. When BMI was added to the model, it was inversely associated with LC (p = 0.003); C-PEP (p = 0.025) and hsCRP (p < 0.001) remained significant but LEP become non-significant. Metabolic markers were not associated with LC in NEVER smokers. **Conclusions:** In EVER smokers, higher pre-diagnosis C-PEP and hsCRP were associated with higher LC risk; inverse associations were seen for LEP and BMI. Future research should replicate our findings and investigate biologic mechanisms. Because these factors are potentially modifiable, intervention studies may be warranted.

Epidemiology and management of HIV-related non-Hodgkin lymphoma (NHL) in the United States (US): Analysis of the National Cancer Data Base (NCDB). *First Author: Adam J. Olszewski, Alpert Medical School of Brown University, Providence, RI*

Background: Antiviral therapy has altered the incidence and prognosis of NHL associated with human immunodeficiency virus infection (HIV+NHL). We analyzed recent trends in HIV+NHL presentation, management and overall survival (OS) using data from the NCDB—a registry capturing about 70% of US cancer cases. **Methods**: We extracted from the NCDB records of 364,422 NHL cases diagnosed in 2004-2012. HIV status was recorded for 57% of cases, identifying 11,409 HIV+ and 197,343 HIV- patients (pts). Trends and relative risks (RR) were evaluated by robust Poisson regression. **Results**: HIV+NHL pts were on average younger than HIV- (median age, 47 versus [*vs*] 67 years), more often male (77 *vs* 52%), black (33 *vs* 8%) or Hispanic (14 *vs* 5%). The histologies of HIV+NHL were: diffuse large B-cell (DLBCL)—46%, Burkitt (BL)—15%, primary central nervous system (PCNSL)—9%, primary effusion (PEL)—1%, indolent B-cell—10%, T-cell—5%, other/unknown—14%. Between 2003 and 2012, the proportion of black pts increased from 28% to 39% (*P*< .0001). The proportion of BL cases doubled among white pts (from 11 to 22%, *P*< .0001), but not for other races (from 14 to 16%, *P*= .06). The rate of chemotherapy (Ct) use increased from 69% to 78% (*P*< .0001). Ct was given to 80% of DLBCL, 90% of BL, 61% of PEL but only 34% of PCNSL pts. In a multivariable model, Ct use was significantly less common in black *vs* white pts (RR, 0.90, *P*< .0001), in facilities reporting ≤ 2 HIV+NHL cases per year (RR 0.92, *P*< .0001), and varied by insurance type. OS improved between 2004 and 2011 (log-rank *P*= .0004 for trend). OS at 3 years was 47% for DLBCL, 48% for BL, 26% for PCNSL, and 28% for PEL. Among pts who received Ct, 3-year OS was 53, 51, 45 and 29%, respectively, which was significantly lower than for HIV- pts (67% for DLBCL, 61% for BL and 47% for PCNSL; stratified log-rank *P*< .0001). **Conclusions**: Changes in the HIV+NHL demographics mirror the high rate of HIV infections among US black and Hispanic men. More HIV+NHL pts receive Ct, and their survival is improving, but disparities in Ct delivery exist that are related to socioeconomic factors and facility expertise. HIV+ DLBCL and BL have similar OS if Ct is given. In contrast, Ct does not alter the poor prognosis of PEL.

Family history of breast cancer in Hodgkin disease and future risk for breast cancer. *First Author: Sarah Violet Colonna, George E. Whalen VA, Salt Lake City, UT*

Background: Women with Hodgkin disease (HD) who undergo thoracic radiation have an extremely high risk of breast cancer (BC), up to 56x that of the average woman. The genetics underlying this increased BC risk is unclear, and we do not know if increased risk is observed in family members. We investigated BC risk among HD patients and relatives of women with HD. **Methods:** Using a genealogical database linked to Utah cancer data from 1966-2011, hazard ratios from Cox models were used to estimate BC risk among first-degree relatives (FDR) of women with HD. We compared female HD probands with BC (N=43) and HD probands without BC (N=837) to population controls age-matched 10:1. **Results:** The 'baseline' BC risk in FDR among BC patients in the Utah population (with no HD) is 1.8-fold (95%CI 1.7-1.8; *P*<0.0001). Among women with HD diagnosed before 2000 (higher radiation exposure) with subsequent BC, their FDRs are at 4-fold BC risk (95%CI 1.9-8.1; *P*<0.0001) compared to controls. Conversely, women with HD have markedly higher BC risk if they have FDR with BC compared to controls (HR=9.1, 95%CI 6.1-13.7; *P*<0.0001) and >2-fold BC risk compared to HD patients with no FDR with BC (95%CI 0.96-5.2; *P*=0.06). **Conclusions:** FDRs of women with HD and BC are at increased risk to develop BC beyond the general ~2-fold risk seen in FDRs of women with BC. Consistently, we found a very pronounced increase in BC among HD patients with FDRs with BC and 2x BC risk compared to HD patients with no BC in FDRs. This suggests an underlying genetic mechanism may predispose women with HD and their relatives to an increased risk for BC. Obtaining a BC family history at HD diagnosis may help personalize treatment around radiation therapy. Further investigation into HD treatment details related to familial and genetic for BC risk is warranted.

BC risk among relatives and HD probands vs. controls.

Relationship	HR	95%CI	P-value
BC in HD probands with BC in FDR	9.2	6.1-13.7	<0.0001
FDR of HD probands with BC (before 2000)	4.0	1.9-8.1	<0.0001
FDR of HD probands with BC	3.3	1.7-6.1	0.0002
HD probands w/BC in FDR vs. HD no BC in FDR (case-case comparison)	2.3	<1.0-5.2	0.06
BC in HD probands, no BC in FDR	2.2	1.4-3.3	0.0003
FDR of BC probands (no HD)	1.8	1.7-1.8	<0.0001
FDR of HD probands with no BC	0.9	0.7-1.2	0.81

Hereditary implications of somatic tumor testing. *First Author: Pauline Funchain, Cleveland Clinic, Cleveland, OH*

Background: Approximately 5-10% of all cancers are due to hereditary causes. Panel testing for somatic alterations to identify therapeutic targets has gained widespread use. Germline (heritable) implications from such testing have not yet been explored. In a prospective cohort study of patients who underwent tumor profiling by next generation sequencing (NGS), we determined the prevalence of potentially germline (PG) alterations and the frequency of referral to genetics professionals. **Methods:** We prospectively accrued 250 patients to an IRB-approved protocol to undergo commercial tumor genomic profiling. Inclusion criteria included pathologic diagnosis of select solid tumor malignancies without a known curative option, age ≥ 18 years, and ECOG PS 0-2. Tumor samples underwent targeted NGS through the FoundationOne panel (Cambridge, MA). Genes captured by this test were classified as PG if the gene is known to cause hereditary predisposition to cancer and has available CAP/CLIA-certified germline testing. **Results:** Of 315 genes tested by tumor genomic sequencing, 41 genes were classified as PG. Alterations were found in 23 PG genes. Of 222 patients with resulted tumor sequencing, 179 (81%) were found to harbor >1 PG alteration. After exclusion of *TP53, APC,* and *CDKN2A*alterations, frequently somatically mutated in tumors, 91 (41%) were found to harbor any PG alteration. 34 patients harbored >1 hit in a single PG gene (e.g. "double mutants"). When considering the mean number of PG alterations found per patient, the top 4 cancer types were glioblastoma, colorectal, bladder, and breast. In this series of 222, 23 (10%) were evaluated by genetics professionals: 3 genetics referrals were a direct result of somatic panel testing, resulting in 1 (33%) previously unknown germline mutation. Germline testing has been completed in 19 patients, and revealed 4 germline mutations and 4 variants of unknown significance. Allelic fractions derived from tumor genomic profiling for these confirmed germline variants ranged between 35-72% (mean: 51%). **Conclusions:** Somatic screening of tumors has germline implications. Tumor and germline testing are not equivalent, and should be done separately. More extensive data are necessary to determine guidelines for genetics referrals.

1524 Poster Session (Board #348), Mon, 1:15 PM-4:45 PM

Clinical outcomes based on multigene profiling in metastatic breast cancer patients. *First Author: Reva Kakkar Basho, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Identifying the clinical impact of mutations in cancer-related genes can help define their role in cancer. Here, we aim to classify frequent hotspot mutations in metastatic breast cancer (MBC) patients and determine how they may affect clinical outcomes. **Methods:** Hotspot mutation testing was conducted in 500 MBC patients using an 11 gene Sequenom (N = 126) and/or 46 or 50 gene Ion AmpliSeq Panel (N = 391). Patients were stratified by hormone receptor (HR) and HER2 status, type of therapy (chemo, endocrine or targeted therapy) and line of therapy. Clinical outcomes including recurrence-free survival from diagnosis (RFS) and time to treatment failure due to progression (TTP) were retrospectively collected, and comparative analysis between patients who did and did not harbor mutations in certain genes was conducted. **Results:** The most frequent genes with hotspot mutations were *TP53* (30%), *PIK3CA* (26%) and *AKT1* (4%). Triple-negative breast cancer patients had the highest incidence of *TP53* (58%) and the lowest incidence of *PIK3CA* (8%) mutations. *TP53* mutation was associated with significantly shorter RFS (median 19 vs 41 months; $P < 0.001$), TTP with first-line (median 6 vs 12 months; $P < 0.001$) and second-line (median 4 vs 7 months; $P = 0.006$) therapy and TTP with chemotherapy (median 6 vs 8 months; $P = 0.005$) and targeted therapy (median 4 vs 14 months; $P = 0.009$) in the first-line setting. Conversely, presence of *PIK3CA* mutation did not significantly affect RFS or TTP with first-line therapy. In HR-positive patients, *TP53* mutation was associated with significantly shorter RFS (median 24 vs 46 months; $P < 0.001$), distant RFS (median 30 vs 46 months; $P = 0.002$) and local-regional RFS (median 51 vs 131 months; $P < 0.001$). However, there was no significant association between TTP and mutation status of *TP53*, *PIK3CA*, or *AKT1* in HR-positive patients treated with endocrine therapy in the first- or second-line setting. **Conclusions:** Correlating clinical outcomes with the presence of hotspot mutations in cancer-related genes can help define the clinical significance of these mutations. In this cohort of MBC patients, *TP53,* the most frequent hotspot mutation, was associated with worse clinical outcomes, both overall and in HR-positive patients. Clinical trial information: NCT01772771.

1525 Poster Session (Board #349), Mon, 1:15 PM-4:45 PM

Whole exome sequencing to identify potentially causative gene variants in hereditary gastric cancer. *First Author: Yiqing Huang, National University Cancer Institute Singapore, National University Hospital, Singapore, Singapore*

Background: Gastric cancer is the leading cause of death in Asia where a small proportion is hereditary. While some causative genes like CDH1 and mismatch repair genes have been well characterized, many remain unidentified. **Methods:** We performed whole exome sequencing on peripheral blood DNA of gastric cancer patients suspected to have an underlying hereditary predisposition, defined as young onset cancer diagnosed at or below age forty, and/or strong family history of cancers. Potentially causative mutations were identified using ANNOVAR, the CADD algorithm and HGMD database. Sanger sequencing was performed to confirm mutations identified. **Results:** Twenty subjects (18 Chinese and 2 Malays) were studied. 70% were males. Median age at cancer diagnosis was 36 (range 24-68). 75% had poorly differentiated adenocarcinomas and 50% had signet ring cells. 9 subjects had young onset cancer without family history, 6 had young onset cancer with family history and 5 had gastric cancer after age 40 but had family history of gastric or Lynch syndrome related cancers. Potentially deleterious germline mutations that may cause hereditary gastric cancer were identified in 9/20 (45%) of subjects. Seven subjects carried 8 deleterious mutations in genes known to cause familial gastric cancer, including CDH1 (n = 1: *c.1888C > G(L630V)*), MLH1 (n = 2: *428T > A(V143D)*, n = 1: *2101C > A(Q701K)*), MSH6 (n = 2: *c.4071_4072insGATT*, n = 1: *3205G > C(G1069R)*) and TP53 (n = 1: *679G > T(G227X)*). A probably deleterious mutation was identified in 1 novel gene, ABCA10 (*1328_1331del*), in 2 patients with young onset gastric cancer without family history; this variant is present in less than 1% of Asians. Five of the 7 distinct deleterious mutations identified were novel. In addition, 6 subjects carried two PLCE-1 variants (*T1469I*, *H1619R)*, while another 6 subjects carried a *MLL3 S3660L* variant, all of which have been reported to be possible low-penetrance variants that increase gastric cancer risk by 1.4 and 2.5 fold respectively. **Conclusions:** In this cohort of Asian gastric cancer patients suspected to have hereditary gastric cancer, potentially causative rare high penetrance and common low penetrance genetic variants were identified.

1526 Poster Session (Board #350), Mon, 1:15 PM-4:45 PM

Amplification of *CRKL* in human cancer: A rare event associated with potential sensitivity to targeted therapy. *First Author: Kai Wang, Foundation Medicine, Inc., Cambridge, MA*

Background: *CRKL* amplification (amp) has been linked to tumor progression and adverse prognosis in solid tumors. Recent evidence suggests that *CRKL* amp may mediate resistance to EGFR inhibitors and may be associated with exceptional tumor response to Src kinase inhibitors. **Methods:** Next generation sequencing based comprehensive genomic profiling (CGP) using hybridization capture of 236 cancer-related genes was applied to ≥ 50 ng of DNA extracted from 33,000 FFPE specimens and sequenced to high, uniform median coverage (> 600X) and assessed for base substitutions, INDELs, copy number alterations and rearrangements. Clinically relevant genomic alterations (CRGA) were defined as those for which anti-cancer drugs on the market or in registered clinical trials could be identified. **Results:** *CRKL* amps (> 6 copies) were identified in 274 (0.8%) patients of median age 62 years (range 19-92) with 137 females and 137 males. There were 18 distinct tumor types featuring *CRKL* amp as show in the table below. Co-existent CRGA associated with *CRKL* amp were *FGFR1* (7%), *RICTOR* (6%), *ERBB2* (6%), *KIT* (6%), *EGFR* (5%), *PTEN* (5%), *NF1* (5%) and *AKT2* (5%). In 3 (1%) cases *CRKL* amp was the only GA and in 41 (15%) *CRKL* amp was the only CRGA. Of 6 *CRKL* amp cases with *EGFR* substitutions, 5 (83%) were in NSCLC consistent with a potential resistance mechanism to anti-EGFR therapy. Case examples of unanticipated major responses of tumors with *CRKL* amp treated with targeted therapies will be presented. **Conclusions:** *CRKL* amp is widely distributed across diverse tumor types and frequently associated with other druggable CRGA. *CRKL* amp may be associated with EGFR TKI resistance in NSCLC. Tumors with *CRKL* amp targeted with Src kinase inhibitors may be responsible for examples of exceptional clinical responses of advanced cancers to this class of therapy.

Selected Tumor Types	# of *CRKL* amp	# of tumors analyzed	% of tumors with *CRKL* amp
Testis + mediastinum germ cell tumors	6	63	9.5%
Bladder	14	562	2.5%
Ovary	28	1464	1.9%
Lung	81	6068	1.3%
Unknown primary carcinoma	33	2779	1.2%
Melanoma	20	1880	1.1%
Liver + bile duct + gallbladder	7	675	1.0%
Soft tissue + bone	11	1088	1.0%
Uterus	7	717	1.0%
Pancreas	10	1215	0.8%
Gastrointestinal tract	23	4622	0.5%
Breast	16	3988	0.4%

1527 Poster Session (Board #351), Mon, 1:15 PM-4:45 PM

Germline testing in hereditary cancer genes subsequent to the identification of mutations in tumor specimens. *First Author: Virginia Speare, Ambry Genetics, Aliso Viejo, CA*

Background: Molecular profiling of tumors is crucial in identifying targeted therapies. Secondarily, tumor DNA sequencing has the potential to reveal germline mutations leading to the diagnosis of a hereditary cancer predisposition. We sought to determine the frequency and clinical significance of germline testing performed at one laboratory subsequent to tumor profiling. **Methods:** Retrospective review of a laboratory database revealed 74 germline test orders following identification of mutations in tumor specimens from 54 patients. Age at cancer diagnosis, family history and a description of the patient's tumor including associated somatic mutations were obtained from test requisitions. Germline targeted sequencing was performed with DNA isolated from blood or saliva. Pathogenic mutations identified in hereditary cancer predisposition genes were included for analysis. **Results:** Ten of 74 (13%) tumor mutations were confirmed in the germline. The remaining mutations are presumed to be somatic. Mutations were identified in 5 of 17 genes with the majority of germline findings in *BRCA1* (3) and *BRCA2* (4). Although *TP53* alterations were most frequently submitted for germline analysis, none were confirmed in the germline, despite 3/18 patients meeting National Comprehensive Cancer Network (NCCN) criteria for *TP53* germline testing. Based on available clinical history, 3 patients who did not meet NCCN testing criteria carried a *BRCA2* germline mutation. **Conclusions:** Patients with germline mutations who did not meet criteria for testing represent a portion of high-risk individuals who may not otherwise be identified in the absence of tumor profiling results. In addition, germline mutation detection varied between genes. These insights may prove useful in identification of patients appropriate for cancer predisposition evaluation.

Gene	# Mutations from Tumors	# Confirmed in Germline (% met testing criteria)
APC	3	0
ATM	2	0
BRCA1	4	3 (100%)
BRCA2	12	4 (25%)
CDH1	4	0
CDKN2A	3	0
CHEK2	1	1 (NC)
MEN1	6	0
MLH1	1	0
MSH2	2	0
MSH6	2	0
NF1	6	1 (100%)
PTEN	6	1 (100%)
RB1	2	0
STK11	1	0

1528 Poster Session (Board #352), Mon, 1:15 PM-4:45 PM

Comparison of genotyping performance in DNA extracted from matched FFPE tumor, FFPE lymph node, and whole blood for pharmacogenetic analyses. *First Author: Daniel Louis Hertz, University of Michigan, Ann Arbor, MI*

Background: Pharmacogenetics requires genetic information from patients' germline DNA.There is concern that DNA extracted from formalin-fixed paraffin embedded (FFPE) tumors may not accurately represent germline DNA due to somatic genetic alterations and technical challenges. Our objective was to compare genotyping performance for DNA isolated from FFPE tumor (T), FFPE non-cancerous lymph node (LN), and whole blood (WB) to determine the extent and source of genotyping inaccuracy in FFPE tumor DNA. **Methods**: Single nucleotide polymorphisms (SNPs) from genes that affect drug elimination, efficacy, and toxicity were genotyped on Sequenom MassArrays using DNA isolated from matched T, LN, and WB samples obtained from patients with early stage breast cancer. The no-call rate was calculated for each tissue type and the discordant call rate was calculated for T and LN by comparison with the WB genotype. **Results**: After quality control, matched samples from 114 patients were genotyped for 247 SNPs in 80 genes. The no-call rate in T (4.3%) was greater than LN (3.0%) and both were greater than WB (0.5%). The discordant rate in T (1.1%) was greater than LN (0.3%). Samples with heterozygous genotypes were more likely to be no- or discordantly-called than homozygous samples (all $p < 0.001$, Table). **Conclusions**: FFPE T no- and discordant-call rates were acceptable (< 5%), though higher in heterozygous samples, suggesting that somatic genetic alterations and FFPE storage have minimal effect and/or FFPE T samples contain sufficient normal tissue for germline genotyping. FFPE T samples can be used in pharmacogenetic research, however, certain genes that are highly altered in somatic tissue require germline specimens and inaccurate genotyping of heterozygous samples precludes use of FFPE T for clinical pharmacogenetics.

No and discordant call rates in each sample type.

		T	LN	WB
No Calls	Overall	4.3% (1221/28158)	3.0% (843/28158)	0.5% (135/28158)
	Homozygous	1.8% (346/18900)	2.5% (468/18900)	-
	Heterozygous	9.5% (864/9123)	4.0% (363/9123)	-
Discordant Calls	Overall	1.1% (306/26824)	0.3% (84/27204)	-
	Hom.	0.2% (33/18554)	0.2% (32/18432)	-
	Het.	3.3% (273/8259)	0.6% (52/8760)	-

1529 Poster Session (Board #353), Mon, 1:15 PM-4:45 PM

Personalized Genomic Analyses for Cancer Mutation Discovery and Interpretation. *First Author: Valsamo Anagnostou, The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: The anticipated widespread adoption of large scale genomic analyses in precision oncology mandates the development of a gene actionability framework. Previous efforts of clinical interpretation of genomic alterations mainly rely on expert opinion and manual curation of the primary literature. Furthermore, analytic challenges such as distinguishing somatic -driver- mutations from germline alterations have limited the interpretation of genomic information. **Methods:** We comprehensively evaluated 815 tumor-normal paired samples from 15 tumor types and identified genomic alterations using next generation sequencing of whole exomes or 111 targeted genes. Tumor and normal data were compared to identify somatic and germline alterations. We extracted information from consensus guidelines (fda.gov), the centralized registry of clinical trials (ClinicalTrials.gov) and published clinical trials to generate a database with actionable genes according to graded levels of evidence. **Results:** These analyses revealed an average of 140 and 4.3 somatic mutations per exome and targeted sequencing respectively. We identified at least one somatic alteration in genes with potentially actionable consequences in 77% of patients analyzed. Most of the actionable changes were associated with current clinical trials (67%) rather than established therapies (33%). More than 90% of genes with actionable alterations were mutated in < 5% of individual tumors. Analyses of matched normal DNA identified germline alterations in cancer predisposing genes in 3% of patients with apparently sporadic cancers. In contrast, a tumor-only sequencing approach followed by bioinformatic removal of common germline variants led to a 31% and 65% false discovery rate in alterations identified in targeted and exome analyses, respectively. **Conclusions:** Our comprehensive actionability framework was used to classify genomic alterations based on existing levels of evidence and could be used as a platform for clinical interpretation of somatic alterations. Our findings suggest that matched tumor-normal sequencing analyses are essential for precise identification of somatic alterations and have important implications in clinical decision making.

1530 Poster Session (Board #354), Mon, 1:15 PM-4:45 PM

The landscape for genetic eligibility to basket clinical trials. *First Author: Todd Cory Knepper, H Lee Moffitt Cancer Ctr, Tampa, FL*

Background: There is a movement toward basket trials, where eligibility is based on molecular aberrations rather than anatomical origin of a cancer. There is a paucity of information on how many cancer patients (pts) meet eligibility for basket trials. This study assessed the genetic eligibility of cancer pts seen at a large cancer center for the currently open basket trials. **Methods:** Moffitt's Clinical Genomic Action Committee (CGAC) database was used to assess 236 pts across 30 cancer types with targeted deep sequencing as part of clinical care between 1/1/2013 and 12/31/2014. Pts were screened for basic histologic and genetic eligibility on all basket trials open in North America in January, 2015 (Novartis Signature, NCI-MATCH, NCI-M-PACT). The trials included 23 different arms utilizing different agents based on 44 different molecular alterations; 11 of these alterations allowed eligibility into multiple trials. **Results:** Among the 236 evaluable pts, 83.5% met genetic eligibility for at least 1 of the arms examined with an average of 2.89 eligible arms per patient and a range of 0 to 15. The percentage of histologically eligible pts meeting genetic eligibility ranged from 0% (non-melanoma or colorectal BRAF V600 mutated solid or hematologic malignancy) to 50.0% (PARP1/2 or TP53 mutated solid tumor) across all treatment arms. Of 188 pts with solid malignancies, 93.6% met genetic eligibility for at least 1 of the trials vs. 45.8% of 48 pts with hematologic malignancies. **Conclusions:** The vast majority of pts within a clinical genetic database who received somatic tumor sequencing met genetic eligibility for at least one aberration-specific clinical trial; however 16.5% of pts overall and the majority of those with hematologic malignancies remained without basket trial options. These results highlight opportunities for enrollment in clinical trials given access to both tumor sequencing and next-generation clinical trials.

	All Pts (n = 236)	Solid Malignancies (n = 188)	Heme Malignancies (n=48)

Patient-reported outcomes associated with population-based Jewish genetic testing for BRCA1 and BRCA2. *First Author: Kelly A. Metcalfe, University of Toronto, Toronto, ON, Canada*

Background: Population based genetic testing for common Jewish mutations in BRCA1 and BRCA2 has been proposed, however it is unclear what the outcomes associated with population based testing are. **Methods:** 6108 unselected Jewish women in Ontario were offered genetic testing for three common Jewish BRCA mutations. Cancer-related distress was measured prior to testing, and at one and two years post-testing. Information on uptake of cancer risk reduction options was collected at two years post-testing. **Results:** Of the 6108 Jewish women tested, 1.1% were found to have BRCA mutation (0.4% BRCA1 and 0.7% BRCA2). None of these women had a previous cancer diagnosis and 62% of the women would not have been eligible for testing based on current criteria. Of the 68 women identified with a BRCA mutation, 3 breast cancers and 1 ovarian cancer were identified on first screenings. Within two years of testing, 28% of women had prophylactic mastectomy and 72% had a prophylactic oophorectomy. Cancer-related distress was significantly higher at one-year post-testing for those with a mutation (mean 20.0, SD = 15.3) compared to those without (mean 9.8, SD = 13.9) ($p < 0.0001$). For women with a BRCA mutation, cancer-related distress declined significantly from one year to two-years post genetic testing ($p = 0.01$). Satisfaction with population based genetic testing was high (mean 4.1; 1 = extremely dissatisfied to 5 = extremely satisfied). After identification of the 68 women with mutations, 128 first degree relatives were eligible for testing, of which 90 were tested (70%) and 32 additional BRCA carriers were identified. **Conclusions:** Population based Jewish genetic testing for BRCA1 and BRCA2 is effective at identifying unaffected women with mutations who otherwise would not be eligible for testing, in addition to their first degree relatives. The majority of women elect for risk reduction surgeries after learning of their BRCA mutations. Increased levels of cancer-related distress in BRCA carriers are transient and decline at two years post genetic testing. We propose that population based genetic testing for BRCA1 and BRCA2 be made available for Jewish individuals who wish to be tested.

1532 Poster Session (Board #356), Mon, 1:15 PM-4:45 PM

Somatic mutation profiling of advanced breast and ovarian cancers according to germline *BRCA1/2* mutation status. *First Author: Neda Stjepanovic, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The risk of breast cancer (BC) and ovarian cancer (OC) is increased in germline *BRCA1/2* mutations carriers (BRCA+). We investigated the somatic mutation profile and clinical impact of targeted sequencing in advanced BC and OC patients (pts) according to germline *BRCA1/2* status. **Methods:** Targeted sequencing with Illumina MiSeq TruSeq Amplicon Cancer Panel (TSACP; 48 non-homologous DNA recombination genes, 212 amplicons, $\geq 500\times$ coverage) was performed using archival tumor and germline DNA from advanced BC and OC pts through an ongoing institutional molecular screening program (NCT01505400). Medical records were retrospectively reviewed for clinical, pathological and germline *BRCA1/2* testing results. **Results:** From May/13 to Oct/14, somatic TSACP testing was completed in 257 pts (106 BC and 151 OC). Germline *BRCA1/2* testing was performed in 118 pts (35 BC [33%] and 83 OC [55%]), primarily in those with family history and/or young age at diagnosis. Among these, 25 pts were BRCA+ (21%), including 4 BC (11%; 25% triple negative [TN]) and 21 OC (25%, all type 2) pts. The BRCA-/unknown group (BRCA-/UK) comprised 102 BC (24% TN and 76% non-TN) and 130 OC (31% type 1, 68% type 2) pts. Using the TSACP, 188 pts (73%) had $\geq$ 1 somatic hotspot mutation with no difference in the number of somatic mutations detected in BRCA+ vs BRCA-/UK (median 1, range 0-3; $p = 0.85$). More BRCA+ pts had *TP53* hotspot mutations compared with BRCA-/UK pts (76% vs 50%, $p = 0.01$). Somatic hotspot mutations in *PIK3CA* were more frequent in BRCA-/UK vs BRCA+ (22% vs 4%, $p = 0.04$). After a median follow up of 8 months, 12 BRCA-/UK pts vs no BRCA+ pts were enrolled in somatic genotype matched targeted clinical trials (5% vs 0%, $p = 0.62$). Seven BRCA+ pts received PARP inhibitors on clinical trials. **Conclusions:** In pts with BRCA+ BC and OC, *TP53* mutations are common while *PIK3CA* or other hotspot somatic mutations are rare. Whether the association between germline *BRCA1/2* and hotspot mutation status is causal or confounded by histological subtypes should be validated in larger cohorts. Broader genomic sequencing may further highlight biological differences amongst BRCA+ and BRCA- tumors and provide more opportunities for genotype-treatment matching.

1533 Poster Session (Board #357), Mon, 1:15 PM-4:45 PM

Multi-gene panel testing in an unselected endometrial cancer cohort. *First Author: Kari Lassen Ring, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Endometrial carcinoma (EC) is associated with multiple hereditary cancer genes including Lynch syndrome (LS) genes, which are estimated to account for 2-6% of all cases. The role of other cancer predisposition genes in EC is unclear. We aimed to determine in an unselected EC cohort the prevalence of germline mutations in LS and other cancer predisposition genes. **Methods:** The study cohort was 381 EC patients unselected for age of dx with banked blood samples available for testing. DNA mutations in 25 cancer genes were identified using a next generation sequencing based panel. Germline sequence variations and large rearrangements were classified for pathogenicity. Patients' clinical data, tumor testing with immunohistochemistry (IHC) for mismatch repair proteins, microsatellite instability, and MLH1 methylation, were abstracted from the medical record. All cases had germline genetic testing regardless of tumor testing status. **Results:** 35 patients (9.2%) had a deleterious mutation (DM). 22 patients (5.8%) had a DM in LS genes (3 *MLH1*, 5 *MSH2*, 2 *EPCAM*, 6 *MSH6*, 6 *PMS2*) and 13 patients (3.4%) had a DM in non-LS genes (4 *CHEK2*, 1 each in *APC, ATM, BARD1, BRCA1, BRCA2, BRIP1, NBN, PTEN, RAD51C*). Compared to patients with no DM, patients with DM in LS genes were younger at diagnosis (mean 51.7 v 61.5, $p < 0.01$), less likely to be overweight (63.6% v 85.5%, $p = 0.01$), more likely to have a tumor in the lower uterine segment (30.0% v 7.5%, $p < 0.01$), and more likely to meet SGO guidelines for genetic assessment referral (59.1% v 24.3%, $p = 0.01$). 3 patients (13.6%) with DM in LS genes were diagnosed $>$ 60 years. Of 20 patients with DM in LS genes and available tumor results, 2 (10%) had a DM (1 *PMS2*, 1 *MSH6*) and IHC results suggestive of sporadic cancer. Patients with DM in non-LS genes were more likely to have serous histology (23.1% v 6.4%, $p = 0.02$) than those with no DM. 3 patients with non-LS DM and serous histology had mutations in *BRCA2, BRIP1*, and *RAD51C*, genes previously linked to hereditary ovarian cancer. **Conclusions:** Results for EC with DM in LS genes were similar to previous findings. Panel testing to include non-LS genes allowed for the identification of possibly novel genes that may be associated with serous-type EC, the most clinically aggressive form of this cancer.

1534 Poster Session (Board #358), Mon, 1:15 PM-4:45 PM

Evaluation of rapid whole-body magnetic resonance as screening strategy for early cancer detection in 57 Brazilian Li-Fraumeni syndrome patients. *First Author: Daniele Paixao, A.C. Camargo Cancer Center, Sao Paulo, Brazil*

Background: Li-Fraumeni Syndrome (LFS) is a rare autosomal dominant syndrome associated with germline mutations in *TP53* gene. Carriers have a high risk for developing multiple early onset cancers, most commonly breast cancer, sarcomas, brain and adrenocortical carcinomas. Screening strategies for early diagnosis in carriers constitute a major challenge due to the diverse spectrum and ages of onset of tumors. Rapid whole body MRI (RWB–MRI) has been proposed as a screening strategy. In Brazil, there is a high prevalence of a founder mutation (p.R337H *TP53*) present in 0.3% of the South/Southeastern Brazilian population. Due to genetic modifiers, tumors occur at a later age in p.R337H carriers. **Methods:** The aim of this study is to evaluate the efficacy of RWB–MRI as a screening strategy in p.R337H *TP53* carriers and in classical LFS mutation carriers. A total of 84 RWB–MRI were performed in 57 *TP53* germline mutation carriers (49 p.R337H *TP53*), including 27 patients who performed a second exam 12 months after the first RWB–MRI. **Results:** Two malignant lesions were detected by RWB–MRI: (1) in a 19–year old p.R337H female carrier RWB-MRI demonstrated bilateral renal cortical alterations, confirmed with abdominal MRI which showed an enhancing solid lesion in the right kidney. The lesion was surgically removed and pathological findings confirmed a papillary renal cell carcinoma; (2) in a 30 year old p.R337H female carrier, RWB–MRI detected a solid right breast nodule. Breast MRI detected two solid lesions. Biopsy of each lesion confirmed diagnoses of a ductal carcinoma in situ and benign phyllodes tumor, respectively. Incidental findings were detected in 26/57 patients and further imaging modalities were performed in 9/26 cases which ruled out malignancies and no unnecessary biopsies were performed. No malignant lesions were detected in 8 classical LFS patients. **Conclusions:** Preliminary results from this study demonstrate the feasibility and effectiveness of RWB–MRI in detecting malignant lesions among 49 p.R337H *TP53* mutation carriers.

1535 Poster Session (Board #359), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling of advanced stage esophageal squamous cell carcinomas (ESCC) and esophageal adenocarcinomas (EAC). *First Author: Adrienne Johnson, Foundation Medicine, Inc., Cambridge, MA*

Background: Esophageal Squamous Cell Carcinomas (ESCC) and Esophageal Adenocarcinomas (EAC) account for $>$ 95% of esophageal malignancies. Using a sensitive sequencing assay, we compared the genomic profiles of ESCC and EAC focused on the ability to identify potential targets for therapy in the 2 diseases. **Methods:** DNA was extracted from 40u of FFPE sections from 71 clinically advanced ESCC and 231 EAC. Next generation sequencing based comprehensive genomic profiling (NGS) was performed on hybridization-captured, adaptor ligation based libraries to a median coverage depth of $>$ 650x for 236 cancer-related genes. The results were evaluated for all classes of genomic alterations (GA). Clinically relevant genomic alterations (CRGA) were defined as GA linked to drugs on the market or under evaluation in mechanism driven clinical trials. **Results:** There were no significant differences in the age range for ESCC and EAC (median: 63 vs. 60 years). All ESCC and EAC were at an advanced stage (Stage III/IV) at the time of sequencing. GA per sample on average in 71 ESCC and 231 EAC were 7.4 and 5.6 respectively. The frequency of CRGA in ESCC (2.6/sample; 94.4% of cases) and EAC (2.7/sample; 93.1% of cases) were similar. CRGA more frequently identified in ESCC than EAC included *PIK3CA* (24% vs 10%), *PTEN* (11% vs 4%), *CCND1* (42% vs 13%) and *NOTCH1* (17% vs 3%). CRGA more frequently altered in EAC than ESCC included *KRAS* (23% vs 6%) and *ERBB2* (23% vs 3%). Other GA that were significantly different in the 2 tumor types included *SMAD4* (1% ESCC vs 14% EAC), *SOX2* (18% ESCC vs 1% EAC) and *NFE2L2* (24% ESCC vs 1% EAC). *EGFR* was altered in 8% of ESCC and 15% of EAC. Clinical case examples of patient responses to targeted therapy will be presented. **Conclusions:** ESCC and EAC share common high frequencies of overall and clinically relevant GA. However, PI3K/mTOR (*PIK3CA* and *PTEN*) and Notch pathway genes were significantly enriched in ESCC, and RAS/MEK pathway genes (*ERBB2* and *KRAS*) were significantly enriched in EAC. Comprehensive genomic profiling shows significant promise to identify CRGA in both ESCC and EAC and lead to potential use of clinical outcome altering targeted therapies in both major types of esophageal cancer.

1536 Poster Session (Board #360), Mon, 1:15 PM-4:45 PM

Is there a role for multi-gene screening panels in patients who previously underwent noninformative genetic testing? *First Author: Melissa K Frey, New York University School of Medicine, New York, NY*

Background: The availability of next-generation sequencing coupled with the recent discovery of multiple cancer-related genes has caused a shift away from single gene testing towards multi-gene panel testing for familial cancer syndromes. However, the utility of multi-gene panels in individuals who previously underwent noninformative genetic screening has yet to be evaluated. We aim to evaluate the use of rescreening and results of multi-gene panels in this rescreened population. **Methods:** We reviewed all patients who had previously undergone genetic testing for familial cancer syndromes and then underwent multi-gene panel testing at a single institution between 9/2013-11/2014. **Results:** One hundred and twenty-four patients with prior non multi-gene panel testing underwent multi-gene panels. One hundred patients (81%) had a history of cancer and 115 patients (93%) had at least one family member with cancer. On primary testing, no deleterious mutations were identified and 11 variants of uncertain significance (VUS) were found in 10 patients (8%). On repeat multi-gene panel testing, 5 patients (4%) had a deleterious mutation, 54 (44%) had VUS and 4 (3%) had a mutation and VUS. Among patients with a VUS on rescreening, 14 (24%) had more than one VUS identified (range 2-4). Rescreening found a total of 9 deleterious mutations and 80 VUS and resulted in a change in mutation characterization for 9 patients and VUS characterization for 48 patients. **Conclusions:** Among patients with negative primary testing there was a 47% rate of change in result characterization with multi-gene panels. Our data suggest that patients with noninformative prior screening may benefit from rescreening with multi-gene panels. As more about mutations now classified as VUS is learned, the additional information offered by multi-gene panel testing may prove to be increasingly relevant.

Do women with *BRCA1* or *BRCA2* mutations have reduced ovarian reserve? *First Author: Kelly-Anne Phillips, Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia*

Background: It is uncertain whether mutations in the DNA repair genes, *BRCA1* or *BRCA2*, result in reduced ovarian reserve. AMH is a surrogate marker of ovarian reserve. This study examined AMH levels of *BRCA1* and *BRCA2* mutation carriers and their non-carrier blood relatives. **Methods:** Eligible women were from families segregating *BRCA1* or *BRCA2* mutations enrolled in the Kathleen Cuningham Foundation Consortium for Research into Familial Breast Cancer (kConFab). Each woman had been tested for the family mutation and had completed an epidemiological questionnaire and provided a blood sample at cohort entry. Women were aged 25-45 years, had no personal history of invasive cancer, had two intact ovaries and were not pregnant or breastfeeding at the time of blood draw. AMH was tested on stored plasma samples using an electrochemiluminescence immunoassay platform. Higher AMH levels are associated with greater ovarian reserve. Associations between AMH level and carrier status were tested by linear regression, using the natural logarithm of AMH as the outcome variable, carrier status as the explanatory variable, and adjusting for age at blood draw, oral contraceptive use, BMI and cigarette smoking. Robust standard errors were estimated to account for the inclusion of multiple members from the same family. **Results:** AMH level was measured for 172 carriers and 216 non-carriers from families carrying *BRCA1* mutations, and 147 carriers and 158 non-carriers from families carrying *BRCA2* mutations. Within both groups, mutation carriers were younger at blood draw than non-carriers ($p \leq 0.031$). Age was negatively associated with AMH level for carriers and non-carriers of *BRCA1* and *BRCA2* mutations ($p < 0.001$). *BRCA1* mutation carriers had, on average, 25% lower AMH levels than non-carriers ($p = 0.022$). There was no evidence of an association for *BRCA2* mutation carriers ($p = 0.94$). Results did not change substantially after excluding women who were post-menopausal or taking oral contraceptives at blood draw. **Conclusions:** This study suggests that women with a germline mutation in *BRCA1* have reduced ovarian reserve. This could have implications for their fertility and family planning.

1538 Poster Session (Board #362), Mon, 1:15 PM-4:45 PM

Predictors of BRCA mutation in male breast cancer. *First Author: Can Ardic, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Breast cancer is uncommon among men. Male breast cancer accounts for less than 1% of all male tumors. Among affected men, it is estimated that 10% have a genetic predisposition for the disease, most of which are determined by BRCA mutations. According to the NCCN guidelines, diagnosis of male breast cancer is sufficient to recommend BRCA genetic testing. In the present study, we evaluated other potential predictors having a BRCA mutation in male breast cancer patients. **Methods:** Men with a personal history breast cancer and who were referred for genetic testing were identified from a prospectively maintained database. Patient characteristics included personal history of other cancers, family history of breast and ovarian cancer, tumor type, estrogen (ER)/progesterone (PR) /Her2 receptor expression, nuclear grade, age of diagnosis, currently known risk factors for male breast cancer (liver cirrhosis, gynecomastia, radiation exposure, and Klinefelter's disease), any hormone replacement therapy, and BRCA results. Univariate and multivariate logistic regression analyses were used to determine predictive factors associated with BRCA mutation. **Results:** After excluding male breast cancer patients presenting for predictive testing, 67 male breast cancer patients were identified. Nine (13%) patients carried a BRCA mutation, all of which were BRCA2. Risk factors that showed significant associations with BRCA mutation included having 2nd degree relatives with breast cancer ($p = 0.0465$) and having first degree relatives with ovarian cancer ($p = 0.0304$). Known risk factors for male breast cancer, previous history of other cancers, tumor markers (ER/PR/Her2, nuclear grade, and tumor type), did not show any significant associations. In multivariate analysis, having first degree relatives with ovarian cancer were more likely to have a BRCA mutation ($p = 0.0251$). **Conclusions:** Factors associated with predicting a positive BRCA result in men with breast cancer include a family history of breast and ovarian cancer as well as radiation exposure. Further larger studies should evaluate whether having solely male breast cancer is a strong enough predictor for BRCA mutations in the absence of factors mentioned above.

1539 Poster Session (Board #363), Mon, 1:15 PM-4:45 PM

Solid tumor profiling via next-generation sequencing to identify tumor-specific actionable variants. *First Author: Sara E. Patterson, The Jackson Laboratory for Genomic Medicine, Farmington, CT*

Background: Different tumor types are often associated with reoccurring mutations. Performing detailed genetic profiling to identify the milieu of actionable gene variants characteristic of specific tumors may guide targeted approaches to treatment, as well as uncover new therapeutic targets. To this end, we used a next-generation sequencing approach to identify characteristic actionable variants across various solid tumor types. **Methods:** DNA from FFPE sections of 58 solid tumor samples (15 colon, 14 ovarian, 13 lung, 11 melanoma, and 5 squamous cell carcinoma) was sequenced using the Jackson Laboratory Cancer Treatment Profile, a 358-gene targeted panel and submitted to the Clinical Genomics Analytical (CGA) bioinformatics pipeline. Resultant variant calls were filtered based on impact and actionable variants (defined as those having therapeutic relevance) were identified through extensive literature review from in-house curation efforts. **Results:** Tumor profiling for actionable variants demonstrated genetic heterogeneity among solid tumor types. Colon tumors contained codon 12 or 13 variants in KRAS (47%; 7/15), and RET G691S (33%; 5/15); lung tumors contained frequent AURKA F31I (31%; 4/13), and KDR Q472H (69% 9/15) variants; melanomas contained BRAF V600 (91%; 10/11) and AURKA F31I (64%; 7/11) variants; squamous cell carcinomas contained frequent FGFR4 G388R (60%; 3/5), with high prevalence of AURKA F31I, RET G691S, and PIK3CA E542K (each 40%; 2/5). KRAS variants were identified in 80% (4/5) of mucinous ovarian tumor samples. Mucinous ovarian tumors were also associated with MET T1010I (29%; 2/5), which was not identified in any other analyzed tumor type. **Conclusions:** Somatic variant profiling in solid tumors is biologically heterogeneous but often results in clinically actionable genomic characteristics. In this survey of 5 different tumor types, we identified various genetic variants including a frequent occurrence of MET T1010I in mucinous ovarian tumors. MET T1010I is an activating mutation in MET that has been demonstrated to enhance tumor cell proliferation and migration, and represents a potential therapeutic target that has not been previously identified in ovarian cancer.

1540 Poster Session (Board #364), Mon, 1:15 PM-4:45 PM

Germline variation in *NFE2L2*/*CUL3*/*KEAP1* and risk of head and neck squamous cell carcinoma (HNSCC). *First Author: Siddharth Sheth, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Nuclear factor (erythroid-derived 2)-like 2 (NFE2L2) is a key transcription factor regulating oxidative stress. Activated NFE2L2 translocates to the nucleus and binds anti-oxidant response elements in the promoter regions of cytoprotective genes. It is negatively regulated by its protein complex partners, CUL3 and KEAP1. Recent HNSCC genome profiling studies identified *NFE2L2*, *CUL3* and *KEAP1* as recurrent somatically altered genes, suggesting an important role in HNSCC carcinogenesis. We hypothesized that germline variation in *NFE2L2*, *CUL3* and *KEAP1*affects risk of HNSCC. **Methods:** The study population consisted of 751 cases (459 oral cavity, 292 oropharynx; 69% smoker) and 862 controls (50% smoker) from the University of Pittsburgh HNSCC case-control study. Subjects were genotyped for 22 single nucleotide polymorphisms (SNPs) located in or near *NFE2L2* (10), *CUL3* (8) and *KEAP1*(4) using Sequenom's iPLEX assay. Odds ratios (OR) for HNSCC risk and corresponding 95% confidence intervals (CI) were calculated using logistic regression models. Additive and dominant genetic models were evaluated; common allele homozygotes were used as the reference group. All analyses were adjusted for age (continuous), sex (male, female), smoking status (never, ever) and alcohol use (never, ever). **Results:** Two SNPs in *NFE2L2* (rs13001694, rs6726395) and two SNPS in *CUL3* (rs1466723, rs3738952) were significantly associated with HNSCC risk in our study population ($P< 0.05$). The minor alleles of these SNPs were associated with increased risk of developing HNSCC (rs13001694, OR: 1.16, 95%CI: 1.00-1.35; rs6726395, OR: 1.17, 95%CI: 1.02-1.35; rs1466723, OR: 1.27, 95%CI: 1.03-1.56; and rs378952, OR: 1.54, 95%CI: 1.20-1.98). **Conclusions:** Our results suggest that germline variation in the *NFE2L2*/*CUL3*/*KEAP1*pathway affects risk of developing HNSCC. Improved understanding of the role of genetic variation in HNSCC carcinogenesis may aid the development of more effective, personalized prevention and diagnostic strategies.

1541 Poster Session (Board #365), Mon, 1:15 PM-4:45 PM

Genetic testing decisions of breast cancer patients: Results from the iCanCare study. *First Author: Reshma Jagsi, University of Michigan Health System, Ann Arbor, MI*

Background: Breast cancer pts at high risk for pathologic genetic mutations should consider testing. Even those without elevated risk may have concerns about genetic predisposition. Little is known about cancer pts' decisions to undergo genetic testing as access to multiple gene panels and rising awareness transforms the decision-making context. **Methods:** We surveyed a population-based sample of early-stage breast cancer pts diagnosed in 2013-14, identified by 2 SEER registries (Los Angeles and Georgia), about experiences with genetic testing after diagnosis. Surveys were completed about 6 months after dx. A "high risk" subgroup was determined based on age, family history, and ancestry, and receptor status. We evaluated patterns of receipt of counseling and correlates of testing in a preliminary sample (response rate 68%). **Results:** Among 2,051 pts analyzed, 728 (35%) were "high risk." Most high risk pts (67%) and half (50%) of others desired testing. Most high risk pts (63%) and 38% of others spoke to a physician or other health care professional about testing. Overall, 23% reported formal genetic counseling (34% of high risk pts, 18% of others), and 28% received testing (46% of high risk pts, 19% of others). On multivariable analysis, test receipt was more common in pts with high risk, invasive vs in situ disease, and higher education. Among high risk pts, non-receipt of testing was associated with in situ vs. invasive disease (OR 1.8, $p = .02$), no family hx of breast cancer(OR 2.4, $p = < .001$), older age (OR 1.9 for +5-yrs, $p < .001$), lower education (OR 1.6, $p = .05$), and Medicaid insurance (OR 2.0 vs private, $p = .03$). Of 362 high risk pts who did not get tested, 54% indicated their doctor didn't recommend it, 10% didn't want it, and 12% said it was too expensive. **Conclusions:** Most newly diagnosed breast cancer pts desire genetic testing, but many do not discuss it with providers. Most high risk pts do not report formal genetic counseling; a substantial number report no discussion of genetic risk at all. Test receipt is reassuringly correlated with risk but also with SES. Providers must ensure that breast cancer patients with interest in genetic risk have adequate discussion, especially as access to more expansive testing soars. Funding: P01-CA-163233.

1542 Poster Session (Board #366), Mon, 1:15 PM-4:45 PM

Assessment of functional impact of germline BRCA1/2 variants located in noncoding regions in families with breast-ovarian cancer predisposition. *First Author: Elizabeth Santana dos Santos, Hospital Sírio Libanês, São Paulo, Brazil*

Background: The molecular mechanism of cancer susceptibility remains unclear for the majority of breast and/or ovarian cancer patients. The screening of the key genes *BRCA1* and *BRCA2* identifies a causal mutation in less than 15% of the families tested. Even if some germline mutations in the regulatory non-coding regions of these genes have been described, their screening is still limited to the coding regions and intron-exon junctions. The aim of this study was to evaluate the potential contribution of non-coding variants on the *BRCA1/2* promoter activity and then in breast-ovarian cancer predisposition. **Methods:** The variants tested were selected from the ENIGMA database (Evidence based Network for the Interpretation of Germline Mutant Alleles) and from the screening of 2 cohorts of patients with *BRCA1/2* negative status and whose personal and/or family history were suggesting a breast-ovarian cancer predisposition. The latter was performed on 4 *BRCA1/2* non-coding regions (promoter regions and intronic regions). The impact of the variants on the *BRCA1/2* gene expression was tested *in vitro*, after transient transfection in MCF-7 and MDA-MB231 breast cancer cells, by Luciferase gene reporter assay. **Results:** A total of 12 *BRCA1* and 8 *BRCA2* variants were tested. We delimited a *BRCA1* promoter region with 3 functionally active variants with a clear repressor impact on the promoter activity. This DNA sequence region corresponds to a putative DP1/E2F1 transcription factor binding site, which has never been described. One *BRCA2* variant in the promoter also showed a significant reduction in the transcriptional level. Two *BRCA1* in the promoter and in intron 2 and two *BRCA2* variants in the promoter increased the promoter activity. All the others were shown to have no impact in our functional assay. **Conclusions:** Through Luciferase gene reporter assay, we identified 8 non-coding and rare variants with a significant impact on *BRCA1/2* promoter activity, 3 of them showing a significant reduction in the transcriptional levels. As further investigation is needed, this approach has helped us to prioritize the studies on those variants.

Transgenerational genomic effect of chemotherapy exposure in testicular cancer survivors. *First Author: Eliezer Mendel Van Allen, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer survivors who receive chemotherapy express concern that these exposures may induce germ cell mutations that lead to transmissible genetic damage in post-treatment children. Preclinical models suggest these mutagenic exposures may result in considerable genomic alterations in post-exposure progeny (e.g. elevated mutation rates, chromosomal abnormalities). Epidemiological studies have not demonstrated a significant increase in congenital abnormalities or genetic syndromes in post-treatment children of cancer survivors, although comprehensive genomic assessments have not yet been performed in this patient population. **Methods:** We identified two testicular cancer survivors who were cured with chemotherapy (bleomycin, etoposide, cisplatin) and had children before and after therapy without cryopreserved sperm. We acquired saliva from patients and their families and performed whole genome sequencing (WGS) from extracted DNA. Genome analysis and de novo mutation discovery were performed using established methods. **Results:** Genomes were sequenced to 50X mean depth. There was no increase in the de novo mutation rate of post-exposure children compared to their pre-exposure counterparts (Table). In fact, post-exposure offspring born two years after treatment had fewer de novo mutations than pre-exposure counterparts. There were no differences in recombination frequency or rearrangements between offspring. **Conclusions:** In two families of male cancer survivors, there was no genomic alteration increase in post-exposure children. The lower de novo mutation rate in early post-treatment children may indicate heightened selective pressure, especially when accounting for increasing paternal age. This study provides possible reassuring evidence for patients undergoing chemotherapy who are unable to have pre-treatment sperm cryopreservation. Broadly, this study illustrates the potential for using WGS to identify environmental cancer treatment effects on the inherited genome.

Somatic mutations in Luminal HER2 negative tumors from young breast cancer patients. *First Author: Giselly Encinas, Departamento de Radiologia e Oncologia, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

Background: Early age patients less than 36 years represent 4% of breast cancer cases and have a higher probability of being *BRCA1/2* mutation carriers. There are indications that tumors from young patients are biologically distinct from older women, however, these tumors have been less studied. Our aim was to identify somatic mutations in luminal tumors from BRCA1/2 wild type young breast cancer patients. **Methods:** Seventy-nine unselected young patients were enrolled. *BRCA1/2* mutations were screened by Sanger sequencing and Multiplex Ligation-Dependent Probe amplification (MLPA). Tumor and blood samples from eight patients (hormone receptor positive, HER2 negative) were selected for whole exome sequencing using Nextera Rapid Capture Enrichment in an Illumina HiSeq 1000, analyzed through MuTect (v1.14), SomaticSniper (v1.0.2) and Strelka (v1.0.1.2). **Results:** Median age of the 79 patients was 32 years (22-35) and luminal subtype was the most frequent (63.1%). Deleterious mutation in *BRCA1/2* genes was detected in 13 patients (*BRCA1*, n = 4 and *BRCA2*, n = 9). One novel mutation was detected in *BRCA1* gene: a stop codon in exon 6 (c.483T > A; p.Cys161Ter). Somatic mutations were evaluated in eight luminal samples and a median of 60 alterations/tumor was detected, varying from 49 to 113. A total of 537 individual genomic alterations were found, comprising 77 non-synonymous and four nonsense base substitutions and 2 splice donor variants. Among these 83 mutations, 56 were detected in potentially driver genes, including genes involved in Hedgehog signaling pathway and GSK3B interactions. Five to ten driver genes were mutated per tumor sample. For non-synonymous point mutations, only *PIK3CA* was repeatedly mutated in three samples; *TP53* was mutated in one sample. **Conclusions:** Besides *PIK3CA* mutation, which is the most frequent alteration in luminal tumors, and *TP53* mutation, at least five other different driver genes may be mutated in tumors from young breast cancer patients.

1545 Poster Session (Board #369), Mon, 1:15 PM-4:45 PM

Patient interest and willingness-to-pay (WTP) out-of-pocket (OOP) for comprehensive tumor genetic profiling (CGP). *First Author: Julie Innocent, Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA*

Background: CGP via multiplex gene panels has emerged as a novel technology to identify mutations in pathologically relevant cancer genes for therapy targeting. While CGP is anticipated to alter the course of standard cancer care, its current clinical role remains ill-defined, and thus its perceived value for patients is unclear. In an effort to understand patient awareness and perceived value of CGP, we explored interest and WTP OOP for CGP among cancer patients receiving active treatment. **Methods:** Fox Chase patients were recruited to complete a 20 min survey. In addition to assessing demographics, cancer stage/treatment, and financial items (income, health insurance, co-pays), we queried awareness of CGP, and interest in CGP to guide therapy using items adapted from previous research by our group. We specifically assessed interest in CGP only if covered by insurance vs interest conditional on paying an OOP cost: (< \$200, \$500, and > \$1000). All p-values are significant at $\alpha = 0.05$ using two-sided Fisher's exact tests. **Results:** Participants were 88 patients of diverse cancer histology, time since diagnosis (51% > 2yrs), therapy line (60% > 2nd line) age (mean 58.9 yrs), sex (38% F), race/ethnicity (20% non-White), family structure (64% married; 21% no children), education [27% < high school (HS)], and financial status (37% income < \$50,000; 38% Medicare/8% Medicaid; 40% reporting difficulty paying co-pays). 61% were aware of CGP, and 67% believed it could improve their treatment. In total, 79% were interested in CGP, with interest higher in younger ($p = 0.005$) and privately insured ($p = 0.01$). Patients with < HS education were less WTP OOP for any costs for CGP beyond those covered by insurance ($p = 0.005$). Those with income > \$50K ($p = 0.06$) and private insurance ($p = 0.001$) were more WTP. Of those WTP OOP, 44% were WTP < \$200, while 24% were WTP \$500 and 32% WTP > \$1000. WTP \$500 or > \$1000 for CGP was associated with White race ($p = 0.05$), education > HS, income > \$50K, and private insurance (all $p \leq 0.001$). **Conclusions:** Patients are interested in CGP and believe it can improve their cancer treatment. Those with lower income, less education and non-private insurance may be less likely to pursue CGP if accompanied by OOP costs.

1546 Poster Session (Board #370), Mon, 1:15 PM-4:45 PM

Evaluation of family history in newly diagnosed children with cancer. *First Author: Kinley Garfield, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: The collection of cancer family history (FH) is a key component for risk assessment in adult cancer patients, but is not routine in pediatric oncology. We collected FH on all newly diagnosed pediatric cancer (PC) patients presenting at Primary Children's Hospital to determine the feasibility of routine FH collection and risk prevalence for hereditary cancer syndromes. **Methods:** Parents of newly diagnosed children (age 0 to 20) were approached for enrollment and given a FH questionnaire to complete and return by mail assessing FH in first- and second-degree relatives. A genetic counselor contacted all participants by phone to review the reported history or to obtain a FH from those who did not return the form. Criteria for genetics referral were based on NCCN or peer-reviewed criteria. **Results:** Of the 91 families that completed a FH, 24 (26%) were considered eligible for further genetic risk evaluation. 16 (17%) warranted referral based on the child's tumor type or personal/ FH criteria, 8 (9%) children did not meet criteria but had a first- or second-degree relative who met criteria for referral. 10 of 16 children meeting criteria were seen for genetic counseling. **Conclusions**: Collecting FH at the time of diagnosis is feasible and identifies at risk individuals for cancer predisposition. Approximately 30% of newly diagnosed PC patients meet criteria for further genetic risk evaluation. This is consistent with data from a survivorship clinic reported by Knapke et al. (2011), although our study enrollment occurred at diagnosis and is not biased by patient mortality. These findings support a high rate of genetic predisposition related to childhood cancer (at least 1 in 4), and highlight the importance of obtaining an accurate FH at the time of initial diagnosis.

Cancer Type	Patients (n)	Child's history + FH warranted evaluation	Child's history warranted evaluation	FH warranted evaluation	Total referrals warranted

Missense variants in Lynch Syndrome genes in endometrial cancer patients characterized by The Cancer Genome Atlas (TCGA) project. *First Author: Christine S. Walsh, Cedars-Sinai Medcl Ctr, Los Angeles, CA*

Background: We sought to characterize the missense variants in the Lynch Syndrome genes in patients with endometrial cancer that had normal germline DNA characterized by TCGA. **Methods**: We obtained institutional IRB approval and approval from the National Center for Biotechnology Information Genotypes and Phenotypes Database (NCBI dbGaP) for data access to TCGA data files. We utilized Variant Call Format (VCF) files to annotate germline single nucleotide variants in exomic regions of the Lynch Syndrome genes (*MLH1, MSH2, MSH6, PMS2*) among 248 patients with endometrial cancer. We used the MetaLR composite score from Annovar, which combines data from SIFT, PolyPhen2, LRT, MutationTaster, MutationAssessor, FATHMM, GERP++, PhyloP and SiPhy for prediction of variant effects on protein function. **Results**: A total of 120 different missense variants from 248 patients were found in the Lynch Syndrome genes (8 in *MLH1*, 26 in *MSH2*, 41 in *MSH6*, 45 in *PMS2*). 82 (68%) of these variants were novel and were not annotated in dbSNP or in publically available databases of Lynch Syndrome variants. None of the 120 missense variants were previously reported deleterious mutations known to cause Lynch Syndrome. Eight variants had a MetaLR score of > 0.9, signifying the highest probability of the variant having a deleterious effect. Of these, the top six variants clustered in exon 4 of the PMS2 gene between codons 105 and 116. Other variants with high MetaLR scores clustered in exon 1 of MSH2. **Conclusions**: We identified a large number of novel missense variants in the MLH1, MSH2, MSH6 and PMS2 genes in patients with endometrial cancer characterized by the TCGA. The variants with the highest probability of having a deleterious effect clustered in exon 4 of *PMS2* and exon 1 of *MSH2*.

1548 Poster Session (Board #372), Mon, 1:15 PM-4:45 PM

Rare germline *TP53* variants in lung adenocarcinoma. *First Author: Erin Michelle Parry, Osler Medical Housestaff Training Program, Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: *TP53* is one of the most commonly altered genes in lung adenocarcinoma, with as many as 50% of all cases possessing somatic inactivating mutations. Germline mutations in *TP53* predispose to a wide variety of cancers in Li-Fraumeni syndrome. While lung cancer is generally not considered a classic Li-Fraumeni malignancy, several studies have indicated it may appear at an earlier age in this cancer-prone syndrome. **Methods:** We tested the frequency of germline *TP53* mutations in an unselected cohort of lung adenocarcinoma cases sequenced as part of The Cancer Genome Atlas (TCGA) project. At the time of data access (October 1, 2014), germline exome and genome data were available for download from 531 subjects, and clinical information was available on 94% of these cases (n = 497). After Data Access Committee approval, we extracted raw bam files that included the *TP53* sequence, called and annotated the variants. We considered variants with high (greater than 20x) coverage, and then excluded those with a minor allele frequency of 0.005 or greater in control populations. Suspected pathogenic variants were then confirmed by examining the matched tumor sequence data or a replicate normal tissue sample using the same methods. **Results:** Four cases carried germline missense variants in *TP53* (0.8%), and all of them fell in the DNA binding domain. Three of the mutations were previously described in Li-Fraumeni syndrome and all of mutations have been reported as somatically mutated in various cancers. The mean age at lung cancer diagnosis was 58 years (range 41-73) and one individual was male. One of the cases was a never smoker (female), and another subject had a prior history of thymic carcinoma, a diagnosis that has been documented in Li-Fraumeni syndrome. **Conclusions:** Our data suggest that a subset of lung adenocarcinoma patients carry germline mutations in *TP53*, pointing to a role for inherited factors in lung cancer susceptibility. This diagnosis may be overlooked in cases where genomic data is filtered for background germline variants, and is relevant for genetic counseling and screening decisions.

1549 Poster Session (Board #373), Mon, 1:15 PM-4:45 PM

Women with breast and uterine cancer in relation to genetic mutation risk: A case-control analysis. *First Author: Michael R. Milam, Norton Cancer Inst, Louisville, KY*

Background: The purpose of this study is to explore the mutation spectrum and prevalence among women with breast and uterine cancer (BUC) who were clinician-referred for multi-gene panel testing. **Methods:** Clinical histories for patients who underwent multi-gene panel testing at a single commercial laboratory (Ambry Genetics, Aliso Viejo, CA) were retrospectively reviewed to select cases with a history of both breast and uterine cancer. Patients underwent comprehensive analysis of 6-28 genes, depending on the panel ordered. Gene-specific mutation frequencies were calculated and compared with age- and ethnicity-matched female controls with no reported personal cancer history that were also referred for multi-gene panel testing. Fisher's exact tests were used to compare categorical variables, and Wilcoxon rank-sum tests were used to compare continuous variables between the 2 groups. **Results:** 319 women with BUC were identified from March 2012 to June 2014. Approximately 13% (n=42) of BUC patients were found to have gene mutations. The majority of the patients were Caucasian (80.6%; 257/319). The average age at first breast cancer diagnosis was 54 years (range 22-82 years) and the average age at uterine cancer diagnosis was 56 years (range 24-87 years). Analysis of gene-specific mutation frequencies revealed that mutations in *BRCA2*, *MSH6,* and *PTEN* were more frequent among cases than controls. **Conclusions:** In this multi-gene panel testing analysis, women with BUC are at greater risk of mutations in genes associated with Lynch Syndrome, Cowden Syndrome, and Hereditary Breast and Ovarian Cancer Syndrome. Further study is needed to explore these potential links and expanded genetic testing of breast and uterine cancer patients should be considered.

	Mutation Frequency		Fisher's Exact Results		
Gene	**Cases**	**Controls**	**Odds Ratio (95% CI)**	**95% CI**	**P-value**
BRCA1	1.4%	1.4%	1.04	[0.2,3.46]	1
BRCA2	3.8%	1.0%	4.02	[1.48, 9.97]	0.003*
CDH1	0.4%	0.1%	3.83	[0.07,73.65]	0.31
MLH1	0.6%	0.1%	4.99	[0.06,391.67]	0.31
MSH2	0.6%	0.1%	4.99	[0.063,391.67]	0.31
MSH6	3.2%	0.4%	8.5	[1.63,55.30]	0.005*
PMS2	0.6%	0.4%	1.66	[0.03,20.84]	0.52
PTEN	1.8%	0.1%	18.62	[3.03,196.06]	0.0004*
TP53	0.4%	0.0%	7.5	[0.10,586.74]	0.22

1550 Poster Session (Board #374), Mon, 1:15 PM-4:45 PM

The impact of a molecular tumor board on treatment decisions for 35 patients: The Dartmouth experience. *First Author: Laura J. Tafe, The Geisel School of Medicine at Dartmouth and Dartmouth Hitchcock Medical Center, Lebanon, NH*

Background: Genetic profiling of tumors is a powerful approach to predict drug sensitivity and resistance. However, oncologists are often unfamiliar with interpretation of genetic data. We established a Molecular Tumor Board (MTB) at our Cancer Center to interpret individual patients' tumor genetic profiles and provide treatment recommendations. **Methods:** DNA from tumor specimens was sequenced in a Clinical Laboratory Improvement Amendments (CLIA)-certified laboratory to identify coding mutations in a 50-gene panel (*n*= 34), or a 255-gene panel (*n*= 1). Cases were evaluated by a MTB composed of molecular and anatomic pathologists, medical oncologists, basic research scientists, and genetic counselors. **Results:** Thirty-five cases were evaluated in one year by the MTB. The most common reason for MTB referral was a request for recommendations on targeted therapies (91.9%), and for potential germline mutations. Tumors exhibited a wide range of genetic heterogeneity: 71 different mutations were found across 30 genes, and 63 mutations were observed only once. In 56.3% of cases (18/32) of advanced/metastatic disease, MTB recommended non-standard therapy with a specific targeted agent (11 clinical trials; 7 off-label use) based on evaluation of tumor genetic profile, and disease and treatment histories. Four patients were subsequently treated with a MTB-recommended targeted therapy; 3 of these 4 patients remain on therapy, 2 of whom have experienced clinical benefit lasting > 10 months. The remaining 14 patients continued on current therapy because disease was stable (*n*= 4), were treated with non-MTB-recommended standard therapy (*n*= 4), declined conventional therapy (*n*= 5), or died prior to receiving further therapy (*n*= 1). **Conclusions:** Case evaluation by a multidisciplinary group of individuals in the context of a MTB frequently shapes treatment options and decisions. Importantly, anticipated obstacles to capitalizing on the benefits of a MTB such as access to drugs were rarely encountered. Instead, the most commonly encountered reasons that MTB-recommended therapy was not administered stemmed from patient preferences, and genetic profiling at a very late stage of disease.

1551 Poster Session (Board #375), Mon, 1:15 PM-4:45 PM

Polymorphisms in the estrogen pathway, estrogen receptor alpha gene (*ESR1*), daily cycling estrogen and mammographic density. *First Author: FrÃ¶ydis Nyborg Fjeldheim, Department of Oncology, Oslo University Hospital, Ullevål, Oslo, Norway*

Background: Single nucleotide polymorphisms (SNPs) involved in the estrogen pathway and SNPs in the estrogen receptor alpha gene (*ESR1, 6q25*), have been linked to breast cancer development. However, whether there is an association between daily estradiol levels, SNPs in *ESR1*and premenopausal mammographic density phenotypes has not yet been ascertained. **Methods:** Estradiol was assessed in daily saliva samples throughout an entire menstrual cycle, in 202 healthy premenopausal women (aged 25-35), participating in the Norwegian Energy Balance and Breast Cancer Aspects (EBBA) I study. DNA was genotyped using the Illumina Golden Gate platform. Mammograms were taken between days 7-12 of the menstrual cycle, and digitized mammographic density phenotypes were assessed using a computer-assisted method (Madena). Multivariable regression models were used to study the association between SNPs in *ESR1*, premenopausal mammographic density phenotypes and daily cycling estradiol. **Results:** We observed inverse linear associations between the minor alleles of 8 of 34 measured SNPs (*rs3020364, rs2474148, rs12154178, rs2347867, 6927072, rs2982712, 3020407, rs9322335)* and percent mammographic density (p values: 0.002 - 0.026), and these associations were strongest in lean women (BMI, $\leq$ 23.6 kg/m^{2}). The odds of above-median percent mammographic density (> 28.5%) among women with major homozygous genotypes were 3-6 times higher than those of women with minor homozygous genotypes in 7 SNPs. Women with *rs3020364*major homozygous genotype had an OR of 6.46 for above-median percent mammographic density (95% Confidence Interval 1.61, 25.94) when compared to women with the minor homozygous genotype. These associations were not observed in relation to absolute mammographic density. No linear associations between SNPs and daily cycling estradiol were observed. **Conclusions:** Our results support an association between eight selected SNPs in the *ESR1* gene and percent mammographic density. The results need to be replicated in larger studies.

1552 Poster Session (Board #376), Mon, 1:15 PM-4:45 PM

Genetic testing for hereditary breast cancer: The decision to decline. *First Author: Brook White, CMC, Charlotte, NC*

Background: Genetic testing is an important component of comprehensive cancer care. Testing for hereditary breast and ovarian cancer syndrome is well established, as commercial analysis of the BRCA1/2 genes has been available since 1996. The National Comprehensive Cancer Network (NCCN) guidelines identify those individuals appropriate for BRCA1/2 analysis, and define management recommendations for mutation carriers. Despite recommendations, not all who meet NCCN criteria undergo genetic testing. We assess the frequency that individuals meeting NCCN criteria decline BRCA1/2 analysis, as well as factors that affect the decision making process. **Methods:** A retrospective chart review was performed from September 2013 through August 2014 of individuals who had genetic counseling at the Levine Cancer Institute (LCI). **Results:** 1083 individuals identified through the retrospective chart review met NCCN criteria for BRCA1/2 analysis. 268 (24.5%) of the 1083 individuals did not pursue genetic testing. Of those who did not undergo testing, 21.3% (N = 57) did not desire testing and 40.3% (N = 108) were advised to gather additional genetic or medical information prior to genetic analysis. The remaining 38.4% (N = 103) had insurance and desired testing but did not pursue due to expense. The majority of the 103 individuals (N = 88) were responsible for the total cost of the test, although some (N = 15) had a prohibitive co-pay expense. **Conclusions:** Our analysis reveals that 38% of patients who meet NCCN guidelines for BRCA testing do not undergo testing based on financial barriers. This highlights the need to address public policy initiatives in this high-risk population.

1553 Poster Session (Board #377), Mon, 1:15 PM-4:45 PM

Identification of tropomyosin kinase receptor (TRK) mutations in cancer. *First Author: Nisha Nanda, Loxo Oncology, San Francisco, CA*

Background: TRK A, B and C, (encoded by NTRK1, NTRK2, and NTRK3 genes, respectively) and their neurotrophin ligands regulate growth, differentiation and survival of neurons. Chromosomal rearrangements resulting in kinase fusions have been described across the NTRK gene family, and may contribute to tumorigenesis in diverse clinical settings. We searched for potentially activating mutations in the NTRK gene family by applying biologically driven ranking criteria to an anonymized next-generation sequencing dataset, sourced from Foundation Medicine (FMI) and Compendia BioSciences (Compendia). **Methods:** Approximately 10,000 patient samples were analyzed for mutations in NTRK1, NTRK2 or NTRK3. Mutation data in other known cancer-related genes were also captured for these tumors. Data were reconciled across the disparate sources by mapping mutations to the canonical transcript for each gene where possible, or to a representative non-canonical transcript when the mutation occurred in a region not contained within the canonical transcript. Mutations were clustered together based on sequence proximity. Mutation groups were ranked by likelihood of oncogenic-activating potential using six biologically-driven component scores. **Results:** 732 distinct mutation clusters were identified across > 20 tumors. NTRK1, NTRK2 and NTRK3 represented 33%, 30% and 37%, respectively, of these mutation clusters. A disproportionate number of the most promising mutation clusters were in NTRK3: 59% of the top 5%, 58% of the top 10%, and 46% of the top 25%. In addition, the top 3 mutation clusters were in the NTRK3 kinase domain, and were observed in head and neck, lung, upper gastrointestinal, melanoma and colon cancers. **Conclusions:** This heuristic identified mutations in the NTRK family, especially in NTRK3, that hold promise as oncogenic activating mutations. The highest ranked mutations deserve further study, as they are clonally present in the kinase domain, exist in the absence of other known oncogenic drivers, and are infrequent in germline databases.

1554 Poster Session (Board #378), Mon, 1:15 PM-4:45 PM

Next-generation sequencing as an informing phenotype: A TP53 example. *First Author: Rosie O Shea, The Mater Hospital, Dublin, Ireland*

Background: Li-Fraumeni (LFS) and Li Fraumeni like (LFL) syndromes are characterised by early onset cancers such as breast cancer, leukaemia, sarcoma, brain tumours and adrenocortical carcinoma, and are defined traditionally by clinical criteria such as Chompret and Eeles. Genetic testing for *TP53* germline mutation is typically undertaken in families that satisfy these clinical criteria. Next generation sequencing and gene panel testing has resulted in more frequent *TP53* testing to include families that don't meet classic testing criteria. We investigated testing criteria and result outcome in a cohort of Irish probands undergoing *TP53*full sequencing. **Methods:** All *TP53 test* requests processed thought the national genetic testing laboratory between 2012 and 2014 were retrospectively reviewed. Family history data including diagnoses and age at diagnosis was ascertained through hospital charts or electronic pedigrees from two adult cancer genetic services in Ireland. Additional data including reason for testing, concordance with LFS/LFL criteria and test results were collected. **Results:** One hundred and thirty five *TP53* test requests were identified. Family history data and test results were available on 123 of the *TP53* test requests (118 female; 5 male). 74/123 (60%) didn't meet classic LFS or LFL criteria and were *TP53* mutation negative. Two individuals from this group harboured pathogenic *TP53* mutations. Both were female and had a personal history of early onset bilateral breast cancer with no reported LFS cancers in the family. 49/123 (40%) met LFS or LFL criteria and were all *TP53*negative, apart from one female with a variant of unknown significance. 22/49 (44%) met Chompret criteria, 19/49 (38%) met Eeles and 7/49 (14%) met Eeles and Chompret and 1/49 (2%)met Classic LFS criteria. **Conclusions:** Stringent testing criteria miss germline mutations in *TP53*. Broadening the criteria for *TP53* testing will redefine the clinical description of LFS and LFL, and improve our understanding of *TP53* mutation expression and penetrance in this syndrome

1555 Poster Session (Board #379), Mon, 1:15 PM-4:45 PM

The influence of BRCA variants of uncertain significance in cancer risk management decision-making. *First Author: Jing-Yi Chern, New York University Langone Medical Center, New York, NY*

Background: Among patients undergoing genetic testing for BRCA1/2 mutations, 7% will harbor a variant of uncertain significance (VUS), a finding with more emotional than clinical weight. The objective of this study was to compare cancer risk management decisions among women with BRCA VUS to those of women with negative results. **Methods:** Between 1/2006-12/2012, we identified patients whose genetic testing results yielded a VUS and those who had definitively negative results at a single institution. VUS patients were matched with negative patients of the same age and testing date. χ^2analyses were used to assess differences between the groups. **Results:** Three hundred and seventy-one patients underwent genetic testing during the study period. Eighty-two (22%) patients had a VUS and were matched with 82 control patients with negative genetic testing. The median age of study patients was 47 years for the 164 patients evaluated. Women with a VUS were more racially diverse than those with negative testing (38 of 82, 46% non-Caucasian vs. 16 of 82, 20%, p= 0.002). VUS patients were less likely to be of Ashkenazi descent (14 of 82, 17% vs. 32 of 82, 39%, p= 0.002). Patients with VUS were more likely to be referred to a gynecologic oncologist (42 of 82, 51% vs. 29 of 82, 35%, p= 0.058). Among VUS patients, 21% (17 of 82) were recommended to undergo ovarian cancer screening and 28% (23 of 82) risk-reducing bilateral salpingo-oophorectomy (RRBSO) vs. 15% (12 of 82) and 28% (23 of 82), respectively, for controls (p = 0.28). Ultimately, RRBSO was performed in 20% (32 of 164) of all patients, with no significant difference in rate of surgery based on the presence of a VUS. **Conclusions:** At our institution, patients with VUS are managed similarly to those with negative BRCA testing. In these groups of patients, screening and prevention strategies need to be individualized. The numbers of patients with VUS are likely to increase with the implementation of multi-gene testing. Our findings underscore the importance of genetic counseling in the management of genetic testing results.

First one thousand families: Our multidisciplinary experience in the heredo-familial cancer unit from a Spanish University Hospital. *First Author: Ivan Marquez Rodas, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain*

Background: Patients with hereditary cancer syndromes (HCS) need a multidisciplinary approach: Different organs and systems may be involved and different risk reducing strategies (medical and surgical) should be provided. In 2010 we implemented a multidisciplinary heredo-familial cancer unit (HFCU) in Hospital General Universitario Gregorio Marañón (Madrid, Spain). **Methods:** A retrospective analysis of the first 1000 families attended in our HFCU (2010-2014). **Results:** 1167 patients, from 1000 different families were attended. 929 patients (79.6%) fulfilled international criteria for HCS; 84 are pending of gathering more information. Genetic test results were available for 426 patients, with 136 cases bearing pathological mutations. New mutation detection rate (first time diagnosis in a family) was 44/235 (18.7%). Two patients with no HCS criteria were diagnosed with BRCA1 and MSH2 mutations respectively. For the 136 patients with a pathological mutation, prophylactic surgery and /or follow up were offered according to international recommendations and patient's preferences (Table). In two BRCA1 mutation carriers, an early ovarian cancer was detected in prophylactic surgery. **Conclusions:** The first one thousand families attended in our HFCU demonstrate that a multidisciplinary assistance is the core of this clinical activity. The intervention resulted in risk reduction surgery in 31% of cases and intensive surveillance in all cases. A longer follow up is warranted in order to evaluate the long-term impact of these interventions and for improving the different steps of the cancer genetic counseling process.

MUTATION CARRIERS (%)	Prophylactic surgery (%)	Only follow-up (%)
BRCA1/2: 96 (70.6)	36 (38)	60 (62)
MLH1/MSH2/MSH6: 18 (13.2)	0	18 (100)

DNA repair landscape of discordant sibling pairs from hereditary breast cancer families. *First Author: Yongli Ji, University of Vermont, Burlington, VT*

Background: DNA repair plays a significant role in carcinogenesis. The aim of this study is to describe the landscape of germline DNA sequence variation among discordant sister pairs (one with and one without breast cancer) from breast cancer families with an emphasis on DNA repair pathways. **Methods:** Six sister-pairs were identified from a cohort of high-risk women at University of Vermont Cancer Center. To be eligible for inclusion families must have at least 3 cases of breast cancer, 1 diagnosed under age 50. The unaffected sister must be older than the affected sister's age at diagnosis. Germline DNA was isolated and full exome sequencing was performed for all 12 women. Computational genomics were utilized to identify putative single nucleotide polymorphisms in DNA repair pathway associated genes. Candidate variants were identified based on the quality of the variant call, distribution among sibling pairs, frequency in the general population, and predicted functional consequences. **Results:** We obtained high-quality exome sequences for each individual. We identified deleterious mutations in several known cancer-associated pathways, including DNA repair. The genetic variants and pathways include (see table): TSC1 (tuberous sclerosis complex) is a tumor suppressor gene; WRN is a member of the RECQ helicase family involved in DNA repair and maintaining genomic stability; PMS2 (postmeiotic segregation increased 2) is involved in mismatch repair;POLQ is a DNA polymerase; POLE is a DNA replicative polymerase. **Conclusions:** Using 6 discordant sister pairs from high-risk families we were able to obtain high-quality sequences and identify several interesting variants in DNA repair pathways. We have enrolled additional sister pairs and are funded to sequence and analyze 8 additional pairs. Future studies will focus on identification of rare familial variants and understanding the functional significance of identified variants.

Variant finding.

Gene	Variant	Findings	Rare?	Predicted Damaging?
TSC1	R37H	Het in one case	✓	✓
WRN	M1187V	Hets in 2 cases	✓	✓
WRN	C1367R	4/6 cases; p = 0.0625	≤ 0.3	✓
PMS2	N335S	Het in one case	✓	✓
POLQ	Q1546X	Het in one case	✓	Gained stop codon
POLE	A252V	Hets in 2 cases	≤ 0.1	Non- synonymous

Intratumoral heterogeneity of cancer driver genomic alterations across several tumor types. *First Author: Kai Wang, Foundation Medicine, Inc., Cambridge, MA*

Background: Intratumoral heterogeneity (ITH) or variations in genomic alterations (GA) between different areas of primary tumors or in their metastases has been an area of intense investigation and is often cited as a reason for failure of targeted therapies. We used an NGS-based comprehensive genomic profiling assay (CGP) to examine 5 tumor types across 10 tissue sections in 5 patients each to determine the impact of ITH on GA relevant to cancer biology (cancer "drivers"). **Methods:** 250 FFPE 40u sections from 25 patients were obtained from 2 separate non-adjacent blocks at levels throughout the entire block thickness. CGP was performed at Foundation Medicine, as previously described (PMID: 24142049). 245/250 sections were processed successfully, obtaining coverage depth > 700x, with all classes of GA (substitutions, indels, copy number alterations - CNA) assessed. Heterogeneity in cancer driver GA was evaluated including raw data review, and associated with clonal architecture. **Results:** 837 total substitutions or indels (short variants – SV) were observed in 245 sections, with 217 assessed to be subclonal based on mutant frequency (MAF) and tumor content. Only 20 SV were not detected in paired sections from same PT, for a discordance rate of 2.3% (20/857). All discordances were in subclonal variants, with avg MAF < 6%. CNA concordance was 90.2%, with half of discordances associated with low tumor purity or coverage bias. Findings were similar across tumor types (Table), with key targetable GA including *EGFR* mutation in lung cancer and *ERBB2* amplification in breast cancer concordant across all sections. **Conclusions:** Our analysis reveals that intratumoral heterogeneity of cancer driver GA is limited. The data supports CGP of a single biopsy section as appropriate in most patients with advanced solid tumors, provided sufficient sensitivity is attained for sub-clonal events in impure clinical tissue.

Concordance	Breast Invasive Duct Carcinomas	Colorectal Adenocarcinomas	Head and Neck Squamous Cell Carcinomas	Renal (1 oncocytoma + 1 chromophobe, 1 urothelial and 2 unclassified carcinomas	Lung (3 adenocarcinomas + 2 squamous cell carcinomas)
Short Variant GA	95.0%	98.5%	99.4%	96.0%	98.1%
CNA	96.3%	86.4%	88.2%	80.0%	90.0%

Feasibility of using memantine in smoking cessation among cancer survivors. *First Author: John Spangler, Wake Forest University, School of Medicine, Winston-Salem, NC*

Background: Memantine, an N-methyl-D-aspartate receptor noncompetitive antagonist, has been proposed for smoking cessation by virtue of opposing the effects of glutamate in the CNS "addiction center," the nucleus accumbens. This study evaluated Memantine's feasibility and preliminary efficacy for quitting smoking among cancer survivors. **Methods:** A prospective randomized feasibility trial was conducted by the Wake Forest CCOP Research Base. Feasibility outcomes included accrual, retention, adherence, and toxicity. Clinical outcomes included smoking cessation at 12 weeks (defined as no smoking in the past week). 130 patients were accrued between 9/12 and 11/13, 65 on Memantine (M) and 65 on Control (C). Ages ranged from 29 to 84 with a median of 57; 85% were female and 85% were Non-Hispanic White. 75% had breast cancer, 12% colorectal cancer, 11% lung cancer, and 2% prostate cancer. On average, patients started smoking at 16, had smoked for 40 years, and smoked a pack a day. Characteristics were similar in the two arms. **Results:** Over 20 CCOP sites participated; accrual was approximately 10 patients per month. Retention at 12 weeks was poor (54% M, 68% C). Self-reported adherence was good while patients were on study (86% M, 93% C). Four serious adverse events were noted (3 M, 1 C), none related to treatment. Toxicities were similar in the two arms. Only two patients reported being smoke-free at 12 weeks, both in the Control arm. The number of cigarettes smoked at 12 weeks was similar in the two arms. **Conclusions:** While accrual was robust and patients reported good adherence, 40% dropped out by 12 weeks and very few patients could remain smoke-free for one week prior to the 12 week evaluation following randomization. Other options for smoking cessation need to be assessed. (Funding for this study was provided by NCI to the Wake Forest CCOP Research Base, grant number U10CA081851). Clinical trial information: NCT01535040.

Hormonal and lifestyle factors as modifiers of risk of breast cancer (BC) in *BRCA1* and *BRCA2* carriers (C). *First Author: Asunción Torres, Servicio de Oncología Médica, Hospital General de Almansa, Albacete, Spain*

Background: Mutations in the *BRCA1/2* genes confer a high lifetime risk of BC. Penetrance varies among populations and individuals suggesting that non-genetic factors may modify the inherited risk. Knowledge of modifiable factors will help to develop preventive strategies. **Methods:** The study was carried out in 874 women (W) with a *BRCA1/BRCA2* germ-line mutation (511 with BC, 51% *BRCA2*) from 414 families, followed at three Spanish Genetic Counseling Units. Participants gave their consent and the study was approved by the ethics committee. The association between BC, hormonal and lifestyle factors was studied using logistic regression. Huber-White robust estimators of variance were employed to take into account correlations between family members. Age, menopausal status and specific mutated gene were included as co-variables. **Results:** While late menarche ($\geq$ 14 years) was associated with a reduction in BC risk in *BRCA1* C (OR:0.48; 95%CI:0.42-0.88, p = 0.016), no similar effect was observed for *BRCA2* W (p = 0.252). Moreover, although pregnancy increased BC risk in both *BRCA1 and BRCA2* C (OR:2.38; 95%CI:1.26-4.49, p < 0.007; OR:1.89; 95%CI:0.91-3.95, p = 0.09 respectively), a deleterious effect of spontaneous abortion was found only in *BRCA1* C (OR:1.66; 95%CI:0.92-3.01, p = 0.09). Furthermore, oral contraceptive (OC) use was also associated with an increased BC risk in the *BRCA1* group (OR:1.65; 95%CI:0.98-2.78, p = 0.058). BMI also increased the risk of BC among *BRCA1* W (p-trend = 0.014). Finally, breastfeeding, smoking, alcohol intake and exercise did not significantly modify BC risk. **Conclusions:** Our preliminary data suggest that the hormonal changes associated with pregnancy increases BC risk in mutation C. Obesity and the use of OC also exert a deleterious effect in *BRCA1* germline mutation C and could be considered as potential modifiable factors for BC prevention in these group of W.

Physical activity, hormone replacement therapy and breast cancer risk: A meta-analysis of prospective studies. *First Author: Cécile Pizot, International Prevention Research Institute, Lyon, France*

Background: A lower risk of breast cancer among physically active women has been frequently reported, but the risk in women using hormone replacement therapy (HRT) appears to be higher. We quantified the association between physical activity and breast cancer, and we examined the influence that HRT use and other risk factors had on this association. **Methods:** After a systematic literature search, prospective studies were meta-analysed using random-effect models. As physical activity assessment and reporting of results were heterogeneous across studies, breast cancer risk associated with the highest level of physical activity was compared with the lowest level of physical activity. Dose-response analyses were also conducted with studies reporting physical activity either in hours/week or in hours of metabolic equivalent per week (MET-h/week). **Results:** The literature search identified 38 independent prospective studies published between 1987 and 2014 that included 4,183,888 women of which 116,304 breast cancer cases. Compared to the lowest level of physical activity, the highest level was associated with a summary relative risk (SRR) of 0.88 (95% CI (0.85, 0.90)) for all breast cancer, 0.89 (0.83, 0.95) for ER+/PR+ breast cancer and 0.80 (0.69, 0.92) for ER-/PR- breast cancer. Risk reductions were not influenced by the type of physical activity (occupational or non-occupational), the place of residence, adiposity, and menopausal status. Risk reductions increased with increasing amounts of physical activity, without threshold effect. In six studies that examined the influence of physical activity according to HRT use, the SRR was 0.78 (95% CI (0.70, 0.87)) in women who never used HRT and 0.97 (95% CI (0.88, 1.07)) in women who ever used HRT, without heterogeneity between studies. A sustained change from being physically inactive to engaging in 4 to 7 hours/week of mainly vigorous physical activity could lead to a 31% (95%CI (22, 40)) risk reduction in women who never used HRT. **Conclusions:** Increasing physical activity is associated with meaningful reductions in the risk of breast cancer. However in women who ever used HRT, the preventative effect of physical activity seems to be cancelled out.

1562 Poster Session (Board #386), Mon, 1:15 PM-4:45 PM

Impact of prior knowledge of mutation status on tumor stage in BRCA1/2 mutation carriers with newly diagnosed breast cancer. *First Author: Clinton Yam, Basser Research Center for BRCA at the Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: BRCA1/2 mutation carriers have an elevated lifetime risk of developing breast cancer. Knowledge of one's BRCA1/2 mutation status may aid earlier detection of breast cancers due to increased awareness and screening with breast MRIs. **Methods:** Retrospective analysis of tumor characteristics of BRCA1/2 mutation carriers known to our institution who were diagnosed with breast cancer from 1/1/2009 - 12/31/2013. **Results:** 106 BRCA1/2 mutation carriers were diagnosed with their first breast cancer during the study period. 82 patients received care primarily at our clinical sites and were included in the study. 19.5% (16/82) were known BRCA1/2 mutation carriers prior to breast cancer diagnosis and the remaining 66 patients had genetic testing after cancer diagnosis. There were no differences in the median age at cancer diagnosis (p = 0.87) or distribution of BRCA1 vs BRCA2 mutation carriers between the 2 groups (p = 0.18). 62.5% (10/16) of known carriers were diagnosed with breast cancer following an abnormal MRI vs 0/66 of those identified as carriers only after breast cancer diagnosis (Table 1). Patients who knew their BRCA1/2 mutation status were more likely to have smaller tumors (p = 0.008) and node negative disease (p = 0.004). There were no differences in the ER, PR or Her2 statuses between the 2 groups. **Conclusions:** BRCA1/2 mutation carriers who have knowledge of their genetic status are more likely to have early stage disease at the time of breast cancer diagnosis, demonstrating the utility of identifying unaffected carriers who benefit from enhanced screening for early detection.

Summary of findings.

	Known at diagnosis (n = 16)		Unknown at diagnosis (n = 66)	p value
Median age	40 (25 - 70)	Years (range)	42.5 (28 - 74)	0.87
BRCA		Number (%)		
BRCA1	11 (68.8)		33 (50)	0.18
BRCA2	5 (31.3)		33 (50)	
Method of diagnosis				
MRI	10 (62.5)		0	<0.001
Mammogram	2 (12.5)		21 (31.8)	
Physical exam	2 (12.5)		45 (68.2)	
Prophylactic Mastectomy	2 (12.5)		0	
T stage				
Tis/T1	15 (93.8)		34 (51.5)	0.008
T2-4	1 (6.3)		31 (47.0)	
Tx	0		1 (1.5)	
Node negative	16 (100)		42 (63.6)	0.004
Stage				
0	4 (25)		3 (4.5)	0.011
I - II	12 (75)		52 (78.8)	
III - IV	0		11 (16.7)	
ER+	8 (50)		34 (51.5)	0.91
PR+	7 (43.8)		32 (48.5)	0.73

1563 Poster Session (Board #387), Mon, 1:15 PM-4:45 PM

Development and external validation of a melanoma risk prediction model using self-assessed risk factors. *First Author: Kylie Vuong, University of Sydney, Camperdown, Australia*

Background: Melanoma incidence rates have been increasing in fair-skinned populations, with Australia having the world's highest melanoma incidence rates. By providing individuals with their overall risk instead of relying on individual risk factors, melanoma risk prediction models may lead to improved risk perception and sun protection behaviours. In addition to their clinical uses, these models may assist in planning intervention trials and population prevention strategies that target particular risk groups. We aimed to develop and validate a melanoma risk model predicting lifetime absolute risk of primary melanoma using self-assessed risk factors. **Methods:** We used unconditional logistic regression with backward selection to develop the melanoma risk model using the Australian Melanoma Family Study, a population-based case-control-family study with 629 population-based cases with first primary melanoma diagnosed before age 40 years and 535 controls from 2001 to 2005. Relative risk estimates from the model were combined with Australian melanoma incidence and mortality data using the Gail method to obtain lifetime absolute risk estimates. Subsequently we validated the model externally using the Western Australia Melanoma Study, a population-based study with 511 case-control pairs from 1980 to 1981. Multiple imputation was used to handle missing data. **Results:** Our model, which includes age, sex, state of residence, hair colour, naevus density, first degree family history of melanoma, previous non-melanoma skin cancer and lifetime sunbed use, demonstrated good discriminative performance on both internal [area under the receiver operating curve (AUC) = 0.71 (95% CI 0.68 - 0.73)] and external validation [AUC = 0.63 (0.60 – 0.65)]. **Conclusions:** The model, which is based on self-assessed risk factors, discriminates well between those with and without melanoma and may be useful in the design of melanoma prevention interventions.

1564 Poster Session (Board #388), Mon, 1:15 PM-4:45 PM

Aspirin and risks of non-colorectal second primary cancer in patients with prior colorectal cancer. *First Author: Yu-Ting Lee, Division of Hematology and Oncology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*

Background: Aspirin has been identified as reducing cancer incidence, especially colorectal cancer (CRC), distant metastasis and mortality. Secondary cancer prevention has not been investigated. To examine the potential effects of aspirin on non-colorectal SPMs prevention among patients with previous CRC **Methods:** We enrolled 92,392 patients with newly diagnosed CRC between January 1, 1997 and December 31, 2011 from the Taiwan's National Health Insurance database. Participants with more than 90 cumulative defined daily doses (cDDD) of aspirin exposure are defined as aspirin users (n = 7,488) compared with non-users (n = 84,904). Development of non-colorectal SPMs was obtained from the Taiwan's National Health Insurance database. The Cox proportional hazards model, and the Fine and Gray's proportional hazards model were used to estimate the cause-specific hazard ratios (HRs) and subdistribution HRs, respectively. Data analysis was conducted in April, 2014. **Results:** During the 15-year study period, 3,880 patients developed non-colorectal SPM among 92,392 recruited CRC participants. We compared 7,488 aspirin users with 84,904 non-users. Overall, the difference for risk of SPM was not significant. The cause-specific hazard ratios (HRs) and subdistribution HRs were 0.99 (95% CI 0.88–1.12) and 1.00 (95% CI 0.88–1.12), respectively. Propensity score analyses were done and matched 6,728 aspirin users with 26,912 non-users. The cumulative incidence of SPM showed no difference (p = 0.824). **Conclusions:** Among patients with prior CRC, aspirin use did not provide chemoprevention in non-colorectal SPMs.

1565 Poster Session (Board #389), Mon, 1:15 PM-4:45 PM

Cancer screening in France: Reaching a plateau? New edition of an iterative nationwide survey. *First Author: Jerome Viguier, Hôpital Bretonneau, Tours, France*

Background: The EDIFICE survey program began in 2005 and set out to ascertain participation rates of the French population in cancer screening and assess changes in these rates over time. After 2005, 2008 and 2011, the latest survey was conducted in 2014, and focused on colorectal, breast, prostate, cervical and lung cancers. **Methods:** EDIFICE 4 was conducted by phone interviews of a representative sample of 1602 subjects (age 40-75), using the quota method. Analysis focused on target populations as defined by guidelines when these exist. **Results:** For breast cancer, the rate of women declaring having had ≥ 1 mammography was 93%/94%/95%/97% in 2005/2008/2011/2014 respectively, with no impact of sociodemographic criteria. As recommended in the French program, a mammography had been done in the previous 2 years for 75%/83%/83%/81%, with a lower participation rate among the 65 to 74-year age group. For colorectal cancer, the rate of individuals declaring having attended ≥ 1 screening procedure, colonoscopy or fecal occult blood (FOB) test, was 25%/38%/59%/60%. The FOB test had been performed according to the recommended timing interval for NA/15%/32%/31%. Colorectal cancer screening has now reached a plateau for both genders, the only significant increase being seen in the 70 to 74-year age group. The rate of men having undergone at least one prostate cancer screening test (PSA and/or digital rectal exam) was 36%/49%/50%/49%, with a decrease in participation rates among the 50 to 59-year age group. For cervical cancer, 99% of women declared having already undergone conventional 'Pap' smears or liquid-based cytology during a gynecological exam. Average age for the 1st test was 26 years. With regard to lung cancer, 11% of participants declared having already undergone a lung cancer screening procedure; this figure was 6% in the first EDIFICE survey in 2005. **Conclusions:** Screening participation rates have stabilized and for most tumor locations, appear to be correlated with the history of implementation of national programs or recommendations. When organized screening programs exist, such as for breast and colorectal cancer, the difference between the plateau levels raises the question of the acceptability of the test.

1566 Poster Session (Board #390), Mon, 1:15 PM-4:45 PM

The influence of inflammation on mammographic breast density in women at increased risk of breast cancer. *First Author: Samir S. Ambrale, University of Vermont, Burlington, VT*

Background: Mammographic density is an important risk factor for breast cancer but the etiology of density is not well understood. Studies suggest that inflammation may play a role in density. We evaluated the association between serum inflammatory markers and breast density in women at increased risk for breast cancer. **Methods:** Women previously enrolled in the University of Vermont IRB-approved High-Risk database were eligible for inclusion if they had a baseline serum sample and a mammogram available within 120 days of each other (N = 174). A subset of eligible women also had a paired serum sample and mammogram at 4 years from study entry (N = 38). Blood samples were analyzed for C-reactive protein (CRP), interleukin-6 (IL-6), interleukin-1b (IL-1b) and tumor necrosis factor-α (TNF-α). Breast density was calculated using 2 methods; the semi-automated Cumulus method and fully automated University of Pennsylvania (UPenn) method. **Results:** Mean age of the cohort was 46.2 (range 24-71 years) and 63.8% were premenopausal. Mean baseline density was 35.8% and 31.8% using the Cumulus and UPenn method respectively. Mean baseline values were 20,005 ng/ml for CRP, 10.6 pg/ml for TNF-α, 0.78 pg/ml for IL-1b and 0.84 pg/ml for IL-6. Body mass index correlated with CRP (spearman correlation coefficient [r] = 0.58; $p< 0.0001$), IL-6 (r = 0.17; $p= 0.003$) and TNF-α (r = 0.19; $p= 0.02$). Linear regression adjusted by age and BMI found that baseline IL-6 had significant association with breast density calculated by either density methods (Cumulus: β coefficient 1.62, $p= 0.04$; UPenn: β coefficient 1.95, $p= 0.01$). No other biomarker had a statistically significant relationship with density. There was no significant correlation between change in inflammatory marker levels and change in density at 4 years. **Conclusions:** Mammographic breast density was found to be elevated among women with higher serum IL-6 levels, a finding that supports prior data suggesting a relationship between inflammation and density. This study strengthens the evidence for consideration of anti-inflammatory agents as chemoprevention for breast cancer. Further research is needed to elucidate the mechanism by which IL-6 is associated with breast density.

1567 Poster Session (Board #391), Mon, 1:15 PM-4:45 PM

Impact of a risk model based on routine lab results on colorectal cancer screening in average risk population. *First Author: Shimon Ben Boursi, University of Pennsylvania, Philadelphia, PA*

Background: Risk scores for colorectal cancer (CRC) screening use limited variables and have low predictive values. We sought to develop and validate a novel CRC risk prediction model based on routinely available data from electronic medical records including laboratory results. **Methods:** We conducted a nested case-control study using a population-based database. The cohort was randomly divided into test and validation datasets. Cases were defined as those with a diagnostic code of CRC, aged 50-85. Subjects with CRC syndromes or IBD were excluded. For every case, 4 controls matched on practice site and duration of follow-up were selected using incidence-density sampling. Lifestyle parameters, medical history, medications, and lab results were examined as CRC risk factors using univariate conditional logistic regression. Variables with p-value < 0.25 were evaluated for the multivariate model, after correcting for linearity, using backward elimination. Discrimination ability was calculated using receiver operator curve (ROC). Goodness of fit was evaluated using the McFadden's R2. For the final model we calculated the net reclassification index (NRI) compared to a model including lifestyle parameters only. **Results:** Our study cohort included 45,498 subjects in the test set (n = 9,299 [20.44%] cases) and 22,490 subjects in the validation set (n = 4,580 [20.36%] cases). A multivariate model based on lifestyle parameters only (age, sex, height, obesity, ever smoking, alcohol dependence and previous screening colonoscopy) had an AUC of 0.58 (95%CI 0.57-0.59) with low goodness of fit. A model based on lab results only (hematocrit, MCV, lymphocytes and neutrophil to lymphocyte ratio [NLR]) had an AUC of 0.76 (95%CI 0.76-0.77) and a McFadden's R2 of 0.21 with a NRI of 47.6%. A combined model including sex, hemoglobin, MCV, white blood cells, platelets, NLR and medication prescriptions for oral hypoglycemics reached an AUC of 0.80 (95%CI 0.79-0.81) with a McFadden's R2 of 0.27 and a NRI of 60.7%. Similar results were shown in the validation set. **Conclusions:** A risk score based on sex, CBC, and medication use has good discriminating power for CRC risk in the average risk population.

1568 Poster Session (Board #392), Mon, 1:15 PM-4:45 PM

Trends in CRC screening by average-risk Medicare enrollees over age 75: 2002-2010. *First Author: Charles L. Bennett, South Carolina Coll of Pharm, Columbia, SC*

Background: Since 2001, Medicare has covered colorectal cancer (CRC) screening for average-risk enrollees. In 2008, the U.S. Preventive Services Task Force (USPSTF) recommended against routine CRC screening of the average-risk over age 75. Although Medicare CRC screening policy has no age limit on screening eligibility, there are concerns about inappropriate use of CRC screening services. **Methods:** The data consist of a 1998-2010 5% non-cancer sample of Medicare enrollees residing in SEER registry areas. We constructed 9-year panel data from 2002 to 2010. Each panel was assembled in the similar fashion. For illustration purpose, average-risk Medicare beneficiaries were included in the 2010 panel if they were 76 years or older in 2010; enrolled in FFS plans and Part A&B benefits in every single month in 2010 and the previous 9 years; not diagnosed with any indications for higher risks in 2010 and the previous 4 years. The outcomes are the up-to-date overall adherence status, and the specific modality (conditional on adherence). Chi-squared tests were used for statistical analyses. **Results:** The sample size of 9-year panel data of average-risk Medicare enrollees over age 75 ranges from 23,536 in 2002, 19,847 in 2008, to 19,609 in 2010. The overall CRC screening adherence rates increased from 12.69%, 17.44% and 20.88%, respectively. For the adherence rates by modality, the rates of adherence to colonoscopy increased from 2.18%, 14.67%, and 19.03%, respectively, while the rates of adherence to other modalities decreased rapidly. There was variation in overall adherence rates. Blacks were less likely than whites to be adherent ($P < 0.01$); women were less likely than men to be adherent. For the subpopulation over age 85, the rates of adherence to colonoscopy were .74%, 7.14%, and 11.24%, respectively. The differences in colonoscopy adherence by race and gender among the subpopulation were consistent to these among the population over age 75 ($P < 0.01$). **Conclusions:** Overall adherence rates have risen rapidly since 2002, largely driven by 2001 Medicare coverage decision on colonoscopy. The high proportion of the average-risk over age 75 who received screening colonoscopy services, a practice against USPSTF recommendation, warrants more research.

1569 Poster Session (Board #393), Mon, 1:15 PM-4:45 PM

Prediction models for primary melanoma: an independent external validation study in an Australian population. *First Author: Kylie Vuong, University of Sydney, Camperdown, Australia*

Background: There are a growing number of melanoma risk prediction models; however few assessed model external validity. External validation refers to the process of establishing model performance in an external, independent population and provides an indication of generalizability. Model performance tends to be poorer when measured in an external, independent data set compared with the data set that was used to develop the model. To help clinicians decide which models are potentially most useful, we assessed the external validity of six published melanoma models on an independent population. **Methods:** The Australian Melanoma Family Study, a population-based, case-control-family study with 629 population-based cases with first primary melanoma diagnosed before age 40 years and 535 controls from 2001 to 2005 were used to validate the models. We compared performance using discrimination (separation of those with and without melanoma) by calculating the area under the receiver operating curve (AUC). **Results:** Model performance ranged from fair to good. The models of Mar [AUC = 0.79 (95% CI 0.73 – 0.79)] and Fears for men [AUC = 0.79 (0.71 -0.86)] showed comparable discrimination. Other models yielded lower discrimination: Guther [AUC = 0.70 (0.67-0.72)], Williams [AUC = 0.66 (0.64-0.69)], Cho [AUC = 0.63 (0.61-0.65)] and Fears for women [AUC = 0.63 (0.56-0.69)]. **Conclusions:** The six models discriminate well between those with and without melanoma in the Australian population suggesting potential for these models to be developed for use in targeted melanoma prevention interventions. However further external validation in different populations and prospective evaluation of efficacy is required before they can be routinely used in clinical settings.

1570 Poster Session (Board #394), Mon, 1:15 PM-4:45 PM

Beliefs and behavior regarding e-cigarettes in a large cross-sectional survey. *First Author: Sebastien Couraud, Acute Respiratory Medicine and Thoracic Oncology Department, Lyon Sud Hospital and Lyon University Cancer Institute, EMR 3738 "Therapeutic Targeting in Oncology", Lyon Sud, Pierre Benite, France*

Background: The use of e-cigarettes has developed dramatically in recent years. However, the role of e-cigarettes in helping cigarette cessation or in lowering social stigma of tobacco use remains controversial. It is therefore useful to assess beliefs and behavior about e-cigarettes. **Methods:** The 4th French nationwide observational survey, EDIFICE 4, was conducted among a representative sample of 1602 subjects aged 40 to 75 years, using the quota method, from June 12 to July 10, 2014. Profile, beliefs and behavior were assessed by phone interviews of the general population with no history of cancer (n = 1463), and compared with those of cigarette smokers and e-cigarette users (eC+). **Results:** Of the 1463 individuals analyzed, 93 (6%) were e-cigarette users (74 current and 19 former cigarette smokers), with a mean daily consumption of 9.9 (±11.0); 88% used nicotine-based e-liquid. Among cigarette users (C+), current C+/eC+ were more likely to be men, to have a lower socioeconomic status (56% vs 39%), and to be more dependent on nicotine according to the Fagerström test (58% vs 46%), in comparison with cigarette smokers alone (C+/eC-). In the general population, 58% believed that e-cigarettes are potentially useful in helping to reduce cigarette smoking, and for 31%, they can help to quit smoking. In contrast, these proportions were 24% and 69% respectively, among e-cigarette users (C+/eC+). In the general population, 42% and 54% believed that e-cigarette smoke is less toxic than cigarette smoke for the user and for passive smokers, respectively. These figures were both greater among e-cigarette users (C+/eC+), reaching 68% and 87% respectively. Of the total population, 12% felt that e-cigarettes are likely to be effective for controlling lung cancer mortality (18% among current smokers vs 9% and 12% in former- and never-smokers), compared to 33% of e-cigarette users (C+/eC+). Lastly, current C+/eC+ smokers believed they have a higher risk of lung cancer than that of current C+/eC- smokers. **Conclusions:** Current cigarette smokers and current e-cigarette smokers both tend to have a lower awareness of e-cigarette toxicity and to emphasize the potential benefit of e-cigarettes for quitting smoking.

1571 Poster Session (Board #395), Mon, 1:15 PM-4:45 PM

Omentin as a potential biomarker related to exercise and cancer risk. *First Author: Michaela Onstad, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Omentin is a protective adipokine whose circulating levels are inversely related to BMI, waist circumference, and insulin resistance. Serum levels are lower in women with endometrial and ovarian cancers compared to healthy controls. Our in vitro studies demonstrate that exogenous omentin suppresses ovarian cancer cell motility and invasion potential and inhibits tumor growth indirectly. Given its inverse relationship with obesity and insulin resistance, we hypothesized that serum omentin can be increased with exercise. **Methods:** We conducted a pilot study of healthy individuals participating in a 10 week community exercise program aimed at training beginning runners for a 5K race. At the start of the program, anthropometric measures were taken, serum collected, and a whole body dual-energy X-ray absorptiometry (DXA) was done to measure percent body fat (%BF) and percent lean body mass (%LBM). These were repeated at completion of the program. Spearman's rank correlation was used to analyze the association between omentin, anthropometric measures and body composition. Paired t-tests and Wilcoxon signed-rank test were used to analyze changes in omentin. **Results:** 40 participants were enrolled and 28 completed all follow-up studies. Baseline omentin was negatively associated with waist circumference ($p = 0.03$) and %BF ($p = 0.01$), and positively associated with %LBM ($p = 0.009$). 11 participants decreased their %BF at completion of the program, whereas 17 had no improvement or increased their %BF. Those who decreased %BF had in increase in serum omentin (median = + 89.23ng/mL), whereas those who had no improvement or increased their %BF showed a decrease in omentin (median = - 69.98ng/mL). The change in omentin was different between these groups, approaching statistical significance ($p = 0.06$). **Conclusions:** Omentin is negatively associated with waist circumference and %BF, and positively associated with %LBM. Changes in serum omentin due to exercise may be reflective of changes in body composition. As the correlation between omentin and cancer risk is further established, it may serve as a useful biomarker for patients to receive specific interventions. Omentin warrants inclusion in future research involving energy balance and cancer.

1572 Poster Session (Board #396), Mon, 1:15 PM-4:45 PM

Effect of green tea catechins in prostate cancer chemoprevention. *First Author: Nagi B. Kumar, H Lee Moffitt Cancer Ctr At Univ of S Florida Coll of Medcn, Tampa, FL*

Background: Preclinical, epidemiological and prior clinical trial data suggest that green tea catechins may reduce prostate cancer (PCa) risk. **Methods:** We, therefore, conducted a placebo-controlled, randomized clinical trial of one year of Polyphenon E (PolyE), a proprietary mixture of green tea catechins containing 400 mgs of epigallocatechin-3-gallate (EGCG) per day, in 97 men with high-grade prostatic intraepithelial neoplasia (HGPIN) or atypical small acinar proliferstion (ASAP) on prostate biopsy. The primary study endpoint was the total number of PCa diagnoses on the PolyE versus placebo arm at one year. **Results:** No differences in prostate cancer rates were observed in the two groups (4/49 PolyE vs 6/48 placebo, $P = 0.25$). A prespecified analysis comparing the combined rates of PCa + ASAP in the subgroup of men with HGPIN-only at baseline, showed a decrease in this composite endpoint (3/26 PolyE vs 10/25 placebo, $P < 0.024$). This was largely driven by a reduction in ASAP (0/26 PolyE vs 5/25 placebo). In another prespecified analysis, a decrease in serum PSA was observed the PolyE arm.(-0.90 ng/mL; 95% CI:-1.67, -0.12; $P < 0.05$). Adverse events related to the study agent did not significantly differ between the two study groups. **Conclusions:** Daily intake of a standardized, decaffeinated catechin mixture containing 400 mgs EGCG per day for 1 year accumulated in plasma and was well tolerated, but did not reduce the likelihood of a subsequent PCa diagnosis in men with baseline HGPIN or ASAP over this period of time. Clinical trial information: NCT00596011.

1573 Poster Session (Board #397), Mon, 1:15 PM-4:45 PM

Do patients with longstanding IBD have higher cancer risk compared to the general population? Results from the IBSEN study. *First Author: Milada Cvancarova, Department of Gastroenterology, Oslo University Hospital, Oslo, Norway*

Background: Crohn's disease (CD) and ulcerative colitis (UC) are chronic relapsing inflammatory bowel diseases (IBDs) that affect the gastrointestinal tract. The incidence and prevalence of IBD have increased worldwide. Involvement of extraintestinal organs is not uncommon; therefore many studies have focused on the risk of organ-specific cancers in IBD patients. In addition to longstanding disease, the presence of primary sclerosing cholangitis, a family history of colorectal cancer (CRC), the degree of inflammation of the bowel, and greater anatomic extension of colitis increase the risk of developing CRC. The aims of the present study were to determine the cancer prevalence in a well-defined population-based cohort of IBD pts 20 years after diagnosis and to compare the risk of cancer development in IBD pts to the general population. **Methods:** The IBSEN (Inflammatory Bowel South-Eastern Norway) study has prospectively followed all patients diagnosed with IBD from 1990 to 1994, in total 843 IBD pts followed regularly for 20 years. All IBD patients were age-and gender matched with 25 individuals from the general population (controls). Complete data on death and all cancers in the IBD cohort and in the controls were collected from the Norwegian Cancer Registry. Overall risk for cancer and CRC-specific risk was computed using Cox model. **Results:** In total we have analyzed 843 IBD pts and 20950 controls. There were 117 (14%) cancers in the IBD patients and 2095 (10%) in the controls. Overall, IBD pts had 1.5 times higher risk of cancer development compared to their matched controls (HR = 1.52 (95 % CI (1.26- 1.83) $p < 0.001$). There was no sex difference in all cancers risk. A total of 19 subjects in the IBD group developed CRC (17) or small bowel cancer (2). Males with IBD had a significantly increased risk of CRC-specific cancer compared to controls (HR = 2.54 (95% CI (1.40-4.63) $p = 0.002$), however this risk was not significant for women (HR = 1.31, 95%CI (0.58-2.98). **Conclusions:** Patients who have had IBD for 20 years have about 50 % higher cancer risk compared to the age- and gender matched controls from the general population. Most of this difference is caused by increased risk for bowel cancer in male IBD patients.

1574 Poster Session (Board #398), Mon, 1:15 PM-4:45 PM

Association between geriatric assessment findings and clinical depression in 1092 older patients with cancer: The ELCAPA Cohort study. *First Author: Christophe Tournigand, APHP, Henri-Mondor Hospital, Oncology department, Creteil, France*

Background: Few studies assessed jointlygeriatric and oncological factors associated with clinical depression in geriatric oncology setting. To assess the prevalence and associated factors of clinical depression in older patients with cancer. **Methods**: We studied a prospective cohort of cancer patients aged ≥ 70 years and referred to geriatric oncology clinics between 2007 and 2012. A multidimensional geriatric assessment (GA) was performed before treatment. Clinical depression was diagnosed by senior geriatricians by a semi-structured interview. It encompassed criteria of the Diagnostic and Statistical Manual of Mental Disorders (4^{th} edition, DSM-IV) and of the International Classification of Diseases (10^{th}edition, ICD-10). Multivariate analysis was based on multivariate logistic models. Systematic adjustement for gender was done. **Results**: Of 1121 consecutive patients, 1092 had available data (mean age, 80.4 years; women, 48.8%; metastases, 51.3%; cancer location: colorectal 21.1%, breast 16.8%, kidney bladder or urinary tract 14.0%, and prostate 11.4%). The overall prevalence of clinical depression was 28.4% (95% confidence interval, 25.7-31.2). Factors independently associated with clinical depression by multivariate analysis adjusting for all following factors and gender were impaired mobility (adjusted OR [aOR], 2.41; 1.64-3.54), impaired functional status defined as ECOG-PS ≥ 2 (aOR, 2.42; 1.83-3.76), inpatient status (aOR, 1.66; 1.18-2.32), metastatic status (aOR, 1.42; 1.01-2.01), inadequate social support (aOR, 1.58; 1.11-2.25), cognitive impairment (aOR, 1.73; 1.23-2.43), polypharmacy defined as five or more nonantidepressant drugs (aOR, 1.70; 1.18-2.44), and multimorbidity ($aOR_{\text{additional CIRS-G point}}$, 1.07; 1.04-1.11). **Conclusions:** In older patients with cancer at various sites and stages, clinical depression was highly prevalent. Clinical depression was independently associated with several GA findings (impaired mobility and function, inadequate social support, cognitive impairment, polypharmacy, and multimorbidity) independently from with gender, tumor site, and metastatic status.

1576 Poster Session (Board #400), Mon, 1:15 PM-4:45 PM

Comparison of breast cancer risk in women with and without systemic lupus erythematosus in a Medicare population. *First Author: Waseem Khaliq, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Studies have suggested a decreased breast cancer risk in patients with systemic lupus erythematosus (SLE). However, these studies enrolled primarily younger patients at lower risk of breast cancer identified from lupus clinics. Therefore, we examined a large population-based cohort assembled from a Medicare beneficiary population to compare the incidence of breast cancer among women with SLE with women without a diagnosis of SLE. **Methods:** We used 20% sample from 2006 Medicare claims data to assemble a cohort of women (N = 3,670,138), 84% of whom were ≥ 65 years. Women with a SLE diagnosis (ICD-9-CM 710.0) and population-based controls were identified and the incidence of breast cancer for women with and without SLE was determined during the following 5 years. **Results:** Of the 18,423 women with SLE who met inclusion criteria, 21% were African Americans and 53% were ≥ 65 years. Among women with SLE and without SLE the age adjusted risk for breast cancer was 2.23 (95% CI, 1.94-2.55) and 2.14 (95% CI, 1.96-2.34) per 100 women over five years respectively. The age and race adjusted incidence ratio for breast cancer was 1.04 (95% CI 0.90-1.21). Stratification by age and race showed no difference in the incidence ratio for breast cancer among women with SLE compared to their respective age-group controls. **Conclusions:** In contrast to clinic based cohorts, we found a similar risk of breast cancer in women with and without SLE in a population based cohort. Because the presence of SLE may affect breast cancer therapies, early detection is critical, so that optimal screening recommendations should be followed.

1577 Poster Session (Board #401), Mon, 1:15 PM-4:45 PM

Factors associated with early mortality in metastatic breast cancer (MBC) in a population based cohort. *First Author: Ines Maria Vaz Duarte Luis, Dana Farber Cancer Inst, Boston, MA*

Background: Significant improvements in survival time have been achieved for patients (pts) with MBC. Nevertheless, some still die soon after diagnosis. Data regarding features associated with early death are limited. **Methods:** Using Surveillance, Epidemiology, and End Results data, we studied 4,032 pts with *de novo* MBC diagnosed between 01/2010-06/2011(when Human Epidermal Growth Factor Receptor 2 [HER2] status started to be recorded) with follow up of at least 6 months. Multivariate logistic regression models assessed features associated with death within 1 and 6 months of diagnosis, adjusting for the variables in the table. **Results:** The median age was 61 (22-99), 75% were white, 93% were insured. Disease subgroups were the following: hormone receptor (HR)+HER2- (61%); HR+HER2+(15%); HR-HER2+ (9%) and triple negative (15%). Approximately 8% died by 1 month and 20% died by 6 months. Older age, lack of insurance, and triple negative subtype were associated with early death. SeeTable. **Conclusions:** Among a population based cohort, one fifth died within 6 months. This study highlights that both clinical factors and insurance type seem to impact early death. These data suggest the importance of studying how differences in insurance reform and other disease characteristics may modify risk for early death and may also inform interventions aimed at those at risk for early death.

Breast cancer in male AYA. *First Author: Rashmi Bawa, John Wayne Cancer Institute, Santa Monica, CA*

Background: Breast cancer is one of the most common cancers in female adolescent and young adults (AYA: ages 15-39 years), which may develop de novo or in patients previously treated for cancer. However, there is scant data about primary or secondary (SMN) male breast cancer in AYAs. This study investigates factors effecting the overall survival (OS) of male breast AYA and compares the demographic, tumor, treatment characteristics, and OS of primary versus SMN in this population. **Methods:** All 589 cases of invasive AYA male breast cancer in the 1998-2010 American College of Surgeons National Cancer Database were examined. Kaplan-Meier with log-rank test and Cox-proportional regression analyses analyzed OS in the entire cohort. Patients were divided into two groups according to primary or secondary occurrence and compared with appropriate statistical methods. **Results:** For the entire cohort, non-white race ($p = 0.004$), government/military/medicare or no insurance ($p < .001$), lower socioeconomic status (SES) ($p = .026$), larger tumor size ($p = 0.034$), distant metastases ($p < .001$), not having any surgery ($p < .001$) or no nodal surgery ($p < .001$) all led to worse OS. On multivariate regression, tumor size (HR 1.02, CI 1.01-1.03), distant metastases (HR 4.95, CI 2.23-10.99), and lower SES (HR 2.15, CI: 1.31-3.49) had worse OS. 35 patients (5.9%) had a SMN, with similar demographic, tumor and treatment characteristics (when stratified by stage) to primary male breast cancers. However, there was a trend for SMN patients to present with less nodal disease (0.063), receive less radiation ($p = 0.068$), and occur less commonly in Blacks ($p = 0.084$). 3-year OS was 86.3% for primary cancer and 76.2% for SMN patients ($p = 0.20$). SMN patients without insurance ($p = 0.035$), with distant metastases ($p = 0.048$), and not having nodal surgery ($p = 0.008$) had worse OS. **Conclusions:** Larger tumor size, distant metastasis and lower SES are associated with worse OS in male AYAs with breast cancer. Outcomes are similar regardless of primary or secondary tumor status.

1579 Poster Session (Board #403), Mon, 1:15 PM-4:45 PM

Treatment intensity differences in screen-detected and community-detected early stage breast cancer (ESBC). *First Author: Kenneth Jack Elder, Royal Melbourne Hospital, Melbourne, Australia*

Background: The value of population based mammographic screening has been questioned by those who believe that the reduction in mortality from earlier diagnosis is outweighed by harms including overdiagnosis and overtreatment as well as harms of false positive recall for assessment. Intensity of treatment received is rarely mentioned in the debate. We hypothesised that screen-detected (SD) cancers would receive less extensive surgical treatment and less intense adjuvant therapies than community-detected (CD) cancers. If demonstrated, the extent of these differences would form an important component of the debate over the role of mammographic screening. **Methods:** Retrospective analysis of a consecutive cohort of female patients aged 40-75 and managed for ESBC between 2009-2013 within a large metropolitan Breast Service in Melbourne, Australia, diagnosed either via a population screening program (SD) or clinically referred to the Service (CD). Data on patient characteristics, symptoms, tumor characteristics and treatment recommendations were derived from hospital records. **Results:** 718 cases were identified. 28 had previous breast cancer and 7 metastatic disease, leaving 682 for analysis. 54% (367/682) were SD. Mean tumor size was smaller in the SD group (1.55cm vs 2.61cm, $p < 0.0001$) and nodal involvement was less common (24% vs 46%, $p < 0.0001$). Compared to CD cases, SD cases received less extensive surgery (mastectomy 14% vs 36% ($p < 0.0001$), axillary dissection 17% vs 40% ($p < 0.0001$)), less intensive adjuvant radiotherapy (radiotherapy after wide excision 93% vs 97% ($p = 0.052$), radiotherapy after mastectomy 34% vs 58% ($p = 0.0039$)). Endocrine therapy was more common in SD cancers reflecting differences in receptor status (93% vs 80% ($p < 0.0001$)), but chemotherapy was much less frequently used (32% vs 65% ($p < 0.0001$)). **Conclusions:** Women diagnosed with ESBC through a population based screening program are less likely to receive mastectomy and/or axillary dissection, less likely to be recommended to receive radiotherapy, and less likely to receive adjuvant chemotherapy. This difference in treatment intensity should be considered in the current debate surrounding mammographic screening.

1580 Poster Session (Board #404), Mon, 1:15 PM-4:45 PM

Association of body mass index with survival outcome in three breast cancer subtypes. *First Author: Takeo Fujii, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: High body mass index (BMI) is a poor prognostic indicator in breast cancer patients. However, data are still limited about the association between baseline BMI and survival according to breast cancer subtype. We evaluated the relationship between BMI and survival among breast cancer receptor subtypes (hormone receptor positive (HR), HER 2 positive (HER), and triple-negative breast cancer (TNBC). **Methods:** This study included 4069 patients with stages I, II, or III breast cancer diagnosed between 1990 to April 30, 2013 who had received neoadjuvant systemic therapy and subsequent definitive surgery collected from Breast Medical Oncology database under IRB-approved protocol. Baseline clinical information including BMI (kg/m^2) was collected, and patient characteristics were tabulated. HR is defined as either estrogen or progesterone receptor positive (positive by immunohistochemistry (IHC) or $> 10\%$ staining) with negative HER2 receptor, and HER2 is defined as HER2 positive (IHC 3+ or HER2/CEP17 ratio ≥ 2.0) regardless of their hormone receptor status. Correlation between BMI as a continuous variable and survival was analyzed by using univariable and multivariable Cox proportional hazard models. **Results:** Median follow-up for survivors was 37 months. Baseline characteristics are shown in Table. A univariable analysis showed a trend towards unfavorable overall survival in TNBC patients whose BMIs were 27.2-40.4. In multivariable analysis, BMI was a significant predictor of poor overall survival only in the HR (hazard ratio 1.017; 95%CI 1-1.033, adjusted $p = 0.046$). **Conclusions:** Our large cohort analysis demonstrated that higher BMI was significantly associated with poor survival only in HR, suggesting that baseline BMI might be a prognostic indicator only for the least aggressive subtype, HR.

	HR (n = 2054)	HER2 (n = 1075)	TNBC (n = 940)
BMI, median (range)	27.6 (15.5-66)	27.5 (15.9-67.6)	28.5 (14.3-61.7)
Recurrence-free survival at 5 years (95%CI)	77.8 (75.5-79.9)	76.4 (73.1-79.3)	63.2 (59.5-66.8)
Overall survival at 5 years (95%CI)	83.4 (81.2-85.3)	82.8 (79.6-85.5)	67.2 (63.3-70.8)

1581 Poster Session (Board #405), Mon, 1:15 PM-4:45 PM

Incidence, prevalence, and risk factors of malignancy in lung transplant recipients. *First Author: Vikas Kumar Singh, UPMC Mckeesport, Mckeesport, PA*

Background: Solid organ transplant is associated with post-transplant malignancy (PTxM) due to chronic immunosuppression, but data is limited in lung transplant recipients (LTRs). Our goal was to analyze the Organ Procurement and Transplant Network (OPTN) database to determine the incidence, prevalence and risk factors for developing PTxM in LTRs. **Methods:** All LTRs in the OPTN database from May 4, 2005 to March 3, 2014 were included in this study. LTRs aged <18 years and those without malignancy follow up data were excluded. Prinary endpoint was the development of PTxM. Multivariate logistic regression was done for non-skin PTxM with variables age, sex, smoking history, previous history of malignancy and pre-transplant diagnosis. **Results:** A total of 10,894 subjects were included. Diagnoses among LTRs were COPD (27%), Idiopathic Pulmonary Fibrosis (IPF) (38%), Cystic Fibrosis (CF) (12%) and others (23%). 791 (7.3%) had history of pre-transplant malignancy. Recurrence rate of pre-transplant malignancy as PTxM was 2.3%. Median follow up time was 4.7 years (IQR 2.0-8.0). Incidence and prevalence are provided in table-1. Post-transplant lymphoproliferative (PTLD) disorder prevalence was 1.3%, of which 50% occurred within one year of transplant. Prevalence of any PTxM was highest in patients with IPF (16%) and lowest among patients with CF(6%). Significant risk factors ($p<0.001$) for non-skin PTxM included: history of previous cancer (Odds Ratio, OR 1.52), age (OR 1.03), smoking history (OR 1.2), male gender (OR 2), and pre-transplant diagnoses of COPD (OR 1.5) or IPF (OR 1.6). **Conclusions:** Prevalence of PTLD was comparable to published prevalence in renal transplant recipients. Prevalence of any type of cancer is significantly higher in LTRs as compared to 0.19% in the general adult population reported by CDC in 2014. Lower prevalence in CF group could be explained by younger median age of 29 in this diagnostic group.

Malignancy incidence and prevalence in adult lung transplant recipient.

	1-Year follow up		Entire follow up period	
Malignancy Type	**Prevalence N (%)**	**Incidence***	**Prevalence N (%)**	**Incidence***

Novel algorithms to predict the occurrence of in-hospital venous thromboembolism in cancer patients: Machine learning classifiers developed from the 2012 national inpatient sample. *First Author: Spencer L. James, Geisel School of Medicine at Dartmouth, Hanover, NH*

Background: Cancer poses a significant risk for venous thromboembolism (VTE), but predicting VTE in patients is challenging. Oncology admissions accrue significant amounts of clinical data, but currently only a limited amount of this data is used to predict VTE. Machine learning is a discipline of computer science whereby computers study high dimensional data features to discover rules that can predict an outcome. The advent of the electronic medical record (EMR) offers a plethora of patient-specific data that could be used for more complex risk modeling, although it is unknown whether this can accurately be used to predict VTE occurrence in the oncology patients. We aimed to measure the accuracy of machine learning classifiers in predicting VTE in patients hospitalized with cancer using information that would be available to the EMR. **Methods:** Using the 2012 National Inpatient Sample (NIS), we applied multiple different machine learning classifiers to develop a predictive model of cancer associated in-hospital VTE and tested its ability to predict which cancer related admissions would be associated with VTE. Accuracy was measured as the percentage of admissions correctly associated with VTE. **Results:** Of the 7,296,968 admissions in the 2012 NIS, 996,506 were associated with a cancer diagnosis, and of those, 47,045 were associated with VTE. Of the patients with a cancer diagnosis, we sampled 1,089 with VTE and 1,089 without VTE. We then conducted 100 train-test simulations where classifiers were trained on a random sample of the data and then made VTE predictions on a separate sample. Of the 100 trials performed, the random forest classifier in the scikit-learn package was able to correctly classify VTE versus non-VTE 74% of the time (range: 69.0% - 79.0%). **Conclusions:** Machine learning classification is capable of harnessing complex signals in clinical datasets and is a promising approach to assess the in-hospital VTE risk of admitted cancer patients. With further validation, such classifiers could be included in EMR systems to provide risk assessment for patient admissions and suggest appropriate use of pharmacological prophylaxis.

Male breast cancer as a second primary cancer (SPC): Increased risk following hematologic malignancies. *First Author: Deborah Elaine Farr, Northwestern University, Chicago, IL*

Background: Male breast cancer accounts for approximately 1% of all breast cancer. The association of male breast cancer with other malignancies has been described; however the risk of males developing breast cancer as an SPC, after specific types of index primary malignancies, relative to population risk, has not been reported. **Methods:** SEER 9 data was used to identify male breast cancer patients with a prior index malignancy. In the period 1973-2011, the five most common index primary sites included breast, prostate, colorectal, ureter and urinary bladder, and hematologic malignancies (leukemia, lymphoma and myeloma). Standardized incidence ratios (SIR) and 95% confidence intervals (95% CI) of male breast cancer as an SPC were calculated (observed/expected rates) for each of these five most common index malignancies. Excess risk was expressed per 100,000. All analyses were conducted using SEER*Stat software, version 8.1.5. **Results:** Over a 38-year period, 512 male breast cancers were identified as second primary malignancies. The most common index malignancies were breast (SIR 28.44, 95% CI 20.32-38.73) hematologic (SIR 1.55, 95% CI 1.11-2.10), ureter/urinary bladder (SIR 1.10, 95% CI 0.80-1.46), prostate (SIR 0.97, 95% CI 0.84-1.11), and colorectal (SIR 0.94, 95% CI 0.72-1.21). Apart from the known association with prior breast cancer, the only significant association was with a prior hematologic malignancy (p-value 0.007). 42.6% of SPC breast malignancies occurred within 5 years of the index malignancy. When incidence rates were compared from 1973-1974 to 2010-2011, the rate of primary breast cancer remained stable at 1.15 and 1.11 respectively, while the incidence rate of breast cancer as SPC increased from 0.12 to 0.39, a 225% increase (p-value < 0.001). **Conclusions:** Compared with the general population, the risk of developing male breast cancer was significantly elevated after initial hematologic malignancies. The risk of developing breast cancer as SPC increased markedly from 1973 to 2011. These observations have implications for clinical surveillance in this population, and point to potential etiologic connections with prior therapy, or with genetics.

Pre-diabetes and breast cancer outcomes: Abrogating the confounding effect of anti-diabetic therapy. *First Author: Varinder Kaur, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Multiple studies indicate that type II diabetes is associated with an increased mortality in breast cancer. However, in these studies the class of anti-diabetic therapy, remains an obvious confounding factor. Higher mortality has been reported in breast cancer patients treated with insulin than with metformin. Choosing a population of breast cancer patients with pre-diabetes, not receiving anti-diabetic therapy, could overcome such confounders. **Methods:** We conducted a retrospective cohort study to evaluate the relationship between elevated random blood sugar (RBS) levels and breast cancer outcomes. Only patients without a previous history of diabetes and who were not receiving any anti-diabetic therapy were included. The effect of elevated RBS on overall survival (OS), event-free survival (EFS) and time to tumor recurrence (TTR) were analyzed using Kaplan-Meier curves and log-rank test, and reanalyzed adjusting for age, race and obesity using multivariate Cox regression. Fisher's exact test was used to compare binary proportions and Spearman rank correlations were used for ordinal category data in conjunction with correlation chi-square tests. **Results:** 234 patients with stage I-III breast cancer (mostly stage II, 177) were analyzed, of which 159 patients had a documented RBS level. 72 patients had elevated RBS ($>$ 120 mg/dL) and 87 had RBS $<$ 120 mg/dL. We observed that patients with elevated RBS experienced significantly shorter OS (HR = 2.89; p = 0.0001), shorter EFS (HR = 2.44; p = 0.0006) and shorter TTR (HR = 2.16; p = 0.023). After adjusting for age ($<$ / $\geq$ 50), obesity and race via Cox regression, elevated RBS continued to display a high and statistically significant association with shorter OS (HR = 3.63; $p < 0.0001$), shorter EFS (HR = 3.20; p = 0.0002) and shorter TTR (HR = 3.52; p = 0.001). Additionally, among patients under 50 years of age, elevated RBS levels were associated with a significantly greater frequency of high grade tumors compared to RBS $<$ 120 mg/dL(80% vs 45%; p = 0.02), suggesting that elevated RBS may have more impact in younger patients. **Conclusions:** High random blood sugar levels, reflective of a pre-diabetic state, are associated with shorter overall survival in breast cancer patients.

"Fight fat with fat": The impact of brown adipose tissue (BAT) on breast cancer prognosis–A retrospective analysis. *First Author: Orlando Esteban Silva, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Two types of adipose tissue exist: white adipose tissue (WAT) and BAT. WAT is the main energy store in humans and is associated with obesity and inflammation. BAT is thought to be protective against obesity and acts as an energy dissipating organ, which may fight obesity by reducing adipokines, inflammatory cytokines, and insulin resistance. The relationship of brown fat activation and cancer prognosis is unknown. We hypothesize that BAT may be protective to breast cancer patients by shifting glucose pool away from tumors and reducing tumor activity. **Methods:** Through a retrospective chart review of over 900 patients treated by the Breast Cancer Group at our institution, we identified 98 patients with BAT on PET CT scans. We collected information on patient demographics, lifestyle, staging and treatments received and response, progression of disease, overall survival, labs (lipids, hemoglobin A1C, Vitamin D, CRP), metabolic syndrome, metformin use, and antidepressants. **Results:** Of the 98 cases identified, 26 had Stage I disease at diagnosis, 32 had Stage II, 27 had Stage III, and 13 had Stage IV. The median age at diagnosis was 46. 62% of patients were Hispanic, 30% Caucasian, and 5% African-American. The majority of cases (86%) were of ductal histology. 77% were ER positive and 24% were HER2 positive. The median BMI of our cohort was 25.1. The 5 year PFS for our cohort was 74.6% (CI 64.2-82.4). The 5 year breast cancer specific OS was 94.2% (CI 86.6-97.6), with OS by stage showing I 100%, II 92.9% (CI 74.6- 98.2), III 91.7% (CI 70.5-97.9), and IV 92.3% (CI 56.6-99.0). While the total OS is within the range of 89.2% reported by SEER, our stage III and IV patients had a markedly improved OS compared to historical controls (41-67% and 15%, respectively, per ACS). **Conclusions:** To date, we have compiled the largest cohort of breast cancer patients with known BAT. While knowledge and clinical applicability of brown fat is still in its infancy, we hope that our study, with its remarkable OS for advanced stage disease, will shed light on the manner in which the presence of brown fat activation affects metabolism, treatment response, tumor microenvironment, and long-term prognosis.

Development of CNS metastasis and subsequent survival in patients with inflammatory breast cancer. *First Author: John Thomas French, MD Anderson Cancer Center, Bellaire, TX*

Background: Inflammatory breast cancer (IBC) is associated with a poor prognosis and high risk of central nervous system (CNS) metastases. We determined the cumulative incidence rate of developing CNS metastasis and overall survival (OS) in stage III IBC patients (pts) compared to pts with non-inflammatory invasive ductal carcinoma (NI-IDC). The purpose of this study was to evaluate the incidence rate of CNS metastasis from 1 year after diagnosis and analyze OS after CNS metastasis occurrence. We also sought to identify prognostic factors using univariate and multivariate competing risk regression models. **Methods:** We performed a retrospective review using the MD Anderson Cancer Center breast cancer database looking at stage III IDC pts treated between 1/1/1984 and 12/31/2011. For inclusion, pts were required to have initiated primary treatment within one year of their diagnosis and have follow-up for at least 1 year before the development of CNS metastasis or death. **Results:** 2323 pts were identified (589 IBC and 1734 NI-IDC). 81 IBC pts developed CNS metastasis compared to 154 NI-IDC pts. The 2-, 5-, and 10-year cumulative incidence rates of CNS metastasis in IBC and NI-IDC were 9.8%, 15.8%, and 17.4% and 6.5%, 10.1%, and 12.7%, respectively. This occurrence was significantly different between IBC and NI-IDC pts ($p = 0.0037$). However, multicovariate competing risk regression models looking at 18 variables in IBC and NI-IDC pts including patient, tumor, and treatment characteristics showed no statistically significant associations with the risk of developing CNS metastasis. In terms of survival, with a median follow up of 7.2 years, median post CNS metastasis OS was not significantly different between IBC (7.6 months) and NI-IDC (5.6 months) pts. At last follow up, 190 pts with CNS metastasis have died. HER2 positive pts had better OS with a median 14.1 months vs 4.3 months ($p = < 0.0001$). In addition, age > 50 ($p = 0.012$) but not IBC status ($p = 0.49$) was a significant predictor of post CNS metastasis survival. **Conclusions:** IBC pts have a higher incidence rate in the development of brain metastasis but OS following brain metastases is similar to its NI-IDC counterpart. Only HER2 status and age appears to play a role in prognosis.

1587 Poster Session (Board #411), Mon, 1:15 PM-4:45 PM

Prevalence of malnutrition in PS 0-1 cancer patients: Results of the NutriCancer2 one-day national survey in 2,197 cancer patients. *First Author: Jean-Philippe Durand, Medical Oncology, Paris Descartes University, Cochin - Port Royal Hospital, AP-HP, Paris, France*

Background: The performance status (PS) measured by the ECOG scale, and malnutrition are both prognostic and risk factors for treatment-related toxicities in cancer patients (pts). In the medical literature, pts characteristics are usually limited to PS without description of the nutritional status. There is a serious issue concerning the under-estimation of the risk prior to anticancer treatments initiation. The prevalence of malnutrition in "fit" PS 0-1 pts remains unknown. **Methods:** We conducted a prospective one-day prevalence survey, NUTRICANCER 2, in 283 wards of private or public hospitals in France in 2012**.** Height, present and usual body weight were systematically assessed in out-pts and in-pts. Malnutrition was defined as a BMI < 18.5 or < 21 in pts older than 75 years, or a loss of body weight $>$ 10% since the diagnosis of malignancy. **Results:** A total of2197 patients (1,132 men and 1,046 women, 19 not evaluable) were included. PS alteration was significantly more frequent in malnourished patients. Indeed, 58.9% of pts with malnutrition had a PS > 2 versus 31% of pts without malnutrition. Malnutrition was found in 48.1% (276/574), 66.7% (166/249), and 69.8% (44/63) of the pts with a PS ranging from 2 to 4, respectively ($chi2 = 223.95$; $p < 0.001$). In pts assumed as fit for chemotherapy, the prevalence of malnutrition was 17.3% (76/440) in PS0 and 33.2% (262/790) in PS1 pts. Almost one third of the patients with apparent good general status were already malnourished and therefore at high risk of severe acute toxicity. **Conclusions:** This national prevalence survey indicates that Performance Status is not sensitive enough for risk assessment in oncology, requiring a systematic nutritional status assessment prior to anticancer treatments initiation.

1588 Poster Session (Board #412), Mon, 1:15 PM-4:45 PM

The long-term use of calcium channel blockers and the risk of breast cancer. *First Author: Sara V. Soldera, Department of Oncology, McGill University Health Center, Montreal, QC, Canada*

Background: The association between calcium channel blockers (CCBs) and the risk of breast cancer is controversial. The objective of this study was to determine whether the use of CCBs is associated with an increased risk of breast cancer overall, and to assess whether this risk varies with cumulative duration of use. **Methods:** A cohort of 273,152 women newly treated with antihypertensive drugs between January 1, 1995 and December 31, 2009, followed until December 31, 2010, was identified using the UK Clinical Practice Research Datalink. CCB use was treated as a time-varying variable, with exposure lagged by one year for latency considerations and to minimize reverse causality. Time-dependent Cox proportional hazards models were used to estimate adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of incident breast cancer associated with the use of CCBs. A secondary analysis was conducted to assess whether the risk varied with cumulative duration of use. All models were adjusted for a number of potential confounders, including age, smoking status, body mass index, alcohol consumption and use of hormone replacement therapy or other prescription drugs. **Results:** During 1,567,104 person-years of follow-up, 4520 women were newly diagnosed with breast cancer (incidence rate: 2.9 per 1000 per year). Compared with other antihypertensive drugs, the use of CCBs was not associated with an increased risk of breast cancer (2.8 vs. 3.1 per 1000 per year, respectively; HR: 0.98, 95% CI: 0.92-1.04). In a secondary analysis, the risk did not vary according to cumulative duration of use (< 5 years, HR: 0.97, 95%: 0.90-1.03; 5-10 years, HR: 1.08, 95% CI: 0.94-1.25; ≥ 10 years, HR: 0.69, 95% CI: 0.36-1.33). **Conclusions:** The results of this large population-based study indicate that the long-term use of CCBs is not associated with an increased risk of breast cancer.

1589 Poster Session (Board #413), Mon, 1:15 PM-4:45 PM

Overall survival in solid tumor patients with abnormal renal function or renal insufficiency. *First Author: Vincent Launay-Vacher, Pitie Salpetriere Hospital, Paris, France*

Background: Data still remain scanty on the potential impact of renal insufficiency (RI) on the mortality of cancer patients. The results of 3 clinical studies we conducted (IRMA-2, CANDY and MARS) were pooled. In all 3, methodology and investigators were the same regarding RI. Pooled analysis was thus allowed to study the potential association between RI and overall survival (OS), and to stratify the risk, if any, depending on the GFR **Methods:** The KDIGO definition and classification of CKD was used. GFR was estimated with the MDRD formula. RI was defined as GFR<60 ml/min/1.73 m^2. **Results:** Population included 5908 solid tumor patients (2181 breast, 854 colorectal, 556 lung, 366 ovarian, 293 prostate for the main tumors). Median age 59.2, mean BMI 24.4, 64.0% were women. 70.7% of these patients were alive at the end of the follow-up period of one year. Univariate analysis reported that RI was strongly linked to mortality ($p < 0.0001$), when analysing together all types of patients and tumors. Furthermore, Hazard-Ratio became statistically significant at a GFR of 85 ml/min/1.73m^2. For non-metastatic patients (n = 4671), RI was also significantly associated with mortality ($p = 0.008$), with a significant higher risk of death starting at a GFR of 86. Finally, multivariate Cox model adjusted for sex, age, metastasis and the 5 main types of tumor reported that GFR was significantly associated with OS with an increased risk of mortality at a GFR of 75. This risk gradually increased along with the decrease in GFR. **Conclusions:** The IRMA studies already reported the high prevalence of RI in cancer patients. But our pooled analysis reported that the reduced OS began at an early stage of CKD, for a GFR< 75. These results underline that assessing, monitoring and managing renal function in cancer patients is crucial in order to prevent or at least minimise renal dysfunction because of its potential impact on survival.

Multivariate Cox model regression.

GFR cut-off	HR [95% CI]; p-value
GFR < 90	HR = 1.03 [0.93-1.14]; p > 0.05
GFR < 85	HR = 1.06 [0.96-1.17]; p > 0.05
GFR < 75	HR = 1.13 [1.02-1.26]; p = 0.01
GFR < 60	HR = 1.15 [1.03-1.27]; p = 0.01
GFR < 30	HR = 1.53 [1.23-1.86]; p = 0.0001

GFR = Glomerular Filtration Rate (mL/min/1.73m^2); HR=Hazard-Ratio

Determinants for no definitive therapy for early-stage non-small cell lung cancer in U.S. population. *First Author: Yu-Wei Chen, Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: Surgery or radiation therapy (RT) remains the definitive treatment for early-stage (Stage I/II) non-small cell lung cancer (NSCLC). Early-stage NSCLC should be treated appropriately since survival decreases progressively with advanced stages. Our study aims to identify the factors associated with receiving no definitive therapy among US patients. **Methods:** Patients ≥ 18 years and diagnosed with stage I/II NSCLC from 2004-2011 in Surveillance, Epidemiology and End Results Program (SEER) were identified. Definitive therapy was defined as receiving surgery and/or RT. Socio-economic characteristics (income, educational status and residence type) were collected at county-level. Predictors for no definitive therapy were estimated with a multivariable logistic regression model. **Results:** A total of 32,401 patients were identified. 4,997 patients (15%) had no definitive therapy and among them only 456 (9%) did not receive surgery due to contraindications/patient refusal. Independent predictors for no definitive therapy include individual characteristics, such as older age, male, African Americans, not-married status, histology types other than adenocarcinoma, as well as county-level characteristics include living in a county with lower median household income, higher percentage of population with education level < high school, and a non-metropolitan setting. **Conclusions:** A significant proportion of patients diagnosed with early-stage NSCLC in the US did not receive definitive therapy. Socio-economic characteristics should be explored further to explain this phenomenon.

Independent Predictors

	Adjusted OR 95% CI
Age (every 10 years increase)	1.86 (1.80-1.92)
Median house Income (every 10,000 USD increase)	0.86 (0.81-0.91)
%Education < high school level (every 20% increase)	1.39 (1.23-1.56)
Sex	
Male vs Female	1.32 (1.02-2.10)
Race	
Black vs White	1.67 (1.51-1.85)
Other vs White	1.14 (0.99-1.31)
Marital status	
Married/Domestic partners	Ref
Single/Divorced/Separated/Widowed	1.96 (1.83-2.10)
Residence	
Non-Metropolitan vs Metropolitan	1.12 (1.02-1.24)
Histology type	
Squamous cell carcinoma vs Adenocarcinoma	1.13 (1.04-1.23)
Others vs Adenocarcinoma	2.37 (2.20-2.56)

1592 Poster Session (Board #416), Mon, 1:15 PM-4:45 PM

Effect of current smoking on risk of triple negative breast cancer. *First Author: Dhivya Prabhakar, University Hospital/Case Western Reserve University, Cleveland, OH*

Background: A number of lifestyle factors have been associated with risk of breast cancer. Studies have suggested that risk factors for triple negative breast cancer (TNBC) are different from other forms of breast cancer, and have suggested that parity, family history and body mass index (BMI) are associated with risk of TNBC. Here we sought to explore these associations and investigate the association of previously underexplored variables with risk of TNBC. **Methods:** Newly diagnosed breast cancer patients (N = 1236) were recruited from University Hospitals Case Medical Center (UHCMC) from 2007 to 2014. Patients were ineligible if they had a prior cancer or were known to be a BRCA1/2 carrier. Controls (N = 936) were recruited from the mammography center at UHCMC and were eligible if they were not diagnosed with cancer and were not known to be BRCA1/2 positive. All participants completed a lifestyle risk factor survey. Medical records were abstracted to obtain ER, PR and HER2 status. Patients were classified as TNBC if ER, PR and HER2 were negative, or non-TNBC if at least one was positive. Statistical significance of differences in physical activity, family history, parity, smoking, hours of sleep per night and BMI for both TNBC patients and non-TNBC patients compared to controls was assessed using a t-test or chi-square test. A multivariate logistic regression was used to assess significance after adjusting for age, race and BMI. **Results:** Of the patients, 121 were classified at TNBC and 932 were classified as non-TNBC. We noted a statistically significant association of current smoking with risk of TNBC (OR = 2.67, 95% CI = 1.05-6.76, p = 0.038 in multivariate regression). There was no association between former smoking at risk of TNBC ($p = 0.28$). There was no association between current smoking at risk of non-TNBC ($p = 0.34$). We did not note a statistically significant association between any other of the risk factors and TNBC ($p > 0.05$). **Conclusions:** There have been mixed results regarding the association of smoking with breast cancer, and, in particular, TNBC. Our data suggests that current smoking is a risk factor for TNBC, but not other subtypes of breast cancer. The lack of association between former smoking and TNBC suggests that quitting smoking may reduce risk.

2000 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Tumor treating fields (TTFields): A novel treatment modality added to standard chemo- and radiotherapy in newly diagnosed glioblastoma—First report of the full dataset of the EF14 randomized phase III trial. *First Author: Roger Stupp, University Hospital Zurich & University of Zurich, Zurich, Switzerland*

Background: TTFields is an established antimitotic treatment modality delivered to patients by a portable, home use, medical device. Here we evaluate whether this antimitotic effect can be translated into improved survival in a clinical setting. Based on a pre-specified interim analysis on 315 patients, the IDMC recommended early trial closure; we here report the first analysis of the full dataset of 700 randomized patients. **Methods:** This prospective phase 3 trial randomized patients with newly diagnosed glioblastoma, after completion of concomitant chemoradiotherapy, to receive either adjuvant temozolomide (TMZ) chemotherapy alone, or TMZ with TTFields (TTF/TMZ). The primary endpoint was progression-free survival, with overall survival, safety, cognitive function and quality of life as secondary endpoints. **Results:** (ITT) From 2009 to 2014, 700 Grade IV astrocytoma (glioblastoma) patients (68% male) were randomized 2:1. Patient characteristics were well balanced: median age was 56 and 57 years in the TMZ and TTF/TMZ arms, respectively. Tumor was resected in 87% of patients. MGMT was centrally assessed in 77% of patients, 35% and 39% of the tumors had a methylated promoter; 10% and 8% of the results were invalid. Median time from diagnosis to randomization was 3.8 and 3.7 months. Progression-free survival was 7.1 for TTF/TMZ vs 4.2 months for TMZ alone, hazard ratio (HR) 0.694 (95% CI 0.558-0.863) log rank p = 0.0010; overall survival 19.4 vs 16.6 months, HR 0.754 (0.595-0.955), p = 0.0222. This translates into 2-year survival rates of 43% (CI 36-50%) vs. 29% (CI 21-38%). No significant added toxicity was seen in the TMZ/TTF arm. Quality of life and gross cognitive function were comparable in the 2 arms. **Conclusions:** This is the first randomized trial demonstrating improved progression-free and overall survival of patients treated with Tumor Treating Fields. It sets a new standard of care for patients with glioblastoma, and warrants further investigation in other clinical indications. Clinical trial information: NCT00916409.

2001 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Long-term analysis of the NOA-04 randomized phase III trial of sequential radiochemotherapy of anaplastic glioma with PCV or temozolomide. *First Author: Wolfgang Wick, Neurology Clinic, Heidelberg, Germany*

Background: NOA-04 compared the efficacy and safety of radiotherapy *versus* (*vs)*chemotherapy in patients with newly-diagnosed, centrally assessed, supratentorial gliomas of WHO grade III and had not demonstrated a difference in efficacy parameters between arms. Here, long-term clinical follow-up for the intention-to-treat population (n = 274) and the biomarker group (n = 207) are presented. **Methods:** Patients with anaplastic astrocytoma (52.6%) and anaplastic oligodendroglial tumors (47.4%) were randomized 2:1:1 (A:B1:B2) to receive radiotherapy to 54-60 Gy or four 6-week cycles of procarbazine, CCNU and vincristine (PCV) or eight 4-week cycles of temozolomide. The primary endpoint was time-to-treatment-failure (TTF) defined as progression after radiotherapy and one chemotherapy in either sequence, or any time before if no further therapy could be administered. Exploratory analyses of the correlation between molecular status and TTF, progression-free (PFS) and overall survival (OS) were part of the study. **Results:** With a median observation period of 11.8 years (ys) median TTF [4.6 (3.4-5.1) ys *vs* 4.4 (3.3-5.3) ys], PFS [2.5 (1.3-3.5) ys *vs* 2.7 (1.9-3.2) ys], and OS [8 (5.5-10.3) ys *vs* 6.5 (5.4-8.3) ys] were not different between arms (A vs B1/B2). Oligodendroglial *vs* astrocytic histology, but more so subgroups according to CpG island methylator phenotype (CIMP) and 1p/19q co-deletion status revealed a strong prognostic value of $CIMP^{pos}$ with (CIMP-codel) *versus* without 1p/19 co-deletion (CIMP-non-codel) *vs* $CIMP^{neg.}$, but no differential efficacy of radio- and chemotherapy for any of the observed endpoints (PFS CIMP-codel: 8.8 (4-11.2) ys for A versus 7.6 (4.1-9.5) ys for B). In $CIMP^{neg.}$ mainly astrocytic tumors hypermethylation of the O6-*methyl-guanyl-DNA methyltransferase*promoter (MGMT) provided a large risk reduction for PFS in arms B1/B2, but not arm A. **Conclusions:** NOA-04 long-term data do not support a differential efficacy of primary temozolomide monotherapy or PCV polychemotherapy *vs* radiotherapy in any of the histological or molecular subgroups of anaplastic glioma. Molecular diagnosis is superior to histology. MGMT is predictive in $CIMP^{neg.}$ gliomas. Clinical trial information: NCT00717210.

2002 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Results of NRG oncology/RTOG 9813: A phase III randomized study of radiation therapy (RT) and temozolomide (TMZ) versus RT and nitrosourea (NU) therapy for anaplastic astrocytoma (AA). *First Author: Susan Marina Chang, UC San Francisco, San Francisco, CA*

Background: TMZ is efficacious in recurrent anaplastic glioma and newly diagnosed glioblastoma. The primary objective was to compare the overall survival (OS) of patients with AA treated with RT and either TMZ or NU. Secondary endpoints were to compare the time to tumor progression (TTP), relative toxicities of the 2 arms and correlate molecular analyses with clinical outcome. **Methods:** Eligibility: age ≥ 18 years, central histological confirmation of AA and KPS ≥ 60. Patients were randomized 1:1 to RT 59.4 Gy with TMZ 200 mg/m^2daily on days 1-5 of the first week of RT with adjuvant TMZ every 28 days for 12 cycles versus NU (BCNU or CCNU). Median survival time (MST) for the NU arm was assumed to be 3 years with an estimated increase in the TMZ arm to 4.5 years- hazard ratio (HR) 0.67. A sample size of 216 patients per arm would provide an overall statistical power of 90% with a one-sided significance level of 0.05. The distribution of the OS of the 2 arms was compared using the Cox proportional hazard model and the log-rank test. **Results:** Because accrual goals were not met, the trial was closed in 2007.From 2002-2007, 196 eligible patients were randomized, 97 (RT+TMZ) and 99 (RT+NU). Stratification factors (age, KPS, surgery) were balanced between the 2 arms. 65% of patients have died at the time of this report and the median follow-up time for patients still alive was 9.1 years (1.9-11.6 years). There was no difference in OS between the RT+TMZ and the RT+NU arm (p-value 0.37). The MST for the RT+TMZ arm is 3.9 years (95% CI 3.0-7.0) and the MST for the RT+NU arm is 3.8 years (95% CI 2.2- 7.0). The associated HR is 0.94 (95% CI 0.67-1.33). The differences in PFS and TTP between the 2 arms were not statistically significant. The RT+NU arm had a significantly higher rate of worse overall grade ≥ 3 toxicity (75.8% versus 47.9% p < .001), mainly related to bone marrow toxicity. **Conclusions:** RT+TMZ did not appear to significantly improve OS or TTP for AA compared with RT+ NU. RT+TMZ was better tolerated. Correlative molecular, genetic and epigenetic analyses with clinical outcome are pending. NCT00004259 Support**:** U10CA21661, U10CA180868, U10CA180822 (NCI) and Schering Plough. Clinical trial information: NCT00004259.

2003 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Continuing or ceasing bevacizumab at disease progression: Results from the CABARET study, a prospective randomized phase II trial in patients with recurrent glioblastoma. *First Author: Elizabeth J. Hovey, Prince of Wales Hospital, Sydney, Australia*

Background: In patients (pts) with recurrent glioblastoma (rGBM), the benefit of bevacizumab beyond progression (BBP) remains uncertain. Retrospective studies of pts with rGBM receiving BBP have been inconclusive. This study prospectively evaluated BBP in patients with rGBM who experienced initial progression while on bevacizumab (Bev). **Methods:** CABARET is a prospective randomized Phase 2 study of pts at first recurrence of GBM (rGBM) who had previously been treated with surgery, radiotherapy and temozolomide. Pts were randomized to carboplatin plus Bev or Bev monotherapy (Part 1). On progression, eligible pts were stratified according to planned additional chemotherapy and then randomized again to continue or cease Bev (Part 2). Those pts on the Bev monotherapy arm in Part 1 could receive carboplatin or supportive care and those who had received Bev + carboplatin in Part 1, ceased carboplatin and could receive temozolomide, etoposide or supportive care; according to clinician choice. Part 2 endpoints included response rate (RR), progression-free survival (PFS) and overall survival (OS). **Results:** Of 120 pts who received treatment in Part 1, 48 (40%) continued to Part 2, with 23 pts continuing Bev and 25 pts ceasing Bev. The median time on treatment was 1.2 months. There were no radiological responses in either arm. Median PFS (Bev vs no Bev) was 1.8 versus 2.0 months (HR 1.08, 95% CI 0.59–1.96, p = 0.81). Median OS was 3.4 versus 3.0 months (HR 0.84, 95% CI 0.47–1.50, p = 0.56). There were no treatment-related deaths or unexpected serious drug-related adverse events. Preliminary assessment of quality of life scores shows no difference between arms. **Conclusions:** Continuing Bev after progression of rGBM did not improve PFS or OS in this prospective study. Clinical trial information: ACTRN12610000915055.

2004 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

NCCTG N0872 (Alliance): A randomized placebo-controlled phase II trial of bevacizumab plus dasatinib in patients with recurrent glioblastoma (GBM). *First Author: Evanthia Galanis, Mayo Clinic, Rochester, MN*

Background: Preclinical data indicate that Src kinase signaling is markedly upregulated at the invasive GBM front following administration of the anti-VEGF antibody bevacizumab (Bev). The broad spectrum Src kinase inhibitor dasatinib can effectively block Bev-induced glioma invasion (Huveldt et al, 2013). We therefore hypothesized that combining dasatinib with Bev could increase Bev efficacy in the recurrent GBM setting. **Methods:** Eligible patients (pts) had progressive GBM; up to 1 chemotherapy regimen was allowed for recurrent disease. Following a 16 pt phase I dose escalation trial that established Bev 10 mg/kg every 2 weeks in combination with dasatinib 100 mg PO bid as the phase II dose of the combination, the randomized placebo-controlled phase II portion of the trial was initiated. The study followed a 2:1 randomization procedure with 85% power to detect a 20% difference in progression-free survival at 6 months (mo) (primary endpoint) between the two arms, and a type I error rate of 0.15 **Results:** This analysis includes 121 evaluable patients. Median follow-up was 6.8 mo for Arm A (Bev/Dasatinib, N = 83 pts), and 7.8 mo for Arm B (Bev/placebo, N = 38 pts). Although a higher percentage of Arm A patients were progression free at 6 mo, (27.16% vs 18.42%), this difference did not reach statistical significance (p = 0.30). There was no significant difference in OS (7.2 mo vs 7.9 mo; HR 0.86, 95% CI 0.56-1.31, p = 0.48). Response rate was 18.3% in Arm A and 26.5% in Arm B (p = 0.48). The overall incidence of grade 3+ hematologic and non-hematologic toxicity was comparable in Arms A and B (19.3% vs 16.7% for hematologic toxicity and 45% vs 43.4% for non-hematologic toxicity). Grade 2+ treatment-related hypophosphatemia and diarrhea were more common in the dasatinib arm than in the placebo arm (21.7 vs 5.3% and 19.3 vs 2.6%, respectively). **Conclusions:** The combination of the Src kinase inhibitor dasatinib with Bev did not improve the outcome of recurrent GBM pts as compared to single agent Bev. Ongoing correlative analysis in baseline tumor samples is exploring associations between sarc family kinase expression (c-Sarc, Lyn, c-Yes) and activation of downstream signaling pathways and outcome. Clinical trial information: NCT00892177.

2005 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

A randomized phase II trial of standard dose bevacizumab versus low dose bevacizumab plus lomustine (CCNU) in adults with recurrent glioblastoma. *First Author: Shiao-Pei S. Weathers, The University of Texas MD Anderson Cancer Center, Brain and Spine Center, Houston, TX*

Background: Antiangiogenic therapy can rapidly reduce vascular permeability, but high doses of bevacizumab (BEV) may induce selective pressure to promote resistance. This trial evaluated the efficacy of low dose BEV in combination with lomustine (CCNU) compared to standard dose BEV in patients with recurrent glioblastoma. **Methods:** Eligibility criteria included age > 18 yrs with recurrent glioblastoma after temozolomide chemoradiotherapy. Patients were stratified by age, KPS, $1^{st}/2^{nd}/3^{rd}$ recurrence, and scheduled surgery and randomized to BEV 5 mg/kg every 3 weeks plus CCNU 90 mg/m^2 every 6 weeks or BEV 10 mg/kg every 2 weeks. The primary objective was progression free survival (PFS) with secondary objectives of radiographic response (RR), 6 month progression-free survival (PFS-6), overall survival (OS), time to progression (TTP), and safety. **Results:** 70 of 82 patients accrued were randomized and 68 were treated from 2010-2014. Median follow-up was 30.5 months. At the time of this analysis, 62 patients had progressed or died. For 68 evaluable patients, median PFS was not significantly longer in the BEV + CCNU arm (4.34 months, CI: 2.96-8.34) compared to the BEV alone arm (4.11 months, CI: 2.69-5.55, p = 0.19). In patients with one recurrence (n = 24 and 23, respectively), there was a trend towards statistical significance in longer median PFS time in the BEV + CCNU arm (4.96 months, CI: 4.17-13.44) compared to the BEV alone arm (3.22 months CI: 2.5-6.01, p = 0.08). Median OS in patients with 1 recurrence on BEV + CCNU was longer (13.05 months, CI: 8-19.17) than those treated with BEV alone (8.79 months, CI: 6.42-20.22, p = 0.77) but this did not reach statistical significance. No unexpected grade 3 or 4 toxicities were observed. The trial was closed early due to futility. **Conclusions:** The combination of low dose BEV + CCNU is a safe and effective regimen. The study was not designed to test only at first recurrence, but in that subgroup there was a strong trend towards the combination supporting the findings of the recently published BELOB trial.With a larger sample size, a statistically significant difference in median PFS between treatments arms would likely have been observed. Clinical trial information: NCT01067469.

2006 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Radiotherapy in relation to temozolomide: Subgroup analysis of molecular markers of the randomized phase III study by the EORTC/NCIC-CTG/TROG/MRC-CTU (EORTC 22033-26033) in patients with a high risk low-grade glioma. *First Author: Brigitta G. Baumert, University of Bonn Medical Centre, Bonn, Germany*

Background: A subgroup analysis based on molecular markers of patients randomized between standard radiotherapy (RT) and temozolomide (TMZ) alone in the randomized EORTC22033 trial. **Methods:** A posthoc analysis of molecular markers was done for 407 patients (of 477 randomized). The IDH status was determined by immunohistochemistry for the most common IDH mutant, complemented by sequencing of *IDH1* and *2* for all negative cases. The status of 1p/19q codeletion was evaluated by LOH or FISH, the *MGMT*promoter methylation status on the HM450k beadchip (Illumina) and classified by MGMTSTP27. **Results:** IDH1 and IDH2 mutations were detected in 83% (327/392) and 2.8% (n = 9). Co-deletions of 1p/19q were identified in 33% (n = 117/357). MGMT was methylated in 90% (135/150), of which 86% were IDH mutant (128/140). For 318 patients the status for both IDH1/2 and 1p/19q codel was available: 269 (85%) were IDHmt, 104 (39%) IDHmt/codel and 49 (15%) IDHwt. Mutation of the IDH 1 or 2 (IDHmt) regardless of 1p/19q co-deletion was a positive prognostic factor. Exploratory analysis of these 318 patients showed that patients with IDHmt/non-codel tumors had a shorter PFS after treatment with TMZ than after RT (HR 1.86; 95% CI, 1.21-2.87; logrank p = 0.0043), while no difference was observed between these treatments for patients with IDHwt, and IDHmt/codel tumors. **Conclusions:** Subgroup analysis suggests that PFS is longer in patients with IDHmut/non-codel tumors when treated in first-line with RT compared to treatment with TMZ. With still only a few events no such difference is visible in 1p/19q co-deleted tumors. However, maturation of survival data is needed to derive more firm conclusions. Clinical trial information: NCT00182819.

	Progression-free survival				
Treatment	Patients	Observed Events	HR (95% CI)	P-Value	Median (95% CI) (Mths)
RT-IDHmt/codel	45	17	1.00	0.0000	61.6 (42.3, N)
RT-IDHwt	29	25	5.4 (2.9, 10.1)	0.0000	19.1 (11.3, 25.7)
RT- IDHmt/non-codel	89	37	1.1 (0.6, 2.0)	0.6655	55.4 (47.9, 65.9)
TMZ-IDHmt/codel	59	24	1.1 (0.6, 1.9)	0.8509	55.0 (37.9, N)

2007 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Molecular classification of diffuse cerebral gliomas using genome- and transcriptome-wide profiling. *First Author: Michael Weller, Department of Neurology, University Hospital Zurich, Zurich, Switzerland*

Background: WHO grade II and III cerebral gliomas represent a major challenge for histological classification and clinical management. Here, we aimed to improve prognostically relevant patient stratification by characterizing genomic and transcriptional profiles in a prospective patient cohort of the German Glioma Network. **Methods:** We performed microarray-based genome- and transcriptome-wide molecular profiling of primary tumor samples from 137 patients with cerebral gliomas. Integrative bioinformatic analyses were employed to define molecular subgroups, which were then related to histology, molecular biomarkers, including isocitrate dehydrogenase 1 or 2 *(IDH1/2)* mutation, 1p/19q co-deletion and telomerase reverse transcriptase (*TERT)*promoter mutations, and patient outcome. **Results:** Genomic profiling identified five distinct glioma groups, including three *IDH1/2* mutant and two *IDH1/2* wild-type groups. Expression profiling revealed eight transcriptionally different tumor groups (five *IDH1/2* mutant, three *IDH1/2* wild-type), which were only partially linked to the genomic groups. Correlation of DNA-based molecular stratification without-come allowed for the definition of three major prognostic groups with characteristic genomic aberrations. The best prognosis was found in patients with *IDH1/2* mutant and 1p/19q co-deleted tumors. Patients with *IDH1/2* wild-type gliomas and glioblastoma-like genomic alterations, including gain of chromosome arm 7q (+7q), loss of chromosome arm 10q (-10q), *TERT* promoter mutation and oncogene amplification, displayed the worst outcome. Intermediate survival was seen in patients with *IDH1/2* mutant but 1p/19q intact, mostly astrocytic gliomas, and in patients with *IDH1/2* wild-type gliomas lacking the +7/-10q genotype and *TERT* promoter mutation. **Conclusions:** DNA-based molecular subgrouping stratified patients into prognostically distinct groups better than histological classification, whereas addition of gene expression data did not further improve prognostic stratification.

2008 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

The landscape and clonal architecture in lower grade glioma. *First Author: Hiromichi Suzuki, Department of Neurosurgery, Nagoya University School of Medicine, Nagoya Ctity, Japan*

Background: Lower grade gliomas (LGGs, WHO grade II/III gliomas) account for approximately one third of all gliomas. Although LGGs are typically slowly progressive, their clinical course is invariably indolent and most patients ultimately succumb to death. In contrast to glioblastoma, our knowledge about the genetic lesions and clonal evolution in LGG is still incomplete. **Methods:** To obtain a complete registry of gene mutations involved in LGG pathogenesis and their role in clonal evolution, we analyzed whole exome sequencing and/or targeted sequencing of 757 LGG cases from Japan and the Cancer Genome Atlas consortium. Clonal evolution in LGG was investigated using multi-time point/regional sampling in 14 cases with LGGs. **Results:** Massive parallel sequencing revealed LGGs were clearly grouped into three subgroups with or without IDH1/2 mutation and 1p/19q loss of heterozygous (LOH). Type I tumor with IDH1/2 mutation and 1p/19q LOH had a most favorable survival and harbored mutations in TERT promoter, CIC, FUBP1 and NOTCH1. Type II tumor with IDH1/2 mutant/1p19q intact subtype represented TP53 bialleleic inactivation and/or ATRX mutations. Type III tumor with IDH1/2 intact showed GBM-like mutation profile and poor prognosis. Multi regional/time-points sampling analysis supported mutational order and revealed a close correlation of regional heterogeneity with the history of clonal evolution, illustrating the way by which a tumor expands from its origin to surrounding regions, while increasing intratumor heterogeneity and spatially intermingling different evolutional branches in periphery. **Conclusions:** Our findings delineated the landscape of gene mutations in LGG. LGG had mutually exclusive mutational patterns with hierarchical order in discrete subtypes. LGG contiguously developed and generated heterogeneity through acquiring new mutations in a complex but ordered fashion.

2009 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

ReACT: Overall survival from a randomized phase II study of rindopepimut (CDX-110) plus bevacizumab in relapsed glioblastoma. *First Author: David A. Reardon, Dana-Farber Cancer Institute, Boston, MA*

Background: EGFRvIII, a constitutively active EGFR deletion driver mutation, is associated with poor long-term survival in glioblastoma (GB). The investigational vaccine rindopepimut consists of a peptide sequence unique to EGFRvIII conjugated to keyhole limpet hemocyanin (KLH), delivered intradermally with GM-CSF. Three phase II studies of rindopepimut in newly diagnosed, resected, EGFRvIII+ GB demonstrated encouraging progression-free survival (PFS), overall survival (OS) and safety profile. Compassionate use experience suggests that rindopepimut may also provide benefit in relapsed GB, particularly with agents such as bevacizumab (BV). **Methods:** In the Phase II "ReACT" study, BV-naïve pts in 1st or 2nd relapse with EGFRvIII+ GB were randomized 1:1 to BV plus double-blinded injection of rindopepimut or control (KLH). Endpoints: 6-month PFS (PFS6; primary), objective response rate (ORR), PFS, OS and safety. **Results:** Accrual is complete (n = 72); study follow-up continues (n = 30). Primary rindopepimut toxicity is Grade 1-2 injection site reaction. For rindopepimut+BV vs. KLH+BV (per investigator; RANO criteria): PFS6 = 27% (9/33) vs. 11% (4/35) (p = 0.048, 1-side chi-square test); ORR = 24% (7/29) vs. 17% (5/30). Central PFS/ORR assessment is underway. Median (95% CI) OS = 12.0 (9.7, -) vs. 8.8 (6.8, 11.4) months (HR = 0.47 [0.25, 0.91]; p = 0.0208), with 8 vs 4 pts progression-free on study. OS analyses favor rindopepimut including when adjusted for various prognostic factors. Rindopepimut induced robust anti-EGFRvIII titers (1:12,800 to 1:6,553,600) in 80% of pts. Rapid anti-EGFRvIII titer generation was associated with prolonged OS (HR = 0.47 [0.18, 1.27]; p = 0.128) within the rindopepimut arm, and was most frequent in pts with KPS ≥ 90 (odds ratio = 9.75; p = 0.007). Additional evaluation of humoral response quality and HLA typing vs. outcome are underway. In an additional cohort of BV-exposed pts (n = 53), four pts experienced objective tumor response. **Conclusions:** These near-final data show that rindopepimut induces potent EGFRvIII-specific immune response and tumor regression, and appears to significantly prolong survival when administered with BV, in pts with relapsed GB. Clinical trial information: NCT01498328.

2010 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Phase II multicenter study of gene mediated cytotoxic immunotherapy as adjuvant to surgical resection for newly diagnosed malignant glioma. *First Author: Laura K. Aguilar, Advantagene Inc, Auburndale, MA*

Background: New therapies are desperately needed for malignant gliomas since aggressive standard of care (SOC) treatment with surgery, radiation, and temozolomide leads to median survival of less than 15 months. Gene Mediated Cytotoxic Immunotherapy (GMCI) generates a polyvalent anti-tumor immune response through local delivery of aglatimagene besadenovec (AdV-tk) plus prodrug, synergizing with SOC to improve patient outcomes. **Methods:** A Phase II open-label multicenter trial was designed to assess safety and overall survival (OS) after GMCI+SOC compared to a concurrent matched control group meeting protocol criteria and SOC at an institution not active in the treatment trial. AdV-tk was injected into the resection bed followed by oral valacyclovir for 14 days. Primary efficacy analysis was planned on the null hypothesis of no improvement in the 2-year survival over the SOC group with planned subset analysis of significant disease prognostic factors. **Results:** From 2006 to 2010, 48 patients completed SOC+GMCI and 134 SOC in the matched cohort. There were no dose-limiting toxicities. Fever, fatigue, and headache were the most common GMCI-related symptoms. Median OS increased by 3.6 months, from 13.5 for SOC to 17.1 months for GMCI+SOC (p = 0.0417). Survival at 1- 2- and 3-years increased from 57%, 22%, and 8% to 67%, 35%, and 19%, respectively. The improvement was mostly in patients that underwent gross total resection: median OS increased from 16.9 to 25 months (p = 0.0492); 1- 2- and 3-year survival rates from 64%, 28% and 6% to 90%, 53% and 32%. **Conclusions:** GMCI can be safely combined with SOC in newly diagnosed malignant gliomas. Survival rates compared favorably to historical reports and a matched control group. Survival outcomes were significantly improved in patients with minimal residual disease after total resection. The 2-year survival rate met the planned statistical threshold for significance. No significant differences were observed for subtotal resections. This is the first study to demonstrate a correlation between maximum debulking and a survival advantage using immunotherapy. These data strongly support further evaluation of GMCI for malignant gliomas. Clinical trial information: NCT00589875.

2011 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Newly diagnosed glioblastoma patients treated with an autologous heat shock protein peptide vaccine: PD-L1 expression and response to therapy. *First Author: Orin Bloch, Northwestern University, Chicago, IL*

Background: Standard therapy for glioblastoma (GBM) consists of surgical resection followed by concurrent chemo and radiotherapy with a median overall survival of 16 months. In this phase II, single arm study, addition of an autologous heat shock protein peptide vaccine was evaluated for newly diagnosed GBM. Expression of PD-L1 on peripheral monocytes has been shown to be elevated in GBM patients and was evaluated as a predictor of survival. **Methods:** Adult patients with GBM underwent surgical resection followed by chemoradiotherapy. Vaccine was generated from tissue obtained at surgery. Key eligibility criteria included ≥ 90% tumor resection and collection of sufficient tumor tissue to generate at least four 25 μg doses of vaccine. Within 5 weeks of completing radiotherapy, patients received weekly vaccinations, followed by adjuvant temozolomide with monthly vaccinations until depletion of vaccine or tumor progression. The primary endpoint was overall survival. Relative PD-L1 expression on circulating monocytes was measured from peripheral blood obtained at surgery. **Results:** A total of 46 patients from eight centers received the vaccine in addition to standard therapy. Median progression-free survival was 17.8 months (95% Confidence Interval [CI], 11.3-21.6) and median overall survival was 23.8 months (95% CI, 19.8-30.2). The vaccine was well-tolerated with no severe (grade 3 or 4) events attributed to vaccination. The median overall survival for patients with high PD-L1 expression (above the median, 54.5% of monocytes) was 18.0 months (95% CI, 10.0 – 23.3) as compared to 44.7 months (95% CI not calcuable) for low PD-L1 expressors (hazard ratio for death 3.35; 95% CI, 1.36 – 8.23; p = 0.003). A multivariate proportional hazards model revealed MGMT methylation status and PD-L1 expression as the greatest independent predictors of survival. **Conclusions:** Vaccination with autologous tumor-derived heat shock proteins improves survival compared to standard therapy for newly diagnosed GBM. Systemic immunosuppression driven by peripheral monocyte expression of PD-L1 is a previously unidentified factor that may mitigate vaccine efficacy. Clinical trial information: NCT00905060.

Brain Tumor Trials Collaborative Bayesian Adaptive Randomized Phase II trial of bevacizumab plus vorinostat versus bevacizumab alone in adults with recurrent glioblastoma (BTTC-1102). *First Author: Vinay K. Puduvalli, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Bevacizumab (Bev) is approved in the US for patients (pts) with recurrent glioblastoma based on response rate. However, adaptive resistance to antiangiogenic agents can result in tumor recurrence. Deacetylase inhibitors such as vorinostat (Vor) have pleotropic effects against several pathways potentially relevant to adaptive resistance to Bev. **Methods:** We conducted a phase II multicenter trial with Bayesian adaptive randomization of patients to Bev alone or Bev+Vor with a primary endpoint of progression-free survival (PFS) and secondary end points of overall survival (OS) and patient-reported symptoms using the M.D. Anderson Symptom Inventory-Brain Tumor (MDASI-BT). Eligible patients were adults ($\geq$ 18y) with histologically confirmed GB who had recurrent disease after prior radiation and temozolomide therapy, KPS $\geq$ 60, and no prior Bev or HDAC inhibitors. **Results:** Of the 90 pts (Bev+V: 49, Bev: 41) enrolled between Oct 2012 and Oct 2014, 83 were evaluable for the primary endpoint (Bev+V: 46, Bev: 37). MDASI-BT scores were available for 81 pts. There was no significant difference between the two arms in median PFS (4.2 vs.3.6 months, p = 0.53) or median OS (8.3 vs. 7.0 months, p = 0.93). Analysis of the MDASI-BT scores showed no significant differences between the two arms in overall symptom burden or interference (p = 0.48, 0.71 respectively). Overall, 61 pts had died by the time of analysis (Bev+V: 35, Bev: 26) with one treatment related death due to pulmonary embolism. Toxicity $\geq$ grade 3 included hypertension (n = 17), neurological changes (n = 2), infections (n = 2), wound dehiscence (n = 2), DVT/PE (n = 2), and colonic perforation (n = 1). **Conclusions:** In this trial, Bev+Vor did not yield an improved PFS or OS or clinical benefit in terms of reduced symptom burden compared with Bev alone in patients with recurrent GB and does not warrant further investigation. To our knowledge, this trial represents the first prospective Bayesian adaptive randomized therapeutic study against gliomas and demonstrates the feasibility of conducting studies with adaptive trial designs in a multicenter setting. Clinical trial information: NCT01266031.

Randomized, placebo-controlled, phase II study of dasatinib with standard chemo-radiotherapy for newly diagnosed glioblastoma (GBM), NCCTG N0877 (Alliance). *First Author: Nadia N. Laack, Mayo Clinic, Rochester, MN*

Background: Dasatinib is a potent oral ATP competitive multi-targeted kinase inhibitor of multiple members of the Src kinase family known to be involved in gliomagenesis, tumor invasion, and radiosensitivity. N0877 is a phase I/randomized phase II trial evaluating the combination of dasatinib, radiation (RT) and temozolomide (TMZ) in newly diagnosed GBM. **Methods:** Following a 13 patient phase I dose escalation trial which established the MTD and phase II dose of dasatinib to be 150 mg PO daily when given with RT and TMZ, the randomized placebo-controlled phase II portion of the trial was initiated. The study followed a 2:1 randomization procedure with 85% power to detect a hazard ratio of 1.6 or higher in overall survival (OS) between the two arms and a type I error rate of 0.10. Dasatinib or placebo was given orally for 42 days, beginning with the first day of RT (total dose 60 Gy) and first dose of TMZ (75 mg/m2/d). Following a 24 - 42 day rest, patients then received 6 cycles (28 day cycles) of dasatinib or placebo (days 1-28) and TMZ (days 1-5). At the completion of 6 cycles of TMZ + dasatinib/placebo, patients continued on dasatinib/placebo only (28 day cycles) until progressive disease. **Results:** Data from 187 of 196 patients enrolled were available for analysis. Median follow-up was 12.6m for dasatinib (N = 133 pts), and 14m for placebo (N = 63 pts). There was no significant difference in PFS between dasatinib and placebo (6.7m vs 7.8m, respectively; HR 0.80 favoring placebo, 95% CI 0.57-1.1, p = 0.18) or OS (15.5m vs 20.6m; HR 0.71 favoring placebo, 95% CI 0.46-1.1, p = 0.12). Response rate (CR+PR) was 10.5% for dasatinib and 8.3% in placebo arm (p = 0.77). The overall incidence of grade 3 or higher hematologic toxicity was lower in the dasatinib arm (43.9% vs 68.8%, p = 0.0012) primarily due to lower rates of lymphopenia. Grade 3 or higher non-hematologic toxicities were similar between arms (53.8% vs 41.3%, p = 0.1384). Analysis by MGMT status will be forthcoming. **Conclusions:** The combination of the Src kinase inhibitor dasatinib with standard RT/TMZ did not improve the outcome of newly diagnosed GBM patients as compared to standard therapy alone. Clinical trial information: NCT00869401.

2014 Poster Discussion Session; Displayed in Poster Session (Board #3), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

A phase II study of galunisertib monotherapy or galunisertib plus lomustine compared to lomustine monotherapy in recurrent glioblastoma. *First Author: Alba Ariela Brandes, Department of Medical Oncology, Azienda USL, Bologna, Italy*

Background: Based on preclinical data suggesting an additive antitumor effect of galunisertib (G), a TGF-β RI kinase inhibitor, and lomustine (L), this study evaluated the activity of G+L in patients (pts) with recurrent glioblastoma (GB). We report safety, population pharmacokinetics (PK), and efficacy final results. **Methods:** G (300 mg/day) was given as intermittent dosing (each cycle = 14 days on/14 days off). L was given on day 7 of cycle 1 every 6 weeks as approved. Pts received L with either G or placebo (P) thereby blinding for G; pts who received G alone were unblinded (randomization 2:1:1). Primary objective was overall survival (OS) assessed by Bayesian analysis incorporating prior clinical data for L. Secondary objectives were safety, progression-free survival (PFS), tumor response assessed by Response Assessment in Neurooncology (RANO) criteria, and population PK analysis. **Results:** 158 pts were randomized to treatment: G+L (N = 79), G alone (N = 39), P+L (N = 40). Study included, male (64.6%), Caucasian (75.3%); mean age 57 years, 63% had ECOG PS 1, 93.7% had primary GB. The median number of cycles for G was 2 in all 3 arms. G PK was not altered by co-administration with L. G was rapidly absorbed and had median half-life of ~8h with moderate between-patient variability on exposure (CV 41%). The median OS (95% CI) for G+L was 6.7 months (5.3-8.5), [HR (G+L):(L+P) 1.13 (0.8-1.7)], 8.0 months (5.7-11.7) for G alone, [HR (G):(L+P) 0.93 (0.6-1.5)], 7.5 months (5.6-10.3) for L+P control arm. Success criteria for superiority of G+L to L+P was not met [P (HR < 1) < 85%]. The median PFS in months (95% CI) were 1.8 (1.7-1.8) for G+L, 1.8 (1.6-3.0) for G, and 1.9 (1.7-1.9) for P+L. Best overall response according to RANO included 1 CR in G+L and 2 PR in G. 34 pts had Grade 3/4 adverse events (AEs) related to study drug, 24% G+L, 13% G, 26% L+P. The most common drug-related Grade 3/4 AEs (G+L, G, L+P) were: thrombocytopenia (8%, 0%, 13%); lymphopenia (9%, 3%, 0%); neutropenia (8%, 0%, 5%). **Conclusions:** The observed efficacy outcomes including OS and PFS were similar in all 3 treatment arms suggesting no efficacy improvement when adding G to L. The treatment was safe and well tolerated in all arms. Clinical trial information: NCT01582269.

2015 Poster Discussion Session; Displayed in Poster Session (Board #4), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Onartuzumab plus bevacizumab versus placebo plus bevacizumab in recurrent glioblastoma (GBM): HGF and MGMT biomarker data. *First Author: Timothy Francis Cloughesy, UCLA, Los Angeles, CA*

Background: The phase II GO27819 study assessed the monovalent MET inhibitor, onartuzumab, plus the anti-VEGF antibody, bevacizumab (O+B) versus placebo plus bevacizumab (P+B) in recurrent GBM. Exploratory univariate biomarker analyses correlated efficacy with levels of the MET ligand HGF and MGMT methylation. **Methods:** GBM patients (pts) at first recurrence after chemoradiation were randomized 1:1 to receive O (15 mg/kg, q3w) + B (15 mg/kg, q3w) or P+B until progression. Primary endpoint: progression-free survival (PFS); secondary endpoints: overall survival (OS), objective response rate (ORR), safety; exploratory endpoint: biomarker analysis. Baseline tumor HGF levels were quantitatively assessed by cobas PCR; MGMT methylation was assessed by Quantitative Methylation Specific PCR. **Results:** In the ITT group (64 O+B, 65 P+B) no difference in PFS, OS or ORR was seen between the arms. A total of 119 pts (58 O+B, 61 P+B) had HGF-PCR results and 110 (56 O+B, 54 P+B) had MGMT data. Assessing the P+B arm only showed that GBM pts may have a worse prognosis if they have high expression of HGF-PCR (PFS HR 1.67; OS HR 1.65) or unmethylated MGMT (PFS HR 3.19; OS HR 3.39). In pts with HGF-PCR expression in the upper 25%, longer PFS (HR 0.37, 95% CI 0.16–0.86; p = 0.0201) and OS (HR 0.29, 95% CI 0.08–1.06; p = 0.0458) were seen with O+B (n = 14) v P+B (n = 16). These pts also had higher ORR with O+B (35.7% v 0%, p = 0.014). Shorter PFS (HR 1.39, 95% CI 0.87–2.20; p = 0.1589) and OS (HR 1.86, 95% CI 1.03–3.36; p = 0.0381) were seen with O+B (n = 44) v P+B (n = 45) in the lower 75% HGF-PCR group. Of the pts analyzed for MGMT methylation, 57.3% had unmethylated MGMT. These pts had higher ORR (15.6% v 8%) and extended PFS (HR 0.46, 95% CI 0.25–0.84; p = 0.0108) and OS (HR 0.53, 95% CI 0.26–1.10; p = 0.0836) with O+B v P+B. Pts with methylated MGMT had shorter PFS (HR 1.52, 95% CI 0.75–3.08; p = 0.2440) and OS (HR 3.18, 95% CI 1.19–9.51; p = 0.0150) with O+B v P+B. **Conclusions:** While the GO27819 ITT results showed no efficacy benefit for O+B, these exploratory data suggest that high HGF levels and unmethylated MGMT are prognostic in GBM and may be predictive of response to onartuzumab. Further research on onartuzumab in these subgroups may be warranted. NCT01632228. Clinical trial information: NCT01632228.

2016 Poster Discussion Session; Displayed in Poster Session (Board #5), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Phase I study of ABT-414 mono- or combination therapy with temozolomide (TMZ) in recurrent glioblastoma (GBM). *First Author: Hui K. Gan, Austin Health and Ludwig Institute for Cancer Research, Melbourne, Australia*

Background: GBM remains almost universally fatal and new therapies are needed. The epidermal growth factor receptor (EGFR) is a key oncogenic target. ABT-414, an antibody-drug conjugate with a toxic payload (monomethylauristatin F) targeted to activated EGFR, showed efficacy in preclinical models. We report the data of patients (pts) with recurrent GBM (Arms B + C) from an ongoing phase 1, open-label, 3-arm study (NCT01800695). **Methods:** Eligible pts (≥ 18 years) had recurrent supratentorial GBM and KPS ≥ 70. ABT-414 was given i.v. every 2 weeks combined with TMZ re-challenge (150–200 mg/m^2 days 1–5 q28; Arm B) or as monotherapy (Arm C). ABT-414 doses were escalated using a modified continual reassessment method. Primary objectives were safety, maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D) of ABT-414; secondary objectives included antitumor activity. **Results:** As of Jan 2015, accrual included 18 pts in Arm B treated in 4 dose groups (0.5, 1.0, 1.25, 1.5 mg/kg) and 28 pts in Arm C treated at 1.25 mg/kg. Median age was 51/57 years (Arms B/C), 50%/50% were male, 56%/75% had KPS ≥ 80, and 11/7 pts had amplified EGFR. Treatment-emergent adverse events (AEs) occurring in ≥ 25% of pts either in Arm B or C were blurred vision (n = 11/15), fatigue (n = 6/10), foreign body sensation in the eyes (n = 8/5), photophobia (n = 5/7), nausea (n = 9/2), constipation (n = 5/1), and GGT increase (n = 5/1). Grade 3/4 AEs in ≥ 10% of Arm B or C pts were keratitis (n = 1/3), GGT increase (n = 3/0), fatigue (n = 2/0), and thrombocytopenia (n = 2/0). Dose-limiting toxicities in Arm B were corneal deposits and GGT increase (n = 1 each); none occurred in Arm C during dose escalation. ABT-414 MTD was 1.5 mg/kg in Arm B and 1.25 mg/kg in Arm C; RP2D is 1.25 mg/kg for both arms. Best objective responses were complete response (CR) in 1 pt and partial responses (PR) in 4 pts in Arm B, and 1 CR and 1 PR in Arm C. EGFR amplification was found in all pts with confirmed responses. Confirmed responses were durable, ranging from 5–16 months. **Conclusions:** The ABT-414 RP2D is 1.25 mg/kg for monotherapy or combined with TMZ. The unique ABT-414 safety profile included ocular AEs. ABT-414 appears to have antitumor activity in recurrent GBM pts, particularly those with amplified EGFR. Clinical trial information: NCT01800695.

2017 Poster Discussion Session; Displayed in Poster Session (Board #6), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Defining the cutoff value of MGMT gene promoter methylation and its predictive capacity. *First Author: Andrea Rocca, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: Adult glioblastoma (GBM) is the most common type of malignant primary brain tumor. Despite advances in treatment, median survival is between 12 and 15 months. Standard care is concomitant radiotherapy (RT)/chemotherapy (CT) and adjuvant temozolomide (TMZ) for 6 cycles. At progression, subsequent treatments are at the discretion of the patient's physician. MGMT gene promoter methylation status is acknowledged worldwide as a predictive marker. When MGMT promoter values fall into a "methylated" range, a better response to TMZ treatment is expected. **Methods:** We retrospectively analyzed data from 105 patients with GBM treated from 2011 to 2014 within the oncology network of the wide catchment area of Romagna, Italy. MGMT promoter methylation status was determined by analyzing 10 CpG islands by pyrosequencing. We evaluated whether variability in the methylation profile of each patient can influence the predictive capacity of MGMT promoter methylation and also aimed to identify the best cutoff value. **Results:** All patients were treated by RT followed by TMZ. MGMT promoter methylation status was classified into three types: unmethylated 0 – 9%, methylated 10 – 29% and methylated 30 - 100%. Statistical analysis showed that an assumed methylation cut-off of 9% led to an overestimation of responders. All of the patients in the 10–29% methylation group relapsed before the 18-month evaluation. Patients with a methylation status > 30% showed a median overall survival (OS) of 25.2 months compared to 15.2 months in all other patients, indicating that this is the best methylation cut-off. We also analyzed the methylation status of each CpG island in patients' profiles but, despite observing a great variability among individual profiles, did not find any correlation between single CpG island values and relapse or death (Wilcoxon test and ROC curves). **Conclusions:** Our results did not highlight an impact of specific CpG island methylation status on the predictive value of MGMT. The predictive role of MGMT promoter methylation was maintained only when 30% was used as cut-off value.

Impact of bevacizumab added to temozolomide-chemoradiation on time to health-related quality of life deterioration in unresectable glioblastoma: Results of a phase II randomized clinical trial. *First Author: Franck Bonnetain, Methodology and Quality of Life Unit, Department of Oncology, EA 3181, University Hospital of Besançon; French National Platform Quality of Life and Cancer, Besançon, France*

Background: Two clinical trials investigating the addition of bevacizumab (BEV) to TMZ treatment (Chinot et al., NEJM 2014; Gilbert et al., NEJM 2014) for unresectable glioblastoma (GB) highlighted an improvement of progression-free survival (PFS) but no effect on overall survival. Health-related quality of life (HRQoL) results were divergent and compromised the conclusion about clinical benefit of bevacizumab. A phase II clinical trial evaluated BEV and irinotecan (IRI) in addition to TMZ-based chemoradiation for unresectable GB (Chauffert et al., Annals of Oncology 2014) was conducted. The primary objective 6-month PFS rate from 50% to 66% was not reached. This present study focuses on the HRQoL analysis (secondary endpoint). **Methods:** EORTC QLQ-C30 and its BN20 brain cancer module were used at baseline, during treatment and every 4 weeks until progression. Time until definitive HRQoL score deterioration (TUDD) was used as a modality of longitudinal HRQoL analyses (Bonnetain et al., EJC 2010), with a 10-point Minimal Clinically Important Difference including or not death as an event. TUDD was estimated with the Kaplan-Meier method. Cox model was used to estimate Hazard Ratios (HR) and its 95% confidence interval (CI). Multivariate Cox model investigated factors associated with TUDD. **Results:** Among the 134 patients included from 2009 to 2011, 101 patients (75%) filled the baseline HRQoL questionnaires (51 in BEV/IRI arm, 50 in TMZ arm). For TUDD or death, patients in BEV/IRI arm presented a longer TUDD than those of TMZ arm for 10/15 dimensions of the QLQ-C30 and 10/11 dimensions of the BN20. As an example, patients in BEV/IRI arm presented a longer TUDD of motor dysfunction than those of TMZ arm (Median 4.6 months (95%CI 3.2-9.4) for BEV/IRI vs. 3.3 (95%CI 2.8-6.7) for TMZ, HR = 0.70 (95%CI 0.45-1.08)). A sensorial deficit is associated with shorter TUDD of Weakness of legs dimension or death (HR = 2.74 (95%CI 1.41-5.30). **Conclusions:** Patients in BEV/IRI arm presented a longer TUDD than those of the TMZ arm. These HRQoL results are consistent to those obtained with AVAGLIO trial suggesting HRQoL benefit for patients with BEV. Clinical trial information: 2008-002775-28.

2019 Poster Discussion Session; Displayed in Poster Session (Board #8), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Outcome of neurofibromatosis type 1 patients treated with first line vinblastine for optic pathway gliomas: A Canadian multicenter study. *First Author: Alvaro Lassaletta, The Hospital for Sick Children, Toronto, ON, Canada*

Background: To date, the first line chemotherapy treatment in the majority of countries for children with NF-1 and OPG is vincristine + carboplatin. Toxicity of this regimen consists mostly in neuropathy, allergic reactions, and hearing loss. Vinblastine has shown promising activity in a phase II study in children with recurrent/refractory low grade glioma (LGG). The aim of this study was to assess the activity of vinblastine in chemotherapy naïve children, and to assess the toxicity profile. **Methods:** Patients < 18 years old with unresectable or progressive LGG were eligible if they had not received any previous treatment with chemotherapy or radiation. Vinblastine was administered weekly at a dose of 6 mg/m2 over a period of 70 weeks. Patients who showed progression on 2 consecutive imaging studies or evidence of clinical progression were removed from treatment. **Results:** Overall, the study enrolled 54 patients with LGG. A total of 13 patients (24.1%) had NF-1. Patients with NF-1were younger at diagnosis: median age 3.84 y (range, 1.74-16.36 y) vs. 7 years in non-NF-1. Tumor location in all NF-1 patients was the optic pathway. Treatment was very well tolerated, however, 5 patients (38%) needed dose reductions. Most common toxicity was hematological: only 1 patient who experienced grade 3+ neutropenia (vs. 10 patients non-NF1). There were only 2 episodes of febrile neutropenia, no RBC transfusions and no toxic death. Best response to chemotherapy was assessed centrally by an independent radiologist: 2 PR, 1 MR, 8 SD, and 2 PD, for a response rate of 23.1%. At a median follow-up of 5.37 years (3.45 – 6.57 years): Only two NF-1patients had progression. Five year progression free survival (PFS) was 85.1± 9.7% (vs. 42±7,9% for all non-NF1, p = 0.01; and 41.7±14% for non-NF1 with OPG, p = 0.01). None of the NF1 patients received radiation (0 vs. 6 patients non-NF1). No patients died of progression (0 vs. 3 patients non-NF1). **Conclusions:** Weekly vinblastine is well tolerated and can be used in NF-1 children with OPG as first line chemotherapy with good results. The toxicity profile is lower than with other chemotherapies, offering a better quality of life to these patients. Clinical trial information: NCT00575796.

2020 Poster Discussion Session; Displayed in Poster Session (Board #9), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

A multi-institutional prospective observational study of stereotactic radiosurgery (SRS) for patients with multiple brain metastases (BMs): Updated results of the JLGK0901 Study—Long-term results of irradiation-related complications and neurocognitive function (NCF). *First Author: Masaaki Yamamoto, Katsuta Hospital Mito GammaHouse, Hitachi-Naka, Japan*

Background: The JLGK0901 study (UMIN ID; 000001812) showed the non-inferiority of SRS alone as initial treatment for patients with 5-10 BMs as compared to those with 2-4 in terms of overall survival as well as most secondary endpoints (Lancet Oncol 2014;15:387-95). However, a study weakness was that observation periods were not long enough to allow confirmation of the long-term safety of SRS alone in patients with 5-10 BMs. **Methods:** This was a prospective observational study of SRS-treated patients with 1-10 newly-diagnosed BMs enrolled at 23 facilities between 3-1-2009, and 2-15-2012. **Results:** The 1194 eligible patients (471 females, 723 males, mean age; 66 [range; 30-91] years), enrolled from March 2009 to February 2012, were categorized into three tumor number groups, i.e., A; 1 (455), B; 2-4 (531) and C; 5-10 (208). During observation periods ranging from 0.3 to 67.5 (median; 12.0, IQR; 5.8-26.5) months as of the end of 2014, SRS-induced complications occurred in 145 patients (12.1%) with the median post-SRS period being 9.3 (IQR; 4.1-17.4) months; 46, 54, 29, 11, and 5 for CTCAE grades 1, 2, 3, 4, and 5, respectively. Cumulative incidences of complications determined with a competing risk analysis (group B vs C) were 8.3% vs 5.8%, 10.9% vs 10.6%, 11.3% vs 12.1% and 12.2% vs 12.9% at the 12th, 24th, 36th and 48th post-SRS months, respectively (HR; 1.052, 95% CI; 0.666-1.662, p = 0.829). NCF maintenance (MMSE decrease < 3 from baseline) rates of groups A/B/C were 92%/91%/89% (p = 0.69), 90%/96%/88% (p = 0.25), 94%/92%/100% (p = 0.75) and 94%/92%/100% (p = 0.51) at the 12th, 24th, 36th and 48th post-SRS months, respectively. These statistical results were confirmed to be similar even with missing data analyses. **Conclusions:** There were no significant differences in the incidences of post-SRS complications and NCF maintenance between groups B and C. We conclude that the already-reported non-inferiority hypothesis of SRS alone for patients with 5-10 versus 2-4 BMs gains further support, in terms of treatment safety, from this longer-term follow-up study. Clinical trial information: 000001812.

2021 Poster Discussion Session; Displayed in Poster Session (Board #10), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Results of a randomized, global, multi-center study of whole-brain radiation therapy (WBRT) plus veliparib or placebo in patients (pts) with brain metastases (BM) from non-small cell lung cancer (NSCLC). *First Author: Pierre Chabot, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada*

Background: Veliparib (V) is a potent, orally bioavailable PARP inhibitor that crosses the blood brain barrier. Phase 2 trials in BRCA pts as monotherapy or in unselected pts in combination with platinum-based chemotherapy have demonstrated evidence of efficacy. V plus radiation has shown promising efficacy in preclinical models and clinically in combination with WBRT. **Methods:** Pts were randomized 1:1:1 to WBRT plus V 50 mg BID (V50), V 200 mg BID (V200), or P BID. Treatment began within 28 days (d) of diagnosis. Pts received 30 Gray WBRT in 10 fractions. V50, V200, or P BID was self-administered starting on d 1 of WBRT and continuing until 1 d after completion. The primary endpoint was overall survival (OS). Survival was assessed at 2 month (m) intervals for 6 m then every 3 m ($\geq$36 m). Pts who received $\geq$1 dose were included in the safety analyses; AEs were compared across arms using Fisher's exact test. **Results:** 307 pts were randomized. OS, intracranial response rate, and time to clinical or radiographic progression were not statistically significantly different between any of the V arms and the P arm. There were no differences in all grade adverse drug reactions (ADRs) across arms and a modest improvement in grade 3/4 AEs in the V arms. **Conclusions:** Although preclinical and early clinical data suggested that V might synergize with radiotherapy, there was no difference in multiple study endpoints between V50 or V200 and P in this setting. Safety parameters observed in the V arms were generally similar to the P arm; no new safety signals of V were identified. Clinical trial information: NCT01657799.

2022 Poster Session (Board #11), Mon, 1:15 PM-4:45 PM

A phase II study of temozolomide in the treatment of adult patients with supratentorial low-grade glioma. *First Author: Michael Traut Wahl, UC San Francisco, San Francisco, CA*

Background: Optimal adjuvant management of low-grade gliomas (LGGs) remains controversial. Radiotherapy has been shown to improve progression-free survival compared to observation, but carries the potential for substantial late toxicity. In an effort to delay or obviate the need for radiation, there has been increasing interest in the use of adjuvant chemotherapy in LGGs. However, there is a dearth of prospective studies with long-term follow-up evaluating the efficacy of adjuvant chemotherapy without radiation in patients with newly diagnosed LGGs. **Methods:** Patients over the age of 18 with histologically proven supratentorial LGG (WHO grade II) who underwent subtotal resection or biopsy were eligible for enrollment. Daily temozolomide (TMZ) was administered at 200 mg/m^2 for 5 days, and repeated every 28 days for up to 12 cycles or until disease progression. Patients were assessed for radiographic response and progression with MRIs every two months during and after treatment. The primary outcome was objective radiographic response rate; secondary outcomes included progression-free and overall survival. **Results:** 120 patients were enrolled in the trial (57 oligodendrogliomas, 20 oligoastrocytomas, 43 astrocytomas), with a median follow-up of 6.9 years. Objective responses were seen in 7 patients (6%), and 86% demonstrated stable or improved disease during treatment with TMZ. Median progression-free survival was 4.2 years, and median overall survival was 9.7 years. Univariate analysis demonstrated oligodendroglioma histology (p = 0.02), subtotal resection (p = 0.009) and lack of tumor crossing midline ($p < 0.001$) were associated with improved overall survival. Treatment was well tolerated with minimal toxicity. **Conclusions:** In this high-risk cohort of newly diagnosed LGGs undergoing subtotal resection or biopsy, adjuvant TMZ alone achieved progression-free survival comparable to that seen in similar cohorts treated with adjuvant radiation. TMZ was very well tolerated, and could be considered as adjuvant therapy in appropriately selected patients. Work is ongoing to determine the demographic, pathologic and molecular characteristics of patients who are optimal candidates for adjuvant TMZ. Clinical trial information: NCT00313729.

2023 Poster Session (Board #12), Mon, 1:15 PM-4:45 PM

Phase I/II study of dianhydrogalactitol in patients with recurrent malignant glioma. *First Author: Kent C. Shih, Tennessee Oncology, Nashville, TN*

Background: Glioblastoma multiforme (GBM) is the most common brain cancer. Front-line systemic therapy with temozolomide is often ineffective due to O^6-methylguanine-DNA-methyltransferase (MGMT)-mediated resistance. Dianhydrogalactitol (VAL-083) is a bi-functional DNA alkylating agent that crosses the blood-brain barrier and overcomes resistance to MGMT in vitro. The goal of this clinical trial is to determine an appropriate dose for phase III trials in refractory GBM. **Methods:** Open-label, single-arm phase I/II dose-escalation study in patients with histologically-confirmed GBM, previously treated with radiation and must have failed both bevacizumab and temozolomide, unless contraindicated. The study utilizes a 3+3 dose-escalation design. Patients receive VAL-083 IV on days 1, 2, and 3 of a 21-day cycle. Tumor response is assessed according to RANO criteria prior to every other 21-day treatment cycle. **Results:** 25 patients have been enrolled across 8 dose cohorts ranging from 1.5 to 50mg/m^2/d. A dose limiting toxicity consisting of grade 4 thrombocytopenia was observed at dose level 8 (50mg/m^2/d). The DLT-related symptoms resolved rapidly and spontaneously without concomitant treatment. Prior to this, other treatment related toxicities have been mild to moderate and included two grade 1 lymphopenias and one grade 1 thrombocytopenia. Maximum tolerated dose (MTD) will be determined based on 3+3 design. Three patients had a response (stable disease or partial response) reporting improved clinical signs (maximum response of 84 wks). Pharmacokinetic analyses show dose-dependent linear systemic exposure with a short plasma 1-2h terminal half-life; Cmax ranged from 1130–739 ng/mL (7.7–5.1μM) at 40mg/m^2/d. Compared to historical trials, the present regimen delivers substantively more drug by Cmax and dose intensity. A dose intensity of 25 mg/m^2/wk in combination with radiation was previously shown superior to radiation alone against GBM; a dose intensity of 50 mg/m^2/wk is achieved in the current trial. **Conclusions:** VAL-083 dosing may be limited by myelosuppression. The MTD will be studied in a Phase II expansion and possible phase III registration trial. Clinical trial information: NCT01478178.

2024 Poster Session (Board #13), Mon, 1:15 PM-4:45 PM

ACRIN 6684: Assessment of tumor hypoxia in newly diagnosed GBM using FMISO PET and MRI. *First Author: Elizabeth Robins Gerstner, Massachusetts General Hospital, Boston, MA*

Background: Tumor hypoxia is a potent mediator of treatment resistance because of the negative impact on the efficacy of radiation and associated poor tumor delivery of cytotoxic chemotherapy. We designed a multicenter study to evaluate if pre-treatment tumor hypoxia as measured by FMISO PET and abnormal tumor vascularity as assessed by MRI are associated with worse survival. **Methods**: Patients with newly diagnosed GBM who had residual enhancing or nonenhancing tumor by local MRI read after surgery were eligible. Patients were treated with standard RT and temozolomide alone or with an additional investigational agent. Prior to start of chemoRT, a PET scan was acquired 110min after FMISO injection and 3 blood draws were acquired to allow for calculation of tumor to blood ratios. MRIs were also performed and included standard anatomic sequences as well as perfusion (DSC) and permeability (DCE) imaging. Cox models tested the association of PET and MRI parameters with OS (primary endpoint) and PFS (secondary endpoint). ROC curve analyses examined whether these parameters could predict survival at 1 year. **Results**: Fifty patients from 11 centers were enrolled. Thirty-eight, 37 and 31 patients had evaluable FMISO PET scans, DSC imaging and DCE imaging, respectively. Median age was 57 (range 27-77). In the univariate model, higher peak SUV was associated with worse survival (HR 1.54, 95%CI 1.00-2.36, p = 0.048) as was mean K^{trans} (HR 1.17, 95%CI 1.02-1.34, p = 0.024) and median K^{trans} (HR 1.32, 95%CI 1.01-1.72, p = 0.045). After adjusting for age and enhancing tumor volume, only mean K^{trans} remained statistically significant. Higher median K^{trans}as well as normalized rCBV and rCBF were associated with shorter PFS. Max SUV, peak SUV, standardized rCBV and normalized rCBF were predictive of survival at 1 year. **Conclusions**: Higher baseline tumor hypoxia was associated with shorter survival, re-iterating the poor prognostic implications of tumor hypoxia. Increased vascular permeability and perfusion measurements at baseline were also associated with worse survival. These results raise the possibility that hypoxia may mediate treatment resistance in areas of tumor expected to have adequate delivery of intravascular therapies across the BBB. Clinical trial information: NCT00902577.

2025 Poster Session (Board #14), Mon, 1:15 PM-4:45 PM

Phase II study of tivozanib, an oral VEGFR inhibitor, in patients with recurrent glioblastoma. *First Author: Xuezhu Cai, Athinoula A. Martinos Center for Biomedical Imaging, Charlestown, MA*

Background: Tivozanib, an oral, pure VEGFR tyrosine kinase inhibitor is an anti-angiogenesis drug which aims to modulate the tumor blood supply. This phase II study was designed to test the effectiveness of tivozanib on tumor vasculature in patients with recurrent GBM. **Methods:** Ten adult patients with recurrent GBM, median age of 62 (range 51-73), were enrolled on a Simon 2-stage design study and treated with tivozanib 1.5mg daily, 3 weeks on/1 week off in 28 day cycles. Brain MRI was done at baseline and after each cycle. The enhancing tumor and surrounding area of abnormal FLAIR hyperintensity were outlined and median tumor cerebral blood flow (CBF) and cerebral blood volume (CBV) values were derived from dynamic susceptibility contrast MRI to assess the performance of tivozanib. Vessel architectural imaging (VAI) was used to measure tumor vessel calibers and relative oxygen saturation. A t-test was used to compare baseline MRI parameters to the pre-cycle 3 visit. A univariate Cox model was used to test the association of each MRI parameter with time to progression. **Results:** Best MacDonald criteria responses were: CR (1), PR (1), SD (4), PD (4) and the median duration of response was only 3.6 mo (1.7-3.8mo) so the study was stopped per planned stopping rule. One patient was taken off study for unacceptable skin toxicity and nine patients for progressive disease. Given the dropout rate, only data up to cycle 3 was included in this analysis. There was no statistically significant change in enhancing tumor volume (p = 0.70), FLAIR volume (p = 0.31), or median CBV (p = 0.13) or median CBF (p = 0.54) within the enhancing tumor. Within the FLAIR hyperintensity, median CBV (p = 0.12) and median CBF (p = 0.41) also did not change significantly. No parameter was associated with time to tumor progression. VAI showed no change in vessel calibers or tissue oxygenation. **Conclusions:** Tivozanib was well tolerated but most patients progressed rapidly. The majority of patients had no significant change in tumor enhancement and perfusion imaging demonstrated insignificant changes in tumor and peritumoral blood volume, flow, vessel caliber, and oxygenation, suggesting that this anti-angiogenic agent had limited impact on brain tumor vasculature. Clinical trial information: NCT01846871.

2026 Poster Session (Board #15), Mon, 1:15 PM-4:45 PM

Characteristics and outcomes of breast cancer patients with leptomeningeal metastasis at Memorial Sloan Kettering Cancer Center (MSKCC). *First Author: Aki Morikawa, University of Michigan, Ann Arbor, MI*

Background: Breast cancer (BC) is one of the most common solid tumors with metastases to the leptomeninges. Disease presentation, prognostic factors, and treatment patterns for BC patients (pts) with leptomeningeal metastasis (LM) are not well-characterized. In this study, we examined pt characteristics and outcomes of BC pts with LM. **Methods:** 318 consecutive BC pts diagnosed with LM from January 1998 to December 2013 were identified. Clinical, pathologic, and treatment information were obtained by retrospective review. Pt characteristics at the time of LM diagnosis (dx) and their associations with time from LM dx to death or last follow up were evaluated by Kaplan-Meier curves, log-rank tests, and Cox proportional hazard models. **Results:** The median age at LM dx was 54 years (range 23-85). Of the 318 pts, 44% were HR+HER2-,18% HR+HER2+, 8.5% HR-HER2+, and 25.5% triple negative;4% had missing information. 43% had cranial LM only, 26% had only spinal LM, and 26% had both; 5% were unspecified due to missing imaging information in either the spinal or cranial compartment. At the time of LM dx, 53% of pts had concurrent progression of non-CNS metastases. LM specific treatment included intrathecal/intraventricular therapy (14.5%), radiotherapy (64%), and IV high-dose methotrexate (20%). There were 292 deaths. The median follow-up for survivors was 10.1 mos (range 0.8 - 93.6). The median survival (OS) from LM dx was 3.5 mos (95% CI: 3.0, 4.0) with 63 pts (20%) surviving > 1 year. Recent diagnosis (after 2006), HER2+ subtype, higher KPS (> 70), cranial site of LM, and control of extra-CNS disease were independently associated with improved OS in multivariate analysis. **Conclusions:** Unexpectedly, the site of LM was an independent prognostic factor. This may be related to biologic, diagnostic, or treatment factors and needs further confirmation. Control of extra-CNS disease, KPS and receptor subtypes should be stratification variables for future clinical trials for LM. Although OS is poor, we have identified a subset of pts who had extended survival (> 1 year). A closer examination to identify factors that contribute to longer-term survival may provide insight to improve management of these pts.

2027 Poster Session (Board #16), Mon, 1:15 PM-4:45 PM

Histopathological markers at craniotomy and outcome in breast cancer brain metastases. *First Author: Megan Jean McKee, UNC Chapel Hill, Chapel Hill, NC*

Background: Brain metastases (BM) are a devastating consequence of advanced breast cancer (BC). Little is known about the clinical significance of histopathological features associated with BM tumor and stroma. Lymphocytic infiltrate (LymInf) has been shown to be predictive of response to therapy in primary BC and prognostic in patients (pts) with triple negative (TN) BC. Increased LymInf has been associated with better prognosis in melanoma BM. In a 3-institution cohort, we report on the association of LymInf and other histopathological markers in BCBM with prognosis. **Methods:** Under IRB approval, a clinically-annotated tumor bank of 83 BCBM was established from craniotomy tissues. LymInf, hemorrhage, and necrosis (Nec) were assessed on H&E stain (score 0-3); gliosis was scored as present/absent. Primary endpoint was survival from craniotomy. The Kaplan Meier method and Log-rank tests were used to evaluate survival. **Results:** Median age was 52 yrs. Median follow-up was 2.74 yrs. Hormone receptor (HR) status was 47% HR+ and 53% HR-. Subtype was: 36% (22/61) HR+/Her2-, 23% (14/61) Her2+, and 41% (25/61) TN. Higher Nec (2-3+) was observed more frequently in TN BCBM (76%) compared to HR+/Her2- (32%) or Her2+ (36%) BCBM, p = 0.004. Across all subtypes, higher Nec was associated with inferior survival post-craniotomy compared to low Nec (median 1.0 v 1.8 yrs, p = 0.02); this trend was notable in the HR+ BCBM (1.3 v 2.5 yrs, p = 0.19). LymInf was observed in 60% (48/81) of BCBM. Across all pts, higher LymInf was not associated with post-craniotomy survival (p = 0.3). In the HR- cohort, any LymInf (1-3+ v 0) was associated with longer survival post-craniotomy (0.9 v 0.3 yrs, p = 0.03); this held true for the TN pts (0.9 v 0.5 yrs, p = 0.14). Any LymInf was also associated with longer survival from diagnosis of primary BC in the TN group (4.3 v 3.1 yrs, p = 0.02). **Conclusions:** Higher necrosis as observed on H&E stain from BCBM at craniotomy is associated with TN subtype and with a negative prognosis. LymInf may be prognostic of an improved outcome, especially in the HR- population. Given that immunotherapy is being used successfully in metastatic melanoma and is being investigated in metastatic BC, evaluation of this approach in patients with BCBM is warranted.

2028 Poster Session (Board #17), Mon, 1:15 PM-4:45 PM

Determining viability of using APNG status as a prognostic marker in patients with glioblastoma multiforme. *First Author: Rikke Hedegaard Dahlrot, Department of Oncology, Odense University Hospital, Odense, Denmark*

Background: Expression of the enzyme alkylpurine-DNA-N-glycosylase (APNG) has been associated with poor outcome in patients with glioblastoma multiforme (GBM). APNG is part of the base excision repair system, and expression of APNG is related to resistance towards temozolomide (TMZ). This study evaluates the prognostic value of APNG in a population-based cohort of 185 Danish GBM patients diagnosed between 2005 and 2009. Due to GBM's cellular heterogeneity, APNG contribution from non-tumor cells was excluded. **Methods:** APNG expression was evaluated using image analysis and a novel quantitative immunohistochemical (IHC) assay (qIHC, Dako), where APNG protein levels were represented through dots. Non-tumor cells, which were found to express APNG, were excluded using an IHC/qIHC double-staining. To verify the qIHC results, APNG was measured in 177 of the patients using a quantitative in-house developed APNG immunofluorescence (IF) assay. MGMT methylation status was obtained in 152 patients by pyrosequencing. **Results:** Using qIHC, median expression of APNG was 0.31 dots/cell (range 0.099-0.96). An optimal cut-point was identified dichotomizing the patients at an APNG value of 0.24 (25% vs. 75% of the patients). In Cox regression high expression of APNG was associated with better overall survival (OS) (HR 0.53, p = 0.001) adjusting for the effect of age, performance status, tumor crossing midline, treatment and gender. APNG was associated with better OS (HR 0.57, p = 0.012) when adjusting for MGMT status. Retesting the cohort using IF, demonstrated similar results (HR 0.81, p = 0.2). Patients with methylated MGMT promoters and high APNG expression demonstrated a better OS, than with non-methylated MGMT promoters and low APNG expression (HR 0.55, p = 0.04). **Conclusions:** APNG measured by qIHC was found to be an independent significant prognostic factor for OS in GBMs, This was supported by IF measurements. Removing bias associated with APNG expression in non-tumor cells in both assays has, in this study contributed substantially to analyze the prognostic value of APNG in GBM patients. We expect that APNG qIHC can potentially identify patients who will not benefit from treatment with TMZ.

2029 Poster Session (Board #18), Mon, 1:15 PM-4:45 PM

A phase I trial of intravenous liposomal irinotecan in patients with recurrent high-grade gliomas. *First Author: Jennifer Leigh Clarke, UC San Francisco, San Francisco, CA*

Background: Treatment options for recurrent malignant glioma are limited. Preclinical activity of irinotecan has been seen in glioma models but only modest efficacy has been noted in clinical studies, perhaps related to drug distribution and/or pharmacokinetic limitations. In preclinical testing, liposomal irinotecan (nal-IRI, also MM-398, PEP02) demonstrates prolongation of drug exposure and higher tissue levels of drug due to slower metabolism. A Phase I study was undertaken in advanced solid tumor patients in Taiwan, and the MTD was 120 mg/m^2; UGT1A1 genotyping was not prospectively undertaken in that solid tumor study. Objectives: To assess the safety and pharmacokinetics (PK) of nal-IRI and to determine the maximum tolerated dose (MTD) in patients with recurrent malignant glioma stratified based on UGT1A1 genotyping. **Methods:** This Phase I study in recurrent malignant glioma stratified patients by UGT1A1 status, to homozygous WT ("WT") vs heterozygous WT/*28 ("HT"). Patients who were homozygous *28 were ineligible. Eligibility criteria included age $>=$ 18, KPS $>=$ 60, not on enzyme-inducing drugs (including enzyme-inducing seizure medications), and no prior treatment with irinotecan. The design was a standard 3+3 Phase I design. Patients who were WT were started at 120 mg/m^2 (the MTD from the Taiwanese study) with dose increases in 60 mg/m^2 increments. Patients who were HT were started at 60 mg/m^2, with dose increases in 30 mg/m^{2}increments. Dosing was given IV every 3 weeks. The DLT assessment period was 1 cycle (21 days). **Results:** In the WT cohort, the MTD was 120 mg/m^2. In the HT cohort, the MTD was 150 mg/m^2. DLTs in both cohorts included diarrhea, some with associated dehydration and/or fatigue. Analysis of PK data is in process, and will be presented at the meeting. **Conclusions:** Nal-IRI had no unexpected toxicities when given via IV. The toxicity profile of the drug was felt acceptable to move forward with additional testing using convection-enhanced delivery into intracranial tumors, and such a Phase I study is currently enrolling at our institution. Clinical trial information: NCT00734682.

2030 Poster Session (Board #19), Mon, 1:15 PM-4:45 PM

Differential molecular expression profile according to glioblastoma (GB) location. *First Author: Emilie Denicolai, AMU, Marseille, France*

Background: Initial GB topography occurred throughout the brain without established specific molecular profile. Our previous study suggested that cortical and subventricular GB exhibit distinct transcriptome profile. Based on these preliminary results, our objective was to evaluated the expression of ten selected genes (*VEGFC*, *FLT4*, *MET*; *HGF*, *CHI3L1*, *PROM1*, *NOTCH1*, *DLL3*, *PDGFRA*, and *BCAN*) according to GB locations. **Methods:** Fifty nine patients with newly GB were retrospectively included according to the availability of pre-surgery MRI and frozen tumors. Tumor locations were classified into cortical and periventricular (PV) locations, which were next segregated according to cerebral lobes: cortical fronto-parietal (N = 19), cortical temporal (N = 5), PV fronto-parietal (N = 12), PV temporal (N = 12), and PV occipital (N = 12). Expression levels of the selected genes were determined using real-time quantitative PCR, and were correlated with tumor locations. **Results:** Cortical GB were characterized by a lower expression of two mesenchymal genes, *VEGFC* (p = 0.001) and *HGF* (p = 0.001), than periventricular GB. Among cortical GB sub-groups, genes expressions were homogenous. In contrast, PV locations exhibit distinct expression profiles. PV temporal tumors were associated with higher expression of two proneural and cancer stem cell genes, *NOTCH1* (p= 0.028) and *PROM1* (p = 0.033) while PV fronto-parietal tumors were characterized by a higher expression of *FLT4* (p= 0.037) and *CHI3L1* (p= 0.006). PV occipital GB were associated with a lower expression of *VEGFC* (p = 0.032) than other PV GB and an over-expression of *MET*, correlated to *MET* amplification. Finally, *VEGFC* and *HGF* expressions were correlated (p < 0.001) as well as *NOTCH1* and *PROM1* expressions (p < 0.001). **Conclusions:** Our results suggest a differential expression profile of the selected genes according to initial GB location. These results should be validated in a prospective study.

2031 Poster Session (Board #20), Mon, 1:15 PM-4:45 PM

Use of a novel radio-sensitizer for treatment of GBM. *First Author: John Lloyd Gainer, Diffusion Pharmaceuticals LLC, Charlottesville, VA*

Background: Trans sodium crocetinate (TSC) was developed to increase tissue oxygenation. Since hypoxia may enhance radiation resistance, we tested TSC along with radiation therapy (RT) in GBM in a Phase I/II trial. 59 patients received TSC in an open GBM clinical trial together with TMZ and RT (www.clinicaltrials.gov , NCT01465347). Although final data for the first 2 years will not be available until late summer 2015, this abstract discusses results from 18 clinical sites which are available at 21 months. **Methods:** 59 patients with newly diagnosed GBM were enrolled between Jan. 2012 and March 2013 into a Phase I/II trial. All patients received standard of care RT and TMZ. In the Phase I portion of the trial TSC was initially administered 3x/week at half-dose to 3 patients prior to RT. Subsequently, 6 additional patients received full dose TSC for 6 weeks in combination with RT. No dose-limiting toxicities were identified in the 9 patients on the Phase I portion of the trial. Fifty additional patients were enrolled in the Phase II trial at full dose TSC in combination with TMZ and RT. Four weeks after completion of RT, all patients resumed TMZ for 5 days every 4 weeks, but no further TSC was administered. All patients were followed with bi-monthly neurologic exams, MRI's, KPS scores and Quality of Life questionnaires. **Results:** At a minimum of 21 months follow-up since the diagnosis of GBM: Radiologic Response: Pseudo progression occurred in numerous patients. Complete responses were observed in 10% of patients. *Survival*: Overall Survival: 38.2%. Survival did not correlate with initial tumor resection: 6/15 patients with original complete resection alive at 21 months and 8/15 biopsy-only patients. *Quality Of Life*: Both KPS scores and questionnaires indicate continued high QOL. *Safety*: Excellent patient toleration of dosing TSC with TMZ. **Conclusions:** TSC was well tolerated in combination with RT and TMZ. Our data at a minimum follow-up of 21 months suggest that TSC may promote radio-sensitization since there was a large incidence of pseudo-progression, with complete tumor regression in about 10% of patients and Overall Survival of 38.2%, This is one of the first demonstrations that a type of oxygen radio-sensitizer can be of benefit, being possible through the novel mechanism of TSC. Clinical trial information: NCT01465347.

2032 Poster Session (Board #21), Mon, 1:15 PM-4:45 PM

Long-term survival in patients with primary CNS lymphoma: Results from the G-PCNSL-SG1 trial. *First Author: Patrick Roth, Department of Neurology, University Hospital Zurich, Zurich, Switzerland*

Background: Although potentially curable, primary CNS lymphoma (CNS) is still a therapeutic challenge and only a minority of patients survive longer than 5 years. The factors which define the prognosis of PCNSL patients have only been partially elucidated. A more detailed insight into the parameters which promote long-term survival in PCNSL may allow for more patient-tailored therapies. **Methods:** We analysed the dataset of patients enrolled into G-PCNSL-SG1, the largest phase 3 study performed in PCNSL evaluating the role of whole-brain radiotherapy after high-dose methotrexate-based chemotherapy. Out of 459 patients with sufficient data quality, we identified 89 patients who had survived for five years or more after surgery and diagnosis of PCNSL. This long-term survival (LTS) cohort was compared with two different reference groups: first, patients who had died within one year of diagnosis for any reason (control 1 = C1 patients) and second, all patients who had survived for more than 1 year, but who did not reach a survival of 5 years from diagnosis (control 2 = C2 patients). Patients censored (i.e. alive but without further follow-up) before 5 years of follow-up were excluded. Within the LTS group, survival after 5 years was analysed using the Kaplan Meier method. **Results:** We compared baseline characteristics and treatment of the 89 patients surviving for 5 years or more with the C1 and C2 control populations. Patients within the LTS cohort were younger and had a higher performance score at diagnosis. Furthermore, they had less frequently multiple tumor manifestations, a better renal function and were less often affected by cardiovascular disease. High-dose methotrexate-based treatment resulted in a higher complete response rate and was associated with less toxicity, particularly a reduced frequency of myelosuppression. Within the group of LTS patients, age at diagnosis was the only prognostic factor for conditional survival from 5 years on. **Conclusions:** Within this large patient population, survival of 5 years or more was reached by approximately a fifth of the patients. Young and fit patients with single lesions are most likely to survive for 5 years or more following diagnosis of PCNSL.

2033 Poster Session (Board #22), Mon, 1:15 PM-4:45 PM

Timed-sequential therapy with mibefradil and temozolomide in patients with recurrent high-grade gliomas: A phase I Adult Brain Tumor Consortium study. *First Author: Matthias Holdhoff, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Mibefradil (MIB) is a selective T-type calcium channel blocker that had previously been approved for treatment of hypertension. MIB has shown significant preclinical activity in many cancers, including high-grade gliomas (HGG). MIB was found to impact cell cycle activity with arrest at G1/S in tumor cells, suggesting a possible chemo-sensitizing effect of the drug if given prior to cytotoxic therapy. This was a multi-center open label phase I study to determine the maximum tolerated dose (MTD) of MIB followed by temozolomide (TMZ) in recurrent HGG and to assess the safety and tolerability of MIB, particularly its myelosuppressive effects, in a timed-sequential combination with TMZ. **Methods:** Adult patients with recurrent HGG (WHO grade III and IV) who were selected to likely have a benefit from repeat treatment with TMZ (no progression $\geq$ 3 months from their last dose of TMZ) were eligible. MIB was given in 4 daily doses (QID) for 7 days followed 24 hours later by standard TMZ at 150-200 mg/m^2 for 5 days per 28-day cycle. Dose escalation of MIB was done using a modified 3+3 design, followed by an extension cohort of 10 patients at the MTD. **Results:** 27 eligible patients with recurrent HGG participated (at time of enrollment, 21 with WHO grade IV, 6 with grade III; median age 50y; median KPS 90). The MTD of MIB was determined as 87.5 mg po QID. Most common side effects (grade 1 and 2) were fatigue, nausea, constipation and anorexia. Grade 3 elevation of ALT/AST was observed in one patient. Dose limiting toxicities were elevation of ALT/AST and sinus bradycardia. 5 partial and 1 complete responses were observed based on review by the sites (response rate 22%; 95% CI:9-42%). Plasma concentrations of MIB achieved a steady-state after 4 days of dosing with a mean peak concentration of approximately 1,700 ng/mL and a peak-to-trough ratio of 1.1 at the MTD. **Conclusions:** MIB followed by TMZ was well tolerated in patients with recurrent HGG. The MTD for MIB in this setting was determined as 87.5 mg po QID. The lack of toxicity, including extensive myelosuppression, and the presence of responses in this selected patient population suggests that this regimen deserves further investigation. Clinical trial information: NCT01480050.

2034 Poster Session (Board #23), Mon, 1:15 PM-4:45 PM

Phase II study of bevacizumab and vorinostat for recurrent glioblastoma. *First Author: Ashley Ghiaseddin, Duke University Medical Center, Durham, NC*

Background: Prognosis for recurrent glioblastoma (GBM) remains dismal with a 9-15% 6-month progression-free survival (PFS). However, the addition of bevacizumab (BEV), a humanized monoclonal IgG1 antibody with effects at human vascular endothelial growth factor, has improved 6-month PFS to 40-50% and median overall survival (OS) to 9.2 months. Vorinostat (VOR) is a small molecule derivative of hydroxamic acid that crosses the blood-brain barrier and has anti-tumor effects directly by inhibition of histone deacetylase and indirectly by anti-angiogenic promotion. In light of VOR's mechanism of action and favorable toxicity/safety profile, we sought to evaluate the efficacy of VOR combined with BEV in recurrent GBM. **Methods:** A phase II single-center open-label, single arm study was performed to evaluate VOR and BEV in recurrent GBM. Primary endpoint was 6-month PFS. Secondary endpoints were safety/tolerability, radiographic response, PFS, and OS. Major eligibility criteria included age $\geq$ 18 yrs, KPS $\geq$ 70 and $\leq$ 2 prior progressions. Dosing regimen was BEV 10mg/kg IV q2weeks combined with VOR 400mg PO daily for 7 days, then 7 days off in a 28 day cycle. **Results:** Forty recurrent GBM patients were enrolled. To date, median follow-up time is 13.2 months with 6-month PFS of 30% (95% CI: 16.8%, 44.4%). Median OS is 10.4 months (95% CI: 9.3-13.1 months). Objective radiographic responses included 9 partial responses, 29 stable responses, and 1 radiographic progression with 1 patient not assessed due to early death (sudden death of vascular origin). Most common treatment related grade 2-3 toxicities were lymphopenia (55%), leukopenia (43%), neutropenia (33%) and hypertension (33%). Grade 4 toxicities were leukopenia (3%), neutropenia (3%), sinus bradycardia (3%), and thromboembolic event (3%). Two deaths occurred on study; one due to disease progression and the other was a sudden death of vascular origin. **Conclusions:** VOR and BEV combination therapy was well-tolerated in recurrent GBM, although it did not improve 6-month PFS when compared to BEV monotherapy. There was a trend towards improved OS in VOR and BEV in comparison to BEV monotherapy. Continued follow-up and research is needed to delineate better the role of chemotherapy in combination with BEV. Clinical trial information: NCT01738646.

2035 Poster Session (Board #24), Mon, 1:15 PM-4:45 PM

Patterns of response and relapse of primary central nervous system lymphomas (PCNSL) following first line of high-dose methotrexate-based chemotherapy (hdMTX): Analysis of a prospective ANOCEF randomized phase II trial. *First Author: Emeline Tabouret, Aix-Marseille University, AP-HM, Service de Neuro-Oncologie, CHU Timone, Marseille, France*

Background: Detailed neuro-imaging analyses of PCNSL are limited. Our objective was to evaluate MRI findings in PCNSL patients treated with hdMTX without radiotherapy, with a particular emphasis on T2-FLAIR MRI abnormalities. **Methods:** We reviewed MRI (T1, T1 post-gadolinium and T2/FLAIR) findings of 85 patients with PCNSL enrolled in a randomized multicenter phase II trial (NCT00503594) evaluating two hdMTX regimens (MPV-A and MTX-temozolomide), conducted in patients aged 60 and older. Response rate (IPCG criteria), number and volume of enhancing lesions, anatomical site, site of relapse and patterns of relapse were analyzed and correlated with outcome. Landmark analyses were performed at 2 and 4 months. **Results:** Objective responses (OR) were: complete response (CR): 56%, uncertain CR: 4%, partial response: 18%, stable disease: 7%, progressive disease: 15%. On multivariate analysis, location in the posterior fossa ($p = 0.008$) and tumor volume ($p = 0.006$), but not lesion number, were significantly associated with survival. OR at the first MRI (2months) and at the end of treatment (4 months) were significantly associated with overall survival in multivariate analysis ($p < 0.001$ and $p = 0.004$ respectively). Early versus delayed CR did not impact survival. Relapse in the brain involved the initial enhancing site, a site at distance, or both in 46%, 40% and 14% respectively. At baseline, non-enhancing T2-FLAIR hypersignal lesions at distance from the enhancing tumor site were detected in 18 patients (23%), among whom 16 (88%) displayed a marked decrease ($>$ 50%) after chemotherapy, confirming their neoplastic nature. Among these 18 patients, ten relapsed, and the initially non-enhancing T2-FLAIR lesions corresponded to the site of an enhancing relapse in half of them (N = 5). **Conclusions:** Relapse after hdMTX at distance from the initial enhancing tumor is frequent and may occur in the area of non-enhancing T2-FLAIR hyper-intensity identified at distance from the enhancing tumor at baseline. Future response criteria should take into consideration non-enhancing T2-Flair lesions.

2036 Poster Session (Board #25), Mon, 1:15 PM-4:45 PM

Comparative impact of treatment on clinical benefit in patients with glioblastoma (GBM) enrolled in the phase II trial of ICT-107. *First Author: Terri S. Armstrong, The University of Texas Health Science Center School of Nursing, Houston, TX*

Background: This study was a randomized double blind placebo-controlled phase 2 trial of dendritic cell(DC) Vaccine ICT-107 following standard treatment in newly diagnosed patients with GBM. Although OS was not different, PFS was longer in those receiving the vaccine. To evaluate the clinical benefit of this prolonged PFS, Karnofsky Performance Status (KPS) and steroid dosing, as well as patient reported QOL using the Functional Assessment of Cancer Therapy –Brain (FACT-BR) were evaluated during the progression free period. **Methods:** The FACT-BR was completed by patients at baseline, and longitudinally during the maintenance phase after four induction vaccinations and at the end of study visit. Corticosteroid dosing and KPS were evaluated throughout the progression free period at monthly timepoints for 12 months and every 6 months thereafter. Between arm differences were evaluated using Fisher test or ANOVA statistics. A p-value of 0.05 was considered significant when comparing the two treatment groups for all analyses. **Results:** Participants (81 patients in the ICT-107 arm and 43 patients in the control arm) completed baseline FACT-BR assessment (97% compliance), with 84% and 68% completing end of cycle 1 and end of study assessments respectively. Quality of life, as measured by the FACT-BR, was maintained equally until progression for ICT-107 and control patients. Performance level, as measured by KPS, was significantly higher during the treatment period in those receiving ICT-107 (p,0.05, Cycles 1-4 or maintenance phase). There was a trend for less steroid usage over time in the ICT-107 arm (30%) versus the control (44%) ($p = 0.1$, log rank). **Conclusions:** Based on these initial analyses of clinical benefit, increased PFS time with ICT-107 is not associated with a detrimental impact on self-report of QOL, and is associated with retention of performance capacity as measured by KPS, and may be associated with a longer corticosteroid free period than those receiving standard treatment. Clinical trial information: NCT01280552.

2037 Poster Session (Board #26), Mon, 1:15 PM-4:45 PM

Correlation of dynamic ^{18}FET-PET with IDH 1 mutation for prediction of outcome in anaplastic astrocytoma WHO° III independently from tumor vascularisation. *First Author: Bogdana Suchorska, Department of Neurosurgery LMU, Munich, Germany*

Background: Patients with an anaplastic glioma (WHO III°) without IDH1 mutation have a comparable disease course to glioblastoma. Dynamic ^{18}FET-PET has been shown to provide prognostic information in malignant glioma independent of other clinical parameters. Here, we analyzed whether dynamic parameters acquired from ^{18}FET-PET imaging correlate with IDH1 mutation status or tumor vessel density regarding the clinical course in anaplastic astrocytoma. **Methods:** 96 patients with a glioma WHO III ° who received a ^{18}FET-PET at primary diagnosis were analyzed with respect to IDH1/2 mutation, *MGMT* promoter methylation, LOH 1p/19q status and vascularity (vessel density quantified by CD34-positive tumor area). The maximum "tumor-to-brain ratio" (TBR_{max}) and the minimum "time-to-peak" (TTP_{min}) were analyzed as ^{18}FET-PET parameters. Clinical outcome measures were progression free survival (PFS) and overall survival (OS). **Results:** Vessel density varied from 1 to 25% and did not have an impact on OS or PFS ($p = 0.09/0.6$); furthermore, it was not intercorrelated with IDH1 mutation status or with TTP_{min}. 54 % of all patients showed no IDH1 mutation. The IDH 1 status did not correlate with TBR_{max} (2.9 vs. 3.2 without vs. with IDH 1 mutation; $p = 0.24$), but with TTP_{min} ($p < 0.001$): 37/41 (90%) patients with a $TTP_{min} \leq$ 12,5 min showed no IDH 1 mutation, while a $TTP_{min} >$ 12.5 min was often associated with IDH1 mutation (31/43 patients (72%), 4 patients could not be evaluated).; In an interim analysis of 53 cases, patients without IDH 1 mutation or with a $TTP_{min} \leq$ 12,5 min had a significantly shorter PFS (10.0 vs. 37.4 months vs. 37.4 months and 9.8; $p < 0.001$) and OS (20.5 and 22.0 months versus median not reached, respectively; $p < 0.001$). In the multivariate analysis, both $TTP_{min}$and IDH 1 status were independent predictors of OS . **Conclusions:** In anaplastic gliomas, early TTPmin ≤ 12.5 min is associated with a lack of IDH 1 mutation, but not with vessel density, MGMT mutation status or LOH 1p/19q. TTP_{min} and IDH1 mutation are both independently associated with clinical outcome.

2038 Poster Session (Board #27), Mon, 1:15 PM-4:45 PM

Prognostic model of lower grade gliomas. *First Author: Kosuke Aoki, Department of Neurosurgery, Nagoya University School of Medicine, Nagoya City, Japan*

Background: Lower grade gliomas (LGGs, WHO grade II/III gliomas) account for one third of all gliomas. Most LGGs generally show a slow progression, but some show a more aggressive clinical course. Large-scale and comprehensiveness in genetical and clinical studies enables establishment of a reliable prognostication system. **Methods:** Status of somatic mutations and copy number variations (CNVs) generated by whole exome/targeted sequencing and SNP array were investigated for 653 patients combined 269 Japanese patients with publically available 384 patients from the Cancer Genome Atlas, who were randomly divided into training (327 patients) and validation sets (326 patients). LGGs were genetically classified into 3 types according to *IDH* mutation and 1p/19q loss of heterozygosity (LOH): Type 1 (mutated *IDH* with 1p/19q LOH), Type 2 (mutated *IDH* without 1p19q LOH), and Type 3 (*IDH* wild type) which also were well correlated with overall survival (OS) (Nature Genetics, in press). In the current study, we sought significant risk factors in each LGG type contributing OS using Cox regression analysis and Akaike information criterion. We validated the accuracy of this classifier in the validation set. **Results:** In the training set, significant risk factors were extracted in Types 1 and 3, but not in Type 2. These types were sub-grouped into low- and high-risk groups (HR = 3.13, 2.81 and 95% CI = 1.36-7.19, 1.25-6.32 respectively). Eventually, all LGGs were divided into low- and intermediate- and high-risk group, showing significantly different OS. The performance of the new model was evaluated by receiver operator characteristic analysis, which showed significantly higher accuracy than previously reported clinical/histological parameters, in particular for long-term prognosis. **Conclusions:** We established a new classifier based on genetic parameters, which provides a reliable tool for predicting OS in LGG patients and should be useful to guide an individual molecular-targeted therapy.

2039 Poster Session (Board #28), Mon, 1:15 PM-4:45 PM

Phase I study of vorinostat combined with isotretinoin and temozolomide in adults with recurrent malignant gliomas. *First Author: Marta Penas-Prado, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Vorinostat (Vor), a histone deacetylase inhibitor, has shown preliminary activity in recurrent GBM. Preclinical studies demonstrated that Vor can overcome resistance to isotretinoin (cRA) and temozolomide (TMZ). We hypothesized that Vor could overcome resistance to cRA and cytotoxic chemotherapy in the treatment of recurrent gliomas. Carboplatin (CBP) was originally selected as the cytotoxic drug since eligible patients would have failed prior standard TMZ therapy. **Methods:** We conducted a Phase I study of combinations of these agents preceding a proposed adaptive randomized 3-arm Phase II study. Adults with recurrent malignant glioma were enrolled into one of 3 arms. Arm 1: Vor + cRA, Arm 2: CBP + cRA, or Arm 3: Vor + cRA + CBP. Dose escalation was by a 3 + 3 design to define the maximum tolerated dose (MTD). Due to excessive toxicity in arms containing CBP, this drug was replaced by dose-dense TMZ due to preliminary evidence of activity in recurrent gliomas. **Results:** A total of 55 patients (8 anaplastic gliomas, 47 GBM) were enrolled from 11/2007 to 03/2012. Among 52 evaluable patients, a total of 11 DLTs were seen, but none after introduction of TMZ to Arm 3. MTDs are summarized in Table. Toxicities included: Arm 1 – neutropenia, thrombocytopenia, pulmonary embolism, elevated AST (DLT), and hypertriglyceridemia (DLT); Arm 2/CBP – neutropenia, thrombocytopenia (DLT), and hypertriglyceridemia; Arm 3A/CBP - thrombocytopenia (DLT) and hypokalemia (DLT); Arm 3B/TMZ – thrombocytopenia, hypertriglyceridemia, fatigue. Best response was stable disease in 26 patients, for ≥ 4 months in 15 patients; 10 patients achieved 6-month progression-free survival; 7 of whom had GBM. **Conclusions:** Two and 3 drug combinations of Vor, cRA, and dose-dense TMZ were well tolerated with MTD that will be used in a multicenter adaptive randomized Phase II study in the near future. Clinical trial information: NCT00555399.

	MTD
Arm 1 (n=14)	Vor 400 mg/day, D 1-14 cRA 100 mg/m^2/day, D 1-21
Arm 2/CBP (n=12)*	CBP AUC 5, D 1 cRA 100 mg/m^2/day, D 1-21
Arm 3A/CBP (n=19)*	De-escalation to dose level -3 (Vor 300 mg/day x 14 days; cRA 100 mg/m^2/day x 21 days; CBP AUC 4)
Arm 3B/TMZ (n =10)	Vor 500 mg/day, D 1-7 & 15-21 cRA 100 mg/m^2/day, D 1-21 TMZ 150 mg/m^2/day, D 1-7 &15-21

*Not going to Phase II

The impact of the time to start radiotherapy (TRT) on overall survival in newly diagnosed glioblastoma. *First Author: Vanessa Montes Santos, Instituto do Câncer do Estado de São Paulo (ICESP), São Paulo, Brazil*

Background: Glioblastoma (GB) is the most common malignant primary brain tumor in adults. The standard therapy for newly diagnosed glioblastoma is surgical resection followed by radiotherapy (RT) and temozolomide (TMZ). In some institutions it is difficult to start radiotherapy within 2 to 4 weeks following surgery, mostly due to logistic limitations. On the other hand it is unclear how TRT impacts OS in GB. This study aims to evaluate the impact of the time to start radiotherapy (TRT) on overall survival of GB treated with TMZ and RT. **Methods:** In this retrospective study we included all consecutive patients with GB treated at the Instituto do Cancer do Estado de São Paulo (ICESP) with TMZ and RT from 2008 to 2014. Patients with recurrent or secondary GB were excluded. TRT was defined as the time between surgery and the first day of RT, measured in days. The primary end point was overall survival (OS) with regard to TRT. Categorical data was showed as frequencies and percentiles. Survival analysis was performed using Kaplan-Meier curves and log-rank test for comparison between survival curves. Univariate and multiple Cox regression model were performed for overall survival, and stepwise forward method was used for selection variables. We considered 5% of level of significance for all hypotheses tests. All statistical analysis was performed using SPSS for Windows v.18. **Results:** A total of 89 patients were included in this study. The median OS was 27 months for the whole group. Median TRT was 70 days. In the multivariate analysis we identified age was the only significant independent predictor for OS. TRT analyzed as a continuous variable did not impact negatively on OS. When considering TRT at cutoff points of 45 and 60 days, again no negative impact on OS was observed, although a trend was observed for a TRT $>$ 60 days. (HR = 1.93 (95% CI 0.99 – 3.75); p = 0.053). The same adverse trend is observed when considering only younger patients (age $<$ 65 y.o.), for a TRT $>$ 60 days (HR = 2.14 (95% CI 0.99-4.67); p = 0.055). **Conclusions:** Within the limitations of this retrospective analysis, we could not show a clear statistical significant adverse impact of TRT on OS in glioblastoma up to 60 days. However it is a possible that a TRT $>$ 60 days adversely affects OS.

2041 **Poster Session (Board #30), Mon, 1:15 PM-4:45 PM**

Does extent of resection matter in recurrent glioblastoma? Lessons from the DIRECTOR trial. *First Author: Bogdana Suchorska, Department of Neurosurgery LMU, Munich, Germany*

Background: The role of surgery for recurrent glioblastoma is under debate. Tumor volume at recurrence was prognostic in single-institution retrospective studies, but no data from prospective multicenter trials for recurrent glioblastoma have been published to date. Here, we report the association with outcome of surgery for recurrent glioblastoma in a well characterized patient cohort treated in the DIRECTOR trial, which evaluated the effect of two different dose-intensified temozolomide regimens at first recurrence of glioblastoma. **Methods:** We analyzed prospectively collected clinical, molecular and imaging data from the DIRECTOR cohort (N = 105). Imaging data was available from 87 patients. Volumetric analysis was performed based on gadolinium (Gd) enhancement on MRI and correlated with progression-free survival (PFS) and overall survival (OS). Proportional hazard models were applied to obtain prognostic factors. **Results:** 71 of 105 patients received surgery at recurrence. Prognostic factors were balanced between patients who had undergone surgery and those who had not, including age (P = 0.358), O^6-methylguanine DNA methyltransferase (*MGMT)* gene promoter methylation (P = 0.965), isocitrate dehydrogenase (*IDH)-1* mutation (P = 0.724), Karnofsky performance score (P = 0.880), or steroid intake before randomization (P = 0.950). Mean tumor volumes in patients who had received surgery were smaller at study entry than in patients who had not undergone surgery (3.0 cm^3 [range 0-37] versus 6.8 cm^3[range 1-23], P $<$ 0.001). The outcomes in patients who did or did not receive surgery at recurrence were similar for PFS (2.0 months [95% CI 3.5-7.1] vs. 1.9 months [95% CI 1.9-6.4], P = 0.1974) and OS (9.2 months [95% CI 8.7-12.6] vs 9.4 months [95% CI 8.3-13.5], P = 0.9538). Among patients who underwent surgery for recurrence, post-surgery imaging was available in 59 cases. In these patients, complete resection of Gd-enhancing tumor (N = 39) versus residual detection of Gd enhancement (N = 20) was associated with improved OS (11.5 months [95% CI 9.3-15.1] vs. 6.7 months [95% CI 5.2-9.5], P = 0.006). **Conclusions:** Surgery at first recurrence of glioblastoma may improve outcome if complete resection of Gd-enhancing tumor is feasible.

2042 **Poster Session (Board #31), Mon, 1:15 PM-4:45 PM**

Effectiveness of transcranial magnetic stimulation in neurooncological patients. *First Author: Dmitriy P. Atmachidi, Rostov Scientific Research Institute of Oncology, Rostov-on-Don, Russia*

Background: Development of technologies of neurooncological treatment has not solved the problem of treatment for malignant brain tumors. Neurological and somatic complications reduce the length and quality of life of patients. Development of systemic therapeutic approach showed the effectiveness of multisystem influence factors. They include low-intensity extremely low frequency variable and static magnetic fields (ELFMF and SMF). The purpose of this study was to improve the results of complex treatment for malignant brain gliomas using transcranial magnetic stimulation (TMS). **Methods:** 30 patients received TMS during adjuvant chemoradiotherapy (CRT) on days 1-20 of the treatment: ELFMF to hypothalamus projection with frequency 0.03; 3; 9 Hz, induction from 5 to 0.8 mT, exposure 7 min.; and in 20 min. – SMF to the area of operation with induction 20 mT, exposure 15 min. X-ray computed tomography was performed using Toshiba-AsteionVR 2002. Toxicity was evaluated according to CTC-NCIC criteria, cerebral symptoms and somatic status (ECOG-WHO performance status) – according to the scale, Karnofsky Performance Score and identification of integral reactions of the body. **Results:** Remission maintained in CRT+TMS in 93.3±4.6 patients vs. 40+9.1% in the control, 2-year survival increased by 2.4 times. Rate and severity of toxic complications, especially neurological ones (cerebral symptoms, disturbances of speech and motor functions) reduced significantly. Dynamics of somatic status improved (0.32 vs. 0.18), as well as Karnofsky index (9.3 vs. 2.6% in the control, p$<$0.05). Rate of stress development decreased by 10.8 times after TMS, antistress responses prevailed. **Conclusions:** TMS in complex treatment for malignant brain gliomas provides protective effect on homeostatic regulation systems, increases body resistance, optimizes rehabilitation and improves quality of life of patients.

2043 **Poster Session (Board #32), Mon, 1:15 PM-4:45 PM**

Mutational analysis of matched initial and recurrent TP53 WT primary GBM. *First Author: David M. Ashley, Andrew Love Cancer Centre, Geelong, Australia*

Background: Glioblastoma (GBM) present as a heterogeneous disease with poor prognosis despite the use of multimodal therapy. Tumours at diagnosis are distinct from their recurrences, the latter being more therapy resistant. Pinpointing the associated molecular alterations may better inform new therapeutic options to tackle resistance of recurrent disease. **Methods:** A study cohort of 29 patients with primary, TP53 wild-type GBM, with associated annotated clinical data were examined. Of these, 409 cancer associated genes, were examined in 21 paired primary/relapse FFPE extracted DNA specimens using the Comprehensive Cancer Panel (Life Technologies) with sequencing to a mean depth of 1200x. Whole exome sequencing (WES; Illumina HiSeq 2000) was conducted on an additional eight patients (paired primary/relapse) to an average of 70-fold coverage. **Results:** An average of 67±3 (range 49-101) non-synonymous variants or frameshift insertion/deletions were detected in tumour specimens at diagnosis and 53±4 (range 32-127) at relapse. Of these, an average of 27±2 and 13±3 variants were unique to tumours at diagnosis and relapse respectively and 50% of variants that were detected in the initial tumour were also present at relapse. WES revealed an average of 9112 somatic mutations across the genome per sample (range 603-47701). As distinct from recent reports of recurrent lower grade glioma very few patients showed a "hypermutable" signature that is characterized by numerous temozolamide (TMZ) associated specific mutations after treatment. In total, only 2/29 samples (7%) appeared to be hypermutated at relapse, with 55.6% of these mutations being attributable to TMZ-associated mutagenesis in the first patient and 44.3% in the second. **Conclusions:** Overallwe observed few consistent differences between paired diagnosis and relapse specimens. In contrast to previous studies we found evidence of hypermutation associated with TMZ treatment in the minority of patients. We propose that this may be related to the wild-type TP53 status in these patient's tumours.

2044 Poster Session (Board #33), Mon, 1:15 PM-4:45 PM

A phase 2 study on efficacy, safety and intratumoral pharmacokinetics of oral selinexor (KPT-330) in patients with recurrent glioblastoma (GBM). *First Author: Ulrik Niels Lassen, Rigshospitalet, Copenhagen, Denmark*

Background: Patients (pts) with recurrent GBM have few treatment options and a poor prognosis. Selinexor is an oral inhibitor of XPO1 mediated nuclear export resulting in nuclear retention of multiple tumor suppressor proteins (TSPs) including p53, pRB, CDKN2A, p21 and FOXO. Mean IC_{50} of selinexor in pt derived GBM neurosphere cultures was 133 nM. In a pt derived orthotopic murine xenograft model, selinexor demonstrated marked inhibition of tumor growth *in vivo* and prolonged survival (P= .001). **Methods**: This study (NCT01986348) is an open label, multicenter, two-arm phase II trial enrolling pts with recurrent GBM after radiation therapy with concurrent and adjuvant temozolomide. Pts in Arm A received 3 doses (50 mg/m^2) of selinexor prior to surgery, and resumed selinexor after surgery. Pts in Arm B received selinexor alone (50 mg/m^2 BIW) until disease progression. **Results**: (Jan 22, 2015) 7 pts (6/1 M/F, median age 57, 1–2 prior treatment regimens) were treated on Arm A and 15 pts (11/4, M/F, median age 62; 1–3 prior treatment regimens) were treated on Arm B. Mean plasma PK concentration was 999 nM (311-2071 nM) and mean tumor concentration was 136 nM (40-291 nM) in 6 pts. Grade 1/2 AE's (Arm B) included thrombocytopenia (27%/27%), anorexia (13%/33%), fatigue (7%/40%), and hyponatremia (47%/0%). One Grade 3 AE was reported in ≥ 2 pts (fatigue) and no Grade 4 AEs were reported. Investigator reported best responses for 12 evaluable pts (Arm B) were: 2 partial responses (17%), 4 stable disease (33%) and 6 progressive disease (50%). Analysis of XPO1 and TSP expression in tumor tissue is ongoing. **Conclusions**: Oral selinexor at 50 mg/m^2 BIW achieves concentrations in GBM tissue exceeding the IC_{50} in pre-clinical models. Main toxicities are fatigue and anorexia. Partial responses and stable disease were observed. Clinical trial information: NCT01986348.

2046 Poster Session (Board #35), Mon, 1:15 PM-4:45 PM

IDH 1 /2 status and low grade gliomas (LGG): Correlation with outcome upfront Pignatti criteria and molecular profile in a retrospective analysis of a single-centre cohort from Spain. *First Author: Olatz Etxaniz, Medical Oncology Department, Institut Catala d'Oncologia, Hospital Germans Trias i Pujol, Badalona, Spain*

Background: Current therapy of LGG is based on clinical, radiologic and histologic (Pignatti prognostic classification) features .In the last years genomic profile of LGG has been investigated showing a new tool to guide therapy . **Methods:** IDH analysis was performed by IDH1 and IDH2 genes sequencing in a series of 58 LGGs diagnosed from 1991 to 2012 and correlated with histology , Pignatti classification , molecular profile (p53 expression , 1p19q deletion status and MGMT promoter methylation) and outcome. **Results:** 56.9% of the pts were male and mean age was 45 years . Histological distribution was 39.7% , 22.4% and 37.9% for Astrocytoma (A), Oligodendroglioma (OD) and Oligoastrocytoma (OA) , respectively . Surgical resection was total in 41.4% , subtotal in 19% and only biopsy in 39.7% of the cases . Pts were classified by Pignatti criteria. Inmediate postsurgery therapy was administered performed in 41.4% of pts. IDH alterations were found in 61.9% (26/42) , 1p19q codeletion in 46.3% (25/54), overexpression of p53 in 17.3% (9/52) and MGMT methylation in 40.4% (19/47) of the cases .Median TTP was 61.6 months (95% CI 25.3-97.9) and median OS was 109.7 months (95%CI 73.0- 146.5). In univariate analysis ,1p19q codeletion ($p = 0.045$) and IDH mutation ($p < 0.001$) were associated with better TTP . Median OS was correlated with Pignatti classification ($p = 0.024$) and IDH mutation ($p < 0.001$) . A trend to a better OS was observed with 1p19q codeletion ($p = 0.052$) and MGMT methylation($p = 0.068$). In multivariate analysis, IDH mutation was the only independent prognostic factor after adjustment for histology, molecular profile and Pignatti criteria in terms of OS (HR = 0.120, 95%CI 0.031-0.459, $p = 0.002$) and TTP (HR 0.237,95%CI 0.072-0.779, $p = 0.018$). **Conclusions:** Our findings confirmed the favorable prognostic independent value of IDH mutation in LGG over other criteria.

2047 Poster Session (Board #36), Mon, 1:15 PM-4:45 PM

Time to response (TTR) and early tumor shrinkage (ETS) in recurrent glioblastoma patients treated with bevacizumab: an exploratory analysis of the prospective randomized AVAREG (ML25739) phase II study. *First Author: Enrico Franceschi, Bellaria Hospital, Bologna, Italy*

Background: The treatment of recurrent glioblastoma (GBM) remains an open issue, and the role of bevacizumab (BEV) has been widely debated since a few studies compared this agent with the standard treatments. **Methods:** a multicenter, randomized (2:1), phase II study (EudraCT: 2011-001363-46) with BEV 10 mg/kg iv every 2 weeks or fotemustine (FTM) 75 mg/m^2 iv day 1-8-15 followed, after a 35 days interval, by fotemustine 100 mg/m^2 every 3 weeks, was conducted. The primary endpoint was overall survival at 6 months (OS-6). ETS was assessed with central review exploratory analysis. T1contrast enhancing area and T2/FLAIR were evaluated as predictors for OS rates with ROC analysis and the test for AUC. The best cut-off values were found with the maximization of Youden's Index. The groups obtained were analyzed with Kaplan-Meier procedure and compared with univariate and multivariate Cox proportional hazards model. **Results:** 91 patients with recurrent GBM were enrolled in 10 Italian centers between 11/2011 and 9/2012. The median age was 57 years (range: 28-78). Fifty-nine patients were enrolled in the BEV arm and 32 patients in the FTM arm. OS-6 was 62.1% (95%CI: 48.4-74.5) and 73.3% (95%CI: 54.1-87.7), OS-9 was 37.9% (95%CI: 25.5–51.6) and 46.7% (95%CI: 28.3–65.7) in the BEV and FTM arms, respectively. Median OS was 7.3 months (95%CI: 5.8-9.2) in the BEV arm and 8.7 months (95%CI: 6.3-15.4) in the FTM arm. The response rate was 29% (95%CI: 18-42) and 9% (95%CI: 2-25) for patients treated with BEV and FTM, respectively. TTR ($p = 0.05$, HR = 0.46, 95%CI:0.21-1.00) and ETS > 15% in T1 contrast enhancing area at first disease assessment ($p = 0.040$, HR = 0.511, 95%CI:0.269-0.971) could predict OS in patients treated with BEV but not with FTM (TTR and ETS with FTM: $p = 0.19$ and $p = 0.4$, respectively). Patients achieving an ETS ≥ 15% had significantly longer OS than those achieving an ETS < 15% (8.4 vs 5.2 months). **Conclusions:** BEV and FTM are both active drugs in recurrent GBM. TTR and ETS might be helpful predictors of GBM outcome in patients treated with BEV. Clinical trial information: NCT01474239.

2048 Poster Session (Board #37), Mon, 1:15 PM-4:45 PM

The role of salvage radiation in recurrent glioblastoma after bevacizumab failure. *First Author: Nehaw Sarmey, Cleveland Clinic, Cleveland Heights, OH*

Background: Bevacizumab is FDA-approved for patients with recurrent glioblastoma (GBM). Despite bevacizumab treatment most patients progress, and there are limited therapeutic options for them. We evaluated the role of radiation therapy (RT) after bevacizumab failure in recurrent GBM. **Methods:** With IRB approval, the Cleveland Clinic's database was used to identify all recurrent GBM patients who received salvage treatment after initial bevacizumab failure. Patients were stratified by whether or not they received a RT-containing regimen. Kaplan-Meier analysis and log-rank method were used to compare overall survival (OS) and progression-free survival (PFS) from time of initial bevacizumab failure. Univariable and multivariable Cox proportional hazards models were used to assess the association between patient and treatment characteristics and OS. **Results:** We identified 108 recurrent GBM patients treated after initial bevacizumab failure. Seventeen patients received a RT-based regimen and 91 patients received a non-RT regimen. Of the 17 patients who underwent some form of RT, 5 received RT alone and 12 received RT in combination with other chemo/targeted therapy (11 received RT with bevacizumab). Six patients underwent stereotactic radiosurgery, and 11 patients received fractionated radiation ranging 20 to 60 Gy (4 patients received standard fractionation of 2 Gy per fraction, 6 patients received a hypo-fractionated regimen of > 2 Gy per fraction, and 1 patient's regimen was unknown). At time of initial bevacizumab failure, both the RT and non-RT groups were similar in age, performance status, and extent of resection. Median OS and PFS for the entire cohort was 6.0 months (95% CI: 5.2, 6.6) and 2.6 months (95% CI: 2.3, 3.1) respectively. The group that received subsequent RT had a statistically significant increase in both OS (8.8 vs 5.4 mos; $p = 0.05$) and PFS (4.1 vs 2.3 mos; $p = 0.006$) when compared to the group that did not receive RT. In both univariate and multivariate analyses, only RT use after bevacizumab failure was predictive of OS. **Conclusions:** In this small cohort, use of salvage RT after bevacizumab failure in recurrent GBM was associated with improved survival. A prospective trial is warranted to confirm this finding.

2049 Poster Session (Board #38), Mon, 1:15 PM-4:45 PM

Graded prognostic assessment index for colorectal cancer with brain metastases. *First Author: Vidhya Karivedu, Fairview Hospital Cleveland Clinic, Cleveland, OH*

Background: Brain metastasis (BM) is a rare but serious neurologic complication of colorectal cancer (CRC). The Disease Specific Graded Prognostic Assessment (DS-GPA) which is based solely on Karnofsky performance scale (KPS) is a commonly used prognostic index in patients with BM. We evaluated DS-GPA and other potential prognostic factors for overall survival (OS) in CRCBM at our institution. **Methods:** With IRB approval, the Cleveland Clinic Brain Tumor and Neuro-Oncology Center's database was used to identify CRCBM patients treated between 2002 and 2014. OS from the diagnosis of CRC BM was the primary endpoint. Cox proportional hazards models with stepwise variable selection were used to identify independent prognostic factors. **Results:** Ninety four patients with median age of 60 years (range; 32-87), were included for analysis. KPS was 90-100 in 35 patients (38%), 70-80 in 35 (39%) and <70 in 20 (23%) patients. Single BM was noted in 53 (56%), 2-3 BM in 25 (27%) and >3 BM in 16 (17%) patients. Eighty nine patients (95%) were symptomatic at diagnosis. Forty nine(52%) patients had supratentorial BM, 25(25%) had infratentorial BM and 20 (21%) had both supra-and infratentorial BM at diagnosis. Initial therapy included whole brain radiation (WBRT) in 31 (33%), stereotactic radiosurgery (SRS) in 22(23%), WBRT + SRS in 11(12%), surgery (S) in 2 (2%), S+SRS in 6 (6%), S+WBRT in 14(15%), S+SRS+WBRT in 1(1%), while 2 patients received only chemotherapy and 5 underwent observation. Median OS from diagnosis of BM was 5.5 months (95% C.I. 3.5-7.5). In multivariate analysis KPS and number of BM were independent predictors of OS. Combining these factors a revised GPA with three groups was defined: unfavorable (total points ≤3), intermediate (4-5), and favorable (≥6 points) with median OS of 2.8, 6.1 and 14.7 months, respectively. **Conclusions:** A revised DS-GPA for CRCBM based on KPS (performance status) and number of BM is proposed.

Factors	No. of points	Hazard ratio	P valve
Number of BM		1.27(1.02-1.59)	0.032
1	3		
2	2		
3	1		
>3	0		
Colon cancer specific GPA (KPS)		0.78(0.63-1.59)	0.015
100	4		
90	3		
80	2		
70	1		
<70	0		

Revised GPA	No. Points	Median OS (mo)
Unfavorable	≤3	2.8
Intermediate	4-5	6.1
Favorable	≥6	14.7

2050 Poster Session (Board #39), Mon, 1:15 PM-4:45 PM

Phase II trial of dovitinib in recurrent glioblastoma. *First Author: Manmeet Singh Ahluwalia, Cleveland Clinic, Cleveland, OH*

Background: Glioblastoma (GBM) is a vascular tumor and bevacizumab (a monoclonal antibody against VEGF-A) is FDA-approved in recurrence. Mechanisms of resistance to anti VEGF therapy include up-regulated FGF signaling and increased PDGF-mediated pericyte coverage. Dovitinibis an oral, small-molecule tyrosine kinase inhibitor of FGFR 1-3, PDGFR β, and VEGFR 1-3. **Methods:** This was a phase II trial in adults with GBM, stratified by prior anti-angiogenic therapy (naive – arm A, refractory – arm B). Arm A's primary endpoint (PE) was PFS6 with a 2-stage accrual design to test the hypothesis that PFS6 was 36% vs. 55%. Arm B's PE was time to progression (TTP) and a one-stage design to test the hypothesis that median TTP could be increased from 1.5 to 3 months. Type I and II error was 10% and 20%, respectively in both arms. Extracellular vesicles (EV) were measured at study enrollment, at the end of cycle 1 (day 28), and at progression (PD) to evaluate response to therapy. **Results:** Nineteen patients enrolled in Arm A and 14 in Arm B. Accrual in arm A was stopped after the first stage due to futility. Overall 64% (21/33) of patients were male, median age at on-study was 57 years (range 26-68), and median KPS was 80 (range 60-90). In Arm A, PFS6 was 5% (1/19), median PFS was 1.8 months (95% C.I. 1.3-2.8) and median OS was 7.9 months (95% C.I. 3.6-11.7). In arm B, median TTP was 1.8 months (95% C.I. 1.0-1.8); median PFS was 1.8 months (95% C.I. 0.7-1.8) and median OS was 3.0 months (95% C.I. 0.8-4.7). In arm A, patients with PD had significantly higher levels of CD14+ EV (median 83289 vs 27500, $p = 0.027$) and CD142+ EV (median 38855 vs. 4675 , $p = 0.042$) compared to stable disease at end of cycle 1. Overall 5 patients (15%) reported grade 4 toxicities and 22 (67%) reported grade 3 reactions, primarily elevated lipids/lipase (42%), fatigue (21%), thromboembolic events (18%), hypertension (9%), and lymphopenia (9%). Other toxicity seen were grade 4 appendicitis/colitis ($n = 1$), oral pain and proteinuria ($n = 1$), and delirium ($n = 1$). **Conclusions:** Dovitinib is not active in recurrent GBM, regardless of prior anti-angiogenic therapy. In arm A, elevated pre-treatment levels of CD14+ and CD142+ EV were associated with PD, suggesting their potential role as a predictor of poor response to Dovitinib. Clinical trial information: NCT01753713.

2051 Poster Session (Board #40), Mon, 1:15 PM-4:45 PM

Incidence of pseudo-progression in low-grade gliomas treated with radiotherapy. *First Author: Sophie E. van West, Erasmus MC, Rotterdam, Netherlands*

Background: Pseudo-progression (psPD) is a well-known phenomenon in high-grade gliomas (HGG) after treatment with radiotherapy/temozolomide. However the incidence of psPD in low-grade glioma (LGG) after radiotherapy (RT) is unknown. Therefore, we retrospectively investigated the occurrence of psPD in a cohort of low grade glioma patients treated with RT. **Methods:** All patients with histologically proven LGG treated with RT between 2000 and 2011 were reviewed. MRI scans were reviewed by two independent reviewers before and after RT in periods of 3-6 months until progression leading to the start of a new treatment as judged by the treating physician. Furthermore clinical data including dexamethasone dose and epileptic activity was taken into account. Pseudo-progression was scored when a new enhancing lesion occurred after RT, and this disappeared or remained stable for at least a year without therapy. **Results:** Seventy-one patients were treated with RT for LGG. Sixty-four patients were deemed eligible for evaluation (3 were lost to follow up and 4 patients were not evaluable, due to a missing scans). The median follow-up was 7 years (range 1- 22 years). The median progression free survival was 3.1 years. The median overall survival time was 5.3 years. Sixty-three patients were evaluable for psPD (1 patient was evaluated for response only, because of gadolinium allergy). psPD was seen in 13 patients (20.6%). In two of these patients epilepsy may have played a role. Pseudo-progression occurred after a median of 10 months in a period of 3 – 78 months. The median duration of psPD was 6 months with a range of 2 – 26 months. It always occurred within the RT fields. The area of the enhancement at the time of pseudo-progression was significantly smaller compared to the area of enhancement during 'true' progression (median size 54 mm^2 (range 12 – 340 mm^2) versus 270 mm^2 (range 30 – 3420 mm^2), respectively; $p = 0.009$). **Conclusions:** psPD occurs frequently in LGG patients treated with RT. This supports the policy to postpone a new line of treatment until further progression is evident, especially when patients have small contrast enhancing lesions in the RT field.

2052 Poster Session (Board #41), Mon, 1:15 PM-4:45 PM

Delineation of MGMT promoter hypermethylation as a predictive biomarker for the A071102 clinical trial of veliparib combined with temozolomide (TMZ) using patient-derived xenograft (PDX) GBM models. *First Author: Jann Nagina Sarkaria, Mayo Clinic, Rochester, MN*

Background: Poly-ADP-ribose polymerase inhibitors have potent sensitizing effects in pre-clinical models. This study was focused on identifying potential biomarkers of response to TMZ combined with veliparib in GBM. **Methods:** The efficacy of 3 cycles of TMZ alone or combined with veliparib (dosed days 1-5 every 28 days) was evaluated in 27 PDX models grown as orthotopic xenografts, with 8-10 mice randomized to each treatment group. **Results:** The combination of veliparib and TMZ was associated with significant survival prolongation ($p < 0.05$ by log-rank) in 8 of 20 MGMT methylated PDXs lines (range: 20 to 150 d increase vs. TMZ alone), as compared to 1 of 7 MGMT unmethylated lines (GBM6: 7 d increase). Comparing the survival ratios (median survival with treatment vs. placebo) across all lines, veliparib/TMZ was associated with a greater efficacy in MGMT methylated lines, as compared to TMZ alone, with an average survival ratio of 4.0 ± 2.0 and 3.0 ± 1.1, $p = 0.0002$ respectively, as compared to 2.4 ± 1.7 and 2.4 ± 1.5, $p = 0.41$ in unmethylated tumors. For the 8 responsive methylated lines, treatment with veliparib/TMZ resulted in an average median survival of 188 days (d) as compared to 121 d with TMZ alone. Exogenously expressed MGMT in GBM12 (MGMT methylated; 75 d prolongation in survival with veliparib/TMZ) resulted in a complete loss of TMZ efficacy with or without veliparib (36 d vs. 34 d, $p = 0.87$). Similar association between MGMT expression and lack of efficacy was observed in GBM28 sublines with an intact vs. homozygous deleted MGMT locus. In comparing in vivo DNA damage signaling, co-treatment with veliparib/TMZ, relative to TMZ alone, resulted in greater phosphorylation of Kap1 (S824), Chk1 (S345), Chk2 (T68), and H2AX (S139) only in MGMT methylated (GBM12, 39) lines. **Conclusions:** While veliparib combined with TMZ conferred profound sensitizing effect in MGMT hypermethylated tumors, the combination was ineffective in unmethylated tumors. Based on these data, MGMT methylation is a predictive biomarker and entry criteria for the randomized Phase II/III A071102 clinical trial testing this combination in newly diagnosed GBM.

2053 Poster Session (Board #42), Mon, 1:15 PM-4:45 PM

The role of temozolomide (TMZ) in the management of anaplastic astrocytoma (AA): A comparison of survival in the era prior to and following TMZ. *First Author: Inas Abuali, Saint Agnes Hospital, Ellicott City, MD*

Background: Adding TMZ to radiation therapy (RT) is common clinical practice for patients with AAs despite the lack of prospective studies documenting a survival advantage. Two retrospective studies, each with methodologic limitations, provide conflicting advice regarding the optimal treatment strategy. **Methods:** This single-institution retrospective study was conducted to determine survival trends in patients with AA. All patients > 18 years with newly diagnosed AA treated at Johns Hopkins from 1995-2012 were analyzed. As we incorporated TMZ into high grade glioma treatment regimens in 2004, patients were divided into pre-2004 and post-2004 groups for analysis. Clinical, radiographic, and pathologic data were collected. **Results:** A total of 196 patients were identified; 74 pre-2004 and 122 post-2004; mean age 47 years (+/-15); 57% male; 87% white, 69% surgical debulking. Baseline prognostic factors did not differ between groups. Chemotherapy was administered to 12% (TMZ = 1, PCV = 2, gliadel = 6) of the pre-2004 patients and 94% (TMZ in all, $p < 0.001$) of the post-2004 patients. The median OS was 32 months (95%CI 23-43 mo) with the post-2004 group faring better (37 mo, 24-64) than the pre-2004 group (27 mo, 19-40). Multivariate analysis controlling for age, Karnofsky performance status, and extent of resection revealed a 37% reduced risk of death (HR 0.63, 0.44-0.91, $p = 0.015$) in patients with AA receiving TMZ. **Conclusions:** This retrospective analysis suggests a significant improvement in the survival of patients with AA receiving TMZ with RT. Until prospective phase III data is available, our findings support the use of TMZ in the management of newly diagnosed AA.

2054 Poster Session (Board #43), Mon, 1:15 PM-4:45 PM

GLIOSTRY (GLIOblastoma regiSTRY) of the AINO (Italian Association of Neuro-Oncology): Analysis of factors influencing survival in glioblastoma patients receiving the nitrosourea fotemustine at first relapse following Stupp regimen. *First Author: Roberta Ruda, Department of Neuro-Oncology, University of Turin and City of Health and Science, Turin, Italy*

Background: patients with glioblastoma failing radiotherapy plus temozolomide are treated in Europe with nitrosourea-based regimens, but factors influencing survival are not entirely known.We investigated the factors influencing survival in a large cohort of Italian glioblastoma patients who received the nitrosourea fotemustine (FTM) at first relapse following the Stupp regimen. **Methods**: survival data and information on demographics, clinical, radiological, molecular and treatments factors were collected in 34 Italian Institutions. PFS and OS curves were constructed using the Kaplan-Meier method and both univariate and multivariate analysis were performed . **Results**: Since 2005, 921 (587 M 334 F, median age 56 yrs) patients were enrolled , and up to date 897 are evaluable. Median PFS following FTM was 103 days. Factors of prognostic significance in univariate analysis were: MGMT methylation (129 d methylated vs 90 d unmethylated tumors, $p < 0.001$) and association with bevacizumab (148 d the association vs 97 d FTM alone, $p < 0.0001$). Both MGMT status with an HR of 0.64 (0.52-0.79), $p < 0{,}001$, and association with bevacizumab with an HR of 0.71 (0.56-0.92), $p < 0{,}008$, remained significant after multivariate analysis. Median OS following FTM was 197 days. Factors of prognostic significance in univariate analysis were age (200 d < 65 yrs vs 182 d > 65 yrs, $p = 0.0102$), Karnofsky Performance Score (213 d KPS 90-100 vs 182 d KPS ≤ 80), extent of initial surgery (213 d gross total vs 184 d partial removal, $p = 0.0022$), MGMT status (246 d methylated vs 176 unmethylated tumors, $p < 0.001$) and association with bevaizumab (238 d association with bev vs 187 d FTM alone, $p = 0.0297$). MGMT status with HR of 0.60 (0.48-0.76), $p < 0.001$, and association with bevacizumab with HR of 0.73 (0.56-0.95), $p = 0.022$, remained significant after multivariate analysis. MGMT methylation was the strongest factor influencing OS from initial diagnosis. **Conclusions**: MGMT is a strong prognostic and predictive factor in GBM patients following FTM. The association of bevacizumab with FTM could be superior over FTM alone.

2055 Poster Session (Board #44), Mon, 1:15 PM-4:45 PM

Phase II trial of bevacizumab in patients with surgery and radiation refractory progressive meningioma. *First Author: Sean Aaron Grimm, Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: Systemic treatment options are limited for meningiomas that progress following surgery and radiotherapy. VEGF is associated with neovascularization, tumor growth, and edema in meningioma. This prospective phase II study was undertaken to determine the efficacy of bevacizumab (BEV), a VEGF ligand binding monoclonal antibody, in patients with progressive benign (BM), atypical (AM), and malignant meningioma (MM) as measured by median 6-month progression free survival (PFS-6). Secondary endpoints included median progression free survival (mPFS), median overall survival (mOS), and radiographic response rate. **Methods:** Patients with histologically confirmed BM, AM, or MM with radiographic progression were eligible. There was no limit on prior therapies. BEV was administered 10 mg/kg intravenously every two weeks. After 6 months of therapy, stable patients were eligible to switch to an every 3-week schedule of BEV (15 mg/kg). Clinical examination and imaging were performed every 4 and 8 weeks respectively for the first 6 months then every 6-12 weeks. Responses were graded using the Macdonald criteria. **Results:** 40 patients were treated: 15 BM, 22 AM, and 13 MM. Median KPS was 80. Median age was 54 (23-81) years. Median number of BEV infusions was 16 (2-62). Grade 3 toxicities included hypertension (10), proteinuria (2), hyponatremia (2), fatigue (1), bruising (1), nausea/vomiting (1), epistaxis (1), pancreatitis (1), perianal infection (1), ataxia (1), and thrombus/embolism (1). Grade 4 toxicities included anemia (1), wound infection (1), elevated lipase (1), and weakness (1). Best responses were stable disease (BM: 100%; AM: 85%; MM: 82%); partial response (BM: 0%; AM: 5%; MM: 0%); progressive disease (BM: 0%; AM: 10%; MM:18%). PFS-6, mPFS, and mOS were 87%, 22.5 months, 35.6 months for BM; 77%, 15.3 months, not reached for AM, and 46%, 3.7 months, 12.4 months for MM. **Conclusions:** Treatment of progressive meningioma with BEV commonly leads to disease stabilization. The results are promising compared to a contemporary meta-analysis, in which PFS6 was 29% and 27% for BM and AM/MM respectively, but require confirmation. Toxicity was minimal and expected for BEV notwithstanding prolonged drug exposure. Clinical trial information: NCT01125046.

2056 Poster Session (Board #45), Mon, 1:15 PM-4:45 PM

Can Diffusion and Perfusion Weighted Imaging predict 1p/19q codeled lower grade gliomas? *First Author: Marica Eoli, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

Background: Several factors influence prognosis of lower grade gliomas, including age, histological diagnosis, 1p/19q chromosome arm deletion (codel 1p/19q), isocitrate dehydrogenase (IDH1/IDH2) mutations. Diffusion and Perfusion Weighted Imaging (DWI and PWI) have been proposed as candidates for survival predictors in glioma patients. **Methods:** To assess the association between mean rCBV, rADC and Cho/Cr ratio values and prognostic biomarkers, we investigated 51 supratentorial grade II (36) and III (15) gliomas by advanced MRI (aMRI), including PWI and DWI, before surgery. Surgical sample histological subtypes and molecular variants (loss of heterozigosity on 1p, 19q, 17p, 9p, 10q; IDH1/IDH2 mutations, O6 methylguanine DNA methyltransferase methylation) were evaluated. **Results:** rCBV and rADC had significantly different values in gliomas with and without 1p/19q gliomas ($2.87 \pm 2{,}4$ vs. 1.29 ± 0.93, $p = 0.01$; $1.55 \pm 0{,}26$ vs. 1.81 ± 0.6, $p = 0.02$ respectively), but not in wild-type and mutated IDH1/IDH2 or grade II and III gliomas ($p > 0.05$). Cho/Cr ratios were similar in all subgroups. All 1p/19q codeleted patients had mutated IDH1/IDH2. Univariate analysis showed significantly longer PFS in patients with 1p/19q codeletion (84 *versus* 51 months, $p = 0.013$), and shorter PFS and OS in wild type IDH1/IDH2 patients (10 *versus* 60 months, $p = 0.0001$; 33 *versus* 80 months, $p = 0.0001$), after a median follow-up of 60 months. The ROC analysis showed that cut-off values of 1.33 for maximum rCBV and 1.77 for minimum rADC could predict the 1p/19q status with 63.4% sensitivity and 90% specificity (area under the curve 0.72, 95%CI 0.58-0.84) and 65.9% and 80% (area under the curve 0.78, 95%CI 0.62-0.87), respectively. **Conclusions:** Maximum rCBV and minimum rADC thresholds could help to predict 1p/19q codeletion and to identify lower grade gliomas with a favorable prognosis.

2057 Poster Session (Board #46), Mon, 1:15 PM-4:45 PM

Is Next Generation Sequencing (NGS) Ready for Routine Clinical Practice in Gliomas? Results of a Prospective Study Utilizing the MSK-IMPACT Assay *First Author: Antonio Marcilio Padula Omuro, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NGS is becoming increasingly available but its relevance in clinical practice has been questioned. In this prospective, IRB-approved study (NCT01775072), we utilized the MSK-IMPACT assay to analyze gliomas in a routine practice setting. The MSK-IMPACT, performed in a CLIA-compliant laboratory, is a multiplexed assay (Illumina HiSeq) providing full exon coverage of 341 cancer related genes, detecting base substitutions, small indels, copy number and select gene rearrangements. **Methods:** After written consent, tumor and germline DNA were analyzed. Mutations were catalogued and compared to TCGA data. Comparison with other profiling methods, i.e. IHC (*IDH-1* R132H mutation), RT-PCR (*EGFRvIII),* Sanger sequencing *(IDH-1/2* mutations) and FISH (*EGFR* amplification, 1p/19q co-deletion) was performed. Participation in clinical trials was recorded. **Results:** N = 104 pts were enrolled (48 glioblastomas, 39 grade III, 9 grade II and 3 grade I gliomas). The mutational landscape was in line with TCGA, including mutations in *TERT* (59%), *TP53* (55%), *IDH-1* (35%), *ATRX* (27%), *PTEN* (22%) *EGFR* (17%), *PIK3CA* (12%) and *BRAF* (2%); four pts displayed a hypermutator genotype. MSK-IMPACT identified all *IDH1/2* mutations, including one *IDH2 R172K* in an IDH-1 R132H IHC-negative tumor. All pure oligodendrogliomas (N = 13) displayed 1p/19q codeletion on MSK-IMPACT. Three pts had 1p/19q codeletion on FISH but not on MSK-IMPACT, but mutational profile/ histology favored non-codeleted glioma, suggesting false-positive FISH results. All FISH *EGFR* amplifications were detected by MSK-IMPACT. Among *EGFR* amplified tumors, MSK-IMPACT disclosed *EGFRvIII* in 55%. To date, 33 pts have been enrolled in trials, including 4 extreme responders in whom results are guiding further drug development. **Conclusions:** NGS with MSK-IMPACT is a highly useful profiling tool, providing prognostic and therapeutically relevant information and guiding patient selection/ interpretation of clinical trials. Given lower cost, higher accuracy and wider range of information provided, this assay replaces with advantages other profiling tools, and is ready for incorporation into routine clinical practice. Clinical trial information: NCT01775072.

2058 Poster Session (Board #47), Mon, 1:15 PM-4:45 PM

Tumor profiling on 1245 gliomas and paired tumor study on 19 high grade gliomas. *First Author: Joanne Xiu, Caris Life Sciences, Phoenix, AZ*

Background: Gliomas are molecularly heterogeneous with genetic alterations driving the growth of recurrences different from the initial tumor. Previous reports showed molecular changes during progression of lower grade gliomas to GBM, driving tumor growth and treatment resistance; however changes during progression of high-grade gliomas have not been systematically reported. **Methods:** 1245 glioma tumors (934 GBM) were tested with multiple platforms including sequencing (SEQ), immunohistochemistry (IHC), fluorescent/chromogenic in-situ hybridization (FISH/ CISH), fragment analysis (FA) and promoter methylation (Me) assay. Metachronous paired tumors from 19 patients (pts) were assessed for biomarker changes over time. **Results:** EGFRvIII was seen exclusively in GBM (16% of GBM) while amplification was more common in GBM than grade II-III tumors (56% vs. 20%, $p < 0.001$). MGMT Me was seen in 47% of all, and was more common in grade II-III (64% vs. 42%, $p < 0.001$). PD-L1 expression on tumor cells was seen in 27% and was more common in tumors without MGMT Me (36% vs. 18%, $p = 0.01$). PD-1 expression on tumor-infiltrating lymphocytes was seen in 48% and was higher in GBM than grade II-III(54% vs. 30%, $p = 0.005$). 38 of 48 sequenced genes had mutations, including BRCA1 (8%) and BRCA2 (6%). 1p19q co-deletion was seen in 26% of grade II-III and 2.9% of GBM. Paired tumors from 19 pts (18 GBM and 1 grade III in both samples) taken at an average of 469 days apart (91-1400) showed that 17 pairs (89%) had one or more biomarker changes over time. 3 of 13 (23%) pairs lost MGMT Me, potentially indicating acquired resistance to temozolomide. EGFR aberrations including amplification (N = 1), mutations on the extracellular (EGFRvIII, N = 1) and intracellular domains (T790M, N = 1; Exon 20 insertion N = 1) were acquired in 3 pairs. One pt, presenting with a PTEN mutation, acquired three additional mutations: cKIT (E583K), PTPN11 (A72T) and PIK3CA (D434N). **Conclusions:** Multiplatform tumor profiling on a large cohort of gliomas confirms tumor heterogeneity. Changes in MGMT Me and EGFR of potential therapeutic importance are frequently observed in high grade gliomas at the time of recurrence, suggesting the need for a re-biopsy for tumor profiling to direct the next line of therapy.

2059 Poster Session (Board #48), Mon, 1:15 PM-4:45 PM

Tumor infiltrating lymphocytes associated with brain metastasis in breast cancer. *First Author: Nicole Olivia Williams, University Hosp/Case Western Reserve Univ, Cleveland, OH*

Background: Breast cancer represents the second most common cause of brain metastasis (BM). Though tumor-infiltrating lymphocytes (TILs) and immunotherapies have been studied in primary breast cancer, little is known about TILs in BM from breast cancer. The aim of this study is to characterize the immune response to BM in breast cancer. **Methods:** The cohort included 75 initial and recurrent BM samples and 20 matched primary breast tumors. Stromal (sTILs) were evaluated on H&E sections and scored according to international TILs working group guidelines and categorized as having no, low (1-5%), moderate (6-20%) or high (> 20%) TILs. Tumor DNA/RNA was extracted on corresponding archival FFPE material. Gene expression profiling was performed using Affymetrix Human Transcriptome Array 2.0 microarrays. PAM50 subtypes were assigned by clustering samples using median-subtracted PAM50 gene expression levels. Gene expression levels of programmed cell death 1 (PD1), programmed cell death ligand 1 (PD-L1), cytotoxic T-lymphocyte associated protein 4 (CTLA4), and forkhead box P3 (FOXP3) were compared in this cohort. **Results:** Of the 75 BM evaluated, 34 (45%) had no sTILs, 29 (39%) had low sTILs, 10 (13%) had moderate sTILS, and 1 (1%) had high sTILs. sTILs were significantly lower in the BM when compared with matched primary tumors ($p = 0.0025$). When comparing the level of BM sTILs in the PAM50 subtypes, the HER2-enriched subtype more commonly exhibited moderate to high sTILs compared luminal A, luminal B, and normal-like ($p = 0.065$). No association was seen between time to develop BM and % sTILs ($p = 0.68$). Though primary and BM were found to express both PD1 and FOXP3, only FOXP3 expression was found to be higher in primary tumors compared to BM ($p = 0.0025$). There was no association between PD1 and FOXP3 expression and PAM50 subtype or BM sTILS ($p > 0.05$). Significant PD-L1 and CTLA4 expression was not identified in primary tumors or BM. **Conclusions:** Overall, BM from breast cancer have relatively low sTILs expression. The expression of PD1 and FOXP3 in BM from breast cancer suggests that further investigation of the immune response in BM and clinical trials with immune checkpoint inhibitors should be considered for this poor prognosis population.

2060 Poster Session (Board #49), Mon, 1:15 PM-4:45 PM

Tumor profiles of brain metastases from NSCLC, breast cancer, and melanoma. *First Author: Santosh Kesari, UC San Diego, La Jolla, CA*

Background: An estimated 70,000 diagnoses of brain metastases (BM) occur each year in the U.S., with an incidence of 5-7% in breast and melanoma and 20% in lung cancer. Despite its prominence, the biology of BM remains poorly understood. Several theories of BM development exist, including the linear progression model, which suggests that the metastatic capabilities of tumor cells develop at primary sites following the accumulation of alterations. The parallel progression model argues that tumor cells disseminate early and accumulate changes independently at the secondary site. We compare the tumor profiles of BM from common cancers to understand the biology and to identify differential treatment strategies. **Methods:** Tumor samples were profiled using a multiplatform service (Caris Life Sciences, Phoenix, AZ), including sequencing (Sanger, NGS), protein expression (IHC) and amplification (ISH). **Results:** 5,391 NSCLC (293 BM, 5,098 lung), 3,595 breast cancer (99 BM, 3496 breast) and 761 melanoma (101 BM, 660 skin) unpaired samples were included. No significant differences were found in 48 genes between BM and the primary tumor sites, with the exception of PIK3CA in breast cancer, which was mutated less in BM vs. the breast samples (10% vs. 26%, p=0.02). In contrast, expression of TOP2A, TOPO1 and TS, and amplification of EGFR, were more prevalent in BM as compared to the primary sites (Table). **Conclusions:** A similar genetic landscape with limited differences was seen in BM of NSCLC, melanoma and breast cancer compared to primary tumors. The limited differences are more consistent with a linear progression model of cancer metastasis. Additionally ,this suggests that both primary tumor and BM would respond to similar chemotherapeutics with the consideration of effective blood-brain barrier-penetrant drugs. Small molecule inhibitors of EGFR could be considered due to increased EGFR amplification and the higher TOP2A, TOPO1 expression prompts consideration of topoisomerase inhibitors like etoposide or irinotecan.

	Brain met %	Primary met%	P
NSCLC

2061 Poster Session (Board #50), Mon, 1:15 PM-4:45 PM

A phase I trial everolimus and sorafenib in patients with recurrent high-grade gliomas: Brain Tumor Treatment Collaborative trial 09-01. *First Author: Jeffrey J. Raizer, Lurie Comp Cancer Ctr of Northwestern Univ, Chicago, IL*

Background: Limited treatment options exist for patients with recurrent Malignant Gliomas (MG), especially after failing Bevacizumab (BEV). Signal transduction pathways involved in gliomagenesis provide therapeutic targets. Everolimus targets mTOR which is an important node downstream from PI3K and Akt. Sorafenib targets Raf, as well as VEGF and PDFG. The rationale for combining these agents is to inhibit two parallel pathways simultaneously. We performed a phase I trial of Everolimus and Sorafenib in patients with recurrent malignant gliomas in preparation for a phase II study. **Methods:** Patients with recurrent MG $>$ 18 yrs, KPS $\geq$ 60, adequate hematologic, renal and hepatic function and no history of HIV or hepatitis were eligible. No limit on prior relapses and BEV exposure was allowed. Enzyme inducing seizure drugs were not allowed. A 3 + 3 dose escalation was used to determine the MTD, defined as the highest dose combination resulting in 0/3 or 1/6 patients experiencing a DLT. The starting dose was Everolimus 5 mg a day + Sorafenib 400 mg twice a day with a plan to increase to a maximum dose of 10 mg a day and 800 mg twice a day over several defined dose levels. A de-escalation level was Everolimus 5 mg/day + Sorafenib 400 mg twice a day for 7 days on and 7 days off. **Results:** 11 men and 2 women were enrolled with a median age of 50 years (19-66) and median KPS of 80 (70-100). All patients had a GBM with 7 receiving prior BEV therapy. In cohort 1, 3 of 6 patients experienced a DLT which were grade 3: fatigue, chest pain, HTN, elevated ALT, hypercholesterolemia and hyperglycemia and one grade 4 hypertriglyceridemia. Dose de-escalation occurred with 1 of 7patients having a DLT of myositis, nausea, fatigue, hypertension and hypercholesterolemia-all grade 3. All patients have died due to disease progression with a median PFS of 4 weeks and OS of 20.9 weeks. **Conclusions:** This phase I study determined the phase II dose in patients with recurrent malignant glioma to be Everolimus at 5 mg daily and Sorafenib at 400 mg BID 7 days on and 7 days off. A phase II trial is on-going investigating this regimen in Bev naive recurrent anaplastic gliomas and GBMs as well as recurrent GBM who failed BEV. Clinical trial information: NCT01434602.

2062 Poster Session (Board #51), Mon, 1:15 PM-4:45 PM

Phase IB trial of carboxyamidotriazole orotate (CTO) and radiotherapy (RT) with concurrent and adjuvant temozolomide (TMZ) in newly diagnosed glioblastoma (GBM). *First Author: Alissa A. Thomas, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CTO is an oral inhibitor of non-voltage-dependent calcium signaling that results in simultaneous modulation of several receptor-mediated signaling pathways. A single-agent phase I trial determined the maximum tolerated dose (MTD) at 427 mg/m2, with a safe toxicity profile. A phase IB in combination with TMZ for recurrent malignant glioma found therapeutic brain tissue concentrations and early evidence of activity, with radiographic responses and median survival of 15 months, prompting this newly diagnosed disease study. **Methods:** Following a 3+3 design, pts were enrolled to receive escalating doses of daily CTO (219-481mg/m2) added to the standard GBM RT regimen (60 Gy concurrent with TMZ 75 mg/m^2 daily, followed by adjuvant TMZ 150-200 mg/m2 X5/28 days). **Results:** All enrolled pts (N = 15) had GBM (methylated MGMT: 33%; unmethylated: 67%). Next generation sequencing (N = 9) showed mutations involving *TERT* (56%), *EGFR* (33%), *IDH-1* (22%) and *TP53* (44%), among others. ChemoRT was well tolerated at CTO doses of 219-481 mg/m^2, with no dose-limiting toxicities (DLT) observed during the DLT period; adverse events included fatigue, nausea, constipation and headache. DLTs were however observed beyond the DLT observation period, and after RT: Gr 3 febrile neutropenia (N = 2), gr 4 neutropenia (N = 1), gr 4 platelets (N = 1) and gr 3 ALT/AST (N = 1). This prompted a halt in dose escalation at 481 mg/m^2 (declared the maximum administered dose, MAD) and expansion of a lower dose level (370 mg/m^2). Efficacy evaluation is ongoing, with one confirmed partial response and stable diseases for 7+ cycles. PK data confirmed therapeutic levels starting at 219 mg/m^2. Tissue and DCE-perfusion MRI correlates are ongoing. **Conclusions:** CTO in combination with RT and TMZ is safe and well tolerated. The MAD dose was 481 mg/m2 and recommended phase II dose is 370 mg/m2, although further evaluation of this dose level and longer follow up may be warranted. Further phase IB studies of CTO should consider designs such as continuous reassessment method, which better address late toxicities in comparison to a 3+3 design. Given encouraging signals of activity, a randomized study is warranted. Clinical trial information: NCT01107522.

2063 Poster Session (Board #52), Mon, 1:15 PM-4:45 PM

Decision support needs analysis in newly diagnosed malignant glioma. *First Author: Lara Kunschner Ronan, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Standard treatment pathways exist for malignant glioma, but are largely palliative. Patients face difficult non-curative treatment decisions. Oncologists may misinterpret patient goals or communicate ineffectively the risks/benefits of treatments. Shared Decision Making in which the patients' values and goals are incorporated into informed consent is ideal in this situation. **Methods:** Ten patients, caregivers and two treating physicians completed questionnaire-based interviews exploring patient perceptions and understanding of standard of care treatment recommendations in the outpatient clinical setting after receiving a post-surgical diagnosis of malignant glioma. Cognitive dysfunction was evaluated with neurological examination, Trail Making Test and Hopkins Verbal Learning Test. Physical and emotional distress was scored with the FACT-BR and KPS. **Results:** Ten patients patients participated. Common themes in the patients' interviews were 1. Fear of "doing nothing", "chemotherapy", loss of function/QOL; 2. Misperception of improvement in prognosis with treatment; 3. Loss of autonomy in decision making to physician and family members; 4. Lack of perception of any options; 5. Need for validation in decision making; 6. Lack of perception of dis/advantages of treatment. All patients and caregivers desired more information than was provided. Patients and caregivers who expressed interest in a second opinion did so with the goal of validating what the treating physician was recommending to improve confidence that the patient was making the "right" decision. The physicians emphasized the expected advantages of improved survival. Physicians and caregivers perceived increased patient independence in decision making than did patient. **Conclusions:** Patients had difficulty formulating and discussing the treatment information provided in a verbal format. While the information given met criteria to form the basis for informed consent and the physicians believed that Shared Decision Making occurred, in fact there was poor understanding of prognosis, advantages and disadvantages of standard of care treatment and patients felt little autonomy. A decision tool to incorporate patients' concerns is under development.

2064 Poster Session (Board #53), Mon, 1:15 PM-4:45 PM

Clinical outcome of adult brainstem glioma treated with concurrent chemoradiotherapy: An institutional experience. *First Author: Haresh Kunhiparambath, All India Institute of Medical Sciences, New Delhi, India*

Background: Brainstem glioma (BSG) is an aggressive tumor of adulthood. Treatment outcomes remain dismal and role of concurrent chemoradiotherapy (CTRT) is not established in these patients .We intended to study the clinical characteristics along with outcome of adult BSG patients treated with CTRT. **Methods:** We retrospectively evaluated 29 patients, age more than 18 years, with BSG treated at our department in the period Jan 2007 to December 2012. Demographic and disease characteristics in this patient cohort were recorded, and their progression free survival (PFS) was analyzed with respect to sex, grade, use of CTRT and adjuvant chemotherapy. **Results:** Median age at presentation was 35 years (range 22-66 years), with a male: female ratio of 2:1.18 patients presented with gait ataxia and 16 presented with cranial nerve palsies.18 patients were diagnosed radiologically as low grade. None of the patient underwent surgery. Radiotherapy dose was 56-60 Gray over 5.5 -6 weeks at 1.8-2 gray/fraction. All patients completed their radiotherapy. 11 patients received concurrent Temozolomide (75 mg/m2), 10 patients received adjuvant Temozolomide (150-200 mg/m2 D1-5 q4 weeks for 3-6 cycles) and 6 patient received both concurrent and adjuvant Temozolomide. Median follow up duration was 9.77 months (range 0.3-54.82 months). At last follow up, 27 patients had progressive disease. Median PFS for the entire group was 64.19 months. PFS was significantly poorer in the patients who received concurrent Temozolomide than those who did not (Median PFS 64.19 vs. NR months; p = .016) on Univariate analysis. Sex, grade, and adjuvant chemotherapy did not statistically alter treatment outcomes. **Conclusions:** Outcome of adult BSG is better in our cohort compared to reported results. CTRT with Temozolomide has detrimental effect on survival and its use should be discouraged. Radiotherapy alone with standard fractionation remains the treatment of choice in inoperable adult BSG.

2065 Poster Session (Board #54), Mon, 1:15 PM-4:45 PM

A phase II study of the combination of BKM120 (buparlisib) and bevacizumab in patients with relapsed/refractory glioblastoma multiforme (GBM). *First Author: Kent C. Shih, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: BKM120 is an orally bioavailable, pan-class I PI3K inhibitor that is known to cross the blood brain barrier. The PI3K pathway is frequently dysregulated in GBM patients causing abnormal cell growth and proliferation. This phase II multicenter study evaluated the combination of BKM120 with bevacizumab in patients with relapsed/refractory GBM. **Methods:** Patients with relapsed/refractory GBM following 1st line radiation/chemotherapy and surgical resection were treated with BKM120 60 mg PO daily and bevacizumab 10 mg/kg IV every 2 weeks of each 4 week cycle. Following an amendment, responses were evaluated every 8 weeks per RANO criteria; prior to this amendment, responses were assessed by MacDonald criteria. Treatment continued until disease progression or intolerable toxicity. The primary endpoint was median PFS. Secondary endpoints included RR, OS and toxicity. **Results:** Sixty-eight patients were treated with a median age of 57 years (range, 19-77). 13 patients (19%) had received prior bevacizumab. Median treatment duration was 16 weeks (range, 1-120); 6 patients (9%) remain on treatment. Disease progression (51%) and toxicity (13%) were the most common reasons for treatment discontinuation. Overall RR was 32% (CR, 2; PR, 20); 18 patients (26%) had stable disease. In patients who received prior bevacizumab, 1 patient each experienced a CR and a PR and 4 experienced SD for a clinical benefit rate (CR+PR+SD) of 46%. Median PFS and OS (95% CI) were 5.3 months (3.8, 7.5) and 10.8 months (9.1, 22) respectively. Treatment-related toxicities included fatigue (37%), hyperglycemia (26%) and increased ALT (25%); 1 patient experienced grade 4 hyperglycemia. Forty patients (59%) experienced CNS symptoms while on study, 5 (13%) of which were treatment-related grade 3 toxicities: mood alteration, suicidal ideation, altered mental status, confusion, and psychosis (1 patient each). **Conclusions:** The combination of BKM120 and bevacizumab was well-tolerated and clinical activity was observed, including 6 patients who received prior bevacizumab. Accrual to this study in patients previously treated with bevacizumab continues. Clinical trial information: NCT01349660.

2066 Poster Session (Board #55), Mon, 1:15 PM-4:45 PM

The effect of regadenoson-induced transient disruption of the blood brain barrier on temozolomide delivery to rat brain parenchyma. *First Author: Sadhana Jackson, Johns Hopkins Univ, Baltimore, MD*

Background: The blood-brain barrier (BBB) poses a serious challenge of effective delivery of systemically administered agents to the central nervous system. Temozolomide is the only systemically delivered chemotherapy to significantly improve survival in patients with glioblastoma with brain concentrations of only 20% of that in blood. Regadenoson is an FDA approved adenosine receptor agonist used for cardiac stress testing, yet has demonstrated transient disruption of rodent BBB allowing dextran (70kD) brain entry. This study was conducted to determine if regadenoson could facilitate entry of temozolomide into normal rodent brains. **Methods:** Temozolomide (50 mg/kg) was administered by oral gavage to non-tumor bearing F344 rats. Two-thirds of the animals received a single dose of intravenous regadenoson 60-90 minutes later. All animals were sacrificed 120 or 360 minutes after temozolomide administration. Temozolomide concentrations were determined using HPLC/MS/MS. **Results:** At 120 minutes, brain temozolomide concentrations were significantly higher when given with regadenoson vs. alone (8.1 ± 2.7 μg/g and 5.1 ± 3.5 μg/g, $P < 0.05$), with a similar trend in brain:plasma ratios (0.45 ± 0.08 and 0.29 ± 0.09, $P < 0.05$). Brain and brain:plasma were increased without statistical significance 360 minutes after temozolomide administration. There was no difference in plasma temozolomide concentrations with or without regadenoson. **Conclusions:** These results suggest co-administration of regadenoson with temozolomide results in 60% higher temozolomide levels in normal brain without affecting plasma concentrations. This novel approach to increasing intracranial concentrations of systemically administered agents can potentially improve efficacy of therapeutic agents used for brain tumors and other neurologic disorders.

2067 Poster Session (Board #56), Mon, 1:15 PM-4:45 PM

Carboxyamidotriazole orotate (CTO) in combination with bevacizumab (BEV) for adult patients with recurrent malignant glioma post-BEV failure: Phase 1. *First Author: Annick Desjardins, Duke University Medical Center, Durham, NC*

Background: BEV is approved for the treatment of recurrent glioblastoma pts, but there is a lack of effective therapies once a tumor recurs on BEV. CTO, an oral inhibitor of non-voltage-dependent calcium signaling, modulates several pathways (EGFR, MEK, RAS, HDAC, HSP90, WNT/B-catenin, Akt, ERK, VEGF, Bcr-Abl). We postulated that combining CTO with BEV may result in greater VEGF inhibition and might allow salvage post-BEV failure. We are reporting on phase 1 of the study. **Methods:** Study objectives are to assess the maximum tolerated dose (MTD), dose limiting toxicity (DLT) and activity of CTO when combined with BEV among pts with recurrent WHO grade III or IV MG post-BEV failure. CTO dose escalation has followed a classical 3+3 design at a dose ranging from 225-642mg/m^2/day. BEV has been administered intravenously at 10mg/kg every 2 weeks. Pharmacokinetic (PK) sampling is performed during cycle 1 at each dose level. MRI of the brain is evaluated at baseline and every 8 weeks using RANO criteria. **Results:** To date, 15 pts have been enrolled on study. All pts have WHO grade IV MG. Median age at enrollment is 54 (32-66) years in eight females and seven males. Of the five pts treated at dose level 1 of CTO (225mg/m^2/day), three remained stable for 4 cycles and demonstrated CAI (the active moiety of CTO in plasma) levels of 2317 and 361 ng/ml. Of the six pts treated at dose level 2 (293mg/m^2/day), one pt remained stable for 7 cycles and one pt experienced a DLT, grade 3 hypertension and fatigue. Four pts were treated on dose level 3 (380 mg/m^2/day), but two pts were not eligible for MTD determination, as they discontinued CTO before the end of cycle 1 without experiencing a DLT. Grade 3 study-related adverse events included: fatigue (n = 1), soft tissue infection (n = 1), proteinuria (n = 2) and hypertension (n = 2). No grade 4 or 5 study-related adverse events have been observed. **Conclusions:** CTO, at a dose of 380mg/m^2/day, given in combination with BEV is safe thus far and tolerable. Non-evaluable pts for MTD are being replaced. Some pts having previously failed BEV have remained stable for a period of time on the combination. Further dose escalation is continuing to determine the Phase II dose. Clinical trial information: NCT01954030.

2068 Poster Session (Board #57), Mon, 1:15 PM-4:45 PM

Oncolytic polio/rhinovirus recombinant (PVSRIPO) against recurrent glioblastoma (GBM): Optimal dose determination. *First Author: Annick Desjardins, Duke University Medical Center, Durham, NC*

Background: The live attenuated oral (SABIN) serotype 1 poliovirus vaccine was modified to contain a heterologous internal ribosomal entry site stemming from human rhinovirus type 2, creating PVSRIPO. PVSRIPO recognizes nectin-like molecule-5, an oncofetal cell adhesion molecule and tumor antigen widely expressed ectopically in malignancy. We report results of a dose finding study evaluating PVSRIPO delivered intratumorally by convection-enhanced delivery (CED). **Methods:** Eligible patients were adults with recurrent supratentorial GBM; solitary tumor 1-5cm in diameter; ≥ 4 weeks after chemotherapy, bevacizumab or study drug; adequate organ function; KPS > 70%; and positive anti-polio titer. The original two-step continual reassessment method dose escalation was amended to decrease to dose level -1 after observing prolonged steroid use in patients treated on higher dose levels. **Results:** Thus far, 20 patients have been treated (1 each at dose levels 1 and 3, 7 at level 2, 2 at level 4, 4 at level 5 and 5 at dose level -1). One dose-limiting toxicity was observed; a grade 4 intracranial hemorrhage at catheter removal (dose level 5). Adverse events possibly related to study include: pyramidal tract syndrome (grade 3, n = 5; grade 2, n = 1; grade 1, n = 1), seizure (grade 3, n = 1; grade 2, n = 1; grade 1, n = 8), lymphopenia (grade 3, n = 1), headache (grade 2, n = 4; grade 1, n = 4), dysphasia (grade 2, n = 3; grade 1, n = 6), paresthesia (grade 2, n = 3; grade 1, n = 5), concentration impairment (grade 2, n = 1; grade 1, n = 9), fatigue (grade 1, n = 7); one each of grade 2 diarrhea and hyperbilirubinemia; and one each of grade 1 fever, cough, nasal congestion, ataxia, eye pain, diplopia, homonymous hemianopia, thrombocytopenia, anemia, nausea and vomiting. Twelve patients remain alive, with pts #1 and #2 now more than 33 and 31 months post-PVSRIPO, respectively. **Conclusions:** Infusion of PVSRIPO via CED is safe thus far and encouraging efficacy results are observed. We are determining optimal phase II dosing. Clinical trial information: NCT01491893.

2069 Poster Session (Board #58), Mon, 1:15 PM-4:45 PM

Targeting dopamine receptor 2 (DRD2) signaling in combination with temozolomide chemotherapy as a novel therapeutic concept in glioblastomas. *First Author: Tor-Christian Aase Johannessen, Kristian Gerhard Jebsen Brain Tumor Research Centre, Department of Biomedicine, University of Bergen, Bergen, Norway*

Background: Glioblastomas are highly resistant to therapy and carry a poor prognosis. Novel therapeutic strategies are urgently needed to improve patient outcome. This study was designed to identify drugs that would sensitize glioblastoma cells to temozolomide (TMZ) chemotherapy. **Methods:** A genome-wide RNAi synthetic lethality screen was performed in glioblastoma cells to identify functional gene sets that would potentiate the effect of TMZ. The Connectivity Map database was then interrogated to identify potential drug candidates that would induce corresponding changes in gene expression. The highest ranked prospective compounds were validated in combination with TMZ in low-throughput cytotoxicity assays. Based on these findings, the most promising compound, the established anti-psychotic agent Thioridazine, was evaluated further in combination with TMZ *in vivo* in a clinically relevant orthotopic xenograft model. **Results:** Thioridazine significantly improved TMZ sensitivity in established glioblastoma cell lines as well as patient-derived cells. The specific chemosensitizing effect of Thioridazine was due to antagonism of dopamine receptor 2 (D_2 receptor; DRD2). Inhibition of D_2 receptor signaling by Thioridazine decreased MAPK and PI3K/AKT/mTor pathway activity through a DRD2/β-arrestin-2/AKT signaling complex. Inhibition of this complex induced non-apoptotic cell death caused by impaired autophagy leading to catastrophic vacuolization. The combination of TMZ and Thioridazine significantly decreased intracranial glioblastoma growth, and improved survival of tumor-bearing mice compared to treatment with TMZ alone. **Conclusions:** Our findings demonstrate that the DRD2/β-arrestin-2/AKT signaling complex connects dopamine signaling to tumor cell survival. We have also identified a novel strategy to inhibit autophagy in glioblastoma cells by antagonizing the D_2 receptor. Due to the low toxicity of Thioridazine and its advantageous pharmacological properties, the presented work suggests that Thioridazine plus TMZ could be used for glioblastoma treatment in an adjuvant setting.

2070 Poster Session (Board #59), Mon, 1:15 PM-4:45 PM

A phase 1b/2 study of the combination of the IDO pathway inhibitor indoximod and temozolomide for adult patients with temozolomide-refractory primary malignant brain tumors: Safety analysis and preliminary efficacy of the phase 1b component. *First Author: Howard Colman, Hunstman Cancer Inst Univ of Utah, Salt Lake City, UT*

Background: Indoleamine 2, 3-dioxygenase (IDO) is a key immune-modulatory enzyme within the IDO pathway that inhibits CD8+ T cells and enhances the suppressor activity of Tregs. IDO is expressed in a large proportion of solid tumors including 50 to 90% of glioblastomas (GBM). High IDO expression is correlated with poor prognosis in GBM. IDO pathway inhibitors such as indoximod (1-methyl-D-tryptophan / D-1MT) can improve anti-tumor T cell response slowing the tumor growth *in vivo*. We have demonstrated a synergistic effect of indoximod when combined with temozolomide (TMZ) and radiation in a syngeneic orthotopic brain tumor model. This phase 1b/2study is designed determine the safety profile and maximal tolerated dose (MTD) of indoximod in combination with TMZ in recurrent refractory malignant brain tumors with subsequent expansion into a phase 2 portion evaluating efficacy of the combination. **Methods:** After progression to standard front line-therapy with TMZ, patients were enrolled in a 3+3 dose escalation study of indoximod (600, 1000 or 1200 mg twice daily orally) with a standard dose of TMZ (150mg/m^2 x 5 days). Indoximod was administered for all 28 days of each treatment cycle. **Results:** 12 patients were required to fully enroll all three dose cohorts with no DLTs requiring cohort expansion at lower doses. Median age was 48.5 years (27-62) with 5 female and 7 male. 83% had a diagnosis of GBM. 6 patients remain on study, the longest on cycle 12. Best responses in these previously TMZ-refractory patients to date include SD in 3 patients lasting between 5 and 10 months duration (ongoing) with one patient demonstrating a progressive, ongoing substantial reduction in tumor size, approaching RANO criteria for PR. No patients to date have experienced a reduction or delay in temozolomide dosing due to the addition of indoximod nor an indoximod related serious adverse event. **Conclusions:** The MTD for indoximod in this combination and setting was 1200mg twice daily. Expansion into the phase 2 portion is proceeding to evaluate the exciting preliminary observations made in this trial. Clinical trial information: NCT02052648.

2071 Poster Session (Board #60), Mon, 1:15 PM-4:45 PM

Identification of glioblastoma patients who stand to benefit from PARP inhibitor therapy. *First Author: Kerrie Leanne McDonald, University of NSW, Kensington, Australia*

Background: The development of effective targeted drugs for the treatment of glioblastoma (GBM) represents a major unmet need. Veliparib (ABT-888; Abbvie) inhibits both PARP1 and PARP2 (poly[ADP-ribose] polymerase). The successful clinical application of veliparib and other PARP inhibitors (PARPi) will be assisted by the identification of predictive biomarkers. **Methods:** Efficacy of veliparib in combination with radiotherapy (RT) was tested on a panel of primary and recurrent GBM patient-derived cell lines (PDCLs). In order to screen for potential biomarkers for PARPi we performed whole genome sequencing (WGS) on sensitive and resistant PDCLs and also measured the expression of 96 candidate DNA repair pathway genes using the RT2 Profiler PCR Array (Human DNA Repair; Qiagen) **Results:** Differential sensitivity to veliparib and RT were observed amongst the panel of PDCLs. Three out of sixteen PDCLs showed hypersensitivity to veliparib/RT. PDCLs sensitive to treatment exhibited a large number of structural variation (SV) events ($>$ 200). The average SV events identified in the resistant PDCLs were $<$ 50. We detected mutations in genes involved in mismatch repair (MMR): *MLH1*, *MSH2*, *MSH6* and *PMS2*. We also detected mutations in other genes involved in DNA maintenance such as *XRCC4*, *FANCA*, *FANCD2*, *ATR*, *RPA1*, *REV3L* and *PARP1* only in the sensitive PDCLs. **Conclusions:** Mutations in DNA maintenance pathways may be a method for selecting patients for therapies involving the combination of DNA damaging agents such as radiotherapy, and PARP inhibitors. Additionally, the signature associated with genomically unstable GBM may be a method of identifying potential responders to PARP inhibitor therapy.

2072 Poster Session (Board #62), Mon, 1:15 PM-4:45 PM

Prospective validation of cerebrospinal fluid (CSF) circulating tumor cells (CTC) to diagnose leptomeningeal metastasis (LM) from epithelial tumors. *First Author: Xuling Lin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The diagnosis of LM remains challenging, as standard diagnostic tools such as CSF cytology and MRI have low sensitivity. We previously showed that detection of CSF CTC by rare cell capture technology (RCCT) may be a more sensitive technique to detect LM from epithelial tumors at early stages. To validate those findings, we evaluated the performance of CSF CTC analysis in a new cohort of patients with a suspicion of LM. **Methods:** In this IRB-approved prospective study, patients with epithelial tumors who had clinical symptoms suspicious for LM were enrolled. All patients underwent MRI and CSF analysis through conventional cytology and enumeration of CSF CTC in that same sample.CSF CTCs were enumerated through an FDA-approved, EpCAM-based enrichment, utilizing RCCT immunomagnetic platforms and antibody covered ferroparticles (Janssen Diagnostics, Raritan, NJ). For the present analysis, samples were considered positive for CSF CTCs when there was at least one CSF CTC detected in a 3 mL sample ($\geq$ 0.33 CSF CTC/mL). Diagnostic performance of CSF CTC was evaluated; the gold standard was either positive CSF cytology or unequivocal findings on MRI. **Results:** 62 patients were enrolled (27 breast, 20 lung, 7 GU, 3 GI, 2 renal and 3 other carcinomas). Among these patients, 21 (34%) had LM based on CSF cytology (n = 8), MRI findings (n = 4) or both (n = 9). CSF CTCs were positive in 27/62 samples (median 19.3 CSF CTC/mL, range 0.3 to 66.7), achieving a sensitivity of 95%, compared to 81% for CSF cytology alone and 62% for MRI alone. There were 7 false positive CSF CTCs, all of which with one or fewer CSF CTCs/mL; specificity was 83%. The one false negative sample also had negative CSF cytology but LM was seen on MRI. **Conclusions:** Detection of CSF CTCs by RCCT is a highly sensitive (95%) method to establish the diagnosis of LM, with superior diagnostic performance as compared to CSF cytology or MRI. However, results showing one or fewer CSF CTCs/mL are of uncertain significance and may correspond to false positive results. Larger studies with longer followup and ROC analysis are needed to investigate alternative CTC enumeration cut-offs to improve specificity.

2073 Poster Session (Board #63), Mon, 1:15 PM-4:45 PM

IDH1 mutation status and outcome in clinical trials for recurrent glioblastoma. *First Author: Jacob Joseph Mandel, Baylor College of Medicine, Houston, TX*

Background: IDH1 mutated glioblastoma (GB) has a better prognosis than IDH1 wildtype GB. Clinical trials for recurrent GB currently do not stratify patients (pts) based upon IDH status. It is not known if pts with IDH1 mutated GB on clinical trials are more likely to have a higher 6-month progression free survival (PFS6) or radiographic response (RR) rate. **Methods:** A retrospective review of GB pts treated at MD Anderson Cancer Center between 2006-2012 identified 330 pts enrolled in recurrent GB trials. 93 pts (28%) either had PFS6 or a complete or partial RR per RANO criteria. 49/93(53%) pts with PFS6 or a complete or partial RR were found to have tumor tissue available for IDH1 testing. A matched cohort of pts on the same recurrent GB clinical trials with tissue for IDH1 testing but no PFS6 or RR was identified based on the specific clinical trial, age and KPS. 49 pts were identified for comparison resulting in a total of 98 patients. **Results:** IDH1 status was obtained in 92 (94%) pts of which 17 (18%) had an IDH1 mutation. Recurrent GB trial was at 1^{st}-4^{th} recurrence with 62% at 1^{st}, 26% at 2^{nd}, 8% at 3^{rd} and 4% at 4^{th}recurrence. Median time from GB diagnosis to recurrent trial was 8.4 months (mo) for IDH1 wildtype GB vs. 10.9 mo for IDH1 mutated GB ($p < 0.66$). PFS6 was seen in 26/49 (53%) pts of which 2 pts IDH status was unknown. 5/24 (21%) pts with PFS6 had IDH1 mutations compared to 5/24 (21%) pts of their matched cohort without PFS6. RR was found in 46/49 (94%) pts of which 4 pts IDH status was unknown. IDH1 mutation was present in 7/42 (17%) pts with RR compared to 10/42 (24%) pts of their matched cohort without RR ($p < 0.49$). For all patients, median PFS on a recurrent trial was 3.68 mo for IDH1 wildtype GB vs. 3.52 mo for IDH1 mutated GB ($p < 0.72$). Median OS on recurrent trial was 8.64 mo for IDH1 wildtype GB vs. 9.59 mo for IDH1 mutated GB ($p < 0.49$). **Conclusions:** IDH1 mutation status does not appear to be predictive of PFS6 or RR in recurrent GB trials. However, further examination in larger randomized prospective studies is needed.

2074 Poster Session (Board #64), Mon, 1:15 PM-4:45 PM

Analysis of BRAF alterations and molecular profiling in glioblastoma and astrocytoma. *First Author: Nadia Faiq, UC San Diego Moores Cancer Center, San Diego, CA*

Background: Although well characterized in pilocytic astrocytoma and pleomorphic xanthroastrocytoma, the prevalence of BRAF alterations in glioblastoma (GBM) and astrocytoma is not well established. Characterization of BRAF mutations in glioblastoma and astrocytoma may identify a subgroup of patients with sensitivity to BRAF inhibitors. **Methods:** DNA was extracted from 95 diffuse gliomas (grade II-IV) at our institution and an independent set of 714 gliomas, and was subjected to hybrid capture for 315 or 265 cancer-related genes plus select intronic regions. Sequencing was performed to a mean coverage depth of $>$ 500x and analyzed for the presence of base substitutions, insertions/deletions, copy number alterations, and rearrangements. **Results:** 7 of 95 gliomas (7.4%) analyzed harbored BRAF alterations; 6 (6.3%) were identified with either a V600E mutation (3 GBM + 1 gliosarcoma) or a D594G mutation (2 GBM). One glioma with a BRAF rearrangement was identified (astrocytoma grade II). There were no alterations found in oligodendrogliomas. Molecular profiles in all 6 tumors with BRAF point mutations were similar; all were wild type for IDH1/2 and exhibited CDKN2A/B loss. Conversely, the BRAF rearrangement was IDH1 mutated and CDKN2A/B intact. To confirm the frequency of BRAF alterations, an independent database of 714 gliomas was queried. Thirty-four (4.8%) tumors were found to have BRAF alterations, including 24 BRAF point mutations. Of those, 96% ($n = 23$) were IDH1/2 wild type and 83% ($n = 21$) harbored CDKN2A/B loss. Conversely, BRAF rearrangements and amplifications ($n = 10$) did not share this profile. 40% harbored IDH1/2 mutations and only 40% displayed CDKN2A/B loss. In our patients, 5 of the 6 with BRAF point mutations are alive. The median overall survival is 28.8 months (10.7-40.6). One patient with recurrent GBM and V600E mutation was treated with the BRAF inhibitor vemurafenib with a PFS $>$ 12 months. **Conclusions:** BRAF alterations occur in GBM and astrocytoma. BRAF point mutations are associated with a specific molecular profile, specifically IDH1/2 wild-type and CDKN2A/B loss. This profile identifies a molecular subgroup of gliomas that may exhibit improved survival and are amenable to targeted therapy with BRAF inhibitors.

2075 Poster Session (Board #65), Mon, 1:15 PM-4:45 PM

Targeting PTBP1 as a therapeutic strategy to reverse lineage-specific splicing of ANXA7 and ensuing EGFR activation in glioblastoma. *First Author: Markus Bredel, University of Alabama at Birmingham School of Medcn, Birmingham, AL*

Background: Tissue-specific splicing involves evolutionarily conserved, alternative exons many of which have functional features that influence cell signalling. The membrane-binding tumor suppressor ANXA7 belongs to a family of proteins involved in endosomal organization and function. ANXA7 contains an alternative cassette exon that shows high prevalence in neurons, but its functional consequence is not well understood. PTBP1 is a ribonucleoprotein that is normally repressed during neuronal development. **Methods:** We used integrated molecular genetic and cell biology analyses, animal modeling, and clinical patient profiles to characterize the role of splicing of ANXA7 during glioblastomagenesis. We examined the cellular and kinomic effects of a new class of PTBP1 modulators and their effects on ANXA7 splicing. **Results:** Lineage-specific splicing of the cassette exon in ANXA7 diminished endosomal targeting of the EGFR oncoprotein and enhanced glioblastoma (GBM) progression. ANXA7 splicing was mediated by PTBP1, which was highly expressed in GBMs due to loss of brain-enriched microRNA miR-124 and to PTBP1 amplification. The alternative ANXA7 splicing trait was present in precursor cells, suggesting that GBM cells inherit the trait from a potential tumor-initiating ancestor. PTBP1 overexpression portended a poor clinical outcome in patients with GBM. Targeting PTBP1 with an FDA-approved compound, identified by a cell-based high-throughput assay that reports on the splicing activity of PTB, reduced PTBP1 levels and reversed ANXA7 splicing and ensuing EGFR activation. It revealed a significant inhibitory effect on GBM cell viability that was enhanced by the addition of radiation. Drug derivatives exerted even more potent effects on cell proliferation alone and when combined with radiation. **Conclusions:** PTBP1 mediates lineage-specific splicing of ANXA7 and eliminates its tumor suppressor function, thereby promoting GBM progression. Pharmacologic targeting of PTPB1 reverses the splicing event and exhibits anti-proliferative effects that are augmented by concurrent radiation, offering a potential new avenue for future therapeutic modulation in glioblastoma.

TPS2076 Poster Session (Board #66a), Mon, 1:15 PM-4:45 PM

A phase I study of TPI 287 concurrent with fractionated stereotactic radiotherapy (FSRT) in treatment of brain metastases from advanced breast and non-small cell lung cancer (NSCLC). *First Author: Solmaz Sahebjam, Moffitt Cancer Center, Tampa, FL*

Background: TPI 287, a member of taxanes diterpenoid (taxoid) family, is a microtubule-inhibitor with significant cytotoxic activity. TPI 287 is not a P-glycoprotein substrate and therefore is able to circumvent resistance associated with the expression of the multidrug-resistance-1 (MDR-1) gene. Preclinical studies have demonstrated that TPI 287 crosses the blood brain barrier and reaches a therapeutic concentration in brain tissue. In vivo models of human breast cancer brain metastasis show that TPI 287 significantly reduces the formation of large brain metastases. The radiosensitizing effect of taxanes is well established. This report describes an ongoing phase I trial of TPI 287 concurrent with FSRT in patients (pts) with 1-3 brain metastases from histologically or cytologically confirmed advanced breast or NSCL cancer. **Methods:** This phase I study employs a standard 3 + 3 dose escalation design exploring 6 sequential dose escalation cohorts (NCT02187822). Pts with up to 3 untreated brain metastases (maximum diameter of each brain lesion $\leq$ 5 cm, maximum tumor volume $\leq$ 120 cc) from breast cancer or NSCLC are eligible. Eligible patients will be treated with FSRT to target brain metastases (25 Gy in 5 daily fractions). TPI 287 is administered intravenously once per week, for total of 3 doses. The first dose of TPI 287 is given concurrently with the first fraction of FSRT. Once the recommended phase II dose (RP2D) is determined, an additional 10 patients will be enrolled in an expansion safety cohort, for a planned total enrollment of 36 patients. The primary study objectives are to determine safety and the RP2D of TPI 287 administered concurrently with FSRT to brain metastases. Secondary endpoints include determination of the pharmacokinetics of TPI 287, preliminary antitumor activity (local control rate, distant intra-cranial control rate, progression-free survival) and evaluating effect of treatment on measures of quality of life. Study Progress: At deadline for abstract submission, 2 patients have been enrolled onto this study. Clinical trial information: NCT02187822.

TPS2077 **Poster Session (Board #66b), Mon, 1:15 PM-4:45 PM**

Phase II study to evaluate the clinical efficacy and safety of MEDI4736 in patients with glioblastoma (GBM). *First Author: David A. Reardon, Dana-Farber Cancer Center Institute and Harvard School of Medicine, Boston, MA*

Background: Programmed cell death ligand-1 (PD-L1) is widely expressed on antigen presenting cells (APC) and other immune cells. PD-L1 binds two important regulatory receptors on T-cells: programmed cell death-1 (PD-1) and CD80/B7. Targeting Programmed Death-1 (PD-1) and its ligand, PD-L1, have demonstrated promising anti-tumor activity among other challenging solid tumors and growing data implicates PD-1/PD-L1 signaling as a significant contributor to immunosuppression in glioblastoma (GBM). PD-1 is expressed by many GBM infiltrating lymphocytes while PD-L1 is expressed by 61-100% of GBM tumors. Furthermore, loss of the PTEN tumor suppressor gene, which occurs in 40-50% of GBM tumors, leads to increased transcription and expression of PD-L1 in GBM. These findings indicate that PD-L1 is an attractive and important therapeutic target in GBM. MEDI4736 (M), a human IgG1κ blocking monoclonal antibody against PD-L1, represents a compelling immune-mediated anti-tumor treatment for GBM. **Methods:** Phase II, multicenter, open-label study (NCT02336165) is evaluating the clinical efficacy and safety of M in GBM patients. Eligible patients include those who are newly diagnosed with unmethylated MGMT GBM scheduled for standard radiotherapy (Cohort A); Bevacizumab-naïve patients with recurrent GBM (Cohort B); and Bevacizumab-refractory patients with recurrent GBM (Cohort C). Cohort A patients will receive M at 10 mg/kg i.v. Q2W for up to 12 months beginning with standard radiotherapy. Cohort B will receive M at 10 mg/kg i.v. Q2W for up to 12 months as monotherapy. Cohort C will receive M at 10 mg/kg i.v. Q2W for up to 12 months in combination with continued bevacizumab at 10 mg/kg Q2W. Primary endpoints include overall survival (OS) at 12 months (cohort A), progression free survival rate at 6 months (PFS-6) (cohort B) and OS-6 (cohort C). Secondary endpoints are safety/tolerability, PFS, median OS, radiographic response, and quality of life (QoL) by EORTC QLQ-C30/BN20. Exploratory endpoints are patient neurologic function using the Neurologic Assessment in Neuro-Oncology (NANO) scale, as well as immuno-correlative biomarkers and pharmacokinetics. Clinical trial information: NCT02336165.

TPS2078 **Poster Session (Board #67a), Mon, 1:15 PM-4:45 PM**

An oxygenation agent and radiation sensitizer, dodecafluoropentane, for the treatment of glioblastoma multiforme. *First Author: Jason D. Lickliter, Nucleus Network Limited, Melbourne, Australia*

Background: Post-resected glioblastoma multiforme (GMB) patients were treated with dodecafluoropentane emulsion (DDFPe) to evaluate the pharmacokinetics (PK), safety and potential survival benefit in combination with the current standard of care: radiation therapy (RT) and temozolomide (TMZ). DDFPe is an oxygen transport agent, which carries more than 100x more oxygen than other tested fluorocarbons. Studies in tumor xenografts show that DDFPe increases tumor pO2 by up to 400% and mitigates radiation resistance (J Biomed Nanotechnology, Vol 11, No 2, Feb2015, pp. 274-281). **Methods:** DDFPe is being dosed using an accelerated escalation design with one patient per dose level. Eligible patients have previously-untreated GBM with residual enhancing tumor on an early post-operative MRI scan, ECOG score 0-2, satisfactory blood counts and adequate renal and hepatic function. Since an increase in the frequency and extent of radiation necrosis is a theoretical risk of increased oxygenation, the location and size of the radiation field must be assessed as having a manageable risk should radiation necrosis occur. NVX-108 is infused intravenously prior to each fraction of radiation (total 60 Gray in 30 fractions), with patients breathing carbogen gas (2% CO2 and 98% O2) concurrently. Blood samples are drawn to evaluate DDFP PK. Objective tumor responses are assessed with serial gadolinium-enhanced MRI scans using RANO criteria. In addition, molecular analysis of tumor biopsies and tissue oxygen level dependent (TOLD) MRI measurement of tumor oxygenation are being used as exploratory predictive and pharmacodynamic biomarkers. The dose escalation schedule will study NVX-108 doses between 0.05 and 0.35 mL/kg in 5 planned dose levels. Dose levels 1 and 2 have been treated without dose-limiting toxicity. Data will be presented summarizing current safety, PK and preliminary efficacy results, as well as our progress in qualifying TOLD MRI as a potential biomarker of tumor hypoxia and re-oxygenation by DDFPe. Clinical trial information: 2014/007283.

TPS2079 **Poster Session (Board #67b), Mon, 1:15 PM-4:45 PM**

CoaGlio IV Trial: Randomized, controlled, triple-blind, multinational phase III study of adjuvant prophylactic anticoagulation in patients with glioblastoma WHO IV. *First Author: Susanne Antje Kuhn, Hospital Ernst von Bergmann, Potsdam, Germany*

Background: Venous thromboembolism (VTE) is a preventable complication in cancer and represents the second most frequent death cause, despite widely available anticoagulants. Further, VTE was proven as paraneoplastic syndrome of tumors, which use the coagulation to support their own aggressiveness. Currently, no guidelines recommend long-term prophylactic anticoagulation, since no data exists to support the use of any officially approved anticoagulant drug. None of the currently available anticoagulants has been adequately tested for its VTE prophylactic power in a cancer patient population. This study aims at providing a rationale for the generation of prophylaxis and treatment guidelines of VTE in cancer patients. This study finally aims to support the long needed completion of paradigm change in oncology since its initial description as Trousseau's syndrome 150 years ago. **Methods:** The controlled, triple-blind, multinational phase III study randomizes pts. in a 1:1 fashion to receive either postop prophylactic anticoagulation with the oral factor X blocker apixaban (2.5mg b.i.d) or placebo over a 12-month-period in addition to the international first line standard therapy (radiochemotherapy with temozolomide (TMZ) + adjuvant TMZ). The power calculation is based on a 10% difference in overall survival, power at 80%, two-sided alpha level of 0.05, 5% drop out, requiring 530 patients over a two year period, with analysis performed two years after last patient recruited. Eligibility includes: adults, good performance status, newly diagnosed glioblastoma WHO IV, no major co-morbidities and no pregnancy. The primary endpoint is overall survival. Secondary endpoints include: progression free survival (PFS) at 6 and 12 months, median PFS, objective tumor response rate, frequency and mortality of VTE, safety and health related quality of life.Pre-treatment bio-resourcing of tumor and blood will enable further correlative translational studies. Progress to date: Trial activation in Fall 2015 at more than 20 centers in Europe and the United States. Trial registration: European Clinical Trials Database EudraCT 2015-000425-37. Clinical trial information: EudraCT: 2015-000425-37.

TPS2080 **Poster Session (Board #68a), Mon, 1:15 PM-4:45 PM**

Phase I study of plerixafor and bevacizumab in recurrent high-grade glioma. *First Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

Background: Although anti-angiogenic therapy for high-grade glioma is promising, responses are not durable. The SDF-1/CXCR4 axis may help mediate resistance to VEGFR inhibition. Plerixafor is a reversible CXCR4 inhibitor that has demonstrated growth inhibition in glioblastoma xenografts. **Methods**: We are conducting a Phase I study to determine the safety and tolerability of plerixafor in combination with bevacizumab in patients with recurrent HGG. In Part 1 of the study, a 3 x 3 dose escalation design to a maximum planned dose level of plerixafor 320 μg/kg on Days 1-21 and bevacizumab 10 mg/kg on Days 1 and 15 of each 28 day cycle was used. DLTs were determined during the initial 4 weeks of therapy and included drug-related Grade $\geq$ 3 non-hematologic toxicities and Grade $\geq$ 4 hematologic toxicities. Part 2 of the study is a surgical study to determine if plerixafor penetrates tumor tissue. **Results**: Part 1 of the study has been completed with 23 patients enrolled. Part 2 of the study is now open with 3 patients enrolled to date. For all 26 patients, the median age is 59 (23-72), median KPS 90 (70-100), 11 women (42.3%). In Part 1, no DLTs were seen at the maximum planned dose level of plerixafor 320 μg/kg + bevacizumb. Treatment has been well tolerated to date with one grade 3 hypophosphatemia and one grade 3 rectal fistula. Preliminary pharmacokinetic data on plerixafor from the first two cohorts compares well with historical PK data. **Conclusions**: Combination treatment with bevacizumab and plerixafor is well tolerated in HGG patients. No DLTs were encountered at the maximum planned dose level. To date, 3 of 10 planned patients have enrolled in the surgical cohort to examine tumor tissue penetration. Updated results as well as preliminary circulating biomarker analysis will be presented. Clinical trial information: NCT01339039.

TPS2081 **Poster Session (Board #68b), Mon, 1:15 PM-4:45 PM**

A phase I study of convection-enhanced delivery of nanoliposomal irinotecan using real-time imaging in patients with recurrent high grade glioma.

First Author: Nicholas A. Butowski, University of California, San Francisco, San Francisco, CA

Background: Cytotoxic drug delivery to high grade glioma (HGG) is limited by the blood brain barrier (BBB). Convection-enhanced delivery (CED) improves chemotherapy delivery by utilizing fluid convection, obviating the challenges of crossing the BBB while minimizing systemic toxicity. CED of a highly concentrated formulation of nanoliposomal irinotecan (MM-398, nal-IRI) has been optimized in animal models of brain tumors and shows superior anti-tumor activity compared to systemic delivery. A major advance in the application of CED is the development of real time CED, which utilizes an interventional MRI suite to visualize the CED process with the aid of a co-convected contrast agent, and thus allows for real time monitoring of drug delivery to the target. **Methods:** With support from a R21 grant, a Phase I study of CED of concentrated nal-IRI using real-time imaging in patients with recurrent HGG is currently open for enrollment. This is a 3+3 dose escalation trial, with dose levels of 20 mg, 40 mg, 60 mg, and 80 mg of nal-IRI, given via up to 3 catheters surgically placed in an intra-tumoral location. The MRI contrast agent gadoteridol (2 mM) will be co-infused via the same catheters. Interim safety, efficacy, and imaging response results will be presented. From the imaging data, the correlation of pre-infusion modeling of drug distribution with post-infusion imaging will be analyzed. This will also allow for determination of the total volume of distribution to volume of infusion (Vd:Vi) ratio for each infusion. Clinical trial information: NCT02022644.

2500 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

A pharmacokinetically (PK) and pharmacodynamically (PD) driven phase I trial of the pan-AKT inhibitor AZD5363 with expansion cohorts in *PIK3CA* mutant breast and gynecological cancers. *First Author: Udai Banerji, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: AZD5363 is a novel potent pan-AKT inhibitor ($IC_{50}$of AKT1, AKT2 and AKT3 of 3, 7 and 7nM respectively) with preclinical activity across a range of models. **Methods:** The trial had an adaptive design that allowed changes in schedule based on toxicity, PK, and PD findings. AZD5363 was administered orally (PO) twice a day (BID). Three schedules were explored: continuous dosing (7/7), four days a week, (4/7) and two days a week (2/7). PD biomarkers including pAKT, pGSK3β, and pPRAS40 were measured by IHC in pre- and post-treatment tumor biopsies. Once a RP2D was established, two expansion cohorts of *PIK3CA*-mutant ER+ve breast (B) and gynecological (G) cancers were explored. **Results:** 47, 21 and 22 patients were treated on the 7/7, 4/7 and 2/7 schedules respectively, with a further 27 and 18 patients recruited to the B and G cohorts to date. The MTDs of 7/7, 4/7 and 2/7 were 320mg BID, 480mg BID and 640mg BID respectively. The dose limiting toxicities (DLTs) were rash and diarrhea for 7/7, and hyperglycemia for 2/7. No DLTs were identified for 4/7. The most common causally-related adverse events $\geq$ CTC Grade 3 were hyperglycemia (20%), diarrhea (10%), rash (10%), nausea (3%) and fatigue (1%). PK profiles at the RP2D of 480mg BID (4/7) showed a multi-dose $C_{ss,max}$ of 1426ng/mL and $AUC_{ss}$of 7952ng.hr/mL, which were consistent with exposures that gave tumor regression in preclinical models. Pre- and post-treatment biopsies confirmed target engagement in tumor tissue, with an increase in pAKT and reductions in pGSK3β and pPRAS40. Based on toxicity, PK and PD profiles 480mg BID (4/7) was chosen as the R2PD for single agent AZD5363, with the option of using 640mg BID (2/7) as a pharmacologically active dose for future combination studies. Target lesion shrinkage was observed in 7/15 and 4/14 in the B and G cohorts respectively to date, and with RECIST responses in evaluable patients of 3/15 (20%) and 1/14 (7%). **Conclusions:** Based on toxicity, PK and PD data two intermittent schedules of AZD5363 have been identified for further exploration. Promising single agent activity has been seen in *PIK3CA*-mutant breast cancer providing support for ongoing combination studies. Clinical trial information: NCT01226316.

2501 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

First-in-human, phase I, dose-escalation study of selective PI3Kα isoform inhibitor MLN1117 in patients (pts) with advanced solid malignancies. *First Author: Dejan Juric, Massachusetts General Hospital, Boston, MA*

Background: PI3K signaling is aberrantly activated in many solid tumors; isoform-selective targeting may enable robust inhibition of this pathway in PIK3CA mutant tumors while sparing signaling in normal tissues. This study (NCT01449370) evaluated the safety, MTD, preliminary antitumor activity and pharmacokinetics/pharmacodynamics (PK/PD) of an investigational PI3Kα isoform-selective inhibitor, MLN1117. **Methods:** Pts age $\geq$ 18 with advanced solid tumors (except primary brain tumors) and known *PIK3CA* mutation status received oral MLN1117 once daily (QD, 100–300 mg) or 3 days per wk (MWF, 200–1200 mg, or MTuW, 200–900 mg) in 21-d cycles. Dose escalation proceeded via a 3+3 design based on cycle 1 (C1) DLTs. Plasma concentrations of MLN1117 for PK analyses were evaluated in C1. PI3K pathway biomarkers were assessed in skin biopsies via immunohistochemistry. **Results:** At data cut-off, 76 pts had enrolled; 24/29/23 pts to QD/MWF/MTuW schedules; median of 3 cycles per group. C1 DLTs occurred in: 2 QD pts (ALT/AST elevation), 4 MWF pts (ALT/AST elevation, hyperosmolar state, nausea, vomiting, diarrhea, dehydration, hyperglycemia and anorexia), and 1 MTuW pt (nausea). MLN1117 MTDs were 150 mg QD and 900 mg for MWF/MTuW. Grade $\geq$ 3 AEs occurred in 54/41/57% of QD/MWF/MTuW pts; 17/14/13% discontinued due to AEs and 13/10/0% died on study. MLN1117 (100–900 mg) exhibited a median T_{max} of ~4 h and a dose-dependent increase in exposure with moderate-high PK variability (mean %CV on $AUC_{0\text{-}24h}$ ~50–70%); wkly exposures in MWF/MTuW pts were ~4 times higher than QD dosing. Mean plasma $t_{1/2}$ was ~11 h with no appreciable accumulation in plasma. MLN1117 200–900 mg suppressed p4EBP1 and pS6 in skin by up to ~100% and 70–90%, respectively, at ~3 h post-single dose. Per RECIST, there were 3/1/0 PRs (QD/MWF/MTuW) in breast and gastric cancers; 4/7/5 pts had stable disease lasting 105–466 d. **Conclusions:** In this first-in-human study (n = 76), the safety profile of MLN1117 was acceptable for MWF/MTuW dosing $\leq$ 900 mg. MWF/MTuW schedules enabled higher doses and weekly exposures vs QD dosing. PD data indicate PI3K pathway inhibition. Objective responses show antitumor activity in advanced solid tumors (n = 4). Clinical trial information: NCT01449370.

2503 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Phase I studies of anti-ENPP3 antibody drug conjugates (ADCs) in advanced refractory renal cell carcinomas (RRCC). *First Author: John A. Thompson, Seattle Cancer Care Alliance, Seattle, WA*

Background: ENPP3 is expressed in greater than 90% of clear cell (CC) and 70% of papillary (PAP) RCC and represents an interesting target in this disease. Hybridoma-derived AGS-16M8F and CHO-derived AGS-16C3F are fully human IgG2k monoclonal antibodies (mAbs), conjugated to microtubule disrupting agent MMAF via a plasma-stable linker, which bind to ENPP3. The 2 ADCs have similar pharmacokinetic and toxicologic profiles. **Methods:** Two phase I studies were conducted sequentially to test safety, PK, and antitumor activity (RECIST v1.1) of AGS-16M8F and AGS-16C3F in CC and PAP RRCC (median prior systemic therapies = 3). ADCs were given q3w until PD or unacceptable toxicity. **Results:** AGS-16M8F and AGS-16C3F studies treated 26 and 34 subjects in dose range 0.6 - 4.8 and 1.8 - 4.8 mg/kg, respectively. Fatigue was the most common adverse event (AE) in both studies. In the AGS-16M8F study, maximum tolerated dose (MTD) was not reached, but 3/8 subjects at 4.8 mg/kg discontinued for ocular toxicity (OT). OTs were most commonly reversible keratopathy. In the AGS-16C3F study, the initial dose of 4.8 mg/kg exceeded MTD; 2/2 subjects had dose-limiting toxicities (DLTs); 1 was grade 4 OT. OTs were also observed at lower doses, usually after 2 doses. This led to a successive de-escalation to 3.6, 2.7, and 1.8 mg/kg. Thrombocytopenia (TCP) was frequently reported but a DLT in only 1 subject at 3.6 mg/kg (AGS-16C3F). PK of both ADCs was comparable. Serum concentrations decreased multi-exponentially; exposure was dose proportional. In both studies, the mean terminal half-life was approx. 7-8 days for the intact drug and approx. 4 days for MMAF. **Conclusions:** Both ADCs tested had associated OT but it was more prominent with AGS-16C3F. However AGS-16C3F was well tolerated at 1.8 mg/kg and showed antitumor activity as evidenced by median disease control of 23+ weeks and durable PR in 2/10 of CC and 1/3 PAP RRCC. A phase II study is planned with AGS-16C3F at 1.8 mg/kg. Clinical trial information: NCT01672775.

2504 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Therapy of advanced metastatic lung cancer with an anti-Trop-2-SN-38 antibody-drug conjugate (ADC), sacituzumab govitecan (IMMU-132): Phase I/II clinical experience. *First Author: Michael J. Guarino, Helen F. Graham Cancer Center at Christiana Care Health System, Newark, DE*

Background: Sacituzumab govitecan (IMMU-132) is a new ADC comprising SN-38, the active metabolite of the topoisomerase inhibitor, camptothecin (irinotecan), conjugated to an anti-Trop-2 antibody. In vitro and in vivopreclinical data suggest that IMMU-132 is a unique ADC, being most efficacious at a high drug-antibody ratio (DAR) of 7.6, and capable of delivering up to 136-fold more SN-38 than its parental drug, irinotecan, in a human cancer xenograft. Trop-2 is widely expressed in most epithelial cancers, including non-small and small cell lung cancers (NSCLC and SCLC). Therefore, the safety and efficacy of this new ADC is being examined in advanced metastatic lung cancers. **Methods:** A phase I/II clinical trial (ClinicalTrials.gov, NCT01631552) is ongoing in subsets of previously-treated patients with metastatic lung cancer, administering IMMU-132 on days 1 and 8 of 21-day treatment cycles. Treatment is continued based on tolerance or until progression, with safety and response assessments made every week and at 8-12 weeks, respectively. Dose reductions and delays allowed most patients to continue treatment until progression. **Results:** Thirty-four lung cancer (15 NSCLC and 19 SCLC) patients with a median of 3 (range, 1-7) prior therapies were given IMMU-132 doses at 8 mg/kg (N = 22), 10 mg/kg (N = 10), 12 mg/kg (N = 2). Tumor responses, including squamous and adenocarcinoma NSCLC types having PR, are summarized in the table below. Neutropenia was the only Grade 3/4 toxicity (G3, 15%; G4, 3%). Other drug-related G3 toxicities included diarrhea (9%), anemia (6%), leucopenia (3%), lymphopenia (3%), pneumonia (3%), vomiting (3%), dizziness (3%). No differences were found between 8 and 10 mg/kg dosing. No pt developed antibodies (ELISA) to the conjugate. **Conclusions:** Repeated cycles of IMMU-132 monotherapy are well tolerated. Objective responses in previously treated metastatic lung cancer encourage further study of IMMU-132 in these cancers. Clinical trial information: NCT01631552.

Tumor type	PR	Disease stabilization (PR+SD)	Clinical benefit (PR+ SD) > 6 mo	Median TPP (Mo)
NSCLC (N = 15)	27%	73%	42%	3.3+
SCLC (N = 19)	26%	53%	29%	2.8+

2505 **Oral Abstract Session, Tue, 8:00 AM-11:00 AM**

A new anti-CEA-SN-38 antibody-drug conjugate (ADC), IMMU-130, is active in controlling metastatic colorectal cancer (mCRC) in patients (pts) refractory or relapsing after irinotecan-containing chemotherapies: Initial results of a phase I/II study. *First Author: Efrat Dotan, Fox Chase Cancer Center, Philadelphia, PA*

Background: Combination chemotherapies with 5-FU, irinotecan, oxaliplatin, anti-VEGF, and anti-EGFR agents have improved the outcome of mCRC pts. However, there is still an urgent need for better therapies to control this disease. IMMU-130 (labetuzumab govitecan), a conjugate of a humanized anti-CEACAM5 antibody, coupled site-specifically to SN-38 (7.6 moles SN-38/IgG) using a proprietary linker, is an attractive therapeutic option for mCRC pts. **Methods:** A phase I/II clinical trial (NCT01605318) was initiated in irinotecan- refractory/relapsed mCRC pts with an elevated CEA ($>$ 5 ng/mL), treated with IMMU-130 once- or twice-weekly at escalating 4-10 mg/kg dosages on weeks 1 and 2 of 3-week cycles. The primary objective of the study was determination of MTD, with secondary objectives of efficacy (by RECIST 1.1), PK and immunogenicity. Treatment was continued until disease progression or intolerance. **Results:** Between Feb 2013 and Nov 2014, 66 patients were enrolled. Median age was 57 years [39-82]. Median prior therapies were 5 [1-9], with 76% and 36% pts receiving prior bevacizumab and an EGFR inhibitor, respectively. Median number of cycles per pt was 2 [1-15]. Fifty-eight patients were evaluable for toxicity, with 3 DLTs (G3 typhlitis, G4 neutropenia and G3 nausea/vomiting $>$ 48h) in all pts. Grade 3/4 drug-related toxicities were found in 25% pts, including neutropenia (G3, 7%; G4, 3%), diarrhea (G3, 2%), anemia (G3, 3%) and lymphopenia (G3, 3%). The dose selected for further study was 10 mg/kg weekly or 6 mg/kg biw. No pt developed antibodies to the conjugate. Tumor reductions were seen in 23/66 (35%) pts, including one PR with 88% best tumor shrinkage still being treated for 52+ weeks, 6 pts with 20-30% tumor reductions, and 16 pts with 0-20% tumor reductions. **Conclusions:** Repeated cycles of IMMU-130 monotherapy had an acceptable toxicity profile. Tumor reductions were noted in 35% of patients despite prior relapse to irinotecan-containing therapies. These results encourage further evaluation of IMMU-130 in combination with other agents in mCRC. Clinical trial information: NCT01605318.

2506 **Oral Abstract Session, Tue, 8:00 AM-11:00 AM**

Dose escalation stage of a first-in-class phase I study of the novel oral ERK 1/2 kinase inhibitor BVD-523 (ulixertinib) in patients with advanced solid tumors. *First Author: Jeffrey R. Infante, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Aberrant MAPK pathway signaling and resultant ERK kinase activity is evident in many oncogene-dependent cancers, and persistent or reactivated ERK signaling is common in intrinsic and acquired drug resistance to approved RAF or MEK inhibitors. This first-in-human trial of BVD-523 (ulixertinib), a selective ERK1/2 kinase inhibitor, was initiated based on its promising preclinical profile. **Methods:** Patients (pts) with advanced solid tumors were recruited into an accelerated 3+3 dose escalation protocol. Primary study objectives included determination of dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), and recommended phase II dose (RP2D); secondary objectives included pharmacokinetic, pharmacodynamic, and preliminary efficacy assessments. **Results:** The dose escalation phase included 27 pts treated with BVD-523 at dose levels of 10, 20, 40, 75, 150, 300, 600, 750, and 900 mg twice a day. DLTs were observed in 5 pts: two with grade 3 rash, one with grade 3 pruritus and elevated AST, one with grade 3 diarrhea, vomiting, dehydration and elevated creatinine, and one with grade 2 hypotension, elevated creatinine, and anemia. The MTD was 600 mg twice a day. The most common adverse events included diarrhea, nausea, vomiting or constipation (89%), rash (any form), dermatitis, or pruritus (78%), fatigue (70%), decreased appetite (37%), dyspnea (33%), and anemia (26%). Pharmacokinetics were generally linear and dose proportional up to 600 mg twice a day. Phosphorylation of the ERK substrates RSK1/2 was inhibited in peripheral blood samples starting at 75 mg twice a day. Metabolic response was observed in 5 of 16 evaluable pts assessed by FDG-PET. One (1) of 26 pts assessed by CT had a best response of partial response, and 7 had stable disease for at least 3 months. **Conclusions:** The ERK 1/2 inhibitor BVD-523 (ulixertinib) achieved pharmacologically relevant exposure and manageable tolerability at its MTD of 600 mg twice a day. Additional safety and preliminary efficacy assessments are underway in a cohort expansion stage of this study in patients with specific tumor genotypes and clinical characteristics treated at the RP2D, as well as in additional phase I and phase II studies. Clinical trial information: NCT01781429.

2507 **Oral Abstract Session, Tue, 8:00 AM-11:00 AM**

Phase II study with Wee1 inhibitor AZD1775 plus carboplatin in patients with p53 mutated ovarian cancer refractory or resistant (<3 months) to standard first line therapy. *First Author: Suzanne Leijen, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: AZD1775 (formerly MK-1775) is a potent and selective inhibitor of Wee1, a kinase that phosphorylates CDC2. Phosphorylation of CDC2 inactivates the CDC2/cyclin B complex and is therefore essential for normal G2 checkpoint function. As most p53-deficient tumors lack a functional G1 checkpoint, they rely on the G2 checkpoint for cell cycle arrest in response to DNA damage. G2 checkpoint abrogation, using a Wee1 inhibitor may therefore sensitize p53 deficient tumor cells to DNA-damaging anti-cancer agents. In a phase I study the maximum tolerated dose (MTD) of AZD1775 in combination with carboplatin demonstrated target engagement (NCT00648648). **Methods:** Patients (pts) with p53 mutated ovarian cancer refractory or resistant ($<$ 3 months) to standard first line therapy (carboplatin plus paclitaxel) were re-exposed to carboplatin (AUC 5), plus 5 bi-daily doses of 225 mg AZD1775 in a 21 day cycle (MTD) (NCT01164995). p53 mutation status was analyzed by both sequencing analysis (TP53 exons 2-10) and AmpliChip TP53 array (TP53 exons 2-11). Response evaluation was performed according to RECIST 1.0, volumetric tumor measurement (enhanced RECIST) and CA-125 blood levels. **Results:** Bone marrow toxicity, fatigue, diarrhea, nausea and vomiting were the most common adverse events. Out of 24 pts enrolled, 22 pts were evaluable for study endpoints. As best response (RECIST 1.0), 6 pts (27%) showed confirmed partial response (PR) with a median progression-free survival (PFS) of 10.9 months. Nine pts (41%) had stable disease and 7 pts (32%) had progressive disease as best response, with a median PFS of 5.3 and 1.3 months, respectively. **Conclusions:** AZD1775 is a first in class Wee1 inhibitor that in combination with carboplatin is well tolerated and shows promising anti-tumor activity in p53 mutated ovarian cancer refractory or resistant ($<$ 3 months) to standard first line therapy. Clinical trial information: NCT01164995.

2508 **Oral Abstract Session, Tue, 8:00 AM-11:00 AM**

Phase II multicenter proof of concept study of AZD4547 in *FGFR* amplified tumours. *First Author: Elizabeth Catherine Smyth, Royal Marsden, London & Surrey, United Kingdom*

Background: *FGFR*1/2 amplification acts as an oncogenic driver in multiple cancers. We investigated the efficacy of AZD4547, a potent orally available selective inhibitor of *FGFR* 1,2 & 3 receptor tyrosine kinases, in *FGFR1/2* amplified cancers. **Methods:** This is a phase II Simon 2 stage design for patients (pts) with *FGFR1* (HER2 negative breast/NSCLC) or *FGFR2* (gastroesophageal) amplified tumors treated with AZD4547 80mg twice daily on an intermittent (2 weeks (wks) on, 1 wk off) or continuous schedule. Eligible pts had progressed following $\geq$ 1 line of prior therapy. *FGFR1/2* amplification was determined centrally using FISH. Primary endpoint is centrally reviewed confirmed response rate (RR), with the study concluding efficacy if $\geq$ 3/17 patients in a cohort had a confirmed response. PET-CT was performed at baseline, D14 and 8 wks, biopsy at baseline and D14 and optionally on progression. Biomarker assessment included phospho-immunohistochemistry, *FGFR* copy number variation in tumor and plasma, and whole exome sequencing. **Results:** We screened 285 pts with advanced cancer, identifying *FGFR1* amplification in 18% (20/111) HER2 negative breast cancer (BC), 9.5% (4/42) NSCLC, and *FGFR2* amplification in 7.6% (10/132) gastroesophageal (GC). Confirmed RR was 33% (3/9) in *FGFR2* amplified GC, and 12.5% (1/8) *FGFR1* amplified BC. All 3 GC responders had a PET response on D14 PET. GC responses were durable; time on treatment was 45, 29 and 27 wks with the last pt ongoing. Common toxicities (all grades and schedules) included fatigue (71%), mucositis (41%), nausea (35%), and nail changes (24%). Asymptomatic retinal pigmented epithelial detachment occurred in 1 pt. Phosphate was elevated in most pts. Exploratory analysis revealed all GC pts with PR had *FGFR2* FISH ratio $>$ 8. Elevated *FGFR2* copy number was detected in free plasma DNA of all GC pts with PR, and no non-responding pt. Analysis of progression biopsies in a responding GC pt identified acquired *KRAS* amplification in progressing disease. **Conclusions:** AZD4547 demonstrated high activity in *FGFR2* amplified GC and lower activity in *FGFR1* amplified BC. Assessment of *FGFR2* copy number in cell free plasma DNA may provide a screening tool to identify *FGFR2* amplified GC. Clinical trial information: NCT01795768. Clinical trial information: NCT01795768.

2509 Poster Discussion Session; Displayed in Poster Session (Board #225), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Preliminary results of TATTON, a multi-arm phase Ib trial of AZD9291 combined with MEDI4736, AZD6094 or selumetinib in EGFR-mutant lung cancer. *First Author: Geoffrey R. Oxnard, Dana-Farber Cancer Institute, Boston, MA*

Background: AZD9291 is an irreversible, mutant-selective EGFR tyrosine kinase inhibitor (TKI) developed to have potency against EGFR mutations, including T790M, while sparing wildtype EGFR. In the previous phase I study of AZD9291, EGFR-mediated toxicity was reduced compared to available EGFR-TKIs. We hypothesized that the safety profile of AZD9291 would permit combinations with other targeted therapies in a tolerable fashion. **Methods**: TATTON (NCT02143466) is a multi-arm phase Ib trial studying AZD9291 in combination with MEDI4736 (anti-PD-L1 mAb), AZD6094 (MET inhibitor) or selumetinib (MEK1/2 inhibitor; AZD6244, ARRY-142886). Eligibility required advanced EGFR-mutant lung cancer, progression on any prior EGFR-TKI, measurable disease, adequate PS (0-1) and organ function, and tissue for correlatives. In each combination, AZD9291 was dosed at 80 mg daily and the 2nd agent was escalated from a dose below the phase II monotherapy dose. Using a rolling 6 design, patients (pts) were randomly allocated to a combination arm. Data included here are preliminary and will be updated for presentation. **Results**: As of 8 January 2015, 42 pts have been enrolled on combination therapy (MEDI4736 = 14 pts; AZD6094 = 7 pts, selumetinib = 21 pts). All 3 combination agents were escalated to their phase II monotherapy doses; an additional arm continues to explore intermittent dosing of selumetinib. Adverse event (AE) data is currently available for 20 pts from all arms and cycles and includes mild/moderate AEs in 16 pts (6 skin, 5 laboratory, 2 gastrointestinal, 3 other) and severe AEs in 4 pts (1 skin, 1 laboratory, 1 gastrointestinal and 1 metabolism); 2 DLTs were reported (fatigue – AZD6094 arm; transaminase elevation – selumetinib arm). To date, 3 partial responses (PR) have been seen with AZD9291/MEDI4736, 2 PR with AZD9291/AZD6094, and 2 PR with AZD9291/selumetinib. Combination dose finding is expected to complete by May 2015. **Conclusions**: The toxicity profile of AZD9291 makes rational combinations with potentially synergistic targeted therapies feasible at biologically active doses. Expansion cohorts are planned for pts with acquired resistance to third-generation EGFR-TKI. Clinical trial information: NCT02143466.

2510 Poster Discussion Session; Displayed in Poster Session (Board #226), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

ABT-414 in patients with advanced solid tumors likely to overexpress the epidermal growth factor receptor (EGFR). *First Author: Glenwood D. Goss, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: Aberrant EGFR expression and signaling has been identified as a hallmark of cancer growth and survival. ABT-414 is an antibody-drug conjugate composed of the antibody ABT-806, targeting active EGFR/mutant EGFRvIII, linked to the anti-microtubule agent monomethylauristatin F. ABT-414 has shown potent antitumor activity in several EGFR-overexpressing tumor xenografts. This phase 1/2 trial evaluates the safety, pharmacokinetics (PK), and efficacy of ABT-414 in patients (pts) with solid tumors (NCT01741727). Herein, we report the ABT-414 maximum tolerated dose (MTD) and preliminary efficacy in an expanded cohort of pts with EGFR-amplified tumors. **Methods:** In the dose-escalation cohorts, pts (≥ 18 years) with advanced EGFR+ solid tumors received escalating doses of ABT-414 intravenously in 2 schedules, either on day 1 or on days 1 and 8 Q3W. Primary objectives included safety, determination of the MTD, the recommended phase 2 dose (RP2D), and the PK profile. In the EGFR-amplified cohort, pts received ABT-414 at the MTD to further assess ABT-414 safety and preliminary efficacy related to EGFR expression. **Results:** By 15 Dec 2014, 53 pts received ABT-414 (dose-escalation cohorts, n = 48; EGFR-amplified cohort, n = 5). Most common treatment-emergent adverse events (TEAEs) were blurred vision (49%, commonly due to transient microcystic keratopathy), fatigue (42%), nausea (42%), and dry eyes (36%). Most common grade 3/4 TEAEs were keratitis (8%), blurred vision (6%), dyspnea (6%), and hyponatremia (6%). Eye pain was the only DLT (n = 1 at 2 mg/kg Q3W). Due to several grade 3 ophthalmologic TEAEs in a single pt treated at 4.0 mg/kg, this dose was considered to exceed the MTD and the RP2D was set at 3 mg/kg Q3W. ABT-414 was the predominant circulating antibody with low levels of unconjugated ABT-806. PK exposure of ABT-414 appeared to be dose proportional. In the EGFR-amplified cohort, 1 partial response was observed (triple-negative breast cancer). Stable disease occurred in 11 of 53 pts (21%). **Conclusions:** The RP2D of ABT-414 (Q3W) is 3 mg/kg. The preliminary efficacy observed in pts with EGFR-amplified tumors suggests antitumor activity and warrants further investigation in this select population. Clinical trial information: NCT01741727.

2511 Poster Discussion Session; Displayed in Poster Session (Board #227), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Phase I expansion of S-222611, a reversible inhibitor of EGFR and HER2, in advanced solid tumors, including patients with brain metastases. *First Author: Sanjeev Deva, King's College London, London, United Kingdom*

Background: S-222611 is an oral, reversible ErbB tyrosine kinase inhibitor of EGFR and HER2 with potent pre-clinical activity. MTD was not reached during dose-escalation, even at the maximum dose of 1600mg QD. PK and efficacy data supported a daily dose of 800mg. A further cohort has been treated to further explore safety and efficacy. **Methods:** Subjects with advanced solid tumors expressing EGFR and/or overexpressing HER2 were enrolled. S-222611 was administered until disease progression or unacceptable toxicity. **Results:** 76 patients (33 male/43 female; median age 62 years [range 31-81], ECOG PS 0/1/2: 24/51/1), were included in this expansion phase, including breast (27), esophago-gastric (30), head & neck (12) and renal (7). Dose reduction was required because of adverse events in 11 patients (14%); the most frequent of such being diarrhea and elevated bilirubin. Only 2 patients discontinued treatment due to drug-related adverse events. Of the 41 patients with HER2-positive cancers (26 breast, 13 esophago-gastric, 2 head & neck), 1 complete response (gastric-esophageal junction cancer) and 5 partial responses (4 breast cancer, 1 gastric cancer) were observed; all these patients had received prior HER2-directed therapy. Prolonged stable disease (≥ 6 months) was observed in 3 additional patients with breast cancer. 6 of the 25 breast patients had brain metastases, in whom 1 intracranial response and 2 prolonged SD (≥ 6mo) were observed. In the EGFR+ve/HER2-ve cohort (n = 35), no RECIST responses were seen, however 4 patients had prolonged stable disease (≥ 6mo). **Conclusions:** S-222621 was well tolerated at a dose of 800mg once daily. Anti-tumour activity, including shrinkage of brain metastases, was evident in a heavily pre-treated population of patients with HER2-positive breast and esophago-gastric cancers. Clinical trial information: 2009-017817-31.

2512 Poster Discussion Session; Displayed in Poster Session (Board #228), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Safety and tolerability of increasing doses of CB-839, a first-in-class, orally administered small molecule inhibitor of glutaminase, in solid tumors. *First Author: James J. Harding, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Glutamine is required for the growth and survival of multiple tumor types. CB-839 is a highly selective, reversible, allosteric inhibitor of glutaminase, a choke point in the utilization of glutamine. CB-839 has broad in vitro and in vivo anti-tumor activity in solid and heme malignancies. **Methods:** CX-839-001 is an ongoing Phase 1 study of escalating doses of CB-839 in advanced and/or treatment-refractory solid tumor patients (pts) to evaluate safety and tolerability, and to identify the recommended Phase 2 dose (R2PD). CB-839 was administered orally continuously in 21-day cycles. Pharmacokinetics (PK) was monitored on Days 1, 15, and 22; pharmacodynamic (PD) assessment of glutaminase activity was measured ex vivo in platelets and tumor biopsies. Additional pts will be enrolled at the RP2D with triple negative breast cancer (TNBC), non-small cell lung adenocarcinoma (NSCLC), renal cell carcinoma (RCC), mesothelioma, and tumors with mutations in enzymes of the TCA cycle. **Results:** 35 pts were enrolled in dose escalation receiving CB-839 doses from 100 to 800 mg TID and 600 mg BID. Exposure increased less than dose proportionally but there was a clear PK/PD relationship with > 90% glutaminase inhibition in platelets when CB-839 exceeded 450 nM; target inhibition was confirmed in tumors. Radiographic stable disease (SD) was observed in 7 (28%) of 25 efficacy-evaluable pts (average duration 107 days; range 59-209) across all diseases and dose levels including TNBC (2/9 evaluable pts), NSCLC (2/4), mesothelioma (2/4) and RCC (1/3). Grade ≥ 3 treatment-related AEs occurred in 7 (20%) of pts, including ALT/AST (4 pts), creatinine, alkaline phosphatase, and GGT increases, lymphopenia, and hypoglycemia (1 pt each). A Grade 3 increase in creatinine considered unlikely related to CB-839 was a DLT at 250 mg TID. CB-839 was absorbed rapidly (T_{max} 1-2 hr fasted and 2-4 hr fed) and cleared with a half-life of about 4 hr. Plasma $C_{min}$was > 450 nM at steady state at the RP2D of 600 mg BID. **Conclusions:** Continuous CB-839 administration showed an acceptable safety profile, significant glutaminase inhibition and preliminary signs of clinical activity in multiple tumor types. Clinical trial information: NCT02071862.

2513 Poster Discussion Session; Displayed in Poster Session (Board #229), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

A first-in-human dose-escalation study of the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of oral 2-hydroxyoleic acid (2-OHOA) in adult patients (pt) with advanced solid tumors including grade III/IV glioblastoma multiforme (GBM). *First Author: Desamparados Roda, The Institute of Cancer Research and The Royal Marsden, London, United Kingdom*

Background: 2-OHOA, is a synthetic hydroxylated lipid that activates sphingomyelin synthase (SGMS) and regulates the lipid content of cell membranes resulting in translocation of Ras to the cytoplasm and inactivation of Ras/MAPK, PI3K/Akt and PKC/cyclin/CDK signaling pathways. 2-OHOA reduces tumor growth in xenograft mice models of prostate, leukemia, breast, colon, breast cancer, and GBM, and also crosses the blood brain barrier. This first-in-human trial was designed to determine the safety, tolerability, and recommended phase 2 dose (RP2D), alongside the PK, PD and anti-tumor profile of 2-OHOA. **Methods:** Eligible pts with advanced solid tumors or grade (G) III/IV GBM received 2-OHOA as a PO suspension, BID in 21-d cycles using a '3+3' dose escalation design. Adverse events (AE) were assessed by Common Terminology Criteria for AE v4; tumor response was assessed every 2 cycles using RECIST 1.1/RANO criteria. **Results:** 17 pts (median age 59 years; range 19-71; 7 GBM and 10 solid tumors) were treated at 5 dose levels: 250-, 500-, 1000, 2000 and 4000-mg BID. Treatment was well tolerated with toxicities limited to grade 1-2 nausea (n = 4), vomiting (n = 6) and diarrhea (n = 6). The PK profile was dose-proportional with no accumulation up to 2000mg BID; t1/2 = 4h. No effect of food was observed. One pt with GBM treated at 500mg BID has a confirmed and ongoing partial response and is currently at cycle (C) 23 of treatment; a 2nd GBM pt has SD after 2 cycles and continues on study. A 3rd pt with progressive mesothelioma demonstrated SD lasting to C15. **Conclusions:** 2-OHOA can be safely administered up to doses of 4000mg BID. Clinical benefit was observed in 3 patients including 1 PR in a pt with GBM. Dose escalation continues to determine a RP2D, followed by a RP2D expansion in patients with both solid tumors and grade III/IV GBM. Clinical trial information: NCT01792310.

2514 Poster Discussion Session; Displayed in Poster Session (Board #230), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Final results of ProGem1, the first in-human phase I/II study of NUC-1031 in patients with solid malignancies. *First Author: Sarah Patricia Blagden, Ovarian Cancer Action Research Centre, London, United Kingdom*

Background: NUC-1031 is a first-in-class nucleotide analogue utilising phosphoramidate chemistry to enhance anti-cancer efficacy and safety. In preclinical studies NUC-1031 demonstrated potent anti-cancer activity, generating high intracellular levels of the active cytotoxic di-fluorodeoxycytidine triphosphate (dFdCTP) by overcoming key drug resistance mechanisms associated with nucleoside analogues. **Methods:** This study was comprised of 1) dose escalation part: 3–8 patients (pts) per cohort received 5-15 minute IV infusion of NUC-1031 starting at 500mg/m^2 once weekly on days 1, 8, 15 in 4 weekly schedule (q4w), or 375mg/m^2 twice-weekly on days 1 & 5, 8 & 12, 15 & 19 q4w and 2) expansion part at the recommended Phase II dose (RP2D). Endpoints were (primary) safety and tolerability, (secondary) pharmacokinetics (PK), pharmacodynamics and efficacy. **Results**: ProGem1 enrolled 68 pts, mean age 56 (20 - 83 yrs), average 2.7 prior lines of chemotherapy (range 1 - 6) with 16 primary cancer types. Dose-limiting toxicities occurred in 4 pts: G4 thrombocytopenia (2); G3 elevated ALT (2). 25 SAEs were 'possibly/probably related' to study drug, and 2 > G2: elevated ALT (4) and lung infection (3). Commonest AEs ≥ G3 'possibly/probably related' were: neutropenia (16), fatigue (13), elevated GGT (10). NUC-1031 was stable, with plasma half-life of 8.3 hours. High intracellular levels of the active anti-cancer agent dFdCTP (Cmax = 475.5 μM/L) were rapidly achieved and maintained for 24 hours. Notable efficacy results were observed: 5 RECIST Partial Responses (10%); 33 Stable Disease (67%) for an ITT disease control rate (DCR) of 56% and on treatment analysis (OTA) DCR of 78%. PRs and SDs were observed in pts refractory/relapsed to prior nucleoside analogue therapy and were durable, mean PFS 6.1 months (range 2 – 20 mths). The RP2D was 825mg/m^2 given on days 1, 8, 15, q4w. **Conclusions**: NUC-1031 has demonstrated impressive clinical activity with durable DCR (ITT 56%; OTA 78%) in a wide range of patients with advanced and rapidly progressing disease. NUC-1031 is well-tolerated at the RP2D. Phase III clinical studies in ovarian, pancreatic and biliary cancers are planned this year and combination studies are currently recruiting. Clinical trial information: NCT01621854.

***TP53* mutations emerge in circulating cell-free DNA obtained from patients undergoing treatment with the HDM2 antagonist SAR405838.** *First Author: James Wilson Watters, Sanofi, Cambridge, MA*

Background: SAR405838 is an oral antagonist of HDM2 that results in p53 induction. In an ongoing Phase I study, p53 activation was demonstrated at doses that have an acceptable safety profile. We sought to develop a method for sequencing circulating cell-free DNA (ccfDNA) for the non-invasive monitoring of genetic changes in the tumor that may impact the activity of SAR405838 **Methods:** Baseline tumor and serially collected plasma samples were obtained from de-differentiated liposarcoma (DDLPS) patients undergoing treatment with SAR405838 at the maximum tolerated dose (300 mg QD). Tumor biopsies were sequenced using the Ion AmpliSeq Cancer Hotspot Panel v2 (Life Technologies). A custom next-generation sequencing targeted gene panel was developed for ccfDNA. Sequencing libraries were prepared using custom xGen Lockdown probes (IDT). Sequencing was performed using the Illumina HiSeq 2500. Mutations were determined using a custom pipeline combining calls from MuTec and Lofreq. Mutation confirmation was performed using RainDance droplet digital PCR. **Results:** Tumor and plasma samples were available from 18 patients. All tumors were determined to be *TP53* wild-type at baseline. From ccfDNA, greater than 10,000X coverage of target sequence was achieved. No *TP53* mutations were identified at variant allele frequency (VAF) > 1% in the baseline ccfDNA samples. 27 non-synonymous mutations in *TP53* were identified at VAF > 1% in ccfDNA from patients undergoing treatment. All *TP53* mutations were previously reported in COSMIC, and all are located in the DNA-binding domain of p53. Mutation VAF increased during treatment, and multiple *TP53* mutations arose within individual patients. All patients undergoing 5 or more cycles of treatment showed evidence of *TP53* mutations in ccfDNA. A subset of mutations was selected for validation and all were confirmed using digital PCR. **Conclusions:** *TP53* mutations appear in the ccfDNA of patients during treatment with SAR405838. This may represent the selection of *TP53* mutant clones that are resistant to HDM2 inhibition. This finding suggests that HDM2 antagonists should be combined with other mechanisms including agents active in p53 mutant tumors.

Genomic mutation profiling (GMP) and clinical outcome of patients treated with buparlisib (PI3K inhibitor) in the "Signature" program. *First Author: Sarina Anne Piha-Paul, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts included in the buparlisib (BKM120) module were analyzed by a tissue-agnostic genetic alteration–specific protocol that matches pts to treatments that target tumors harboring PI3K pathway–activated tumors. The pts are identified via standard of care physician-directed profiling. **Methods:** Pts with measurable advanced malignancies and no established standard therapy options were eligible. A local CLIA-certified test was sufficient for eligibility, and broad molecular profiling of pt tumors (confirmatory analysis of inclusion genetic alteration) was performed centrally post hoc. The primary objective was to assess clinical benefit (CB; CR + PR + SD at 16 weeks) by local investigator assessment. Buparlisib was given orally (100 mg once daily). Analysis correlating GMP with treatment outcomes will help determine the significance of these mutations. **Results:** GMP data were available for 76 pts across 19 tumor types (colorectal [14; 18%], sarcoma [11; 15%], ovarian [10; 13%], and head and neck [9; 12%]. Rare tumors included vaginal [1] and appendix [1]]. Median age: 60 years (range, 24-80), 49 women (65%), median number of prior therapies: 3 (range, 1-16). Baseline actionable alterations (local labs) included 38 PIK3CA mutations (50%), 17 PTEN mutations (22%), 16 PTEN losses (21%; IHC), 7 PIK3CA amplifications (9%), and 2 PIK3R1 mutations (3%). The concordance of baseline actionable alterations between local and central labs was 67%. Overall, 11 pts (15%) achieved CB. DNA from all pts was assayed by NGS, covering a panel of 288 cancer genes. Based on the assay, the tumors had a median of 4 mutations (range, 0-12) and tissue-specific patterns of mutation burden (lowest in cervix and sarcomas: 2; highest in colorectal and vaginal: 5+). The number of prior therapies did not correlate with the mutation load. Fewer mutations were noted in pts with CB. Most commonly altered genes (8+ pts): PIK3CA, PTEN, KRAS, TP53, APC, CDKN2A, RB1, and ERBB2. Aberrations in APC, BRCA2, CDKN2A, EP300, FBXW7, LRP1B, MLL2, PTEN, RB1, and SMAD4 were enriched in pts with no CB. **Conclusions:** Buparlisib showed activity in some pts, indicating that specific mutations may correlate with poor outcome. Clinical trial information: NCT01833169.

2517 Poster Discussion Session; Displayed in Poster Session (Board #233), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Alka-372-001: First-in-human, phase I study of entrectinib – an oral pan-trk, ROS1, and ALK inhibitor – in patients with advanced solid tumors with relevant molecular alterations. *First Author: Filippo G. De Braud, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: Entrectinib (formerly RXDX-101) is a potent and selective oral small molecule inhibitor of the TrkA/B/C, ROS1, and ALK kinases. Schedule A (fasted, 4d on/3d off for 3wks, 1 wk rest) demonstrated significant antitumor activity (ASCO 2014). This abstract reports completion of Sch A and two other ongoing dosing schedules (B and C). **Methods:** Pts with advanced solid tumors with molecular alterations in TrkA, ROS1 or ALK were treated in Sch B (QD) or Sch C (4d on/3d off), both in fed state. **Results:** 31 pts were treated in Sch A (N=19), B (N=6), or C (N=6). In Sch A, doses $>$ 800 mg/m^2 did not increase exposure significantly. Thus, accrual in Sch A was closed. Various dose levels (mg/m^2) were explored in Sch B [200 (n=3); 400 (n=3)] and Sch C [400 (n=3); 800 (n=3)]. 7 pts had objective responses: 6 PR, 1CR (see Table). We are the first to report clinical activity of a Trk inhibitor in a pt with *NTRK1*+ (encoding TrkA) CRC. Of 7 *ROS1*-rearranged evaluable/measurable NSCLC pts, 4 have had an objective response (ORR: 57%), with a median duration of 6+ months. Moreover, in *ROS1* pts treated at $\geq$ 400 mg/m^2, the ORR was 80% (4 of 5 pts). Entrectinib is well tolerated. The majority of pts reported G1/ G2 AEs. 13 pts reported $\geq$ G3 AEs. Asthenia and muscle weakness were possibly related $\geq$ grade 3 AEs (both reversible). No DLTs have been reported to date. In Sch A, entrectinib was readily absorbed and exposures increased dose-proportionally up to 800 mg/m^2. In fed state, entrectinib exposures were approx. 2x compared to fasted state. **Conclusions:** In this trial with entrectinib administered in 3 different dosing schedules, significant antitumor response was observed in pts with relevant molecular alterations, notably *ROS1*-rearranged NSCLC at doses $\geq$ 400 mg/m^2/day and the only *NTRK1* rearranged pt treated to date. Accrual in Sch B and C continues until RP2D is achieved, followed by dedicated studies in selected tumor types. Clinical trial information: NCT02097810.

Objective responses.

Tumor type (alteration)	Sch/Dose (mg/m^2)	Best Response	Duration of Response (cycles)
NSCLC (*ALK*)	A/800	PR	10
NSCLC (*ROS1*)	A/1200	PR	14+
	C/400	PR	7+
	C/400	CR	5+
	B/400	PR	3+
CRC (*NTRK1*)	A/1600	PR	3
Neuroblastoma (*ALK*)	A/800	PR	9

2518 Poster Discussion Session; Displayed in Poster Session (Board #234), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

First-in-human, phase I study assessing imalumab (Bax69), a first-in-class anti-oxidized macrophage migration inhibitory factor (oxMIF) antibody in advanced solid tumors. *First Author: Devalingam Mahalingam, Cancer Therapy and Research Center, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: MIF is a pleiotropic cytokine involved in tumor proliferation, invasiveness, angiogenesis, and the proinflammatory microenvironment. oxMIF is the pathogenic form mainly in tumor and its surrounding stroma. Imalumab (Bax69) is a novel recombinant, fully-human, monoclonal antibody that targets oxMIF, inhibiting tumorigenesis. Preclinical data demonstrated that Imalumab has antitumor activities and acceptable toxicities. **Methods:** The primary endpoint of this dose-escalation study (3+3 design) was to assess maximum tolerated dose (MTD). The secondary endpoints were to assess antitumor activity, safety, pharmacokinetics (PK), and pharmacodynamics (PD). Patients (pts) received intravenous (IV) Imalumab [28-d cycles; 2 dose schedules (DS)]: biweekly in all solid tumors (DS1); weekly in metastatic colorectal cancer (mCRC) (DS2). **Results:** As of Dec 2014, 28 pts were analyzed. DS1 = 19pts in 6 cohorts (1, 3, 10, 25, 37.5, and 50 mg/kg), and DS2 = 9 pts in 2 cohorts (10& 25 mg/kg). AUC and C_{max}increased with dose. Dose escalation was stopped at 50 mg/kg (DS1) and 25mg/kg (DS2). An MTD was not reached for either DS. One pt reported dose-limiting toxicities: hypersensitivity pneumonitis (DS1; 50 mg/kg). There were no other grade 3 & 4 treatment related adverse events (trAEs). Grade 2 trAEs include: fatigue (n = 2), peripheral edema (n = 1), infusion reaction (n = 1), urticaria (n = 1). About 86% of pts had no trAE $>$ G1. Stable disease (SD) $\geq$ 4 mo was seen in 7 heavily pre-treated pts, including 1 pt with NSCLC who achieved SD $>$ 13.4 mo. In DS2; Pre- and on-therapy tumor biopsies showed satisfactory tissue penetration of Imalumab with regulation of PI3K-AKT-mTOR downstream signaling, TNF-α signaling, anti-inflammatory cytokines (IL-1 and IL-10), and apoptosis in all 5 biopsy evaluable patients. Based on clinical PK & PD study, 10mg/kg weekly was considered a biologically active dose and sufficient to reach $\geq$ 95% target binding by the end of first cycle. **Conclusions:** Imalumab was well tolerated and showed single agent antitumor activity in heavily pretreated pts. An MTD was not reached. Recommended phase II dose (RP2D) is 10 mg/kg IV weekly. NCT01765790 Clinical trial information: NCT01765790.

2519 Poster Discussion Session; Displayed in Poster Session (Board #235), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

First-in-human phase I administration of YS110, a monoclonal antibody directed against the CD26 immunostimulatory molecule in advanced cancer patients. *First Author: ERIC ANGEVIN, Institut Gustave Roussy, Villejuif, France*

Background: YS110 is a recombinant humanized IgG1 monoclonal antibody that selectively binds with high affinity to the extracellular domain of the CD26 antigen. Preclinical evaluations of YS110 have demonstrated promising anti-tumor effects in cancer cell lines and xenografts expressing the CD26 antigen without significant side effects in toxicology studies (up to 100 mg/kg as single dose or 30 mg/kg for 5 weekly doses in monkeys). **Methods:** Escalating doses of YS110, using a standard 3+3 escalation scheme, were administered intravenously once every 2 weeks for 3 doses at 0.1, 0.4, 1 and 2 mg/kg and then based on PK data, once every week for 5 doses at 2, 4 and 6 mg/kg in solid tumors pts with confirmed CD26$^+$tumor expression ($\geq$ 20% of the tumor cells). This FIH study was designed to determine the MTD and RD, assess tolerance, PK and PDs of YS110. **Results:** 34 heavily pre-treated pts, including 23 pts with mesothelioma and 10 with renal cell carcinoma, were enrolled. A total of 232 infusions (median 3 [range 1-30]) of YS110 were administered across 6 dose levels ranging from 0.1 to 6 mg/Kg. MTD was not reached and 2 DLTs (1 pt with Gr 3 anaphylactic reaction at 1 mg/kg and 1 pt with Gr 3 allergic reaction at 2 mg/kg) were reported. Recovery was obtained with dose omission. Pts with a medical history of allergy were excluded and corticoids prophylaxis improved safety profile. No dose-dependent AEs were observed. Low grade asthenia (33.3%), hypersensitivity (30.0%), chills (13.3%), pyrexia (13.3%), nausea (13.3%), vomiting (10.0%), and headache (10.0%) were reported. Blood exposure PK parameters (AUC and Cmax) increased in proportion with the dose. Cytokines and immunophenotyping indicated CD26 target modulation. Prolonged stabilization was observed in 13 pts out of 25 evaluable pts. **Conclusions:** YS110 is well tolerated with preliminary evidence of activity. Combination with chemotherapy will be investigated. Clinical trial information: 2008-004407-56.

First-in-human dose escalation, safety, and PK study of a novel EFNA4-ADC in patients with advanced solid tumors. *First Author: David S. Hong, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PF-06647263 is an anti-EFNA4 antibody drug conjugate (ADC) comprised of a humanized mAb (huE22), a hydrazine linker, and calicheamicin. Ephrin-A4 (EFNA4) is overexpressed in tumor versus normal tissue in a number of human tumors. PF-06647263 induced tumor regression in triple negative breast cancer (TNBC) and ovarian cancer (OVCA) xenograft models. **Methods:** Patients (pts) with solid tumors unseleceted for EFNA-4 expression are receiving escalating doses of PF-06647263 once every 3 weeks (Q3W) or weekly (QW) in 2-6 patient cohorts. The following doses have been evaluated: 0.015, 0.030, 0.050, 0.075, 0.100, and 0.134 mg/kg Q3W and 0.01 and 0.02 mg/kg QW. Once the maximum tolerated dose (MTD) is determined, expansion cohorts for patients with EFNA4-expressing TNBC and platinum-resistant OVCA are planned. Standard definitions are being used to classify hematological and non-hematological dose limiting toxicities (DLT). Serum pharmacokinetic (PK) and anti-drug antibody (ADA) development are also being assessed. **Results:** Data are available on 24 pts treated- 15 Q3W and 9 QW. Among the 24 pts (20F/4M), the mean age was 59 years (35-82). Total number of administered cycles is 55 (Q3W) and 26 (QW), and DLTs, were observed in 0 and 1 pts in the Q3W and QW regimens, respectively, during the first cycle. The most common adverse events (AE) were nausea (50%), fatigue (50%), decreased appetite (38%), diarrhea (33%), vomiting (33%), thrombocytopenia (TCP) (33%), abdominal pain (29%), and blood bilirubin increase (29%). One patient experienced Grade 4 neutropenia and the AEs with Grade 3 severity observed in more than 2 patients were mucosal inflammation (n = 3; 12%) and bilirubin increase (n = 2; 8%). Preliminary evidence of activity includes confirmed partial response (PR) in 2 pts (OVCA and TNBC). Two additional unconfirmed PRs (TNBC and peritoneal cancer) have also been recorded. **Conclusions:** PF-06647263 is a novel anti-EFNA4-ADC which to-date is well-tolerated in pts with advanced malignancies. Dose-escalation is continuing and updated safety, efficacy, and preliminary PK data will be reported at the meeting. Clinical trial information: NCT02078752.

2521 Poster Session (Board #237), Sat, 8:00 AM-11:30 AM

Phase I study of ontuxizumab, a humanized monoclonal antibody (mAb) recognizing endosialin in Japanese patients (pts) with hepatocellular carcinoma (HCC). *First Author: Masafumi Ikeda, National Cancer Center Hospital East, Chiba, Japan*

Background: Endosialin is a cell surface glycoprotein that is expressed on cells involved in the development of tumor vasculature, primarily pericyte and stromal fibroblast. Ontuxizumab is a humanized IgG1κ mAb that is the first clinical stage agent to target Endosialin. Based on the safety profile obtained in the dose escalation portion of this study, 3 dosage cohorts were expanded to further characterize the safety, pharmacokinetics (PK), and preliminary efficacy of Ontuxizumab in advanced HCC pts. **Methods:** HCC pts with Child-Pugh (CP) A who have no other appropriate treatment were enrolled at 4 study sites to 3 dosage cohorts; 4 and 8 mg/kg weekly, and 12 mg/kg biweekly as 4 weeks a cycle. Primary objective was safety. Efficacy endpoints were Response rate by RECIST v.1.1, Disease Control Rate (DCR) and Time to Progression (TTP). **Results:** Fifteen pts with advanced HCC pre-treated at minimum with sorafenib have been enrolled. Of these, 11 and 4 pts presented with ECOG 0 and 1 respectively, while 10 and 5 pts presented with CP A5 and A6 respectively. The PK profile from the HCC cohort was consistent with those of the dose escalation cohorts with other solid tumors. There were no significant differences for C_{max} and AUC of Ontuxizumab between HCC and other solid tumors. Mean $t_{1/2}$was 99.0 - 216 hours after multiple administrations. Safety profile was mainly characterized by Gr 1-2 events. Treatment related adverse events (AEs) were observed in 10 of 15 pts. The most common AEs were hiccups (20%), ALT increased, AST increased, blood bilirubin increased, hypoalbuminaemia and malaise (each 13%). There were 3 treatment related Gr 3-4 AEs (ALT increased, AST increased and hyperglycaemia), and no treatment related serious AEs. No CRs or PRs were reported; DCR was 60% with TTP ranging 1.4 to 12.9 months. Five pts (33%) showed tumor shrinkage and durable (over 6 months) SD was observed in 3 pts (20%). **Conclusions:** Ontuxizumab appears generally well tolerated in this HCC population with a PK profile consistent with the profile in other solid tumors. Preliminary efficacy results suggest that Ontuxizumab at minimum 4 mg/kg weekly warrants further investigation for clinical activity in HCC. Clinical trial information: NCT01773434.

2522 Poster Session (Board #238), Sat, 8:00 AM-11:30 AM

Phase I trial and pharmacokinetic study of Tanibirumab, a fully human monoclonal antibody to the vascular endothelial growth factor receptor 2 in patients with refractory solid tumors. *First Author: Su Jin Lee, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Tanibirumab is a fully human monoclonal antibody to the vascular endothelial growth factor receptor 2 (VEGFR-2). We conducted a first-in-human phase I study of Tanibirumab in patients with solid tumors which were refractory to standard chemotherapy. Primary endpoints are evaluating safety, pharmacokinetics (PKs), estimating maximum-tolerated dose (MTD) and recommended phase II dose (RP2D). **Methods:** We designed to escalate Tanibirumab at 9 different dose levels with 3+3 method and Tanibirumab (1-28mg/kg) was administered intravenously on D1, 8, 15 in 28-day courses. Dose limiting toxicities (DLTs) were assessed in only first cycle of treatment and response evaluation was performed every 2 cycles. The effects of Tanibirumab on serum VEGF, soluble VEGFR-2, PlGF and correlation between VEGF, VEGFR-2 expression in archival tumor tissue and efficacy were planned. **Results:** From October 2011 to September 2013, a total of 26 patients with refractory solid tumors were enrolled. The median age was 58 years (range, 27-75) and 20 patients were male. Most common tumor type was colorectal cancer (N = 18) and 7 patients had history of previous bevacizumab treatment. As hemangioma continued to occur, last dose level, 28m/kg was not performed. DLTs were not found, and MTD was confirmed as 24mg/kg. Hemangioma was observed in 50% of patients, but most of those were grade 1-2 which disappeared after discontinuation of study drug. Among 18 patients of efficacy set, no objective response was observed, but 11 patients showed stable disease. PKs were characterized by dose-dependent linear exposure and mean trough concentrations exceeded biologically relevant target levels at 12mg/kg and above. Serum VEGF, soluble VEGFR-2, PlGF increased at 4mg/kg dose level and above. **Conclusions:** Treatment with Tanibirumab showed tolerable toxicity profile and modest clinical efficacy in patients with refractory solid tumors. We have a plan to conduct phase II trial in patients with glioma. Clinical trial information: NCT01660360.

2523 Poster Session (Board #239), Sat, 8:00 AM-11:30 AM

Molecular characteristics in breast cancer tumors treated with neoadjuvant chemotherapy with and without bevacizumab: Results from NeoAva—Randomized phase II study. *First Author: Olav Engebraaten, Oslo University Hospital, Oslo, Norway*

Background: The molecular characteristics of responding and non-responding breast cancers when treated with antiangiogenic therapy are largely unknown. **Methods:** To investigate molecular alterations in tumors treated with antiangiogenic therapy, the NeoAva study included patients with HER2 negative primary tumors of $\geq$ 25 mm that were randomized (1:1) to receive chemotherapy (4 x FEC100 + 12 weeks of taxane-based therapy) with or without bevacizumab. Tumor material was obtained at screening, 12 weeks into treatment and at surgical removal at 25 weeks. mRNA expression profiling was performed (Agilent). In this study, 131 patients were evaluable for tumor response. **Results:** pCR in breast and axilla were obtained in 14 (21.1%) patients in the chemo+bev arm, and in 7 (10.6%) patients in the chemo-only arm. The overall pCR rates were higher in the ER negative tumors compared to ER positive tumors ((9 of 23) vs (12 of 108)). Addition of bevacizumab seemed to improve pCR in the ER positive patient group (9 vs 3) and not in ER negative patient group (5 vs 4). Tumors that achieved pCR showed a significant higher expression of genes (n = 362) enriched for immune response related pathways, compared to the tumors that did not achieve pCR in the ER positive group. The identified immune gene signature predicted response independent of the PAM50 proliferation signature and VEGF pathway signature, particularly in the bevacizumab treated group ($p < 0.001$). Proliferation scores regressed across time-points in response to therapy ($p < 0.001$), and bevacizumab treatment accelerated the reduction of the proliferation score in the ER positive tumors. In response to therapy, tumors achieved a better prognosis profile, i.e. Luminal A or Normal-like profile. ER positive tumors, particularly Luminal B showed significant differences in gene expression and associated pathways between two treatment arms (chemo only and chemo+bev), while minimal change was observed for ER negative/Basal-like tumors. **Conclusions:** The immune signature was found to be a strong predictor of response in ER positive tumors, particularly in tumors treated with chemotherapy combined with bevacizumab. Clinical trial information: NCT00773695.

2524 Poster Session (Board #240), Sat, 8:00 AM-11:30 AM

Bevacizumab plus Letrozol (LEA clinical trial phase III). Using hypertension for finding biomarkers of efficacy. *First Author: Juan de la Haba-Rodriguez, Medical Oncology Department University Reina Sofia Hospital. Biomedical Research Institute Maimonides, Cordoba, Spain*

Background: The LEA study compares the combination of endocrine therapy plus bevacizumab (ET-B) against endocrine therapy (ET), as first line treatment in patients (pts) with advanced breast cancer. It failed to demonstrate superiority for the combination (JCO 2015 in press). Some retrospective studies have shown that pts developing hypertension (HT) whilst on antiangiogenic treatment have a better outcome. Polymorphisms in several HT-related genes might contribute to inter-individual differences in response to these treatments. The aim of this study is to analyze the predictive value of HT for bevacizumab efficacy. Associations between polymorphisms in genes related with HT and bevacizumab efficacy were assessed. **Methods:** The LEA study randomized 380 pts in two treatment arms, ET-B (191 pts) and ET (189 pts). We collected Grade 1-4 HT in all pts and genotyped eleven polymorphisms in HT-related genes (ACE, AGTR1, AGT, VEGF, ADRB1, ADRB2, GNB3, NOS3) in germinal DNA from 117 of these pts (ET-B:67/ ET:50). **Results:** A higher rate of HT was associated with the bevacizumab combination arm (17% vs 62% pts ET vs ET-B arm, $p < 0.001$). Pts developing HT had a better response rate (45% vs. 27% in pts with HT vs no HT, $p < 0.001$), as well as a longer progression free survival (PFS) (21.9 vs 12.0 months, HR = 0.55 (95%CI:0.43–0.71), $p < 0.001$) and overall survival (OS) (48.6 vs 41.6 months, HR = 0.55 (95%CI:0.38–0.79), $p = 0.0010$). The association found between HT and ET-B, and between HT and efficacy was maintained in the genotyped subpopulation. The variant in the angiotensin converted enzyme (ACE) rs1799752 (287pbIN/DEL) and in the angiotensin receptor type 1 (AGTR1) rs5186 (M235T) were associated with HT ($p < 0.05$). In the ET-B arm, we found a correlation between rs1799752 ACE IN/DEL and PFS ($p = 0.04$), and between VEGF2578 and OS ($p = 0.0045$). **Conclusions:** HT is correlated with better clinical outcomes in pts treated with the ET-B combination. These results provide preliminary evidence of the predictive role of polymorphisms in HT-related genes in bevacizumab efficacy. The real interest of these polymorphisms should be further elucidated in larger prospective studies.

2525 Poster Session (Board #241), Sat, 8:00 AM-11:30 AM

A phase 1 trial of a potent and selective VEGF receptor inhibitor, apatinib, in patients with advanced solid tumors. *First Author: Sunil Sharma, University of Utah Huntsman Cancer Institute, Salt Lake City, UT*

Background: VEGF-mediated signaling pathways are critical to tumor growth. Apatinib mesylate is a novel, oral angiogenesis inhibitor that potently and selectively inhibits vascular endothelial growth factor receptor-2 (VEGFR-2). **Methods:** Apatinib mesylate was administered once daily as oral monotherapy starting at 100 mg/day and escalating to 250, 500, 750, or 850 mg/day, with dose expansion at the up to 850mg/day or maximum tolerated dose levels. The primary objective was to determine the safety and tolerability of continuous oral Apatinib mesylate in patients with recurrent solid tumors. A secondary endpoint was response to treatment. **Results:** In this Phase 1 trial, 25 patients were treated and evaluated for safety and tolerability**.** The dose levels were: 100 mg/day (n = 5); 250 mg/day (n = 9); 500 mg/day (n = 4); 750 mg/day (n = 4); and 850 mg/day (n = 3). Median age was 62 years (range, 33–76 years), and median prior number of therapies was 3.5 (range, 0-8 therapies). There was 1 dose-limiting toxicity (malignant hypertension, 250mg/day). Among 19 evaluable patients, after 2 cycles, there was 1 (5.3%) partial response, 11 (57.9%) stable disease, and 7 (36.8%) disease progression. Pharmacokinetic data will be presented. **Conclusions:** Apatinib mesylate monotherapy was well tolerated in patients with recurrent solid tumors in this phase 1 trial with preliminary evidence of promising antitumor activity. The recommended phase 2 dose for further development was 850 mg/day. Clinical trial information: NCT01497704.

2526 Poster Session (Board #242), Sat, 8:00 AM-11:30 AM

Phase I study of the combination of alisertib (MLN8237) and gemcitabine in advanced solid tumors. *First Author: Edward Jae-hoon Kim, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Aurora Kinase A (AKA) is a key mitotic regulator overexpressed in multiple solid tumors. This open-label dose escalation phase I study evaluated the safety and tolerability of alisertib (MLN8237), an oral AKA inhibitor, in combination with gemcitabine. **Methods:** Patients (pts) > 18y with refractory solid tumors received 28-day cycles of gemcitabine on days 1, 8, 15 and alisertib twice daily on days 1-3, 8-10, and 15-17. Gemcitabine was given at a standard dose of 1000mg/m^2. Four dose levels (DL) of alisertib (20-50mg) were planned following a conventional 3+3 design to investigate the occurrence of dose limiting toxicities (DLT) over cycle 1, and to determine the maximum tolerated dose (MTD) and recommended phase II dose (RP2D). Anti-tumor activity was assessed by response rate (RECIST 1.1) and progression-free survival. **Results:** Twenty-one pts were treated with median age 57 y [42-75]; 48% male; PS 0 (7 pts), 1 (13 pts), or 2 (1 pt); median prior therapies was 2 [0-7]; tumor types were NSCLC (7); colorectal (3); poorly differentiated neuroendocrine (3); small cell lung (2); head and neck (2); 1 each of pancreatic, gallbladder, small bowel, and mesothelioma. A median of 4 cycles [1-13] were administered. Two pts experienced DLTs: 1 pt at DL3 had grade 3 urinary tract infection; 1 pt at DL4 developed grade 3 oral mucositis, hyponatremia, and dehydration. The maximum administered dose (DL4) achieved 900 mg alisertib per cycle and was tolerated (1 DLT in 6 pts). Grade 3–4 hematologic toxicities observed included neutropenia (57%), leukopenia (48%), anemia (24%), and thrombocytopenia (14%). Hyponatremia (19%) was the only non-hematologic toxicity observed in > 10% of the pts. Ten of 14 evaluable pts (71%) had stable disease as their best response with remaining 4 pts having disease progression. **Conclusions:** Alisertib can be safely administered with gemcitabine and the R2PD for alisertib is 50 mg PO BID on days 1-3, 8-10, and 15-17 in combination with full dose gemcitabine. Further clinical evaluation of this combination is warranted and a pre-planned expansion is ongoing in pts with pancreatic adenocarcinoma including evaluation of pharmacokinetic interaction of the combination at the MTD. Clinical trial information: NCT01924260.

2527 Poster Session (Board #243), Sat, 8:00 AM-11:30 AM

First-in-human Phase 1 safety, PK, and PD study of the CDK4/6 inhibitor G1T28. *First Author: Renger G. Tiessen, PRA Health Sciences, Groningen, Netherlands*

Background: G1T28 is a highly potent and selective CDK4/6 inhibitor being developed as an IV agent for targeted bone marrow chemoprotection and as an oral antineoplastic agent. The CDK4/6 pathway is critical in regulating cell proliferation of certain tumors. In addition, hematopoietic stem and progenitor cells (HSPCs) are dependent upon CDK4/6 for proliferation. Transient G1T28-induced G1 cell cycle arrest of HSPCs renders them resistant to the cytotoxic effects of chemotherapy. Thus, G1T28 could be used for chemoprotection (reduction of chemotherapy-induced myelosuppression) in patients with CDK4/6-independent tumors, or as an antineoplastic agent in patients with CDK4/6-dependent tumors. **Methods:** The objective of this study was to assess the safety and tolerability of G1T28, as well as to characterize PK and PD (NCT02243150). Part 1 was a double blind, placebo-controlled, single escalating dose study in healthy volunteers of both sexes, where subjects were randomized (3:1) to receive G1T28 or placebo as a single 30-minute IV infusion. In Part 2, 8 subjects will receive single escalating oral doses of G1T28 in three dosing periods. PD assessments included evaluation of *ex vivo* stimulation of lymphocytes and bone marrow cell cycle analysis. **Results:** 45 subjects have enrolled in the study to date. In Part 1, G1T28 was administered at doses of 6, 12, 24, 48, 96 and 192 mg/m^2. G1T28 was well tolerated, with no dose limiting toxicities or serious adverse events reported. In Part 1, G1T28 exposure (Cmax and AUC) increased proportionally with dose, while clearance was relatively constant. G1T28 at 96 and 192 mg/m^2 demonstrated a robust pharmacodynamic effect with a dose-dependent decrease in phytohemagglutinin (PHA)-stimulated lymphocyte proliferation *ex vivo*. **Conclusions:** G1T28, a novel CDK4/6 inhibitor, is well tolerated and demonstrates predictable PK and robust PD activity. Based on these results, IV G1T28 will be investigated in Phase 1b/2a studies in patients with CDK4/6-independent tumors to evaluate its potential as a targeted bone marrow chemoprotectant. In addition, the oral formulation will be assessed as an antineoplastic agent in patients with CDK4/6-dependent tumors. Clinical trial information: NCT02243150.

2528 Poster Session (Board #244), Sat, 8:00 AM-11:30 AM

Overcoming the proliferation rate paradox: Clinical evaluation of a continuous dosing scheme of the novel oral Eg5 inhibitor 4SC-205. *First Author: Klaus B. Mross, Klinik für Tumorbiologie, Freiburg, Germany*

Background: Mitotic proteins, like Eg5, are exclusively expressed during mitosis. Targeted therapy directed against such proteins prevents side-effects like peripheral neuropathies. However, mitosis is a timely restricted event and doubling times of human solid tumours (~120d) largely exceed the ones observed in preclinical models. Therefore, continuous exposure at the target site is mandatory. Here we present a clinical dosing scheme for the Eg5i 4SC-205 to address these challenges **Methods:** Time-dependent anti-proliferative effect of 4SC-205 on spindle check point (SAC) deficient (H929, HT29) and proficient (HCT116, NCCIT) cell lines was investigated. Apoptosis induction was assessed by western blot analysis for Noxa, Mcl-1 and caspase 3. 59 patients (pts) with solid tumours were enrolled in a Phase I study and dosed either once weekly (ow) at days 1 and 8 or twice weekly (tw) at days 1, 4, 8, and 11 or continuously (con) within a 21-day cycle. **Results:** Effects on proliferation and apoptosis inductionin SAC deficient/proficient cell lines was time-dependent. SCA deficient cells required up to 96h incubation to establish the full IC_{50}. 46 pts were enrolled in the discontinuous dosing arms with either once weekly (ow) or twice weekly (tw) (dose levels: 25mg (N = 3), 50mg (N = 3), 100mg (N = 6), 150mg (N = 6) and 200mg (N = 13) ow; at 50mg (N = 3), 75mg (N = 7), and 100mg (N = 5) tw). 13 patients were evaluated for con. dosing at 10mg (N = 3), 20mg (N = 6), and 30mg (N = 4). Response acc. to RECIST was not observed. Overall, 22% of pts. were stabilized into follow-up after 6 weeks. One patient is still on treatment at 20mg daily. The median time on study of pts receiving continuous dosing of 20 mg was 162 days. In contrast, the overall median time on study was 42 days under ow or tw dosing. **Conclusions:** Prolonged exposure is needed for 4SC-205 to inhibit proliferation and to induce apoptosis in SAC deficient cell lines. This requirement was translated into the clinic utilizing a continuous dosing scheme. 4SC-205 can be safely administered at an oral daily dose of 20mg (= RP2D). Promising long-term disease stabilization is observed under continuous dosing. Clinical trial information: NCT01065025.

2529 Poster Session (Board #245), Sat, 8:00 AM-11:30 AM

Evaluation of targeted bone marrow arrest by G1T28, a CDK4/6 inhibitor in clinical development to reduce chemotherapy-induced myelosuppression. *First Author: Patrick J. Roberts, G1 Therapeutics, Inc, Research Triangle Park, NC*

Background: Myelosuppression is the major dose-limiting toxicity of chemotherapy, which limits dose intensity. G1T28 is a highly potent and selective CDK4/6 inhibitor in development as an IV agent to provide targeted bone marrow chemoprotection in patients with CDK4/6-independent tumors. Hematopoietic stem and progenitor cells (HSPCs) are dependent upon CDK4/6 for proliferation; G1T28 induces a transient G1 cell cycle arrest that renders HSPCs resistant to the cytotoxic effects of chemotherapy. In preclinical models, this results in faster recovery of all blood cell counts following chemotherapy and preservation of long-term hematopoietic function. **Methods:** To rationally design tolerable and active chemotherapy combination regimens with reduced multi-lineage myelosuppression, the magnitude and duration of G1T28-induced HSPC G1 arrest in human bone marrow was characterized. Data from 3 species (mouse, rat, dog) were used to evaluate dose response relationships for HSPC G1 cell cycle arrest and to construct a cross-species allometrically-scaled PK/PD model. Model simulations and human PK/PD data from a Phase I trial (NCT02243150) were used to predict the biologically effective dose (BED) in humans. In this trial, the BED was assessed by obtaining bone marrow aspirates and evaluating G1 arrest of HSPCs by flow cytometry. **Results:** Preclinical PK/PD modeling outputs and clinical data predicted the BED in humans to be 192 mg/m^2. Specifically, a 15mg/kg dose of G1T28 in dogs produced robust and sustained bone marrow arrest for ~24 hours and had a similar PK exposure to the predicted human BED. A single bone marrow aspirate from 12 subjects following 192 mg/m^2 (baseline, n = 5; 24 h post-G1T28, n = 3, or 32 h post-G1T28, n = 4) demonstrated a robust G1 arrest of multiple progenitor subsets at 24 h, with early progenitors persisting in G1 arrest to 32 h. **Conclusions:** A single IV administration of G1T28 at the BED of 192 mg/m^2 produced robust inhibition of HSPCs within the bone marrow for > 24 hours. Based on these results, Phase 1b/2a studies are planned to evaluate the potential of G1T28 in reducing multi-lineage chemotherapy-induced myelosuppression. Clinical trial information: NCT02243150.

2530 Poster Session (Board #246), Sat, 8:00 AM-11:30 AM

SLC1A5 to predict outcome with chemotherapy in early triple-negative breast cancer. *First Author: Anna Maria Affan, St Vincent Charity Medical Center, Cleveland, OH*

Background: TNBC are high grade tumors which have a poor prognosis. SLC1A5 is a neutral amino acid transporter found in these tumors and high levels correlate with aggressive biological behavior. By targeting SLC1A5 function, tumor cell growth can be inhibited and autophagy activated which should result in improved survival benefit for patients with TNBC. We evaluated the role of SLC1A5 on tumor death rate in patients who were treated with chemotherapy for early TNBC. **Methods:** A retrospective, cohort study of patients with TNBC was performed to evaluate survival compared with the level of expression of SLC1A5. A histogram was constructed to determine a median point which could be used to define a "high" versus "low" score. Five was used as the average cut-point. Thereafter to determine overall survival, Kaplan-Meier product-moment technique (K-M) was used, with comparisons between groups made by using the log rank test. Statistical significance was taken as $p < 0.05$. **Results:** The cohort consisted of 171 patients with TNBC. The median age was 51 years with similar distribution between node positive and node negative cases. Survival information was available for 112 patients with data available on the SLC1A5 score. There was a significant association of the outcome of interest, overall survival, with the SLC1A5 score with a worse outcome noted in tumors with higher expression ($p = 0.00189$). Furthermore, 80 patients with TNBC who received chemotherapy with higher levels of SLC1A5 showed worse survival ($p = 0.0005$). Additionally, the relationship between SLC1A5 and hypoxia-induced upregulation of Carbonic Anhydrase IX (CAIX), was explored using the Welch Two Sample t-test. There was a significant association with higher levels CAIX associated with higher SLC1A5 ($p = 0.0189$). **Conclusions:** This study suggests that SLCA15 is associated with tumor hypoxia and worse outcome in chemotherapy treated patients. The results emphasize the importance of evaluating proteins involved in cell metabolism and autophagy, to aid in the development of novel targets. The relationship of CAIX with SLCA15 implies that the latter may be involved in tumor hypoxia that needs further exploration in additional cohorts and clinical trials.

2531 Poster Session (Board #247), Sat, 8:00 AM-11:30 AM

Phase I dose-escalation study with extended daily administration of Debio1143, an oral inhibitor of apoptosis protein inhibitor, in patients with solid tumors. *First Author: Henry C. Pitot, Mayo Clinic, Rochester, MN*

Background: Inhibitors of apoptosis proteins (IAPs) play a critical role in modulating multiple processes, including caspases activation and NF-κB signaling. Because high expression of IAPs represent a frequent oncogenic event in human cancers, therapeutic targeting of IAPs is considered as a promising approach. The small molecule Debio 1143 is a potent orally-active IAP antagonist able to promote apoptosis in tumour cells by restoring caspase activity, and modulating NF-κB signaling and TNFα effects in various preclinical models. A shorter schedule of Debio1143 (daily x 5, every 21 days) was well tolerated in cancer patients up to 900 mg QD. **Methods:** Oral Debio1143 was administered to patients with advanced solid tumors according to a novel extended schedule: daily x 14, every 21 days. The starting dose was 200 mg QD. The MTD was exceeded when any two patients within the same cohort experienced dose-limiting toxicity (DLT). Serial blood samples and urine were collect on cycle 1 for PK and PD assessments. **Results:** Six-teen patients received doses from 200 to 400 mg QD. Only one DLT (G3 reversible ALT and ALP elevation) was reported at 200 mg. Most common AEs of any grade deemed related to study drug were fatigue (31%), nausea (29%), decreased appetite (20%), vomiting (16%), diarrhea (14%) and rash (14%). Average tmax and t½ were about 2 and 7 h, respectively. Exposure increased in a relatively dose- proportional manner without accumulation over 14 days. The exposure of the main metabolite Debio1143-MET1 increased in a greater than dose proportional manner. Renal excretion of Debio 1143 was less than 15% of dose. Rapid and sustained degradation of cIAP-1 in surrogate tissue was observed at all doses. Debio1143 induced plasma MCP-1, TNFα, M30 and M65 increase. No changes were observed for IL-8. No responses were seen in 16 evaluable patients. **Conclusions:** The MTD was not reached and 400 mg was the highest tested dose. The extended schedule administration of oral Debio 1143 was well tolerated with significant PD activity at the doses investigated. A phase Ib trial of this extended schedule of Debio1143 in combination with concurrent chemo-radiation in LA-SCCHN is ongoing. Clinical trial information: NCT01078649.

2532 Poster Session (Board #248), Sat, 8:00 AM-11:30 AM

First-in-human study of TAS-115, a novel oral MET/VEGFR inhibitor, in patients with advanced solid tumors. *First Author: Nobuaki Matsubara, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Aberrations in the MET receptor tyrosine kinase pathway occur in various human malignancies (via MET amplification, mutation, or overexpression) driving cell proliferation, survival and metastasis. TAS-115 is a novel oral MET/VEGFR inhibitor with preclinical activity in human tumor models. This dose escalation study evaluates TAS-115 in patients (pts) with advanced solid tumors. **Methods:** In this Phase I study, the primary objective is to determine the MTD and RD of TAS-115, secondary objectives included safety and tolerability, antitumor activity, and PK. Eligible pts (aged ≥ 20 years, ECOG PS ≤ 1) had tumors that are refractory to standard therapy. The accelerated titration and 3+3 design are used in this study. TAS-115 is administered continuously 21 days in one cycle. **Results:** Phase I was begun in Oct 2011. The drug formulation has been changed because of the saturation of absorption. Phase I using the new formulation was restarted from Dec 2013. As of Jan 15 2015, 18 pts were enrolled in the dose escalation phase of new formulation (67% male, median age 61 years, 55% PS 0). The numbers of types of tumors were gastrointestinal stromal tumor in 3, gastric in 3, colorectal in 2, bile duct in 2, breast in 2, and others in 6 pts. Pts were treated in 5 dose cohorts of 200-800 mg. DLTs occurred at 800 mg in the 2 pts, which included grade 3 thrombopenia with hemorrhage and grade 3 rash. The frequent drug-related AEs (all grade ≥ 35%) were edema (67%), AST increase (61%), fatigue (56%), ALT increase (50%), rash (50%), leucopenia (44%), neutropenia (39%), thrombopenia (39%). TAS-115 exposure was generally increased with dosage. Mean C_{max} and AUC_{last} at 800 mg were 4,910 ng/mL and 39,400 ng*h/mL, respectively, with a mean T_{max} of 1.3 hrs and apparent $T_{1/2}$of 13.7 hrs. Preliminary efficacy was observed in 5 pts. 2 pts maintained SD more than 12 and 24 weeks, respectively, and reduction of SUV in PET was observed in 5 pts. Biomarker analysis including MET status is also evaluated and will be presented. **Conclusions:** TAS-115 was well tolerated and the safety profile was confirmed up to 800 mg. The ongoing dose escalation is still under evaluation and RP2D will be determined. Clinical trial information: JapicCTI-111645 and 132333 Clinical trial information: JapicCTI-111645 and JapicCTI-132333.

2533 Poster Session (Board #249), Sat, 8:00 AM-11:30 AM

First-in-human study of LY3039478, a Notch signaling inhibitor in advanced or metastatic cancer. *First Author: Christophe Massard, Gustave Roussy Cancer Campus, Villejuif Cedex, France*

Background: LY3039478 (LY) is an orally bioavailable, potent, and highly selective Notch inhibitor (Notch 1-4). We report on safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity of LY. **Methods:** Eligible pts (ECOG $\leq$ 1) had relapsed solid tumors, adequate hematologic, renal, and hepatic functions. Using a predictive pre-clinical PK/PD model and non-clinical toxicology data, a dose range of 2.5-100 mg was selected. LY was given three times a week (TIW) on a 28-day cycle until disease progression. Dose escalation used 3+3 design with probability toxicity band modelling. Safety assessments were based on CTCAE V4.0. Primary objective: to define the recommended phase 2 dose of LY; additional objectives: PK, PD (Aβ in plasma and a panel of 46 genes expressed in skin), and preliminary antitumor activity. **Results:** 55 pts were treated. The most common related toxicities ($\geq$ 10% of pts) included diarrhea (42%); vomiting (40%); nausea (36%); asthenia (33%); decreased appetite (25%); hypophosphatemia (18%); mucosal inflammation (16%); weight decreased (15%); hair color changes and dry skin (13% each); dry mouth (11%). 5 dose-limiting toxicities were observed in cycle 1: thrombocytopenia grade 4 in 3 pts (20mg, 30mg, and 60mg), nausea and asthenia grade 3 in one patient (100mg) and colitis grade 3 (100mg). Other observed grade 3/4 toxicities related to LY in $>$ 1 patient included hypophosphatemia (5 pts) and vomiting (2 pts). Maximum tolerable dose (MTD) was defined as 75 mg TIW. AUC and C_{max} appeared to increase in a dose proportional manner. There was no accumulation with multiple dosing with an elimination half-life of approximately 6-8h. Dose dependent inhibition of plasma Aβ and target genes (in skin) was observed. At the recommended dose of 75mg TIW, preliminary data indicate approximately 80% inhibition of Aβ, $>$ 50% inhibition of HES1, NRARP, and CCND1. Additional inhibited genes included HES2, HES4, HES5, HEYL and MYC. 6 pts received $\geq$ 6 cycles (range 6-18). Best observed response is PR in a patient with ER+/PR+ HER2-breast cancer. **Conclusions:** The recommended dose for LY monotherapy is 75 mg TIW with manageable toxicities and significant target inhibition. Further exploration of LY monotherapy is ongoing. Clinical trial information: NCT01695005.

2534 Poster Session (Board #250), Sat, 8:00 AM-11:30 AM

Trends in the characteristics, dose-limiting toxicities and efficacy of phase I oncology trials: The Cancer Research UK experience. *First Author: Han Hsi Wong, Cancer Research UK Centre for Drug Development, London, United Kingdom*

Background: Phase I oncology trials are crucial in cancer drug development and have evolved over the years. We examined the trends in trial characteristics, dose-limiting toxicities (DLTs) and efficacy, and questioned whether the concepts of DLT and maximum-tolerated dose (MTD) were still helpful. **Methods:** Cancer Research UK Centre for Drug Development (CRUK CDD) sponsors phase I trials across the UK. We reviewed our experience of adult trials between 1995 and 2013. **Results:** Forty-nine trials were divided into two groups based on the starting date for recruitment: 1995-2003 (24 trials, n = 603) and 2004-2013 (25 trials, n = 750). From 1995-2003 to 2004-2013, there was a shift towards studying biological and targeted agents. Patients in the later years tended to be older, had a greater disease burden and were more likely to have received prior treatment, although baseline haematology and biochemistry test results were no worse. The incidence of DLTs was similar in both year groups (10.1% vs 11.5%; risk of death 0.7% vs 0.3%). DLTs such as neuropathy, stomatitis and thrombocytopenia were less common in the later trials, while the frequency of elevated liver enzymes was greater. Non-classical DLTs also emerged in the later trials, including hypertension, hypophosphatemia, cardiac and ophthalmic toxicities. Of a total of 219 DLT events, only four fell outside the protocol-defined criteria for a DLT. The overall disease control rate increased from 27.9% in 1995-2003 to 36.0% in 2004-2013 (P = 0.0033) due to improved disease stabilisation, and there was a trend towards a lower rate of progressive disease as best response (51.0% vs 46.3%, P $>$ 0.05). Objective response rates as high as 33.3% (radioimmunotherapy in lymphoma) were observed, and were both disease- and agent-dependent. Doses at or above the MTD were associated with response to cytotoxics and radioimmunotherapy but not to other targeted agents. **Conclusions:** CRUK CDD phase I oncology trials continue to provide clinical benefit to participants while minimising toxicities, and DLT remains a helpful concept. However, pharmacodynamic rather than MTD endpoints are becoming increasingly important in defining the dose for subsequent trials.

2535 Poster Session (Board #251), Sat, 8:00 AM-11:30 AM

A phase I study of intravenous artesunate (IV AS) in patients with solid tumors. *First Author: John F. Deeken, Inova Comprehensive Cancer and Research Institute, Mclean, VA*

Background: Although the artemisinin class of anti-malarial drugs has shown significant anti-cancer activity in preclinical models, no prospective clinical trials have so far been performed. Proposed anticancer mechanisms include: DNA damage, inhibition of angiogenesis, TRAIL-mediated apoptosis, and inhibition of several signaling pathways. We performed a phase I clinical study to determine the maximum tolerated dose (MTD), and the dose limiting toxicities (DLTs) of IV AS. **Methods:** Patients (Pts) with refractory solid tumors were enrolled in this accelerated titration dose escalation study with planned dose levels of 8, 12, 18, 25, 34 and 45 mg/kg given on days 1 and 8 of a 21 day cycle. One patient would be treated at each dose level until a $\geq$ level 2 toxicity occurred during cycle 1, then a traditional 3+3 dose escalation rule would apply until 2 of 6 patients experienced DLTs on a dose level. Intensive PK was performed. Archived tumor blocks were obtained for correlative studies. **Results:** Between 01/2013 and 04/2014, 19 pts were enrolled, 17 of whom were evaluable for toxicity; 16 were evaluable for efficacy. The median age was 59, 12 (63%) were female, and 10 (52%) were Caucasian. The first pt on 8mg/kg had a Gr 3 non-DLT toxicity, so 3+3 dose escalation was then initiated. DLTs were seen at dosages of 12 (1 of 6 patients), 18 (1 of 6) and 25mg/kg (2 of 2), and were neutropenic fever (Gr 4), hypersensitivity reaction (Gr 3), AST elevation (Gr 4), and nausea/vomiting (Gr 3), respectively. The MTD was determined to be 18mg/kg. Grade 3/4 AEs seen in 2 pts each (12%) were: LFT abnormalities, anemia, neutropenia, and febrile neutropenia. One pt died on study related to disease progression and was deemed to not be drug related. No responses were observed; 3 patients had prolonged stable disease for 8, 10, and 11 cycles with ampullary, renal, and ovarian cancer, respectively, for a disease control rate of 19%. Tumor expression of transferrin and ABCB6 did not correlate with disease control. PK results will be presented. **Conclusions:** The MTD of IV AS is 18mg/kg on this schedule. Treatment was well tolerated at that dose level. Modest clinical activity was seen.

2536 Poster Session (Board #252), Sat, 8:00 AM-11:30 AM

Phase Ib study of afatinib plus standard-dose cetuximab in patients (pts) with advanced solid tumors. *First Author: Anas Gazzah, Drug Development Department, Gustave Roussy, Villejuif, France*

Background: Afatinib combined with cetuximab has shown activity in pts with *EGFR*mutation-positive NSCLC and acquired resistance to EGFR tyrosine kinase inhibitors. Targeting the ErbB pathway may also be beneficial in other tumor types; for example, squamous cancers have high levels of EGFR overexpression. This Phase Ib study assessed afatinib plus standard-dose cetuximab in pts with other advanced solid tumors. **Methods:** In Part A, a 3+3 design was used to determine the maximum tolerated dose (MTD) of afatinib (from 30 to 40 mg daily) plus cetuximab (400 mg/m^2 loading dose followed by 250 mg/m^{2}weekly). Treatment was administered until disease progression or unacceptable toxicity. Dose-limiting toxicities (DLTs) in cycle 1 were used to determine MTD. In Part B, MTD was assessed in 3 expansion cohorts (squamous NSCLC, squamous cell carcinoma of head and neck [HNSCC], other tumors). **Results:** In Part A, 3 pts received afatinib 30 mg in cohort 1, and 6 received afatinib 40 mg in cohort 2. No DLTs were observed in either cohort; MTD was defined as afatinib 40 mg once daily plus standard-dose cetuximab. In Part B, 39 pts have been treated to date at MTD (7 squamous NSCLC, 9 HNSCC and 23 other). Pts were heavily pre-treated (median 3 lines of prior therapy). Among the 45 pts receiving afatinib 40 mg, the most frequent drug-related adverse events (AEs; all grades [G], n [%]) were rash/acne (37 [82%]), diarrhea (28 [62%]), stomatitis (16 [36%]) and fatigue (13 [29%]). 12 pts had drug-related G3 AEs (most commonly rash/acne (5 [11%]) and fatigue (2 [4%]). There were 2 drug-related G4 AEs (hyperlipasemia and hypersensitivity) and no drug-related G5 AEs. Preliminary efficacy results showed that 38% of pts in the expansion cohort had stable disease (SD); 4/7 (57%) in squamous NSCLC, 3/9 (33%) in HNSCC, 8/23 (35%) in other tumors; no objective responses have been reported to date. Median duration of disease control was 12 weeks. **Conclusions:** MTD was defined as afatinib 40 mg once daily plus cetuximab 250 mg/m^2 weekly (after 400 mg/m^2 loading dose). At MTD, AEs were mild-to-moderate with no unexpected AEs. SD was observed in 38% of heavily pre-treated pts with squamous NSCLC, HNSCC, and other tumor types. Updated efficacy results will be presented. Clinical trial information: NCT02020577.

2537 Poster Session (Board #253), Sat, 8:00 AM-11:30 AM

Phase I trial of the HSP-90 inhibitor PU-H71. *First Author: John F. Gerecitano, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: PU-H71 (PU) is an HSP-90 inhibitor that can be labeled with ^{124}I without altering its biochemical properties. Intratumoral drug concentration can be calculated based on ^{124}I-PU-H71 (*PU) PET imaging, leading to a surrogate marker of intratumoral pharmacokinetics. **Methods:** Patients (pts) with previously treated solid tumors, lymphoma and myeloproliferative neoplasms (MPN) on ruxolitinib were eligible. PU was given days 1, 4, 8, 11 each 21 days at escalating dose levels using a Continuous Reassessment Method (CRM). The primary objective was determination of the MTD. Secondary objectives included plasma and intratumoral PKs measured by pre- and on-treatment core needle biopsies (CNB) and by *PU PET imaging. **Results:** To date, 40 pts have received PU at doses from 10-400mg/m^2. 37 are currently evaluable for DLT, and the last 3 pts needed (per CRM) are being enrolled. Five pts experienced DLTs: 1 (of 2) at 400 mg/m^2 - grade 3 mucositis; 4 (of 7) at 350 mg/m^2 – 1 pt grade 3 AST and ALT, 1 pt grade 3 nausea/vomiting + grade 2 intolerable myalgia, 1 pt grade 3 anemia, 1 pt grade 2 intolerable headache. Related grade 3 toxicities seen in more than one pt include: AST (n = 2), atrial fibrillation (n = 2), diarrhea (n = 2), hypertension (n = 2), hyponatremia (n = 3), lymphopenia (n = 6) and WBC decrease (n = 2). Grade 4 toxicities include lymphopenia (n = 2), amylase (n = 1), and urine output decrease (n = 1). Intratumoral concentrations of 0.5 – 8 μM (greater than the IC50 for most cancer cells) were consistently achieved 24h after first dose at doses of 50 - 300 mg/m^2, suggesting that target saturation may be achieved below DLT-related doses. Tumor regressions included: 22.6% in a cervical SCC pt (140 mg/m^2), 8.3% in a triple negative breast cancer pt (300 mg/m^2), 25.6% in an ER positive breast cancer pt (400 mg/m^2), 20.8% in a penile SCC (350 mg/m^2) pt and 20.6% in a Marginal Zone Lymphoma pt (50 mg/m^2). One MPN pt decreased WBC and increased hemoglobin > 1 unit. 23 pts had *PU PET imaging. 13 of these had CNBs. Intratumoral concentrations measured both ways were in close concordance. **Conclusions:** PU is a well tolerated HSP-90 inhibitor with signals of activity seen in several tumor types.*PU can be used to visualize PU uptake and *PU PET scans can be used to estimate intratumoral concentrations of PU. Clinical trial information: NCT01393509.

2538 Poster Session (Board #254), Sat, 8:00 AM-11:30 AM

Safety and pharmacokinetics (PK) of cabazitaxel (C) in patients (pts) with hepatic impairment (HI). *First Author: John Sarantopoulos, Institute for Drug Development, Cancer Therapy and Research Center, University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: C studies excluded pts with HI. A Phase I dose-escalation study (NCT01140607) assessed the effect of HI on C PK and safety in pts with advanced solid tumors. **Methods:** Pts with normal hepatic function (NHF; bilirubin [B] ≤ ULN; aspartate aminotransferase [AST] ≤ ULN), mild (MiHI; B > 1– ≤ 1.5 x ULN or AST > 1.5 x ULN), moderate (ModHI; B > 1.5– ≤ 3 x ULN) or severe (SHI; B > 3–10 x ULN) HI received C dose escalation starting at 25, 20, 10 or 10 mg/m^2, respectively. Endpoints were cycle 1 (C1) dose-limiting toxicities (DLTs), safety and PK. Plasma PK were derived by non-compartmental analysis. HI effect was assessed by linear mixed-effects modeling on clearance normalized to body surface area (CL/BSA) and exposure normalized to dose. **Results:** Pts (43 [6 NHF, 18 MiHI, 12 ModHI, 7 SHI]) had a median age of 60 years (range 18–79); 52% were male; 81% had ECOG performance status 1. Colon and liver tumors were most common (19%; prostate 7%). Maximum tolerated doses (MTD) were 20 (MiHI) and 15 mg/m^2 (ModHI). The SHI cohort was discontinued early (first pt treated at 20 mg/m^2 died). Median number of C cycles (range) at MTD were: NHF 3 (1–4); MiHI 2 (1–31); ModHI 2 (1–3). In evaluable pts, C1 DLTs were seen in 3/4 NHF, 3/11 MiHI and 1/6 ModHI pts at MTD, and 0/6 SHI pts at 10 and 15 mg/m^2. The most frequent DLT was grade 4 febrile neutropenia (FN). The most frequent C-related, grade 3–4 toxicities were neutropenia (42%), FN (16%) and anemia (12%). PK was assessed in 36 pts (6 NHF, 15 MiHI, 9 ModHI, 6 SHI). CL/BSA was lower (geometric mean 13.4 L/h/m^2) than typical values (26.4 L/h/m^2) in NHF, but similar in MiHI (23.5 L/h/m^2) and ModHI (27.9 L/h/m^2). CL/BSA in SHI was 18.1 L/h/m^2. Compared with MiHI, CL/BSA increased 19% in ModHI (geometric mean ratio 1.19; 90% CI 0.74−1.91), but decreased 23% in SHI (0.77; 0.39−1.53) (39% with erratic PK profiles excluded [0.61; 0.36–1.05]), and AUC_{last}/dose decreased 14% in ModHI (0.86; 0.50−1.46) and increased 17% in SHI (1.17; 0.63–2.14). No change in C free fraction was seen. A pt with cholangiocarcinoma on study had stable disease at cycle 32. **Conclusions:** Cabazitaxel tolerability was similar in pts with MiHI, ModHI or NHF, and consistent with prior reports. There is no evidence that MiHI or ModHI results in a substantial decline in C CL. Clinical trial information: NCT01140607.

2539 Poster Session (Board #255), Sat, 8:00 AM-11:30 AM

Phase 1 study of BPM 31510 (Ubidecarenone) in patients with advanced solid tumors (ST): Use of multiomics platform to evaluate reversal of Warburg effect. *First Author: Ralph Zinner, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BPM 31510 is a small molecule that targets the metabolic machinery of the cancer microenvironment to create a hallmark shift from lactate dependency towards mitochondrial oxidative phosphorylation, reversing the Warburg effect. Preclinical data indicate BPM 31510 causes this shift resulting in tumor regression and enhances the antitumor activity in combination with chemotherapy agents in a priming schedule. This is the first clinical study to evaluate BPM 31510 at a 4-days (d) continuous infusion in four arms; as a single agent, and in combination with Gemcitabine, 5-FU or Docetaxel. **Methods:** Eligible patients (pts) (aged ≥ 18 y) had previously treated relapsed/refractory ST. Pts in the monotherapy arm received IV BPM 31510 for 4 d in continuous infusion in 28-d cycles. Pts in the combination arms were primed for 3 wks and then started in a weekly dosing (either gemcitabine, 5-FU or docetaxel) after the BPM 31510 infusion in a 6-wk cycle. Doses were escalated in a 3+3 schema. Phase I endpoints were safety, PK and Multi-Omics based pharmacodynamics. Tumor response is evaluated at wk 2 and every 4 -6 wks. **Results:** As of 01 Dec 2014, 56 pts have been enrolled. Pts have been treated at 3 dose levels up to 137 mg/kg. No DLTs or treatment-related SAEs have been reported. MTD has not yet been established. Most frequently reported related AEs in all 4 arms were grade 1-2 INR prolongation that resolved after Vitamin K administration. No bleeding reported. Grade 1-2 thrombocytopenia has been seen in the Gemcitabine arm requiring dose modification. PK data indicated linear distribution. 12/25 pts (48%) that are evaluable for efficacy after cycle 2 showed various responses including: tumor reductions, decrease FDG, arrested tumor progression, stable disease, decrease in tumor markers, QOL improvements. Integrated multi-omics technology showed reversal of the Warburg effect in selected pts. **Conclusions:** Emerging data from this study suggest that BPM 31510 is well tolerated in monotherapy or in combination with chemotherapy agents. Early anti-tumor activity is seen. Dose-escalation on a 6-day infusion schedule is ongoing to determine the recommended phase II dose Clinical trial information: NCT01957735.

2540 Poster Session (Board #256), Sat, 8:00 AM-11:30 AM

Preliminary clinical pharmacokinetics and pharmacodynamics of Debio 1347 (CH5183284), a novel FGFR inhibitor. *First Author: Claudio Zanna, Debiopharm International SA, Lausanne, Switzerland*

Background: Deregulated fibroblast growth factor receptor (FGFR) signaling is associated with tumorigenesis. Debio 1347 is an orally-available ATP competitive inhibitor of FGFR 1, 2 and 3 with preclinical data showing high target-specificity and antitumor activity across models of FGFR amplified, mutated or translocated tumors for various human malignancies. Debio 1347 is currently investigated in selected patients harboring FGFR genetic alterations. **Methods:** The first-in-human, phase I dose-escalation study enrolls patients with advanced solid tumor malignancies harboring defined activating alterations of FGFR 1, 2, or 3. Patients receive Debio 1347 orally once daily. With a starting dose level of 10 mg the study follows a 3+3 dose-escalation scheme on a modified Fibonacci sequence (MH Voss et al, abstr TPS2629^, ASCO 2014). Debio 1347 plasma levels are measured after single and repeated dosing using a validated LC-MS/MS assay. The PD profile of Debio 1347 is also assessed by measuring plasma levels of several biomarkers including FGF23 and phosphate. PK/PD relationships are explored graphically. **Results:** Preliminary data from 22 patients treated with 10-40 mg/day during the dose escalation phase of the trial indicate that Debio 1347 is rapidly absorbed with a median tmax occurring at 3 hours post-dose. Apparent oral clearance (CL/F) and volume of distribution (Vz/F) are on average 8 L/hour and 130 L, respectively. Plasma levels generally decrease mono-exponentially with an average half-life of 11 hours. Debio 1347 plasma exposure is dose-proportional and accumulation after 28-day repeated dosing is in general insignificant. Plasma PD markers show time-dependent changes in several patients, particularly on higher dose levels enrolled to date, and appear correlated with Debio 1347 plasma levels. Hyperphosphatemia starts to be observed after 8 days of treatment in several patients and returns to normal values in few days in case of treatment withdrawal. **Conclusions:** The PK and PD properties of Debio 1347 suggest a once daily oral dosing regimen is appropriate and preliminary PD findings are indicative of Debio 1347 target engagement in patients with FGFR gene alterations.

2541 Poster Session (Board #257), Sat, 8:00 AM-11:30 AM

A phase I study of BI 853520, an inhibitor of focal adhesion kinase (FAK), in patients with advanced or metastatic solid tumors. *First Author: Alona Zer, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: BI 853520 is a potent and highly selective inhibitor of FAK. In the dose-finding part of this study in patients (pts) with advanced or metastatic solid tumors, the maximum tolerated dose (MTD) was determined as 200 mg in a continuous oral daily dosing schedule in 28-day cycles. Dose limiting toxicities included proteinuria grade 3 and fatigue grade 3. Preliminary pharmacokinetic (PK) data support the once-daily dosing schedule. BI 853520 is now evaluated at the MTD in expansion cohorts of selected tumor types. **Methods:** Pts with metastatic or advanced-pancreatic adenocarcinoma (PAC), platinum-resistant ovarian cancer (OC), esophageal cancer (EC) and soft tissue sarcoma (STS) are treated with 200 mg of BI 853520. Selection criteria: radiologically demonstrated progressive disease in 6 months before study entry and consent for tumor biopsies for biomarker assessment. Endpoints include further determination of safety profile (NCI Common Terminology Criteria for AEs (v4.03)), PK, pharmacodynamics (PD) and efficacy, determined according to RECIST v1.1 criteria. **Results:** To date, 41 pts have been treated: 8 PAC, 11 OC, 8 EC, 14 STS. Male/female ratio: 12/29, median age 62 years (range, 21–78 years), ECOG PS 0/1:10/31. Drug-related adverse events (AEs) in $>$ 10% of pts included proteinuria (58.5%), nausea (58.5%), diarrhea (48.8%), vomiting (36.6%), fatigue (19.5%), decreased appetite (14.6%), dyspepsia and dysgeusia (both 12.2%), in the majority of grade 1–2. Proteinuria grade 3 was reported in 8 pts and reversible upon treatment interruption. Ten pts underwent dose reduction. Three drug-related serious AEs have been reported of which none were fatal. Preliminary PD analysis in fresh tumor biopsies (pFAK) shows target engagement. Preliminary efficacy: of 30 evaluable pts 8 pts had stable disease lasting 2-6 cycles in PAC (3 pts), OC (1 pt), EC (1 pt) and in STS (3 pts), and 22 progressed. **Conclusions:** The safety profile of BI 853520 is favorable. Preliminary analysis shows anti-tumor efficacy in pts with progressive disease. Recruitment is ongoing and an update on all study endpoints will be provided at the meeting. Clinical trial information: NCT01335269.

2542 Poster Session (Board #258), Sat, 8:00 AM-11:30 AM

Phase I study of the safety and tolerability of the Exportin 1 (XPO1) inhibitor Selinexor (SXR) in Asian patients (pts) with advanced solid cancers. *First Author: David Shao Peng Tan, National University Cancer Institute, Singapore (NCIS), Singapore, Singapore*

Background: SXR is an orally administered potent XPO1 inhibitor that forces nuclear retention and activation of multiple tumor suppressor proteins resulting in tumor cell death. SXR was evaluated in Asian pts with advanced cancer to assess safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PDn) and efficacy. **Methods:** SXR dose escalation was initiated in a 3+3 design on a twice weekly continuous 28 day cycle, schedule 1 (S1), but stopped due to persistent drug-related adverse events (AEs). Two further schedules were explored: S2, once weekly continuously every 28 days, and S3, twice weekly for 2 weeks of a 21 day cycle. Serial tumor biopsies were performed pre- and 6-8 weeks post SXR. RECIST/ Cheson lymphoma criteria for response was evaluated every 2 cycles. **Results:** 18 pts (median age 61 yrs; ECOG 0-1) received escalating doses of SXR across 3 schedules. In S1 no dose-limiting toxicity (DLT) occurred at expanded dose-level (DL) 1 (40mg/m^2, 6pts), but was stopped due to persistent $\geq$ G2 AEs (fatigue [50%], hyponatremia [50%], anorexia [17%]) post cycle 1. In S2, at DL1 (50mg/m^2, 3pts) and DL2 (60mg/m^2, 3pts), G1/2 AEs were hyponatremia (67%), nausea (33%), fatigue (50%) and anorexia (50%) with no $\geq$ G3 AEs. In S3, at DL1 (40mg/m^2, 3 pts) and DL2 (50mg/m^2, 3 pts); AEs were hyponatremia G1/2 (50%) and $\geq$ G3 (50%), nausea G1/2 (33%) and $\geq$ G3 (17%), fatigue G1/2 (67%) and $\geq$ G3 (33%), anorexia G1/2 (67%). No DLTs occurred in S2/S3. PK analysis demonstrated SXR exposure with no accumulation and comparable half-life and clearance when compared with non-Asian pts. At 40mg/m^2, $AUC_{0\text{-}inf}$ (5,222 ng*h/mL) was comparable to the anti-tumor exposure observed in mice and dogs. Mean T_{max} = 2hrs and $T_{1/2}$ = 5.7 hrs. Reduced cellularity and proliferation with increased fibrosis and apoptosis was seen in tumors post-SXR administration. Of 13 evaluable pts, best responses were PR in 2pts with refractory diffuse-large B-cell lymphoma, SD in 8 pts (colorectal [n = 2], pancreas, squamous cell tongue, non-small cell lung, ovarian and hepatocellular carcinoma [n = 2]), and PD in 3pts. **Conclusions:** Dose-escalation of SXR is ongoing on S2 and S3 with more G3 AEs seen in S3. Promising antitumor activity was observed. Clinical trial information: NCT02078349.

2543 Poster Session (Board #259), Sat, 8:00 AM-11:30 AM

Predicting outcomes in patients with advanced malignancies treated on Phase 1 clinical trials. *First Author: Kit Man Wong, University of Colorado, Denver, CO*

Background: Appropriate selection of patients fit for Phase 1 trials is critical to avoid harm and maximize the potential for benefit, yet this can be challenging. Previous studies of prognostic factors demonstrated mixed results and many were limited by small cohorts. There is no consensus on the optimal prognostication strategy. We analyzed outcomes and prognostic factors of a large cohort of Phase 1 patients treated at an academic center. **Methods:** 779 patients with advanced solid malignancies enrolled on Phase 1 trials from 2001-2009 at the University of Colorado were included. Baseline patient, disease and lab parameters, trial characteristics and outcomes were extracted from a prospective IRB-approved database. Associations between clinical factors and 90-day mortality (90DM), overall survival (OS), progression-free survival (PFS) and response rate (RR: CR+PR) were analyzed by multivariate Cox or logistic regression. **Results:** The study population had a median age of 59 (18-87) years and 49% males. Gastrointestinal (GI) cancers were most common (30%). 151 (19%) patients had $\geq$ 3 metastatic sites, mainly lungs (37%) and liver (33%), while 350 (45%) had $>$ 2 prior lines of therapy. The experimental regimen consisted of: 88% targeted, 1% cytotoxic, 11% both. Median PFS and OS were 8.0 (95% CI 7.6-8.4) and 31 (95% CI 27-34) weeks, respectively. The 90DM rate was 31% and RR was 3.1%. The likelihood of 90DM was associated with high LDH ($>$ 2.5x upper limit of normal (ULN) vs. $<$ ULN: adjusted odds ratio (aOR) 4.6, 95% CI 1.7-12.2) and low albumin ($<$ 30 vs. $>$ 35g/L: aOR 5.1, 95% CI 3.0-8.7). Independent factors for poor OS included breast, gynecologic and GI tumors, LDH $>$ ULN, ALP $>$ ULN, albumin $<$ 35g/L, and Hb $<$ 80g/L. Shorter PFS was also predicted by these factors (except ALP), as well as $>$ 2 prior treatments, use of targeted therapy alone and $\geq$ 2 agents. Addition of cytotoxics to a targeted agent significantly increased response (aOR 6.5, 95% CI 2.5-16.8). **Conclusions:** This single-center cohort of Phase 1 patients is characterized by a unique set of prognostic factors, some of which are consistent with prior studies. Tumor type, LDH, ALP, albumin and Hb are potential determinants of OS. Further validation of these prognostic factors is warranted.

2544 Poster Session (Board #260), Sat, 8:00 AM-11:30 AM

First-in-man combination phase I study of TAS-114 and S-1 in patients (pts) with advanced solid tumors. *First Author: Toshihiko Doi, National Cancer Center Hospital East, Chiba, Japan*

Background: TAS-114 is a first-in-class oral deoxyuridine triphosphatase inhibitor, which acts as a modulator of the pyrimidine nucleotide metabolic pathway. We are conducting a first combination phase 1 dose escalation and expansion study of TAS-114 and S-1 to investigate the safety, maximum-tolerated dose (MTD), pharmacokinetics (PK), pharmacogenomics and preliminary antitumor efficacy in pts with advanced solid tumors refractory to standard therapy. **Methods:** TAS-114 was administrated orally BID for 14 days followed by 7 days rest at the starting dosage of 5 mg/m^2 with the fixed dosage of S-1 (30 mg/m^2). Dose-limiting toxicity (DLT) was evaluated during the 1st cycle in dose escalation cohort (DEC), using a 3 + 3 design. Expansion cohort (EC) is conducted in parallel with DEC at the dosage which was confirmed tolerable in DEC. **Results:** As of 25 September 2014, 56 pts were enrolled with 36 pts in the DEC and 20 pts in the EC. In DEC, dosage of TAS-114 was escalated up to 240 mg/m^2 with a MTD not yet reached. In EC, TAS-114 was administrated at the dosage of 120 and 160 mg/m^2 with the fixed dosage of S-1 (30 mg/m^2). Currently, we are planning the dose escalation of TAS-114 with Japanese approved fixed dose of S-1 (36 mg/m^2). A recommended phase 2 dose is expected to be reached soon. Two pts at the dosage of 10 and 240 mg/m^2 developed DLTs, including grade 2 platelet count decreased and grade 3 aspartate aminotransferase increased. The most common treatment related adverse events were white blood cell decreased, anemia and rash. TAS-114 exposures tend to increase dose-dependently with large inter-individual variability. Preliminary antitumor efficacy was observed with acceptable safety in pts with NSCLC, gastric cancer and pancreatic neuroendocrine tumor. Especially, partial responses were confirmed in 2 of efficacy evaluable 6 pts with NSCLC. Further safety, PK and efficacy data will be presented. **Conclusions:** The combination therapy of TAS-114 and S-1 was well tolerated in pts with severe treated advanced solid tumors, resulting in the promising antitumor efficacy. Further safety and efficacy of this combination therapy will be investigated in this phase 1 and subsequent phase 2 study. Clinical trial information: NCT01610479 Clinical trial information: NCT01610479.

2545 Poster Session (Board #261), Sat, 8:00 AM-11:30 AM

Phase 1, first-in-human study of ARQ 087, an oral pan-Fibroblast Growth Factor Receptor (FGFR) inhibitor, in patients (pts) with advanced solid tumors. *First Author: Kyriakos P. Papadopoulos, START Center for Cancer Care, San Antonio, TX*

Background: ARQ 087 is a novel, orally bioavailable, ATP-competitive inhibitor of multiple kinases, including FGFR1-3. It has potent *in vitro* and *in vivo* inhibitory effects on a variety of human tumor cell lines and xenograft models dependent on FGFR signaling. **Methods:** This first-in-human 2-step study was initiated in pts with advanced solid tumors. Step 1: dose escalation/food-effect to characterize PK, safety, maximum tolerated and recommended Phase 2 Dose (RP2D; unselected for FGFR aberration). Step 2: expansion cohort to to assess safety and clinical activity of ARQ 087 in selected tumor types, including FGFR gene amplification, translocation and mutation. Assessments included tumor molecular status, response by RECIST v.1.1 every 8 weeks (wks), plasma concentrations of FGF19, 21, 23, fasting glucose and phosphate. **Results:** 61pts were treated (dose range 25-425mg QOD or QD) in Step 1; the majority were female (61%), mean age 64 yrs (34 -78). The RP2D was defined as 300 mg QD continuous dosing. Dose-limiting toxicities included increased liver enzymes (reversible Grade (G) 3 AST increase). Common drug-related adverse events (AEs; mostly G $\leq$ 2) were fatigue (53%), elevated LFTs (45%), nausea (45%), vomiting (20%) and diarrhea (20%). Only 2 pts (3%) experienced G1 drug-related hyperphosphatemia. Drug $t_{1/2}$ was 2-11 days, PK was unaffected by food. FGF 19/21/23 concentrations post-treatment were increased 1.5-6 fold. Ten pts in Step 1 had confirmed stable disease (SD) $\geq$ 16 wks (adrenocortical [2], endometrial, ovarian, NSCLC, choroidal melanoma, carcinoid, sarcoma [3]). A squamous NSCLC pt with Src amplification had SD (24% tumor reduction) for 32 wks. One adrenocortical carcinoma pt with FGFR1 amplification remains on study $>$ 22 months. Two ongoing pts with intrahepatic cholangiocarcinoma with FGFR2 fusions demonstrated a partial response and SD $>$ 24 wks with 26% decrease in target lesions, respectively. **Conclusions:** ARQ 087 has manageable, mostly G $\leq$ 2 AEs. It has demonstrated preliminary antitumor activity in pts with FGFR-pathway aberrations. Further evaluation of ARQ 087 in pre-defined tumor types is ongoing. Clinical trial information: NCT01752920.

2546 Poster Session (Board #262), Sat, 8:00 AM-11:30 AM

Dermatologic toxicities of 3,517 solid tumor patients on phase I clinical trials of the National Institutes of Health Cancer Therapy Evaluation Program (CTEP). *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Dermatologic adverse events (AEs) can be key determinants of overall drug tolerability, and the maximum tolerated and recommended phase II doses of therapy on phase I trials. We present the largest dedicated analysis of dermatologic AEs on phase I trials to date. **Methods:** Data from a prospectively maintained database of solid tumor patients (pts) enrolled onto CTEP-sponsored phase I trials from 2000 to 2010 was analyzed. Cumulative incidence, site, type, and timing of drug-related dermatologic AEs were described and compared between pts who received molecularly targeted agents (MTAs), cytotoxic therapy, or a combination of both. **Results:** 3,517 solid tumor pts and 6,165 unique drug-related dermatologic AEs were analyzed: 1,545 pts on MTA only trials, 671 on cytotoxic only trials, and 1,392 on combination MTA and cytotoxic trials. Percent grade 1, 2, 3, and 4 dermatologic drug-related AEs were 75.5%, 22.6%, 1.9% and $<$ 0.1%, respectively. Most common drug-related dermatologic AEs were alopecia (23%) and maculopapular rash (21%). Of 1,270 pts with drug-related dermatologic AEs, timing of worst drug-related toxicity was: 743 pts (cycle 1), 303 (cycle 2), and 224 (cycle 3 or later). While cumulative incidence of $\geq$ grade 3 drug-related dermatologic AEs increased to 2.4% by cycle 6, it was only 1.6% at the end of cycle 1. Cumulative incidence of drug-related dermatologic AEs was highest in pts with MTA only therapy, and significantly differed by dose level ($p < 0.001$). In pts who received MTA only therapy, drug-related dermatologic toxicity was most common for combination kinase inhibitor-containing therapy ($p < 0.001$). **Conclusions:** A substantial proportion of drug-related dermatologic AEs occurs after the traditional DLT monitoring period. Future phase I trial designs should account for delayed toxicities to avoid defining intolerable doses of study therapy.

2547 Poster Session (Board #263), Sat, 8:00 AM-11:30 AM

A first in human Phase I/II study of NUC-1031 in patients with advanced gynecological cancers. *First Author: Sarah Patricia Blagden, Ovarian Cancer Action Research Centre, London, United Kingdom*

Background: Acquired resistance to chemotherapy hampers patients'survival from many gynecological malignancies. NUC-1031, a first-in-class nucleotide analogue, utilises phosphoramidate chemistry to overcome key drug resistance mechanisms and enhance anti-cancer activity. **Methods:** NUC-1031 was given as a single injection either 1) on days 1,8, & 15 of a 28 day cycle (q4w) in doses ranging from 500mg/m^2 to 1000mg/m^2, or 2) as a twice weekly schedule on days 1 & 5, 8 & 12, 15 & 19 q4w at 375mg/m^2. Primary endpoints were safety and tolerability, and secondary endpoints were pharmacokinetics (PK), pharmacodynamics and efficacy. **Results:** Of 68 patients (pts) enrolled in this study, 18 had primary gynecological cancers: 13 ovary/fallopian tube (comprising high grade serous (HGS) (10), G2 endometrioid (2), mixed clear cell/serous (1)), 3 endometrium (comprising G3 serous (2), MMMT (1)), and 2 cervix (SCC). Pts had a mean age of 59 years (age range 42-78 yrs) and received an average of 3.5 prior chemotherapy regimens. All pts with HGS cancers were platinum resistant with average platinum-free interval 3.7 months (range 0.3 – 6.9 mths). NUC-1031 was well tolerated. In total 9 SAEs were reported in 7 pts. The most common AEs of grade $\geq$ 3 considered 'possibly/probably related' to the study agent were: myelosuppression (8); fatigue (6); GGT (3). The PK profiles revealed high and sustained intracellular levels of the active metabolite dFdCTP (AUC of 2.1 nmol/million cells/hr) over 24 hrs. Fourteen of the 18 pts had received at least 2 cycles of NUC-1031 and were evaluable for RECIST assessment of response. Significant disease control rate (DCR) was observed: 2 Partial Responses (14%); 11 Stable Disease (79%) for an ITT DCR of 72% and on treatment analysis (OTA) DCR of 93%. The mean PFS was 7.5 months (range 3 – 15 mths), with 3 pts showing ongoing disease control. **Conclusions:** NUC-1031 showed clear signs of clinical activity in patients with gynecological cancers, OTA DCR 93%. The agent was well tolerated, with durable SD and PR observed, PFS 7.5 months. A Phase Ib study of NUC-1031 in combination with carboplatin is ongoing. Phase III studies are planned in both platinum sensitive and refractory gynecological cancers. Clinical trial information: NCT01621854.

2548 Poster Session (Board #264), Sat, 8:00 AM-11:30 AM

Biomarker analysis from a Phase I study of copanlisib with expansion cohorts in solid tumors with and without PIK3CA mutations and NHL. *First Author: Carol Elaine Pena, Bayer HealthCare Pharmaceuticals, Whippany, NJ*

Background: Copanlisib is a novel, selective, reversible, pan-Class I phosphatidylinositol-3-kinase (PI3K) inhibitor with potent activity against both the δ and α isoforms. Safety and tumor response data from the first-in-man phase I trial have been reported (Patnaik et al., 2012, ASH), with two patients with follicular lymphoma ongoing as of January 2015, with partial responses lasting 1380 and 909 days. A secondary objective of the study was to identify biomarkers associating with copanlisib response. **Methods:** After dose escalation, expansion cohorts were enrolled and treated at the maximum tolerated dose (0.8 mg/kg, iv, on days 1, 8 and 15 of a 28-day cycle), including solid tumors (n = 25) with and without PIK3CA mutations, and non-Hodgkin lymphoma (NHL; n = 9). PIK3CA, BRAF, and KRAS mutations were tested using digital PCR on archival tumor samples and circulating tumor (ct) DNA from plasma (BEAMing). Next generation sequencing (NGS) of tumor genes and IHC for PTEN were performed on archival tumor samples. **Results:** Ten of 25 solid tumor patients (40%) had mutations in PIK3CA in tumor (BEAMing: 5/22; NGS: 4/9) and/or ctDNA (7/25), of which 8 had breast cancer; 2 of 22 tested (9%) had KRAS mutations. None of the NHLs tested had PIK3CA or KRAS mutations. PTEN loss was identified by IHC in 9 of 18 (50%) solid tumors, and in 1 of 7 (14%) NHLs tested. PTEN mutations were detected in 2 of 11 cases; both had PTEN loss. Of the 9 solid tumor patients with PTEN loss, 1 had a complete radiological response (CR) lasting more than one year and 2 had extended stable disease (SD) ($\geq$ 4 cycles); conversely, of the 9 without PTEN loss, none had an objective response (OR) or extended SD. The CR was in an endometrial cancer patient with PTEN loss and both PTEN and PIK3CA mutations. However, PIK3CA mutations alone did not seem to enrich response rate, as 3 of 10 (30%) patients with PIK3CA mutations and 4 of 15 (27%) without had either an OR or extended SD. **Conclusions:** PTEN loss, but not PIK3CA mutations alone, may enrich for response to copanlisib in this mixed solid tumor expansion cohort. The CR to copanlisib in the presence of both PTEN and PIK3CA aberrations may be due to multiple mechanisms leading to PI3K pathway activation. Clinical trial information: NCT00962611.

2549 Poster Session (Board #265), Sat, 8:00 AM-11:30 AM

Phase I trial of tivantinib in combination with carboplatin and pemetrexed as first-line treatment in patients with advanced nonsquamous non small cell lung cancer or malignant pleural mesothelioma. *First Author: Paolo Andrea Zucali, Department of Oncology, Humanitas Research Hospital - Humanitas Cancer Center, Rozzano, Italy*

Background: Tivantinib (T) is a selective non-ATP competitive oral inhibitor of MET receptor. Preclinical data showed that MET inhibition blocks Malignant Pleural Mesothelioma (MPM) and Non Small Cell Lung Cancer (NSCLC) cell growth and migration. Adding T to standard first-line chemotherapy may improve efficacy. **Methods:** Patients (pts) with advanced MPM or non-squamous NSCLC were eligible to receive escalating doses of T combined with carboplatin (C) AUC 5 i.v. d1-q21 and pemetrexed (P) 500 mg/m2 i.v. d1-q21 as first-line treatment. After 6 cycles of CP, T is continued as maintenance therapy until progression. Pts must be chemo-naïve with ECOG Performance Status (PS) < 2 and adequate bone marrow, liver, and kidney functions. A standard 3+3 dose-escalation design was employed starting from dose level 0 (T 240 mg BID). The primary endpoint of the phase I study was to assess the maximum tolerated dose (MTD), defined as the highest dose level at which no more than 1 of 6 pts experiences a dose limiting toxicity (DLT) during the first cycle. To evaluate the anti-tumor activity (MPM pts: 3-month PFS%; NSCLC pts: 5-month PFS%) and the pharmacokinetics of the combination, a phase Ib trial is still ongoing. **Results:** From April 2013 to September 2014, 12 pts were enrolled in the phase I study; mean age was 69 years (range, 37-73 years), M/F: 9/3, ECOG PS 0/1: 5/7, MPM/NSCLC: 6/6. The MTD was reached at dose level 0 (T 240 mg BID). DLTs (2 neutropenia G4, 1 thrombocytopenia G4) were observed in 2 pts, both at dose level 1 (T 360 mg BID). The most common all-grade toxicities were nausea/vomit (67%), anemia (58%), neutropenia (50%), and asthenia (50%). G3/4 treatment-related AEs were reported in 6 pts (50%) and all were hematological (neutropenia, thrombocytopenia, anemia). All pts received 6 cycles of CT. Among 12 evaluable pts, 1 had CR, 4 PR, and 7 SD as best response. **Conclusions:** Adding T to CP is safe with preliminary evidence of antitumor activity. T 240 mg BID in combination with C AUC 5 i.v. d1-q21 and P 500 mg/m2 i.v. d1-q21 represents the recommended dose for phase II trials. Clinical trial information: NCT02049060.

2550 Poster Session (Board #266), Sat, 8:00 AM-11:30 AM

SORAVE: A phase I trial to evaluate safety and efficacy of combination therapy with everolimus and sorafenib. *First Author: Christian Mattonet, Lung Cancer Group Cologne, Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

Background: Combined inhibition of signaling pathways interfering with angiogenesis and cell proliferation may overcome mechanisms of drug resistance in tumors. We evaluated the combination of the multikinase inhibitor sorafenib (S) and the mTOR inhibitor everolimus (E) and assessed pharmacodynamic (PD) activity of E by PET. **Methods:** Patients with relapsed solid tumors received escalating doses of E 2.5-10.0mg/d in a 14 days monotherapy run in phase followed by combination therapy with a fixed dose of S 800mg/d from day 15. Further patients were treated with the MTD in an extension phase. The primary aim was to define a safe and feasible combination treatment regimen. DLT was defined as any drug related toxicity of CTC IV° or requiring hospitalization or interruption of therapy for > 2 weeks within the first 29 days of treatment. Pharmacokinetic (PK) analyses were performed on days 5, 14 and 29 combined with explorative PD assessment of E by FDG-PET on days 1, 5 and 14 of treatment. Efficacy was assessed by CT (RECIST 1.1) every six weeks of combination treatment. **Results:** 31 patients (mean age 58.5 years) were enrolled and evaluable from October 2009 to December 2013, of which 16 (51.6%) had NSCLC. DLT was not observed according to protocol definition in the dose finding phase (18 patients), however the MTD for treatment of further patients was defined at 7.5mg/d E + 800mg/d S due to toxicities at 10mg E occurring after the DLT-defining interval (leucopenia / thrombocytopenia III° and pneumonia III°). The median PFS of all treated patients was 99 days (95% CI 85.7 - 112.3), the median OS was 178 days (95% CI 116.9 - 239.1). In 24 of 29 evaluable patients (82.8%) a decrease in SUVmax of the hottest lesion could be observed in PET, the best response as by PERCIST criteria was PR in 7 (21.4%) and SD in 21 (72.4%) patients. No patient reached PR in CT scan whereas 8 of 21 (38.1%) evaluable patients showed confirmed SD over at least 14 weeks. **Conclusions:** Treatment of patients with relapsed solid tumors with a combination of 7.5mg/d E and 800mg/d S is safe and feasible. Most tumors show a moderate metabolic decrease in PET, however this seems to reflect more a pharmacodynamic effect than long term disease control observed in this group of patients. Clinical trial information: NCT00933777.

2551 Poster Session (Board #267), Sat, 8:00 AM-11:30 AM

Phase 1 study of the folic acid (FA) and tubulysin B hydrazide (TubBH) small molecule drug conjugate (SMDC) EC1456 in patients (pts) with advanced cancers (CA). *First Author: Daniela Matei, Indiana Univ Simon Cancer Ctr, Indianapolis, IN*

Background: The folate receptor (FR) is expressed in many cancers, with limited expression in most normal tissues. EC1456, a potent SMDC of FA and the anti-tubulin cytotoxic TubBH, targets delivery of TubBH to FR-expressing cells. EC1456 demonstrated potent activity in paclitaxel- and cisplatin-resistant FR expressing cells. In murine models of FR-expressing xenografts, EC1456 caused complete tumor regression without significant toxicity. Enhanced anti-tumor activity was observed when EC1456 was combined with platinum, taxanes, and topotecan in preclinical models. These data led to this clinical evaluation of EC1456 in advanced CA pts. **Methods:** The primary objective is to determine the MTD of EC1456 administered on 2 schedules (BIW: days 1, 4, 8, 11 q 21 or 28 days [dosages: 0.5-6.0 mg/m^2)], or QW: days 1, 8 q 21 days (dosage: 1.5-6.0 mg/m^2). Key inclusion criteria: age $\geq$ 18 years, ECOG PS 0–1, and adequate organ function. ^{99m}Tc-etarfolatide scan to evaluate FR status is to be obtained on enrolled pts. Dose escalation follows the "3+3" protocol for BIW cohort, and continuous reassessment method for QW cohort. Cycle 1 DLT evaluation must be completed for each schedule cohort prior to dosing a new cohort. **Results:** 16 pts have been treated: median age: 67.5 (48-86), M/F: 7/16. 11 pts have received 50 cycles of EC1456 BIW (median 2; range: 1-16), and 5 pts have received 19 cycles of EC1456 QW (median 4; range: 1-8). The only DLT and treatment related (TR) SAE occurred at 4.5 mg/m^2 QW schedule (Grade 3 infusion reaction). There have been no TR-deaths, Grade 4 toxicity, or toxicity causing dose delay, omission or reduction. Most TR-AEs have been Grade 1-2. Stable disease $>$ 14 cycles has been observed in 2 pts with FR expression on ^{99m}Tc-etarfolatide SPECT scan (mesothelioma; GEJ CA) on BIW schedule, and SD $>$ 6 cycles in 1 pt (leiomyosarcoma) on QW schedule. **Conclusions:** Due to the DLT on the QW schedule, cohort expansion is ongoing at 3.5 mg/m^2. Dose escalation of EC1456 BIW is ongoing. EC1456 is generally well tolerated. PK data are anticipated in May 2015. Clinical trial information: 001999738.

2552 Poster Session (Board #268), Sat, 8:00 AM-11:30 AM

ANG1005 for brain metastases from breast cancer: 18F-FLT-PET and MRI as complementary approaches to response assessment. *First Author: Susan Elaine Bates, Medical Oncology Branch, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: ANG1005 is a novel drug conjugate consisting of 3 molecules of paclitaxel covalently linked to Angiopep-2, designed to cross the blood brain barrier (BBB) via endocytosis after binding to LRP-1. A multi-center Phase II study with the primary endpoint of intra-cranial response in patients with brain metastases from breast cancer is ongoing. At the NCI a biomarker substudy is evaluating ^{18}F-FLT (3'-Fluoro-3' deoxythymidine)-PET for response assessment. **Methods:** ANG1005 was administered IV at 550 mg/m^2 q21d to patients with measurable brain metastases from breast cancer. All patients underwent imaging before and after cycle 1 with ^{18}F-FLT, a thymidine analog and novel imaging agent; its retention reflecting DNA synthesis. We compared FLT PET images with Gd-MRI contrast scans for brain metastasis detection and response assessment. Both dynamic and static images were obtained. The % change after ANG1005 was determined, with 20% considered significant. Nine of 10 planned patients have been accrued. **Results:** Eighteen metastatic brain lesions in 8 patients were analyzed. The maximum standard uptake value (SUVmax) ranged from 0.8 to 4.0 in the baseline scan, mean 1.8. Twelve of the 18 lesions showed a $>$ 20% change post therapy. The average % change was -24.8% (range: 11 to -66.8%) using SUVmax, and -7.7% using tumor to normal ratios. The FLT-PET uptake reduction exceeded the MRI result in 4 patients. Two patients had confirmed partial responses lasting 6 and 14 cycles, respectively. Six patients had stable disease, receiving a median 6 cycles. The best tumor reductions, as determined by MRI per CNS RECIST v1.1 ranged from -5% to -60% in lesion size, compared to baseline. **Conclusions:** CNS metastases from breast cancer require new CNS-directed therapies designed to cross the BBB, such as the paclitaxel conjugate ANG1005. Given that contrast-enhanced MRI detection of brain metastases represents gadolinium leakage through the BBB, rather than actual tumor volume, better approaches are needed to assess drug efficacy. Pilot evaluations of FLT-PET imaging of brain metastases suggest that it is a promising tool that may serve as a complementary assessment method for CNS disease. Clinical trial information: NCT01480583.

2553 Poster Session (Board #269), Sat, 8:00 AM-11:30 AM

Pharmacologic advantage (PA) of intraperitoneal (IP) nab-paclitaxel in patients with advanced malignancies primarily confined to the peritoneal cavity. *First Author: Mihaela C. Cristea, City of Hope, Department of Medical Oncology and Therapeutics Research, Duarte, CA*

Background: *nab*-Paclitaxel is albumin-bound paclitaxel that achieves higher intratumoral concentrations and undergoes receptor-mediated transcytosis across cell membranes. Previous clinical trials have demonstrated an advantage to IP chemotherapy. A phase I study was undertaken to evaluate the safety, tolerability and pharmacokinetics of IP *nab*-paclitaxel. **Methods:** Eligible pts received IP *nab*-paclitaxel on D1, 8, 15 of a 28-day cycle with a 3+3 dose-escalation design. Plasma and peritoneal pharmacokinetic (PK) samples were drawn prior to dose, immediately upon completion of infusion, 1, 2, 4, 6, 8, 12, 24 and 48 hours post-dose on C1D1 and C1D15. **Results:** The trial is complete with 27 pts with peritoneal carcinomatosis secondary to GYN (n=14), GI (n=12) malignancies and 1 pt with peritoneal mesothelioma. The starting dose level was 35mg/m^2 and escalated to 170mg/m^2. The MTD of IP *nab*-paclitaxel was established at 140 mg/m^2. DLTs included grade 3 neutropenia resulting in treatment delay >15 days, grade 3 abdominal pain and grade 4 neutropenia > 7 days. Plasma and IP PK data are summarized below in the Table. Over the four dose levels, the data show a ~150-fold PA to IP *nab*-paclitaxel with low intra-pt variability. The lowest PA was 50-fold. **Conclusions:** PK results suggest a significant PA to IP *nab*-paclitaxel (i.e. higher peritoneal exposure compared to plasma).The inter- and intra-patient variability appears to be low. The plasma AUC's resulting from IP *nab*-paclitaxel at the MTD of 140 mg/m^2 are similar to plasma AUC's associated with IV *nab*-paclitaxel at 100 mg/m^2. In addition to achieving high local drug levels in the peritoneum, patients are also exposed to therapeutic systemic drug levels. This study was funded by the National Comprehensive Cancer Network (NCCN) with support from Celgene Corporation. Clinical trial information: NCT00825201.

nab-Paclitaxel Dose (mg/m^2)	N	Treatment Day	Plasma AUC (mg/L x hr)	Peritoneal AUC (mg/L x hr)	Ratio (%)
35	1	Cycle 1 Day 1	0.6	89	160
		Cycle 1 Day 15	0.5	93	172
70	1	Cycle 1 Day 1	1.5	299	194
		Cycle 1 Day 15	1.6	321	199
90	1	Cycle 1 Day 1	1.1	207	94
		Cycle 1 Day 15	1.1	194	72
112.5	3	Cycle 1 Day 1	3.0 (0.8-4.2)	305 (210-427)	134 (50-389)
		Cycle 1 Day 15	2.5 (0.6-3.2)	290 (230-358)	118 (88-403)

2554 Poster Session (Board #270), Sat, 8:00 AM-11:30 AM

A phase I study of ARQ 197 in combination with temsirolimus in advanced solid tumors. *First Author: Christos Kyriakopoulos, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: A wide variety of human cancers exhibit dysregulated c-Met activity that has implications in oncogenesis. Phosphorylation of c-Met results in activation of the PI3K/AKT/mTOR pathway. Combined blockade of c-Met and mTOR pathways has shown efficacy in preclinical studies. ARQ 197 (tivantinib) is a c-Met inhibitor and temsirolimus is a selective mTOR inhibitor. We aimed to determine the maximum tolerated dose (MTD), dose-limiting toxicities (DLT), adverse events (AEs), clinical activity and pharmacokinetic (PK) parameters of the above combination. **Methods:** This open-label phase I study used a 3 + 3 dose escalation design. Patients (pts) in cohorts of 3 were treated with escalating doses of ARQ 197 (120-360 mg tablets orally twice daily) and temsirolimus (20 mg IV weekly) followed by dose expansion at MTD. Separate cohorts were planned for poor and extensive ARQ 197 metabolizers based on CYP2C19 genotypes. Cycles were 28 days besides cycle 1 that was 35 days to allow for PK analysis. **Results:** 21 pts (median age 57 [range 29-71]) were enrolled for dose escalation. All were extensive CYP2C19 metabolizers. The most common types of cancer were colorectal (6 pts), ovarian (4 pts), renal (2 pts) and pancreatic (2 pts). In the dose escalation cohort, 16/21 pts were evaluable per protocol. They remained on study for a median of 73.6 days (range 15-296). The MTD was ARQ 197 240 mg bid and temsirolimus 20 mg once weekly. DLTs included grade (gr) 4 neutropenia (2 pts; 1 with gr 3 febrile neutropenia) and gr 3 abdominal pain (1 pt). The most common AEs at least possibly related to therapy included: fatigue (62%; gr 1-2 in 12 pts, gr 3 in 1 pt), anemia (48%; gr 2 in 9 pts, gr 3 in 1 pt), nausea (48%; gr 1-2 in 9 pts, gr 3 in 1 pt), vomiting (48%; gr 1-2 in 9 pts, gr 3 in 1 pt) and diarrhea (48%; gr 1-2 in 9 pts, gr 3 in 1 pt). 1 pt with ovarian cancer had a confirmed partial response and remained on study for 9 months. A second pt with ovarian cancer has stable disease and remains on study at 5 months. 4 of 6 pts have been enrolled to the dose expansion cohort and are in cycle 1. Data from the dose expansion will be presented. **Conclusions:** The combination of ARQ 197 with temsirolimus appears to be well tolerated with evidence of clinical activity. The MTD expansion and PK analysis are ongoing. Clinical trial information: NCT01625156.

2555 Poster Session (Board #271), Sat, 8:00 AM-11:30 AM

First-in-human phase I study of the DNA repair inhibitor DT01 in combination with radiotherapy in patients with in transit melanoma. *First Author: Christophe Le Tourneau, Institut Curie, Department of Medical Oncology, Paris, France*

Background: DT01 is a double stranded DNA oligonucleotide conjugated to cholesterol, which mimics "false" double strand breaks (DSB). DT01 triggers DNA repair proteins trapping, thereby inhibiting their repair activity. In non-clinical studies, DT01 showed antitumor activity as a single agent and in combination with radiotherapy (RT) in several tumor types including melanoma. No NOAEL could be defined. **Methods:** Subcutaneous peritumoral and intratumoral injections of DT01 were evaluated in combination with RT in a first-in-human phase I trial in patients (pts) with unresectable in-transit metastases of melanoma. Each pt received RT at a standard dose (3Gy/d 5 days/week for 2 weeks) on all selected tumor lesions, while only one or two tumor lesions were treated with DT01 3 times a week during both weeks of RT. A 3+3 dose escalation design was used. DT01 dose levels explored were 16, 32, 48, 64, and 96 mg. RT was given using a rectangular field by a linear accelerator. Tolerance was assessed using NCI CTCAE v4.3 and efficacy using modified RECIST criteria 1.1. **Results:** Seventeen pts (16 eligible) were included in the trial, of whom received RT alone in 31 and RT + DT01 in 31 tumor target lesions. As no dose-limiting toxicity was observed, the maximum tolerated dose was not reached. Most frequent adverse events were reversible grade 1 and 2 injection site reactions. PK analyses suggested a systemic passage of DT01 in a non-linear fashion. Overall response rates (ORR) were 68% and 48% in tumor lesions treated with RT + DT01 and RT alone, respectively. Notably, ORR correlated with blood AUC ($p = 0.01$), suggesting 1) an anti-tumor activity of DT01, and 2) a systemic effect of DT01. **Conclusions:** DT01 in combination with RT is safe in patients with metastatic in-transit melanoma, and provides antitumor activity in DT01-treated and non-treated lesions possibly explained by a systemic distribution of the drug. Clinical trial information: NCT01469455.

2556 Poster Session (Board #272), Sat, 8:00 AM-11:30 AM

Rationale for the combination of veliparib with platinum-based chemotherapy. *First Author: David Maag, AbbVie, North Chicago, IL*

Background: Owing to the role of PARPs in DNA damage repair, PARP inhibitors (PARPi) are under clinical investigation as anticancer therapies with a focus on tumors with impaired homologous recombination or regimens containing DNA damaging chemotherapies. Pre-clinical evidence indicates that PARPi potentiate the cytotoxicity of platinums. A recent Phase II study suggested evidence of a benefit in both progression and survival when veliparib was added to carboplatin and paclitaxel in the treatment of advanced NSCLC. **Methods:** *In vitro*efficacy was evaluated in GFP-overexpressing cell lines cultured as 3D spheroids. *In vivo* efficacy was determined in xenograft tumor-bearing SCID mice. PARP1 trapping was evaluated by cellular fractionation and immunoblotting. Bone marrow toxicity was determined with CFU assays. **Results:** We have developed a method to monitor the growth of 3D spheroids *in vitro* in real time. In this system, veliparib potentiated the activity of platinums in numerous models. Likewise, veliparib potentiated the activity of platinums in multiple xenograft models *in vivo*. PARP trapping was undetectable when PARPi were combined with cisplatin. PARPi differed in the extent to which catalytic inhibition and trapping could be resolved. PARPi with more potent trapping activity induced greater cytotoxicity in bone marrow CFU assays than equipotent inhibitors with weaker trapping activity. **Conclusions:** Veliparib potentiates the activity of platinum agents *in vitro* and *in vivo*; however the mechanisms underlying this activity remain unclear. PARP trapping is a recently characterized mechanism central to the synergistic cytotoxicity of PARPi and temozolomide. In contrast, our results suggest that PARP trapping is not required for the combination activity of PARPi and cisplatin. Our observation that potent trapping activity is associated with cytotoxicity towards myeloid and erythroid progenitors suggests that trapping may contribute to the anemia and myelosuppression observed in patients treated with PARPi. As such, PARPi capable of catalytic inhibition at concentrations where trapping is undetectable may be more suitable for combination regimens in which trapping is not required for activity.

2557 Poster Session (Board #273), Sat, 8:00 AM-11:30 AM

Genomic landscape of DNA repair genes in cancer: Mutation and copy number variation (CNV) frequencies. *First Author: Jonathan Anker, Northwestern University, Chicago, IL*

Background: DNA repair genes are frequently mutated in cancer, with different cancers linked to specific repair pathways. However, much remains unknown, including whether these mutations drive cancer or are a result of the disease. We have reviewed genome sequencing data of tumor samples to identify DNA repair genes that are frequently mutated or display high CNV. **Methods:** We created a comprehensive list of DNA repair genes and indirectly involved caretaker genes. The mutation and CNV frequencies of these genes were recorded from the COSMIC database (cancer.sanger.ac.uk). **Results:** Of the 193 genes analyzed, 24 had a mutation frequency of greater than 1.0% across all cancers. Table 1 lists the 10 genes most frequently mutated (overall and by common cancer types; n > 19,778 for each gene overall) or with CNVs (n > 4,118 for each gene). Colorectal, skin, lung, and breast cancer were most associated with DNA repair mutations. There was an inverse correlation as genes with a high CNV gain displayed a low CNV loss frequency, and vice versa ($p < 0.001$). **Conclusions:** Multiple DNA repair pathways were affected in each cancer type. Interestingly, genes with high frequency CNVs were either predominantly CNV gain or loss, but not both, providing evidence that these are functional alterations. This study provides comprehensive lists of candidate genes to be further studied as biomarkers for genomic instability or novel therapeutic targets. Table 1: Direct (bold) and indirect DNA repair genes most frequently mutated or with CNV gain or loss in cancer.

Phase I clinical trial of temozolomide and methoxyamine (TRC-102) in patients with advanced solid tumors. *First Author: Jennifer Rachel Eads, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Temozolomide (TMZ) is an alkylating agent that generates DNA adducts that are repaired by direct DNA and base excision repair mechanisms. Methoxyamine (MX, TRC-102) is a small molecule that potentiates TMZ by binding to apurinic and apyrimidinic sites after removal of N3-methyladenine and N7-methylguanine, inhibiting site recognition of apurinic/apyrimidinic (AP) endonuclease. We conducted a phase I trial to determine the maximum tolerated dose (MTD) and dose-limiting toxicities (DLTs) of intravenous MX when given with oral TMZ. **Methods:** Patients (pts) with advanced solid tumors, progression on standard treatment, and no CNS involvement were enrolled. A standard 3+3 design was used to assess TMZ (150-200 mg/m^2 orally) and MX (15-150 mg/m^2 IV). Dose Levels (DL) 1-3: TMZ day 1, MX day 4 in first 14 day cycle (C), TMZ days 1-5, MX day 1 in subsequent 28 day C; DL 4-7: TMZ days 1-5, MX day 1 of 28 day C. DLT period was 42 days for DL 1-3 and 28 days for DL 4-7. Tumor response assessed per RECIST and AEs by CTCv4. Pharmacokinetics (PK) of 1-hour MX infusion and comet assays on peripheral blood mononuclear cells were performed. **Results:** 38 pts were enrolled: 45% male, 82% white, 16% African American, 2% Asian, median age 59.5 years (38-76), mean number of C 2.9 (1-13). No DLTs were observed. Grade 3 AEs: fatigue (n = 2), lymphopenia (n = 2), anemia (n = 1), INR (n = 1), leukopenia (n = 1), neutropenia (n = 1), allergic reaction (n = 1), constipation (n = 1), psychosis (n = 1) and paranoia (n = 1). Late grade 4 AEs: thrombocytopenia (n = 2) and confusion (n = 1). Partial response was seen in 1 pt with pancreatic adenocarcinoma (PAC) (8 mo); prolonged stable disease in 1 pt with PAC (4 mo), pancreatic neuroendocrine tumor (NET) (9 mo), small bowel NET (5.5 mo), ovarian cancer (12.5 mo) and non-small cell lung cancer (5.5 mo). MX PK was linear with dose and was not affected by concomitant TMZ. Geometric means (SD) were: t½ 45.6 (11.5) h, Cl 31.7 (15.6) L/h/m^2 (n = 31). **Conclusions:** TMZ 200 mg/m^2 may be safely administered with MX 150 mg/m^2 with minimal toxicity. Evidence of antitumor activity was observed, particularly in pancreatic adenocarcinoma and neuroendocrine tumors. Further studies assessing this drug combination are warranted. Clinical trial information: NCT00892385.

2559 Poster Session (Board #275), Sat, 8:00 AM-11:30 AM

Using gamma-H2AX and H2AX quantitative ELISA for monitoring DNA damage induced by chemotherapeutic agents and irradiation exposure. *First Author: Jiuping Jay Ji, National Clinical Target Validation Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD*

Background: Gamma-H2AX (γH2AX) is a biomarker for DNA double-strand breaks and programmed cell death, but variable relative amounts of H2AX in different samples causes ambiguity in the meaning of the γH2AX level unless it is related to total H2AX levels. We developed a 96-well plate-based ELISA for quantifying γH2AX and H2AX levels in crude extracts of tumor cells, CTCs and biopsy tissues and are validating it for applications in irradiation exposure monitoring and in pharmacodynamic evaluation of anti-cancer agents. **Methods:** The ELISA was used to analyze extracts of several NCI60 tumor cell lines that had been exposed to a variety of agents, including ionizing radiation, inhibitors of Top-1 (CPT, SN-38, Topotecan), PARP (ABT-888, AZD-2281, MK-4827) and ATR (VE-821, VE-822, AZD-6738, Compound 45, NU-6027), and their combinations. Combination regimens of CPT-11 with PARP inhibitors (ABT-888, AZD-2281, MK-4827) were further evaluated in vivo in the A375 xenograft mouse model. Patient samples obtained for research purposes were also examined by ELISA for feasibility and utility. **Results:** In vitro, dose-dependent increases in the ratio of γH2AX to H2AX were detected after escalating ionizing radiation exposure and concentration-dependent increases after Top-1 exposure. Treating with inhibitors of PARP or ATR alone did not significantly induce γH2AX. Combinations of Top-1 inhibitors with PARP or ATR inhibitors led to synergistic induction of DNA damage. Among five ATR inhibitors evaluated in combination with Top-1 inhibitors, VE-822 and AZD-6738 were observed to have the highest synergy for γH2AX induction, while NU-6027 showed none. Combinations of CPT-11 with ABT-888, AZD-2281 or MK-4827 showed synergistic induction of γH2AX in A375 xenografts in vivo. Additional testing of human specimens including PBMCs, bone marrow and tumor biopsies proved the assay's clinical suitability and potential advantages. **Conclusions:** A newly developed quantitative ELISA for measuring both γH2AX and H2AX is ready for clinical validation for monitoring DNA damage induced by chemotherapeutic agents or irradiation exposure. Funded by NCI Contract No. HHSN261200800001E.

2560 Poster Session (Board #276), Sat, 8:00 AM-11:30 AM

A phase I study of pazopanib (PAZ) in combination with abexinostat (ABX) in patients (pts) with metastatic solid tumors. *First Author: Rahul Raj Aggarwal, UC San Francisco, San Francisco, CA*

Background: PAZ is a tyrosine kinase inhibitor of VEGFR, PDGFR, and C-KIT approved for use in renal cell carcinoma (RCC) and soft tissue sarcoma (STS). ABX is a potent pan-HDAC inhibitor (HDACi). Pre-clinical models suggest that HDACi-mediated epigenetic modulation of VEGF expression potentiates PAZ's efficacy and may reverse therapeutic resistance. We therefore designed a Phase I clinical trial combining ABX with PAZ in pts with advanced solid tumors. **Methods:** The primary objective was to determine the maximal tolerated dose (MTD) of PAZ plus ABX. Secondary objectives included pharmacokinetics (PK) and efficacy. Altered histone acetylation post treatment denoted HDACi activity and served as a pharmacodynamic (PD) marker in peripheral blood mononuclear cells. PAZ was dosed days 1-28 and ABX days 1-5, 8-12, and 15-19 of 28-day cycle (schedule A) at a starting dose of 400 mg/day and 45 mg/m^{2}orally twice daily respectively. An alternate ABX dosing schedule of days 1-4, 8-11, and 15-18 was also investigated (schedule B). **Results:** 36 patients with advanced solid tumors were enrolled (N = 22 schedule A; N = 14 schedule B). There were six dose-limiting toxicities (DLTs) (5 on schedule A, 1 on schedule B), including fatigue (N = 2), thrombocytopenia (N = 2), and elevated AST/ALT (N = 2). The most common grade ≥ 3 related adverse events observed include thrombocytopenia (8%), fatigue (8%), and diarrhea (6%), the majority of which occurred with schedule A. The MTD was PAZ 800 mg/day + ABX 45 mg/m^2 BID on schedule B. 5 of 29 evaluable pts (17%) (including 2 RCC pts) experienced a partial tumor response (PR). All 6 pts with prior disease progression on PAZ monotherapy had reduction in tumor burden on study. 12 out of 29 evaluable pts (41%) experienced stable disease or better for ≥ 6 months, and two pts with PRs remain on study for > 2 years. PK and PD analyses are ongoing. **Conclusions:** In the first trial to explore the combination of ABX with PAZ in RCC and other solid tumor malignancies, the combination was well tolerated, particularly with schedule B ABX dosing. Preliminary evidence of anti-tumor activity was observed, notably in pts with progression on prior PAZ monotherapy. The promising efficacy in RCC is being further evaluated. Clinical trial information: NCT01543763.

2561 Poster Session (Board #277), Sat, 8:00 AM-11:30 AM

Pharmacokinetics/pharmacodynamics (PKPD) of blinatumomab in patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (r/r ALL). *First Author: Min Zhu, Amgen Inc., Thousand Oaks, CA*

Background: Blinatumomab is a CD19-directed bispecific T-cell engager antibody construct indicated for treatment of Ph-negative r/r ALL. We evaluated blinatumomab PK/PD and explored their associations with efficacy/safety in 189 r/r ALL patients in a phase 2 study (Topp et al. *Lancet Oncol* 2015;16:57). **Methods:** Blinatumomab was given by continuous IV infusion (4 wk on/2 wk off) for ≤ 5 cycles (Cycle 1: 9 μg/d days 1–7; then 28 μg/d; thereafter: 28 μg/d). Association between exposure and measures of efficacy (complete response [CR]/CR with partial hematologic recovery [CRh] within the first 2 cycles) and safety (cytokine release syndrome [CRS]; neurologic events [NE]) was evaluated by logistic regression. Impact of covariates on exposure-response was assessed in multivariate analyses. **Results:** Blinatumomab PK was linear; mean (SD) serum steady state concentration (C_{ss}) at 28 μg/d was 621 (502) pg/mL in Cycle 1. IL-6, IL-10 and IFNγ were transiently elevated in > 50% of pts on days 1–2 of Cycle 1, much less in later cycles; interpatient variability was high. In Cycle 1, mean peripheral B cells fell from 4660 to ≤ 10 cells/μL. Responders had lower percentages of $CD19^+$ B cells and bone marrow (BM) blasts and higher percentages of $CD3^+$ T cells and granulocytes at screening than nonresponders ($P < .001$); absolute counts were not associated with response. In multivariate analyses, higher C_{ss} (OR, 1.90 [95% CI, 1.12–3.21]; $P = .017$), higher peak IL-10 levels (1.59 [1.13–2.22]; $P = .007$) and lower percentage of BM blasts at screening (0.78 [0.69–0.89]; $P < .001$) were associated with CR/CRh. No association between C_{ss} and time to CR/CRh was found after adjusting for percentage of blasts and B/T cell ratio. Higher platelet counts (0.996 [95% CI, 0.992–1.0]; $P = .03$), $CD19^+$ B cell counts at screening (0.90 [0.84–0.97]; $P = .004$) and C_{ss} (1.40 [1.01–1.94]; $P = .046$) were associated with time to NE. Cytokine peaks were not associated with NE or CRS. C_{ss} was not associated with CRS. **Conclusions:** We found empirical associations of blinatumomab PK, PD and disease-related prognostic factors with CR/CRh and NE. Confounding factors and confirmation of the associations deserve further evaluation. Clinical trial information: NCT01466179.

2562 Poster Session (Board #278), Sat, 8:00 AM-11:30 AM

Pharmacogenetic variants associated with differential sirolimus clearance in pediatric patients. *First Author: Jordan Wright, Cincinnati Childrens Hosp Med Ctr, Cincinnati, OH*

Background: Sirolimus inhibits the mammalian Target of Rapamycin pathway and is widely used in organ transplantation and treatment of malignancy. CYP3A5*3 polymorphisms have been shown to influence sirolimus clearance in solid organ transplant patients, but effects of other drug metabolism enzyme and transporter (DMET) gene polymorphisms have not been investigated thoroughly. We hypothesized that additional variants, alone or in combination, would better predict sirolimus clearance in pediatric and young adult patients with neurofibromatosis type 1 (NF1) associated plexiform neurofibromas and complex vascular malformations (CVM). **Methods:** Patients treated with single agent sirolimus (N = 74) had pharmacokinetic parameters including clearance measured in two studies of NF1 and CVM. Patients were genotyped for 1,931 known polymorphisms using the DMET Microarray (Affymetrix). Initial statistical analysis included univariate linear regression on SNPs with a minor allele frequency of > 0.05 for each of the clinical trials. Subsequently, the datasets were combined and a univariate regression analysis was obtained on the combined data. SNPs for which the association was strengthened in the combined dataset were then placed in a final multivariate regression model. **Results:** The final multiple regression analysis included five SNPs that were significant at $p < 0.05$: rs776746 (CYP3A5*3 6986 A > G), rs909530 (FMO3 855 C > T), rs1339067 (SLC15A1 1347 T > C), rs2276299 (SLC22A8 723 T > A), and rs6774801 (CYP8B1 6468 A > C). The model had an overall F-value of 7.83, p-value < 0.0001, and R-square of 0.38. **Conclusions:** Our analysis identified a multivariate model with five SNPs, of which four are novel and not previously described in the literature. The CYP3A5*3 allele, which has been identified in other studies, was significant in our analysis, offering additional support for the role of this SNP in sirolimus metabolism. Future studies in larger populations are needed to confirm this model, and will lead to potential pharmacogenetically-guided dosing for the safe and effective use of sirolimus.

2563 Poster Session (Board #279), Sat, 8:00 AM-11:30 AM

Mass balance study of TAS-102 using ^{14}C labeling analyzed by accelerator mass spectrometry. *First Author: James J. Lee, University of Pittsburgh, Pittsburgh, PA*

Background: TAS-102 is composed of trifluridine (FTD) and tipiracil hydrochloride (TPI) in a 2:1 ratio. FTD is a thymidine analog, and is degraded to inactive trifluoromethyluracil (FTY) by thymidine phosphorylase (TPase). TPI inhibits degradation of FTD by TPase, increasing systemic exposure to FTD. TAS-102 demonstrated improvement in overall survival in patients with metastatic colorectal cancer refractory to standard therapies. Although the metabolism of FTD has been reported, the metabolic fate and excretion of TAS-102 is unknown. **Methods:** Patients with advanced solid tumors (6 M/2 F; median age 58 years; PS 0-1) enrolled. Group A (N = 4) received 60 mg TAS-102 with 200 nCi [^{14}C]-FTD, and group B (N = 4) received 60 mg TAS-102 with 1000 nCi [^{14}C]-TPI orally. Plasma, blood, urine, feces, and expired air (group A only) were collected up to 168 h, and were analyzed for ^{14}C by accelerator mass spectrometry and for components of TAS-102 by LC-MS/MS. **Results:** FTD: Approximately 10% of plasma ^{14}C AUC is accounted for by FTD (7%) and FTY (3.5%). The long half-life of ^{14}C in plasma (>300 h) is in line with the moderate recovery of FTD-related ^{14}C in the excreta over the 168 h collection period. ^{14}C was mostly excreted in urine, and only very little was in feces and expired air, suggesting good absorption and limited metabolism of the pyrimidine ring. TPI: Approximately 36% of plasma ^{14}C AUC is accounted for by TPI. ^{14}C was mostly excreted in feces likely due to poor absorption of TPI. The majority of absorbed ^{14}C was excreted into urine. **Conclusions:** The mass balance of FTD and TPI as part of TAS-102 was successful. The majority of the ^{14}C-TPI dose was recovered in feces. Approximately 60% of the ^{14}C-FTD dose was recovered, largely in urine. The current data with the ongoing hepatic and renal dysfunction studies will provide a better understanding of the TAS-102 dispositional profile. Clinical trial information: NCT02031055.

2564 Poster Session (Board #280), Sat, 8:00 AM-11:30 AM

First-in-human phase I trial of the PI3Kb-selective inhibitor SAR260301 in patients with advanced solid tumors (NCT01673737). *First Author: Philippe L. Bedard, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: SAR260301 (SAR) is a potent (IC_{50} 52 nM) PI3Kb inhibitor selectively inhibiting the PI3K pathway in PTEN-null models. This phase I Sanofi sponsored study was initiated to evaluate SAR maximum tolerated dose (MTD), overall safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary antitumor activity in patients with advanced solid tumors. **Methods:** Patients (pts) with locally advanced/metastatic solid tumors, ECOG PS ≤ 1, and adequate organ function were eligible. PTEN was evaluated in archival tissue by IHC. SAR was orally administered fasted in 28-day cycles. Dose escalation used an overdose control Bayesian strategy. Serial PK sampling was performed on Days 1 and 28 of Cycle (C) 1, and at C2 for food effect evaluation (n = 6). Platelet phospho-AKT (pAKT) was assessed at pre- and post-SAR for PD by MesoScale Discovery. Physiologically based PK modelling (PBPK) was used for exposure predictions. **Results:** 21 pts were treated at 6 dose levels from 100 mg QD to 800 mg BID. The MTD was not reached. Two DLTs were observed: Gr 3 pneumonitis (400 mg BID) and Gr 3 increase in GGT (600 mg BID). No other Gr ≥ 3 related AE was reported. The most frequent related AEs (≥ 3 pts): nausea (3), vomiting (3), and diarrhea (3). SAR absorption was rapid (t_{max} 0.5-1.5h) and showed a biphasic elimination profile with a rapid decrease in concentration after C_{max}. No significant accumulation or deviation from dose proportionality was observed. C_{max} and AUC_{tau} decreased respectively by 56% and 22% with food. Maximal inhibition of pAKT/tAKT in platelets correlated with exposure at steady state; C_{max} thresholds for 60% & 80% inhibition were respectively ~ 7 & ~11 μM. Concentrations > 7 μM were reached in 3 pts but for no longer than 2h out of 24h. The PBPK model predicted that doses > 1.2g BID would be needed to reach concentrations sufficient to maintain PD effect between doses. No objective response were documented in this study (3 of 21 pts had PTEN-null disease). **Conclusions:** SAR has an acceptable safety profile at pharmacologically active doses. However, the rapid clearance of SAR does not allow for sustained pathway inhibition that is required for anti-tumor activity in preclinical models. Clinical trial information: NCT01673737.

2565 Poster Session (Board #281), Sat, 8:00 AM-11:30 AM

Effect of itraconazole and rifampin on the pharmacokinetics of olaparib tablet formulation in patients with advanced solid tumours: Phase I open-label studies. *First Author: Elizabeth R. Plummer, Northern Centre for Cancer Care, Newcastle-upon-Tyne, United Kingdom*

Background: The metabolism of olaparib (Lynparza) is mediated predominantly by CYP3A4/5 enzymes. Two Phase I studies are reported here investigating pharmacokinetic interactions between olaparib (tablet formulation) and itraconazole, a potent CYP3A4 inhibitor (Study 1, NCT01900028), and rifampin, a potent CYP3A4 inducer (Study 2, NCT01929603). **Methods:** In Study 1, 59 eligible patients (pts) received a single oral dose of olaparib 100 mg on Day 1 and olaparib 100 mg plus itraconazole 200 mg on Day 9; itraconazole 200 mg was administered once daily (qd) on Days 5–11. In Study 2, 22 pts received a single oral dose of olaparib 300 mg on Day 1 and single oral dose olaparib 300 mg plus rifampin 600 mg on Day 14; rifampin 600 mg qd was administered on Days 5–17. **Results:** Co-administration with itraconazole in Study 1 resulted in a significant increase in mean C_{max} (treatment ratio 1.42; 90% CI: 1.33, 1.52) and mean AUC (treatment ratio 2.70; CI: 2.44, 2.97) compared with olaparib alone. Olaparib absorption was slightly slower in the presence of itraconazole (median [range] t_{max}, 1.50 [0.5–12] hours) vs olaparib alone (1.03 [0.5–8.25] hours). In Study 2, a significant decrease in olaparib bioavailability was observed when co-administered with rifampin (decrease of 71% in C_{max} [treatment ratio: 0.29; 90% CI: 0.24, 0.33] and 87% in AUC [0.13; 90% CI: 0.11, 0.16]) vs olaparib alone. Median t_{max}, was reduced in the presence of rifampin (0.78 [0.27–5.95] hours compared with 1.49 [0.57–3.05] hours for olaparib alone). In both studies, the majority of adverse events were of mild or moderate severity; safety data were consistent with the known safety profile of olaparib. **Conclusions:** It is recommended that potent CYP3A enzyme inhibitors (eg. itraconazole, telithromycin, clarithromycin, ketoconazole, voriconazole, nefazodone, posaconazole, ritinovir, lopinavir, indinavir, saquinavir, nelfinavir, boceprevir, telaprevir) or inducers (eg. phenytoin, rifampin, carbamazepine, St John's Wort) be avoided during olaparib treatment. Clinical trial information: NCT01900028/NCT01929603.

2566 Poster Session (Board #282), Sat, 8:00 AM-11:30 AM

A first-in-human study of the dual ROCK I/II inhibitor, AT13148, in patients with advanced cancers. *First Author: Dionysios Papadatos-Pastos, The Institute of Cancer Research and The Royal Marsden, London, United Kingdom*

Background: AT13148 is a first-in-class, orally bioavailable, dual ROCK I/II inhibitor, which potently inhibits ROCK I/II (6, 4 nM), PKA (3 nM), AKT (38 nM) and p70S6K (8 nM). Broad anti-cancer activity has been demonstrated in a number of pre-clinical models. **Methods:** Patients (pts) with advanced solid tumors were enrolled into successive dose escalation cohorts of a minimum of three and maximum of six patients. AT13148 was dosed orally on days (D) 1, 3 and 5 of every week. Pharmacokinetic (PK) parameters were assessed and pre- and post-tumor biopsies, platelet-rich plasma (PRP) and hair follicles were analysed to evaluate target inhibition of AKT (p-AKT, p-S6K and p-GSK3B) and PKA (p-VASP). **Results:** 30 pts (16 male, 14 female) were treated with AT13148. Dose escalation started at 5 mg with doubling through 6 cohorts (10, 20, 40, 80 and 160 mg). Following the appearance of grade 2/3 toxicities in pts dosed at 160 mg (hypotension, headache and diarrhea), further dose doubling was not considered and the dose was increased by 50% to 240 mg. Thus far, at this dose there was one DLT of elevated liver enzymes which was reversible on treatment withdrawal. The cohort is currently being expanded to 6 pts. The most common drug-related toxicities in the study so far have been nausea, anorexia, headache and hypotension. PK analysis showed a dose proportional increase in AUC (382-13382 nM.h) and Cmax (21-450 nM) up to 160 mg ($r2 = 0.98$) on the first dose. Preliminary PD analyses in PRP have shown a $\geq$ 88% increase in p-AKT from baseline at cycle 1 D 15-22 ($p \leq 0.01$) in the 160 mg cohort, a 17-21% decrease in pGSK3B from baseline at 6 h and 48 h post-dose ($p \leq 0.03$) in the 160 mg cohort, and a 45% decrease in p-VASP from baseline at 48 h post-dose ($p = 0.004$) in the 80 mg cohort. **Conclusions:** AT13148 was administered orally on D 1, 3 and 5/week in an intermittent schedule and has currently reached a dose of 240 mg. At this dose there have been predictable tolerable 'on target' toxicities and dose escalation is ongoing. **Clinical trial information:** NCT01585701. Clinical trial information: NCT01585701.

2567 Poster Session (Board #283), Sat, 8:00 AM-11:30 AM

Patterns of hepatic impairment in phase I clinical trials. *First Author: Aaron Scott Mansfield, Mayo Clinc, Rochester, MN*

Background: Liver impairment confounds dosing of anti-neoplastic agents. The Cancer Therapy Evaluation Program (CTEP) at the National Cancer Institute (NCI) sponsors standard phase I clinical trials (P1CT) to determine the safety of novel agents and combinations, and hepatic dysfunction phase I clinical trials (HDCT) to determine safe doses for patients with varying degrees of liver dysfunction. We sought to compare patterns of liver injury, number of cycles administered, and reasons for discontinuation between HDCTs and P1CTs in a meta-analysis. **Methods:** The records of participants of 51 NCI-sponsored phase I clinical trials conducted between 1994 and 2014 were reviewed. The NCI's Organ Dysfunction Working Group's definitions of liver impairment were used to classify subjects. Peak liver test results were used to classify patterns of liver impairment using the US Food and Drug Administration's (FDA) R ratio and modified Hy's law (aminotransferase $\geq$ 3xULN, total bilirubin $>$ 2xULN without elevated serum alkaline phosphatase & no other explanation for abnormalities). The Kruskal-Wallis one way analysis of variance was used to compare groups and the Pearson test was used for contingency analyses. **Results:** There were 513 subjects treated on HDCTs and 1328 subjects treated on P1CTs with a median age of 58.6 years [51-66 interquartile range (IQR)] and 59 years (49-67 IQR) respectively. 55.6% and 49.9% were male, on P1CTs and HDCTs respectively. Subjects received a median of 2 cycles of treatment on HDCTs and P1CTs. Cholestatic peak patterns of liver impairment by the FDA R ratio were more frequent in HDCTs than P1CTs ($p < 0.0001$). Criteria for Hy's Law were met in eleven patients on P1CTs. Disease progression was the most common reason for treatment discontinuation, followed by adverse events in HDCTs and P1CTs. Subjects with severe liver function abnormalities on HDCTs typically received one cycle of treatment, and 9.9% died on study compared to those with less severe hepatic dysfunction (range of 3.0-3.7% $p < 0.0001$). **Conclusions:** Subjects on HDCTs are more likely to experience cholestatic peak patterns of liver function abnormalities, but receive a similar number of cycles of therapy, and discontinue from trial participation for similar reasons as those on P1CTs.

2568 Poster Session (Board #284), Sat, 8:00 AM-11:30 AM

Predictive PK/PD models for hematological toxicities to inform MTD determination and regimen selection for ADCs. *First Author: Santhosh Palani, Clinical Pharmacology, Biotechnology Clinical Development, Pfizer Inc., La Jolla, CA*

Background: Off-target hematological toxicities have primarily been dose-limiting for ADCs. Here, we present a PK/PD model framework where the incidences of hematological toxicities can be predicted across ADCs if they share the same linker/payload (LP), and can be predicted across regimens within an ADC. Having prior knowledge of the MTD can provide a safe and efficient dose-escalation design, reduce the number of patients receiving sub-efficacious doses and aid in regimen selection. **Methods:** A semi-mechanistic PK/PD model of neutropenia (NP) for SGN-35 was constructed using a previously established structural model. Published ADC thrombocytopenia (TCP) PK/PD models were also utilized. **Results:** *Predicting across regimens*:Due to the availability of the clinical data in multiple regimens for T-DM1 and SGN-35, models developed using data from Q3W regimen were utilized to predict the toxicity incidences of QW regimen. T-DM1 Q3W model predicted 10% grade 3+4 TCP in patients at QW MTD, matching with the clinically observed incidence of 11%. SGN-35 Q3W model predicted 19% grade 3+4 NP at QW MTD, which is consistent with the clinically observed incidence of 10%. *Predicting across ADCs*: Since SGN-35, CDX-011 and PSMA-ADCs share the same LP (vcMMAE), we utilized the SGN-35 model to predict incidences for CDX-011 and PSMA-ADC. SGN-35 Q3W model predicted 18% and 50% grade 3+4 NP incidences for the 1.9 mg/kg CDX-011 and 2.8 mg/kg PSMA-ADC, respectively, again in concordance with the observed incidences of 26% and 55%. *Predicting across ADCs, regimens and populations*: As CMC-544 and GO share the same LP (abCali), we predicted TCP incidences for GO in AML patients from the Q4W CMC-544 model developed with data from NHL patients. The model predicted grade 3+4 TCP incidence of 98% for GO regimen of 9 mg/m^2 (2 doses, 14-days apart), which agrees with the observed incidence of 99%. **Conclusions:** Robust predictability of hematological toxicity is demonstrated across 5 ADC, 2 toxicities and 3 regimens. With prospective validation, the approach presented here can help construct a safe and efficient dose-escalation scheme, provide a projected MTD, and assist in optimal regimen selection for ADCs entering clinical development.

2569 Poster Session (Board #285), Sat, 8:00 AM-11:30 AM

Regulatory considerations for clinical pharmacology during development of antibody-drug conjugates. *First Author: Stacy Shifflett Shord, US Food and Drug Administration, Silver Spring, MD*

Background: Antibody-drug conjugates (ADCs) provide unique challenges during clinical development, as these products are a heterogeneous mixture of a monoclonal antibody and a small molecule payload. As such, the current paradigm has been to conduct studies that characterize the clinical pharmacology of both the antibody and small molecule components of the ADC. We have compiled a database of ADCs approved and under development to assess the study designs and outcomes to guide future FDA regulatory recommendations on evaluation of the clinical pharmacology for ADCs. **Methods:** Investigational New Drug (IND) applications, Biologics License Applications (BLA), product labeling and published literature were reviewed to develop the database. A description of the indication, antibody target, payload, linker, clinical pharmacology studies and available study results were compiled and analyzed. **Results:** Approximately 50 ADCs are currently under development and two ADCs are approved (Adcetris, Kadcyla). The most common payloads are auristatins (~60%) and maytansinoids (~20%), and the most common linkers are cleavable (~90%). Three components (i.e., conjugate, total antibody, and payload) were characterized to describe the pharmacokinetics of Adcetris and Kadcyla. While both the Adcetris and Kadcyla labeling describes the potential for drug interactions, dedicated drug interaction studies were only conducted for Adcetris. Organ impairment studies for both Adcetris and Kadcyla suggest decreased tolerability in patients with varying degrees of hepatic or renal impairment. **Conclusions:** As most ADCs are in early clinical development, FDA recommendations for clinical pharmacology studies are still evolving. Currently available data suggest that the pharmacokinetics of at least two components (e.g., conjugate and payload) should be described and incorporated into population and exposure-response analyses. The potential for drug interactions should be addressed. Organ impairment studies should be conducted with a specific focus on the assessment of safety, as well as on pharmacokinetics.

2570 Poster Session (Board #286), Sat, 8:00 AM-11:30 AM

A phase I, first-in-human study to evaluate the tolerability, pharmacokinetics and preliminary efficacy of HuMax-tissue factor-ADC (TF-ADC) in patients with solid tumors. *First Author: Ulrik Niels Lassen, Rigshospitalet, Copenhagen, Denmark*

Background: TF-ADC is an antibody drug conjugate composed of a TF-specific human IgG1 monoclonal antibody conjugated to a microtubule disrupting agent Monomethyl Auristatin E (MMAE). TF-ADC is presently being tested in an ongoing Phase I dose-escalation study (NCT02001623) in patients (pts) with locally advanced and/or metastatic solid tumors known to express TF. **Methods:** The primary study objective is to assess the tolerability of TF-ADC. In addition, maximum tolerated dose (MTD), pharmacokinetics and preliminary efficacy will be evaluated. Pts with cancer of the ovary, cervix, endometrium, bladder, prostate (CRPC), esophageal, SCCHN and lung (NSCLC) will be included. This is a classical 3+3 dose escalation study followed by cohort expansion. Responses are evaluated according to RECIST 1.1. **Results:** Eighteen pts have been enrolled across the first 6 dose cohorts (0.3-1.8 mg/kg). Mean number of prior lines of therapy is 3.7 (range 1-14). The most common AEs seen in $\geq$ 4 pts are fatigue, anemia, epistaxis, nasal congestion, pyrexia, and diarrhea. Elevation in liver enzymes was seen in 9 pts mainly grade (Gr) 1 including 2 pts with Gr 3 single events. One event of fatal pharyngeal hemorrhage in the 0.6 mg/kg cohort has been reported in a SCCHN pt with normal coagulation values previously treated with 3 lines of therapy including radical radiotherapy. Relationship with trial drug could not be excluded. Five pts experienced related AEs Gr $\geq$ 3. Seven SAEs were observed in 5 pts (transaminitis Gr 3, pharyngeal hemorrhage Gr 5, fever Gr 1, myalgia pain Gr 2, dyspnea Gr 2, hyponatremia Gr 3, gastritis Gr 3). No significant changes in coagulation parameters and no DLTs have been observed. Preliminary evidence of activity includes prolonged disease stabilization in 1 ovarian cancer pt (23 weeks), 2 CRPC pts (18 and 36 weeks) and a confirmed PR in an ongoing pt with cervical cancer. **Conclusions:** Preliminary data demonstrated manageable toxicity, with no DLTs observed and no changes in coagulation values up to 1.8 mg/kg. Preliminary evidence of anti-tumor efficacy is encouraging and study design allows for increased exposure to establish therapeutic window. Clinical trial information: NCT02001623.

2571 Poster Session (Board #287), Sat, 8:00 AM-11:30 AM

Exhaustive single nucleotide polymorphism (SNP) analysis of *DPYD* exome in breast cancer patients (pts) receiving capecitabine. *First Author: Marie-Christine Etienne-Grimaldi, Centre Antoine Lacassagne, Nice, France*

Background: Consensual *DPYD* variants *2A, D949V and I560S are associated with fluoropyrimidine toxicity (*Caudle, CPT 2013*). Full sequencing of *DPYD* exome was conducted in a prospective cohort of advanced breast cancer pts receiving capecitabine (88.5% monotherapy) to examine relationships between *DPYD*SNPs and toxicity. **Methods:** 243 over 303 pts included in 12 French institutions were analyzed. Digestive, neurologic and hematotoxicity over cycles 1-2 showed 10.3% G3 (25 pts) and 2.1% G4 (5 pts), including one toxic death. *DPYD* exome along with flanking intronic regions (20 bp), 3'UTR and part of 5'UTR (500 bp upstream transcription initiation) were sequenced on MiSeq Illumina (Integragen, PCR multiplex, 97% coverage on average, HWE checked). **Results:** In addition to consensual variants *2A, D949V and I560S carried by 7 pts (all heterozygous), 45 SNPs were identified: 7 in 3'UTR, 17 in coding regions (4 synonymous including E412E; 13 missenses including V732I, R592W, I543V, S534N, S492L, M406I, D342G, M166V, T65M, C29R), 18 in flanking intronic regions, 3 in 5'UTR. The number of variant alleles per pt varied from 0 (8 pts) to 16. In total, 11 SNPs have not been previously described (dbsnp 141 database), including 3 missense variations each heterozygous in 3 separate pts: R696H (exon 17), F100L (exon 4) and A26T (exon 2). The patient with toxic death carried one D949V allele and 3 variant alleles in 3'UTR (rs291592, rs291593). First analysis of consensual variants showed that they were associated with G3-4 toxicity (RR = 6.69, $p < 0.001$, sensitivity 16.7%) but not with G4 toxicity. Adding the variants previously shown to possibly decrease DPD activity (*Offer, Cancer Res 2014*), i.e. R592W, S492L and D342N/G, increased sensitivity on G3-4 (23.3%, RR = 7.03, $p < 0.001$) and was predictive of G4 toxicity (sensitivity 40%, RR = 15.4, $p = 0.015$). Of note, adding the new F100L variant further improved predictivity of genotyping on both G3-4 (sensitivity 26.7%, RR = 7.60, $p < 0.001$) and G4 toxicity (sensitivity 60%, RR = 31.36, $p = 0.001$). **Conclusions**: Present data confirm the impact of consensual variants on capecitabine toxicity and reveal the existence of a novel *DPYD* variant, F100L, associated with G4 toxicity. Clinical trial information: 2008-004136-20.

2572 Poster Session (Board #288), Sat, 8:00 AM-11:30 AM

Identification of candidates for sorafenib dose-escalation using sorafenib plasmatic concentration monitoring: Proof of concept. *First Author: Jennifer Arrondeau, Medical Oncology, Paris Descartes University, Cochin - Port Royal Hospital, AP-HP, Paris, France*

Background: Sorafenib is approved in various advanced cancers, including hepatocellular carcinoma (HCC), differentiated iodo-resistant thyroid cancer (DTC), and renal cell carcinoma (RCC). We previously described that sorafenib plasmatic concentrations may decrease over months. We examined the inter-individual variability of sorafenib exposure at the time of disease progression to identify a subset of patients likely to benefit from dose increase. **Methods:** Patients treated with sorafenib from October 2008 to December 2014 were included in the analysis. Adverse events were prospectively collected and graded using the National Cancer Institute Common Terminology Criteria. The sorafenib plasma concentrations were prospectively determined by liquid chromatography, 30 days after treatment initiation (Cm1) and at disease progression (Cp). Variations of sorafenib concentrations were analyzed using the Wilcoxon test. **Results:** A total of 124 patients (85 males and 39 females) were studied, 68 having a sorafenib concentration measurement at the time of disease progression. The primary tumor was HCC (n = 46), melanoma (n = 32), DTC (n = 20), RCC (n = 16) or others (n = 9). In the 37 patients without change in dose between treatment initiation and disease progression, the sorafenib dose-normalized concentration decreased significantly over time : median sorafenib Cm1 was 5.54 mg/L while the median sorafenib Cp was 5 mg/L ($p = 0.018$). When considering all patients at disease progression, 53 patients (43%) had no limiting toxicity, and the inter-individual variation in sorafenib Cp was very large: median Cp 3.82 mg/L; range 2.08-132.9 mg/L. Among the 34 patients with sorafenib Cp $<$ 3.82 mg/L, 22 (65%) had no limiting toxicity, allowing to increase sorafenib dose for treatment optimization, which resulted in clinical benefit in 45% of patients, the more dramatic being 1 complete response in a choroidal melanoma patient, and a 36.9 months disease control in a DTC patient. **Conclusions:** A subset of patients with disease progression due to sorafenib underexposure and who may respond after dose increase can be identified using sorafenib plasmatic concentration monitoring.

2573 Poster Session (Board #289), Sat, 8:00 AM-11:30 AM

Population pharmacokinetics and dosing implications for cobimetinib in patients with solid tumors. *First Author: Kelong Han, Genentech, Inc., South San Francisco, CA*

Background: Cobimetinib (COBI), an inhibitor of mitogen-activated protein kinases, when combined with vemurafenib (VEM) has been shown to significantly improve PFS ($p < 0.001$) over VEM alone in patients with BRAF V600 mutated melanoma in the Phase 3 study, coBRIM. This analysis aimed to characterize COBI PK and evaluate impact of clinically relevant covariates on COBI PK and exposure to inform dosing. **Methods:** Plasma samples (n = 4886) were collected from 487 patients with various solid tumors (mainly melanoma) in 3 clinical studies (MEK4592g, NO25395, GO28141). COBI was administered orally, once daily on a 21-day-on/7-day-off, 14-day-on/14-day-off or 28-day-on schedule in a 28-day dosing cycle as a single agent or in combination with VEM. COBI doses ranged from 2.1 to 125 mg. Nonlinear mixed effect modeling was used for PK analysis. **Results:** A linear two-compartment model with first-order absorption, lag time and first-order elimination described COBI PK. The typical estimates (inter-individual variability) of apparent clearance (CL/F), central volume of distribution (V/F) and terminal half-life were 322 L/day (58%), 511 L (49%) and 2.2 days, respectively. Inter-occasion variability on relative bioavailability (F) significantly improved the fitting and was estimated at 46%. CL/F decreased with age. V/F increased with body weight (BWT). However, the impact of age and BWT on COBI steady-state exposure (peak and trough concentrations and AUC following 60 mg 21-day-on/7-day-off) was limited (< 25% changes across the distribution of age and BWT in the population studied). No significant difference in COBI PK parameters or steady-state exposure was observed between patient subgroups by gender, renal function, ECOG score, hepatic function tests, race, region, cancer types, V600 mutation subtype and co-administration of moderate and weak CYP3A inducers or inhibitors and VEM. **Conclusions:** A population PK model was developed for COBI in cancer patients. Age and BWT were the only statistically significant variables influencing COBI PK, but showed minimal impact on steady-state exposure, suggesting no need for dose adjustment and supporting the recommended daily dose of 60 mg 21-day-on/7-day-off for all patients.

2574 Poster Session (Board #290), Sat, 8:00 AM-11:30 AM

Recommendations in a new drug application review for dose optimization to potentially improve gastrointestinal tolerability of a tyrosine kinase inhibitor. *First Author: Ruby Leong, US Food and Drug Administration, Silver Spring, MD*

Background: On April 29 2014, the U.S. FDA approved ceritinib for the treatment of patients with anaplastic lymphoma kinase (ALK)-positive metastatic non-small cell lung cancer (NSCLC) who have progressed on or are intolerant to crizotinib. At the approved dosing regimen of ceritinib 750 mg once daily taken on an empty stomach, diarrhea, nausea, vomiting, or abdominal pain occurred in 96% of 255 patients with dose modification in 38% of patients. Anecdotal reports from patients and investigators suggest that gastrointestinal (GI) tolerability may improve when ceritinib is taken with food; however, administration of ceritinib with food increases exposure and may also increase the occurrence of non-GI related toxicities. **Methods:** Data were obtained from the multicenter, single-arm registration trial in 255 patients with ALK-positive tumors who received ceritinib 750 mg daily under fasted conditions and from a food effect study in healthy subjects. Exposure-response relationships for safety endpoints were evaluated by logistic regression analyses and Kaplan-Meier analyses using average exposure quartiles. **Results:** Compared to fasting conditions, a high-fat meal and a low fat meal increased ceritinib AUC_{inf} by more than 50%. Higher systemic exposure appeared to be associated with more frequent and earlier safety events including overall Grade 3-4 adverse reactions (ARs), and individual ARs such as ≥ Grade 3 AST/ALT elevation and ≥ Grade 2 hyperglycemia. Higher systemic exposure also appeared to be associated with earlier and more frequent dose reductions or interruptions. A pharmacokinetic / pharmacodynamic analysis showed concentration-dependent QTc interval prolongation. **Conclusions:** The analyses along with the observed safety data led to an FDA requirement to conduct a postmarketing clinical trial to evaluate a lower dose of ceritinib taken with a meal (providing similar systemic exposure to that of the 750 mg dose taken under a fasted state) that potentially improves GI tolerability.

2575 Poster Session (Board #291), Sat, 8:00 AM-11:30 AM

When investigating predictive biomarkers, beware of the qualitative interaction. *First Author: Howard M Mackey, Genentech, Inc., South San Francisco, CA*

Background: The investigation of predictive biomarkers in clinical trials often involves estimation of the biomarker by treatment interaction effect (Royston and Sauerbrei, *Journal of Clinical Oncology* 2008). A so-called *qualitative interaction* (Gail and Simon, *Biometrics* 1985) occurs when a subgroup of patients appear to benefit from treatment while another subgroup is harmed. Spurious, statistically significant interactions are more likely to be observed as *qualitative interactions* than so called *quantitative interactions, i.e.* interactions where no subgroup is harmed. Thisissueisexemplifiedbyrecentstudyresults(*e.g.*,http://www.cancernetwork.com/gastrointestinal-cancer/amgen-halts-rilotumumab-development-due-increased-death-signal), highlighting the challenges to developing personalized therapies. **Methods:** We graphically and statistically illustrate how, under the null hypothesis of no treatment or biomarker effects, spurious qualitative interactions occur much more frequently than quantitative interactions, potentially leading to erroneous conclusions regarding a biomarker's clinical utility. Following the approach of Mackey and Bengtsson (*Contemporary Clinical Trials* 2013), we propose a strategy for investigating potential predictive biomarkers that focuses on detecting clinically meaningful treatment effects, as opposed to focusing on interactions which have greater variability. We provide sample size formulae and an inference approach for use in proof-of-concept oncology clinical trials with time-to-event data. **Results:** By targeting inference on the *maximal* and *minimal* biomarker effects (*i.e.* the largest- and smallest levels of clinical benefit), the proposed method yields lower false positive rates and higher power for detecting the presence of biomarker subgroups than standard approaches. For fixed false positive rates and power, sample size savings were found to be as large as 40%. **Conclusions:** This new inferential method improves on existing approaches of identifying predictive biomarkers by minimizing false positive risks associated with qualitative, biomarker by treatment interactions.

2576 Poster Session (Board #292), Sat, 8:00 AM-11:30 AM

Carboplatin dosing based on estimated Glomerular Filtration Rate (GFR) using IDMS creatinine: A comparison of estimated GFR based on IDMS creatinine in the Cockroft-Gault (CG) formula (IDMS-GFR), with measured GFR using ^{51}Cr-EDTA (^{51}Cr-GFR). *First Author: James R. Whittle, Royal Melbourne Hospital, Melbourne, Australia*

Background: ^{51}Cr-GFR is considered a gold standard of GFR assessment, but the CG formula is routinely used to estimate GFR for dosing of Carboplatin. Gynaecological cancer trials adopted the convention that Carboplatin be dosed at AUC5 in patients using ^{51}Cr-GFR, and AUC6 in patients using IDMS-GFR. IDMS-GFR is routinely capped at 125ml/min for Carboplatin dosing, as low IDMS levels in patients with normal renal function can generate spuriously high GFR estimates. **Methods:** We performed a multicenter retrospective study of patients who had a ^{51}Cr-GFR assessment, with a matched serum IDMS creatinine. IDMS-GFR and ^{51}Cr-GFR were compared in each patient. Carboplatin dose based on ^{51}Cr-GFR in the Calvert formula at AUC 5 was used as the reference. **Results:** 551 patients were available for analysis. Median age 62 (19 – 90), 64% female. Indication for GFR evaluation: malignancy (85%), assessment for live kidney donation (12%), other (3%). Median ratio of IDMS-GFR : ^{51}Cr-GFR 1.04 (0.43 – 3.38); < 0.8 in 72 patients (13%), > 1.2 in 180 patients (33%). Median (IDMS-GFR - ^{51}Cr-GFR) +3.95ml/min (-81 – +176). Mean percentage error (MPE) was 12%. Despite capping of IDMS-GFR at 125ml/min, its use in the Calvert formula at AUC6 would have underdosed 99 patients (18%) by > 100mg Carboplatin compared to ^{51}Cr-GFR at AUC6, and overdosed 128 patients (23%) by the same amount. 104 patients (19%) would be overdosed by > 20%. The convention of the use of AUC5 in patients who have ^{51}Cr-GFR, and AUC6 in patients who have IDMS-GFR (capped), would lead to differences in planned dose between the 2 methods of > 100mg in 326 patients (59%), and by > 20% in 264 (48%). Univariate analysis identified BMI (> 35, MPE 39%), gender (female MPE 15%), GFR indication (malignancy MPE 11%) as risk factors for overestimate of GFR by IDMS-GFR, and BMI < 20 for underestimate (MPE -3.5%). **Conclusions:** IDMS-GFR is an unreliable surrogate for ^{51}Cr-GFR. The convention of considering AUC5 carboplatin based on ^{51}Cr-GFR, and AUC6 carboplatin based on calculated GFR, as equivalent is invalid, and should be abandoned.

2577 Poster Session (Board #293), Sat, 8:00 AM-11:30 AM

Results of OAK: A phase 1, open-label, multicentre study to compare two dosage forms of AZD5363 and to explore the effect of food on the pharmacokinetic (PK) exposure, safety, and tolerability of AZD5363 in patients with advanced solid malignancies. *First Author: Emma Jane Dean, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: AZD5363 is a potent pan-Akt inhibitor and acts on cancers by blocking a cell survival pathway. AZD5363, administered to patients in the fasted state, was originally formulated as a capsule (C). For patient convenience and ease of manufacture a tablet (T) formulation has been developed. *In vitro* work has indicated that T and C perform similarly; PK comparability needed to be verified to introduce T to the clinical programme. The effect of food on PK, safety and tolerability was unknown. **Methods:** Part A assessed whether PK of T was comparable to C when both were given as a 480 mg bd dose in a 4 days on / 3 days off schedule; patients received T (Week 1) followed by C (Week 2). Part B examined the effect of a standardised meal on PK of T; patients received T in the fasted state (Week 1) and 30 minutes after a meal (Week 2). PK was assessed on the last day of weekly dosing in each of the cross-overs. **Results:** Part A data are available in 13 evaluable patients. AUC_{ss} and $C_{ss,max}$ observations for T and C were comparable with GLS mean ratios (90% CIs) of 0.9 (0.79 to 1.03) and 1.01 (0.88 to 1.16) respectively. CIs of the ratios lay within the 0.75 to 1.33 pre-specified limits. Median $t_{ss,max}$ was shorter for T than C (1.03 vs 2.03 h respectively), consistent with the *in vitro* dissolution data. T and C safety data were comparable and consistent with the known safety profile for AZD5363. Part B data are available from 10 patients. PK profiles for T(fasted) versus T(fed) indicated a later t_{max} and lower exposure in the fed state. GLS mean ratios of $C_{ss,max}$ and AUC_{ss}were 0.86 (0.74 to 1.01) and 0.68 (0.57 to 0.81) respectively. No significant differences in safety profiles were noted between the fasted and fed states. **Conclusions:** PK, safety and tolerability of the tablet and capsule formulations of AZD5363 are comparable. Tablets are being introduced across the ongoing clinical trials. Food has been shown to reduce the rate and extent of absorption of AZD5363 without a discernible effect on safety and tolerability; the existing food restrictions in ongoing clinical trials will be maintained. Clinical trial information: NCT01895946.

2578 Poster Session (Board #294), Sat, 8:00 AM-11:30 AM

Exposure-response (E-R) and case-control analyses of ramucirumab leading to recommendation for dosing optimization in patients with gastric cancer. *First Author: Runyan Jin, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Ramucirumab was approved for the treatment of advanced gastric or gastro-esophageal junction adenocarcinoma in combination with paclitaxel based on an efficacy and safety trial that demonstrated 2.2 months (median) of overall survival (OS) benefit with a hazard ratio of 0.81 ($p = 0.02$) for patients treated with ramucirumab plus paclitaxel as compared to patients treated with placebo plus paclitaxel. In exploratory Kaplan-Meier survival analyses stratified by model predicted ramucirumab minimum concentration after first dose ($C_{min,1}$), the OS effect was only shown for the patients with $C_{min,1}$ greater than the median value. Further exploratory E-R analyses were conducted. **Methods:** Data for E-R analyses were obtained from a randomized (1:1), double-blind, placebo-controlled, efficacy and safety trial that randomized 665 patients. Case-control analysis was conducted to match patients in the placebo arm to patients in each $C_{min,1}$ quartile subgroup (Q1-Q4) based on key baseline prognostic factors, which could potentially confound assessment of therapeutic benefit from ramucirumab. The relationship between $C_{min,1}$ and OS based on exposure subgroups and matched placebo controls was re-evaluated by Kaplan-Meier analyses. **Results:** Four baseline prognostic factors were identified: ECOG performance status (0 vs. 1), tumor differentiation (well, moderately, poorly or unknown), Asian (yes or no), and the total number of target and non-target tumor lesions (≤ 4, 4-8 or ≥ 9). These were used for selection of case-controls. Kaplan-Meier curves showed no apparent difference in OS throughout the treatment period for the Q1 and Q2 subgroups and $>$ 4-month difference in estimated median OS for the Q3 and Q4 subgroups as compared to their corresponding controls. **Conclusions:** An incremental OS benefit was observed with increasing exposure of ramucirumab after case control, suggesting that patients with higher ramucirumab exposure may derive more benefit from the addition of ramucirumab to paclitaxel. These analyses led FDA to recommend a post-marketing clinical trial to explore the benefits and safety of a higher dosing regimen of ramucirumab.

2579 Poster Session (Board #295), Sat, 8:00 AM-11:30 AM

Population pharmacokinetic (PK) analysis of TAS-102 in patients (pts) with metastatic colorectal cancer (mCRC): Results from 3 phase 1 trials and the phase 3 RECOURSE trial. *First Author: James M. Cleary, Dana Farber Cancer Institute, Boston, MA*

Background: TAS-102 is comprised of an antineoplastic thymidine-based nucleoside analog, trifluridine (FTD), and the thymidine phosphorylase inhibitor, tipiracil hydrochloride (TPI), at a molar ratio of 1:0.5 (weight ratio, 1:0.471). The efficacy and safety of TAS-102 in pts with mCRC refractory to standard therapies were evaluated in the RECOURSE trial. The major elimination pathways of FTD and TPI are by thymidine phosphorylase metabolism and renal excretion, respectively. Objectives of the current analysis were to establish population PK models for FTD and TPI, and to identify significant intrinsic and extrinsic factors that influence drug exposure. **Methods:** The population PK approach used the nonlinear mixed-effect modeling program. The analysis consisted of sparse sampling data in RECOURSE (n = 139 of 800 pts, 3 time points) and extensive sampling data in 3 TAS-102 phase 1 trials (n = 102) [Japanese dose-finding study (*Br J Cancer.* 2012;107:429-434), PK contribution study (NCT01867866), and QTc study (NCT01867879)]. **Results:** Actual doses based on body surface area (BSA) were similar among studies except for the Japanese dose-finding study. The 1- and 2-compartment models with transit and first-order absorptions were adopted for FTD and TPI, respectively. BSA clearly related to the central volume of distribution (Vd/F) and creatinine clearance (CLCR) was a significant covariate for apparent oral clearance (CL/F) in the final models of FTD and TPI. Serum albumin (ALB) was a significant negative covariate for CL/F of FTD. The fixed effect for individual CL/F and Vd/F were modeled as follows: FTD: Vd/F (L) = $10.0 \times (BSA/1.81)^{0.94}$, CL/F (L/h) = $2.93 \times (CLCR/103)^{0.507} \times (ALB/3.90)^{-0.633}$; TPI: Vd/F (L) = $192 \times (BSA/1.81)^{1.46}$, CL/F (L/h) = $88.7 \times (CLCR/103)^{0.592}$. **Conclusions:** Renal function and body size were the primary determinants of the PK of TAS-102, highlighting the importance of monitoring renal function in pts treated with TAS-102. Dosing of TAS-102 by BSA is adequate to reduce the variability of exposure to FTD and TPI. Significantly, the PK parameters did not vary with race, age, gender, or hepatic function. Clinical trial information: NCT01607957.

2580 Poster Session (Board #296), Sat, 8:00 AM-11:30 AM

A phase I, first-in-human study of argx-111, a monoclonal antibody targeting c-met in patients with solid tumors. *First Author: Philippe G. Aftimos, Institut Jules Bordet – Université Libre de Bruxelles, Brussels, Belgium*

Background: Dysregulation of the tyrosine kinase receptor c-Met, is associated with tumorigenesis, metastasis and progression via hepatocyte growth factor (HGF)-dependent or-independent mechanisms. **Methods:** ARGX-111, a monoclonal IgG1 SIMPLE Antibody glyco-engineered for enhanced ADCC properties (POTELLIGENT), is currently being investigated in a Phase 1 clinical trial (accelerated titration design) in patients with advanced solid tumors (NCT 02055066). **Results:** As of January 2015, 16 patients (median age: 59 years; prior chemotherapy/targeted therapies/biological therapies: 81%/44%/31%;) with tumors staining positive ($>$ 50% of tumor cells) for c-Met by immunohistochemistry have been treated at 4 dose levels (0.3, 1, 3, and 10 mg/kg IV q3 weeks; n = 2, 2, 9, and 3, respectively) and received a total of 41 cycles (median = 2; range 1-9). Patients with different histologies were enrolled (5 upper GI, 3 RCC, 2 pancreas, 2 NSCLC, 2 cervix and 2 others). The most common drug-related adverse events (AE) were: infusion-related reaction (IRR) (56%), fatigue (38%) and diarrhea (25%). Drug-related Grade 3 AEs (IRRs) were observed in 2 patients. The MTD was 3 mg/kg IV q3 weeks. Pharmacokinetics were dose-linear, with a half-life of 3-4 days. Serum HGF levels remained stable during treatment. *Ex vivo*ADCC and depletion of circulating c-Met+ cells were observed in all patients and NK cell counts remained stable during treatment across all dose levels. One patient with metastatic, c-Met amplified gastric cancer refractory to platinum and taxane-based chemotherapy regimens, was treated at 0.3 mg/kg (escalated to 1.0 mg/kg) and maintained stable disease by RECIST for 6 months, associated with mixed metabolic response on PET scan, and a more than 50% reduction in CTCs. **Conclusions:** Recruitment of the safety expansion cohort is ongoing. Full results will be presented at the meeting. Clinical trial information: NCT 02055066.

Dose	0.3 mg/kg	1 mg/kg	3 mg/kg	10 mg/kg
C_{max}(mean) (μg/ml)	5.6	11.4	43.4	113.2
ADA	No	No	No	No
HGF levels	Stable	Stable	Stable	ND
ADCC	Yes	Yes	Yes	Yes
NK-cell count	Stable	Stable	Stable	Stable

2581 Poster Session (Board #297), Sat, 8:00 AM-11:30 AM

Comparison of adult oncology phase 1 trials to pediatric oncology phase 1 trials of targeted therapies. *First Author: Vivek Subbiah, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Intractable aggressive cancers continue to take the lives of children, adolescents and young adults at the prime of their lives. The prior era of drug development wherein pediatric cancer becomes the last cancer to be tested with novel agents, 'if' the agent seems promising in adult cancers may need to be re-visited. Phase 1 trials are the first critical step in drug development. Data based on cytotoxic chemotherapy phase 1 trials demonstrated a strong correlation between adult and pediatric maximum tolerated dose (MTD)s. We sought to compare pharmacokinetic (PK) parameters and dosing of small molecule inhibitors and monoclonal antibodies (MAbs) studied in adult vs. pediatric phase 1 trials. **Methods:** We conducted an extensive review of all published pediatric phase 1 trials of small molecule inhibitors and MAbs, and their corresponding adult phase 1 trials. Multiple data elements including MTD, recommended phase 2 dose (RP2D), and dose-limiting toxicity (DLT) were collected from pediatric and adult phase 1 trials. PK parameters for the small molecules including drug clearance (CL), area under the concentration curve (AUC), and half-life were analyzed. **Results:** We identified 25 targeted agents (21 small molecules, 4 MAbs) and compared data from the pediatric and adult trials. The MTD was not reached for 14 of the 25 (56%) agents in adults (3/25), pediatric patients (7/25), or both (4/25). Excluding the agents for which the MTD was not reached, the median ratio of pediatric to adult MTD was 1. PK data was available for 13 small molecules and 2 MAbs. The median ratio of pediatric to adult PK parameters for small molecules was: 0.9 for drug CL, 1 for AUC, and 0.8 for half-life. There was substantial heterogeneity in the PK parameters investigated across the studies. **Conclusions:** The PK and MTD of small molecule targeted agents in pediatric and adults patients are comparable. Initial pediatric dosing close to the adult MTD or RP2D and extrapolation of PK data from adults may help expedite drug development of these agents in children. Standardized strategies to study and report PKs are needed.

2582 Poster Session (Board #298), Sat, 8:00 AM-11:30 AM

The association of relative survival benefit and approval of oncological drugs: An analysis of oncology drug advisory committee reviews. *First Author: Idoroenyi Usua Amanam, St. Mary Medical Center, Long Beach, CA*

Background: To evaluate the association of relative survival benefit (additional benefit / historic control) as a modality to predict for oncology drug approval. **Methods:** Data was extracted from transcripts of drug license application sessions of the FDA's Oncology Drug Advisory Committee (ODAC). Relative survival benefit (RB) is defined as the percent survival improvement associated with new therapy over standard therapy. SAS was used to conduct statistical analysis. **Results:** The FDA approved 13 of 29 oncological drug license applications from 2001 to 2014. 5 breast, 3 pancreatic, 3 renal, 3 ovarian, 2 hematologic, 2 prostate, 2 soft tissue sarcoma, 2 lung, 2 bone metastasis, 2 brain, and 2 skin drug applications were reviewed by the FDA. 11 (38%) drug license applications used overall survival (OS) as an endpoint, 8 (28%) used PFS, and 10 (34%) used both OS and PFS as endpoints. The median relative benefit (RB) of all reviewed end points (n = 39) was 15.1% (range: 0% to 190%). Of the studies that used PFS (n = 18) vs. OS (n = 21) as an endpoint, the average relative benefit was 70% (range: 7% to 190%) and 11% (range: 0% to 50%) ($p < 0.01$), respectively. Using the median RB of 15%, drugs with a greater RB had an approval rate of 68%, while drugs with a lower RB had an approval rate of 6% ($p = 0.24$). Subset analyses of studies using OS or PFS as the primary endpoint showed no difference in approval of drugs with RBs higher or lower than the median ($p = 0.47$, $p = 0.066$, respectively). Analysis of the years 2001-6, 2007-10, and 2011-14 showed significant increases in RB ($p < 0.01$) and drug approval ($p = 0.032$) as well as greater use of PFS rather than OS as an endpoint in studies ($p = 0.017$). **Conclusions:** The use of relative survival benefit may assist as a predictive indicator for prediction of FDA approval of novel anti-cancer agents. Researchers may need to consider using relative survival benefit to improve the success of FDA approval of novel drug agents.

2583 Poster Session (Board #299), Sat, 8:00 AM-11:30 AM

A phase I dose escalation study of the tolerability of the oral VEGFR and EGFR inhibitor vandetanib (V) in combination with the oral MEK inhibitor selumetinib (S) in solid tumors. *First Author: Wasiru Olugbenga Saka, Oxford University Hospitals NHS Trust, Oxford, United Kingdom*

Background: The clinical utility of agents that target EGFR and VEGFR signaling in Non-Small Cell Lung Cancer (NSCLC) is limited by resistance due to emergent alternative growth stimulatory pathways, particularly that of MEK. Thus, there is a strong rationale for developing a strategy to combine EGFR, VEGFR and MEK inhibitors. **Methods:** Patients (Pts) aged > 18y, life expectancy > 12w and cytologically proven solid tumors for which no conventional therapy exists were eligible to participate. Six dose levels have been explored. PK samples were obtained on D4, 15 and 29. Pts remained on treatment until progressive disease or unacceptable toxicity. **Results:** 41 pts of median age 62y (36 – 80y); M-20, F-21; lung-23, CRC-9, Mesothelioma-3, pancreas-2, Other-4 were enrolled. 40 pts were eligible for safety assessment. Median treatment time was 10 w (range 2-44 w). GI and skin toxicities were the most prevalent related AEs (GI: 124 AEs in 88% pts; Skin: 74 AEs in 95% pts). Sixteen related eye disorders were seen in 12 pts to include retinal detachments-6 (G1-2) and retinopathies-2 (G2 and 3). Evidence of dose dependent skin and eye toxicity was observed. Six DLTs were identified; Cohort (Coh) 1 - G3 hypertension, Coh 3 & 5a - G2-3 eye events (3 AEs), Coh 4 - G3 bradycardia and Coh 5b - G3 raised ALP. The PK data for V alone and in combination with S were similar to those previously reported for either drug alone. **Conclusions:** V and S have overlapping toxicities, yet the combination has been manageable, with the AE profile consistent with the known monotherapy profiles. A higher incidence of reversible eye events was observed in combination than with single agent S. PK has shown no drug interaction. S dose of 100mg once daily or 50mg twice daily is the MTD in combination with V. V combination MTD to be confirmed. Stable disease was confirmed in four NSCLC patients who received 6-10 cycles. An expansion cohort in NSCLC with known EGFR, VEGFR and MEK activation status will open with anti-tumor efficacy endpoint. Clinical trial information: NCT01586624.

Cohort	V Lead in (po) Days 1-4	V Steady state (po) Days 5-14	S (po), from Day 15, in combination with steady state V
1	300mg od	100mg od	25 mg bd
2			50 mg bd
3			75 mg bd
4			100mg od
5a			125mg od
5b		200mg od	50 mg bd

2584 Poster Session (Board #300), Sat, 8:00 AM-11:30 AM

Phase I study of the mTOR inhibitor sirolimus and the HDAC inhibitor vorinostat in patients with advanced malignancies. *First Author: Haeseong Park, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Preclinical models suggest synergistic anticancer activity of histone deacetylase (HDAC) and mTOR inhibitors by reducing activity of AKT/mTOR and HDAC. **Methods:** This is a phase I study (NCT01087554) to determine the safety, maximum tolerated dose (MTD)/recommended phase II dose (RP2D) and dose limiting toxicities (DLT) of the mTOR inhibitor sirolimus (1mg-5mg PO daily q 28 days) and HDAC inhibitor vorinostat (100mg-400mg PO daily q 28 days) in patients with advanced cancers. The expansion cohorts at RP2D, which included optional pre- and post-treatment tumor biopsies and other pharmacodynamic (PD) and pharmacokinetic (PK) endpoints, enrolled patients with classical Hodgkin lymphoma (cHL), hepatocellular carcinoma (HCC), perivascular epithelioid cell tumor (PEComa) and other cancers. **Results:** From March 2010 to August 2014, 102 patients were treated (dose escalation, n = 69, expansions, n = 33). cHL (n = 22) and HCC (n = 12) were most common diseases. Patients (n = 66), who either had DLT or completed the first cycle without dose modifications were evaluable for DLT asessment, which included grade (G) 4 thrombocytopenia (n = 10) and G3 mucositis (n = 1). Sirolimus 5mg and vorinostat 300mg was declared as MTD. Because of significant non-DLT hematological toxicities, sirolimus 4mg and vorinostat 300mg was established as RP2D. All G 3/4 drug related toxicities (including DLT) were thrombocytopenia (37%), neutropenia (13%), anemia (8%), mucositis (3%), diarrhea (3%), fatigue (2%), febrile neutropenia (1%), peripheral neuropathy (1%). 57 (56%) patients required dose modifications. Of 102 patients, 78 had at least one restaging imaging;7 (7%; cHL, n = 6; peripheral T-cell lymphoma, n = 1) had a complete response, 7 (7%; cHL, n = 6; PEComa, n = 1) had a partial response and 3 (3%, HCC, n = 2, fibromyxoid sarcoma, n = 1) had stable disease for 12 months or longer. Among the responders, two had known aberrations in the PI3K pathway (TSC2 and PIK3CA). PD studies and PK analysis are pending. **Conclusions:** The combination of sirolimus and vorinostat is well-tolerated at RP2D and demonstrates promising activity in lymphoma, PEComa and HCC. Further investigation is warranted in these disease types. Clinical trial information: NCT01087554.

2585 Poster Session (Board #301), Sat, 8:00 AM-11:30 AM

Dose-escalation of the first-in human phase I/Ib study of ABTL0812, a novel antitumor drug inhibiting the Akt/mTOR pathway in patients with advanced solid tumors. *First Author: Laura Vidal Boixader, Hospital Clinic Barcelona, Barcelona, Spain*

Background: ABTL0812 is a novel drug with reported preclinical activity in several tumor types. *In vitro* and *in vivo* assays have shown that ABTL0812 is an inhibitor of the Akt/mTOR pathway by a novel mechanism of action. **Methods:** A Phase I/Ib First in Human (FiH) clinical trial started on February 2014 (NCT02201823) in which patients with solid tumors and no standard treatment were enrolled. ABTL0812 was administered daily, by the oral route in 28-day cycles. The primary objective of the trial was to obtain a maximum tolerated dose and a recommended phase II dose (RP2D). The secondary objectives of the trial were assessment of dose-limiting toxicity (DLT), response rate, progression-free survival and overall survival. Pharmacokinetic (days 1 and 29) and pharmacodynamic (inhibition of the phosphorylation of Akt in platelets at day 29 vs. predose, as biomarker) end-points were also introduced. The study design consisted in a 3+3 dose escalation with up to five cohorts. An expansion phase with 12 patients is planned. **Results:** The dose-escalation, in which 15 patients were recruited, started at 500 mg/day and was completed in December 2014 at 4,000 mg/day. ABTL0812 showed overall a good safety profile. Grade 1-2 adverse events included swallowing disturbance, asthenia, increase of hepatic enzymes, hyperglycemia and nausea; grade >2 adverse events were rare and included anemia and asthenia. No DLTs were observed and therefore, RP2D has been determined as 1,300 mg tid by pharmacokinetic-pharmacodynamic modeling of drug plasma concentrations at steady state vs. platelet pAkt inhibition. One patient with endometrial cancer and one patient with sigmoid colon cancer currently show stable disease (SD) after 10 and 5 months of treatment, respectively. **Conclusions:** RP2D of ABTL0812 has been determined. ABTL0812 has demonstrated a good safety profile, with only mild adverse events. Additionally, ABTL0812 has shown activity on biomarkers, and hints of activity in two patients presenting prolonged SD. Clinical trial information: NCT02201823.

2586 Poster Session (Board #302), Sat, 8:00 AM-11:30 AM

Phase I study of pemetrexed and sorafenib in advanced solid tumors. *First Author: Andrew Stewart Poklepovic, Virginia Commonwealth Univ Health Sys, Richmond, VA*

Background: Pemetrexed (Pem) blocks thymidylate synthase, activates AMPK, and inactivates mTOR, increasing autophagy. Sorafenib (Sor) also stimulates autophagy through down-regulation of GRP78/BiP and ER stress signaling. Preclinical data demonstrated the combination of Pem and Sor caused synergistic cell death through a form of toxic autophagy. A phase I trial evaluating the combination of Pem and Sor in advanced solid tumors was initiated. **Methods:** An open-label, dose escalation study was conducted in patients (pts) with advanced malignancies. Standard 3+3 dose escalation design was used, with escalating doses of Pem (500 mg/m^2-1000 mg/m^2 IV) every 2 weeks with Sor (200-400 mg PO BID) continuously (cohort A). The initial 4-week period (Cycle 1) was used for dose-limiting toxicity (DLT) assessment. After treatment of 24 pts on cohort A, it was determined that continuous dosing of Sor with any dose of Pem was associated with unacceptable cumulative constitutional symptoms beyond Cycle 1. The protocol was amended to evaluate intermittent Sor (BID dosing days 1-5 of each Pem dose) (cohort B). Radiographic assessments were conducted every 8 weeks using RECIST 1.1. **Results:** Thirty-seven pts were enrolled and 36 treated, 24 on cohort A and 12 on cohort B. The MTD in cohort A was defined as Pem 500 mg/m^2 and Sor 200 mg PO BID on a continuous schedule. Dose reductions for cumulative toxicity became necessary in the majority of patients in cohort A. Intermittent dosing was more tolerable, with 0/12 cohort B pts experiencing DLTs, treated at both 500 mg/m^2 and 750 mg/m^2 of Pem every 2 weeks with intermittent Sor at 200-400 mg. Of the 36 treated pts, best responses to date are 1 CR, 4 PR, 10 SD, 15 PD, 2 NE, and 4 TETE. Five pts with progressive breast cancer were identified as responders. One PR and the CR had durations of response approximating 1 year. All responding pts were heavily pretreated, with a median of 6 prior lines of therapy. Cutaneous, nodal, and visceral metastases were all observed to respond to treatment. **Conclusions:** The RP2D for the combination is Pem 750 mg/m^2 IV every 2 weeks with Sor 400 mg PO BID days 1-5 with each dose of Pem. A phase II study in breast cancer is planned. Clinical trial information: NCT01450384. Clinical trial information: NCT01450384.

2587 Poster Session (Board #303), Sat, 8:00 AM-11:30 AM

Phase I study of INC280 plus erlotinib in patients with MET expressing adenocarcinoma of the lung. *First Author: Caroline Elizabeth McCoach, University of Colorado School of Medcn, Aurora, CO*

Background: MET dysregulation is one mechanism of EGFR-TKI (epidermal growth factor receptor-tyrosine kinase inhibitor) resistance in patients (pts) with EGFR mutated lung cancer. INC280 is a potent oral small molecular inhibitor of the MET kinase. Inhibiting both pathways may circumvent EGFR-TKI resistance. A phase I study of INC280 plus erlotinib (E) to determine the maximum tolerated dose, dose limiting toxicity (DLT), pharmacokinetics (PK) and preliminary antitumor activity of this combination was conducted. **Methods:** Using a 3 + 3, dose escalation design, INC280 was increased over 5 dose levels (DL) from 100 - 600 mg po bid. Daily E was given at 100 mg in DL1 and 150 mg in DL2- 5. Both agents were given for 28 days (1 cycle). Key eligibility included: lung adenocarcinoma with MET expression by a CLIA certified lab, age $\geq$ 18 years old, ECOG PS of ≤ 2, acceptable organ function, and >1 systemic therapy for advanced disease. **Results:** 18 pts have been treated on 5 dose levels. Pt characteristics: median age 59, M/F (7/11), ECOG 0-1/2 (16/2), MET expression by IHC/FISH/RT-PCR/NGS (6/2/9/1), EGFR mutated tumors (8) and prior E treatment (12). 14 patients have completed at least 1 cycle. One DLT (grade (Gr) 3 neutropenia) occurred in DL 5 (INC280 600mg bid, E 150mg daily). Common drug-related adverse events (AE) of any Gr were diarrhea and rash (47% each), fatigue (40%), increased AST and ALT (27% each), nausea, anorexia and paronychia (27% each). Drug-related Gr 3/ 4 AE were anorexia, increased amylase or lipase and neutropenia (all 7%). PK analysis revealed that INC280 exhibited a linear PK and no interaction with E. Of the 12 evaluable pts, 6 had stable disease (3 EGFR mutated) and 2 with EGFR mutated tumors had a minor response (10-29% decrease in target lesion size). Seven pts received treatment for $\geq$ 3 months (5 EGFR mutated). **Conclusions:** In patients with MET-expressing lung adenocarcinoma, INC280 plus erlotinib is feasible, tolerable and demonstrates anti-tumor activity. Expansion cohorts will enroll pts with EGFR mutated tumors refractory to an EGFR-TKI or EGFR-TKI naïve in the first-line setting and in wild type EGFR pts who are EGFR-TKI naïve as second or third-line therapy. The recommended phase II dose and updated results will be presented. Clinical trial information: NCT01911507.

2588 Poster Session (Board #304), Sat, 8:00 AM-11:30 AM

Phase I combination of pazopanib and everolimus in *PIK3CA* mutation positive/PTEN loss patients with advanced solid tumors refractory to standard therapy. *First Author: Heloisa Veasey Rodrigues, Centro de Oncologia e Hematologia - Hospital Israelita Albert Einstein, Sao Paulo, Brazil*

Background: Combining agents that block both the VEGF and PI3K/AKT/mTOR pathways may be synergistic. We explored a novel dosing schedule to assess safety, toxicity and activity in patients with advanced solid tumors. **Methods:** Patients with refractory solid tumors were enrolled in a modified 3+3 Phase I dose escalation study to determine dose limiting toxicities (DLTs) and the maximum tolerated dose (MTD) of a combination of everolimus (mTOR inhibitor) and pazopanib (tyrosine kinase inhibitor with anti-VEGF activity). An expansion cohort selected for patients with molecular alterations in the PI3K/AKT/mTOR pathway. **Results:** Sixty-two patients were enrolled; median age was 60 years; 29 were women. The MTD was pazopanib 600mg every other day (QOD) alternating with everolimus 10mg PO QOD. DLTs were grade 3 thrombocytopenia and creatinine elevation. Most common toxicities of any grade were thrombocytopenia, transaminitis, leukopenia/neutropenia and lipid abnormalities. Among 52 patients evaluable for response, the clinical benefit rate (CBR) was 27% (14/52) including four partial responses (PR), and 10 stable disease (SD) $\geq$ 6 months. 26 of 45 patients evaluated for molecular alterations had at least one alteration in the PI3K/AKT/mTOR pathway. CBR in patients with a matched alteration was 27% (7/26) versus 26% (5/19) for patients without an alteration ($p = 0.764$). However, 64% of those with CBR and molecular testing done for alteration in the PI3K/AKT/mTOR pathway were positive. **Conclusions:** Combination treatment with pazopanib and everolimus was well tolerated and demonstrated activity in solid tumors. Further exploration of this combination and molecular correlation with treatment outcomes is warranted. Clinical trial information: NCT01430572.

2589 Poster Session (Board #305), Sat, 8:00 AM-11:30 AM

Phase I study of receptor tyrosine kinase (RTK) inhibitor, MGCD265, in patients (pts) with advanced solid tumors. *First Author: Christian K. Kollmannsberger, BC Cancer Agency, Vancouver Cancer Centre, Vancouver, BC, Canada*

Background: MGCD265 is a spectrum-selective and ATP-competitive inhibitor with MET and Axl as clinically relevant RTK targets. In nonclinical studies, MGCD265 demonstrated anti-tumor activity in cancer models exhibiting dysregulation of MET or Axl RTKs. **Methods:** Phase I objectives were to evaluate the maximum tolerated dose (MTD), safety, pharmacokinetics (PK), pharmacodynamics (PD) and clinical activity of MGCD265. Eligible pts with advanced solid tumors received MGCD265 on Cycle 1 Day 1, then continuous dosing starting on Cycle 1 Day 3 for 21-day cycles. PK/PD were evaluated after single dose and repeated administration. **Results:** 12 pts (6 males; median age 57 years; range 48-75) with advanced malignancies were treated with 600, 1200 or 1050 mg BID of MGCD265 in non-aqueous suspension capsules. At 1200 mg BID, 2 out of 6 evaluable pts experienced DLT (G3 fatigue; G3 diarrhea). 1050 mg BID was defined as the MTD with no DLTs in 3 pts. Treatment-related AEs ($>$ 20% all grades) included diarrhea, nausea, vomiting, fatigue, AST increase, ALT increase and lipase increase. Stable disease of at least 6 weeks was observed (n = 2). At MTD, preliminary data show that steady state average and maximum concentrations were 501 and 562 ng/mL, respectively; the area under the concentration-time curve for the dosing interval was 6010 ng●h/mL. Preliminary data show that plasma concentrations exceeded levels projected for near complete inhibition of both MET and Axl for the full dosing interval. Maximal increase of plasma soluble MET ectodomain (sMET) was observed at each dose level including those associated with sustained steady state plasma concentrations (C_{min}) as low as 200 ng/mL, suggesting that the MET pathway was inhibited at all 3 dose levels and concentrations achieved in this study. **Conclusions:** MGCD265 is well tolerated at the MTD of 1050 mg BID. Based on safety, PK data and PD data suggesting robust inhibition of MET and Axl, the expansion phase of the study began recruitment in December 2014. Patients with NSCLC and other solid tumors with specific genetic alterations for *MET* and *AXL* will be enrolled. Clinical trial information: NCT00697632.

2590 Poster Session (Board #306), Sat, 8:00 AM-11:30 AM

Phase I study of the PI3K/mTOR inhibitor PF-05212384 in combination with other antitumor agents. *First Author: Zev A. Wainberg, UCLA Medical Center, Los Angeles, CA*

Background: Inhibition of phosphatidylinositol-3-kinase (PI3K)-mediated signaling may overcome resistance to different classes of chemotherapies as well as epidermal growth factor receptor (EGFR) inhibitors. PF-05212384 (PF384) is an intravenous (IV) inhibitor of PI3K/mammalian target of rapamycin (mTOR) in development for metastatic colorectal cancer and other solid tumors in combination with other agents. **Methods:** An ongoing phase I dose escalation study is enrolling cohorts of 3–6 patients (pts) to determine maximum tolerated dose (MTD) and safety of PF384 plus docetaxel (arm A), cisplatin (arm B), or the EGFR tyrosine kinase inhibitor dacomitinib (arm C). Eligible pts have castrate resistant prostate cancer, advanced breast cancer, or non-small cell lung cancer (NSCLC; arm A); urothelial transitional cell cancer, triple negative breast cancer, or NSCLC (arm B); or refractory Her2+ breast cancer, Her2+ esophagogastric cancer, head and neck squamous cell cancer, or EGFR-mutated NSCLC (arm C). Dose assignment is guided by a modified toxicity probability interval method (arms A,B) or zone-based design (arm C). Pts receive a lead-in PF384dose 7 (arms A,B) or 14 days (arm C) prior to cycle 1 day 1. Then, pts receive weekly PF384plus standard chemotherapy (docetaxel or cisplatin 75 mg IV every 3 wk) or dacomitinib (30–45 mg/d orally; started 7 days prior to cycle 1 day 1). Primary endpoint is cycle 1 dose-limiting toxicities (DLTs), including lead-in dose. Secondary endpoints include pharmacokinetics, tumor response, and PI3K pathway protein biomarkers. **Results:** 52 pts received escalating doses (90–150 mg) of PF384: 14, 12, and 26 pts in arms A, B, and C. Drug-related adverse events in $>$ 30% pts were neutropenia, mucositis, and nausea in arm A; nausea, decreased appetite, fatigue, vomiting, anemia, and hypomagnesaemia in arm B; and mucositis, diarrhea, nausea, dermatitis acneiform, and decreased appetite in arm C. There were no DLTs in arms A or B; in arm C, DLTs were grade 3 mucositis, pneumonitis, and rash, and grade 2 fatigue ($<$ 75% of planned dose received). **Conclusions:** PF384can be combined with docetaxel, cisplatin, or dacomitinib with a manageable toxicity profile. Dose escalation to determine MTD is ongoing. Clinical trial information: NCT01920061.

2591 Poster Session (Board #307), Sat, 8:00 AM-11:30 AM

Efficacy, safety, biomarkers, and phase II dose modeling in a phase I trial of the oral selective c-Met inhibitor tepotinib (MSC2156119J). *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute At HealthONE, Denver, CO*

Background: Tumor c-Met overexpression is associated with tumor aggression and poor prognosis, making it a target for therapy. This phase I study (NCT01014936) in patients (pts) with advanced solid tumors provided data that allowed determination of a recommended phase II dose (RP2D) for the selective oral c-Met inhibitor tepotinib (MSC2156119J). **Methods:** Primary objectives were to determine the MTD and RP2D. Secondary endpoints included antitumor activity, safety, pharmacokinetics (PK), and pharmacodynamics. Pts received tepotinib according to one of three 3-weekly regimens (R): 30–230 mg/d d1–14 followed by 7-d rest (R1); 30–115 mg/d 3x/week (R2); or 300–1400mg/d d1–21 (R3). Interim PK and biomarker data were analyzed using a population modeling approach. Using these data and the exposure/target inhibition relationship established in mice, a human population PK model was developed to simulate c-Met inhibition profiles in humans and determine the biologically active dose of tepotinib. **Results:** As of 9/30/2014,143 pts had been enrolled (R1 = 42; R2 = 45; R3 = 56). The MTD was not reached at $\leq$ 1400 mg/day d1–21 (R3). Among the 56 pts treated with R3 (c-Met overexpressing 12; amplified 4; overexpressing and amplified 3), treatment-related adverse events (trAEs) were observed in 61%. Of these, $>$ 75% experienced trAEs of worst grade 1/2. Seven pts (13%) experienced trAEs of worst grade $\geq$ 3: fatigue (2), peripheral edema (2), ALT increase (1), AST increase (1), hyponatremia (1), edema (1), and thrombocytopenia (1). Of the 56pts treated with R3, 2 had a PR and 7 had SD as their best overall response. Patients with PRs had tumors with c-Met overexpression or amplification, as did 2/7 pts with SD. A biologically active dose of 500 mg/d was selected as the RP2D based on a translational modeling approach, with simulations indicating that $\geq$ 95% pMET inhibition was required for tumor regression. Human population PK simulations suggested that tepotinib 500 mg daily could achieve continuous pMET inhibition of $\geq$ 95% in 90% of the population. **Conclusions:** Tepotinib is well tolerated and shows antitumor activity, particularly in pts with c-Met overexpressing/amplified tumors. Clinical trial information: NCT01014936.

2592 Poster Session (Board #308), Sat, 8:00 AM-11:30 AM

A phase 1 first-in-human (FIH) dose-escalation (DE) study of the oral dual PI3K/mTOR inhibitor PQR309 in patients (pts) with advanced solid tumors: Final DE results. *First Author: Rebecca Sophie Kristeleit, University College London Cancer Institute, London, United Kingdom*

Background: PQR309 is a novel, orally bioavailable, balanced pan-PI3K, mTORC1 and mTORC2 inhibitor. **Methods:** An accelerated 3+3 DE, open label Phase 1 trial of continuous once daily (OD) PQR309 to evaluate safety, pharmacokinetics (PK) and pharmacodynamics (PD) in pts with advanced solid tumours was performed. Pts had no standard therapeutic options. An expansion cohort at maximum tolerated dose (MTD) is planned. The starting dose of PQR309 was 10mg OD. The dose limiting toxicity (DLT) period was the first cycle of treatment, 21 days (d). Paired tumour biopsies (PTB) were collected. **Results:** 25 pts (18F:7M) were enrolled as of January 2015 and treated at 11 doses ranging from 10-150mg. Common adverse events (AE) ($\geq$ 30% pts) included fatigue, hyperglycaemia, nausea, diarrhea, constipation, rash, anorexia and vomiting. Grade (G) 3/4 drug-related AE were seen in 11 and 3 pts respectively. The most common drug-related AE $\geq$ G3 was hyperglycaemia observed in 7 pts. DLT occurred in 2/6 pts at 100mg OD associated with sequential AE G2-4; one patient (pt) with $>$ 14d interruption in PQR309 due to G2-4 rash, hyperbilirubinaemia, suicide attempt and one pt with dose reduction to 80 mg due to G2-3 fatigue, diarrhea, transaminitis, both during cycle 1. Preliminary PK shows fast absorption (T_{max} 1-2h), dose proportionality for C_{max} and AUC and an estimated $T_{1/2}$ of around 20 hours, consistent with PQR309 *in vivo* models. Preliminary PD analysis of 16 phosphoproteins (PP) involved in PI3K/mTOR/MAPK signalling in PTB shows marked decrease of p-Akt, pS6 and p4EPB from 40mg OD with moderate inhibition of p-Erk. A partial response (PR) in a pt with metastatic thymus cancer (ca) and *RICTOR* gene amplification, 24% disease volume reduction in a pt with sinonasal ca and PIK3CA E545K mutation and stable disease for over 16 weeks in a pt with clear cell Bartholin's gland ca have been observed. **Conclusions:** The MTD and recommended phase-2 dose of PQR309 is 80mg OD. PD shows PI3K pathway PP downregulation in PTB and PK is dose-proportional. Clinical activity including a PR has been observed in pts with known PI3K pathway dysregulation. Recruitment in the 80mg and planned expansion cohort is ongoing. Clinical trial information: NCT01940133.

2593 Poster Session (Board #309), Sat, 8:00 AM-11:30 AM

A phase Ib dose-escalation study of GSK2256098 (FAKi) plus trametinib (MEKi) in patients with selected advanced solid tumors. *First Author: Hendrik-Tobias Arkenau, Sarah Cannon Research United Kingdom, London, United Kingdom*

Background: The focal adhesion kinase (FAK) and MAPK pathways share common upstream activators and contribute to cell proliferation, differentiation, migration and survival. Dual inhibition of both pathways with GSK2256098 and trametinib, respectively, are synergistic in cellular growth and survival assays, especially in mesothelioma cell lines. **Methods:** This phase Ib study (NCT01938443, funded by GSK) evaluated GSK2256098 twice daily combined with trametinib once daily in pts with advanced solid malignancies enriching for mesothelioma. The objectives were to determine the maximum-tolerated dose (MTD), safety, pharmacokinetics (PK), and pharmacodynamics (PD). **Results:** As of 25 Nov 2014, 24 pts were enrolled (14 M, 10 F; median age 66 yr (range 30 to 78)). GSK2256098 at 250 or 500 mg twice-daily (BID) was orally co-administered with trametinib at 0.25, 0.375, 0.5 or 1 mg once-daily (QD) in 28-day cycles. Systemic exposure to trametinib was 2-4 X > than predicted for monotherapy causing DLTs (skin rash) and dose de-escalation. GSK2256098 PK was unchanged in the presence of trametinib. The MTD was determined to be GSK2256098 250 mg BID plus trametinib 0.5 mg QD and exposure for both agents are at concentrations that achieve antitumor activities *in vitro*. DLTs were observed in 6 pts (25%) at dose levels 0.5 or 1.0 mg trametinib + 500 mg GSK2256098. Median exposure was 52 days (range 17 - 181). Common adverse events (AEs), regardless of study drug relationship, were nausea (58%), diarrhea (38%), rash (33%), pruritus (33%), and vomiting (29%). Grade 3 AEs occurred in 9 individual pts (38%), and 1 (4%) Grade 4 AE occurred. One Grade 3 AE of increased CPK occurred at the MTD. Tumor biopsy PD data indicate FAK target engagement. Of 12 mesothelioma pts, 8 (67%) had stable disease lasting > 6 weeks reported as best response. **Conclusions:** The MTD for combined GSK2256098 and trametinib was reached, and the preliminary safety and PK/PD profile justifies further exploration. Clinical trial information: NCT01938443.

2594 Poster Session (Board #310), Sat, 8:00 AM-11:30 AM

NCIC CTG IND.206: A phase II umbrella trial of sunitinib (S) or temsirolimus (T) in advanced rare cancers. *First Author: Janet Dancey, NCIC Clinical Trials Group at Queen's University, Kingston, ON, Canada*

Background: Patients (Pts) with rare cancers have few treatment options due to the challenges of conducting clinical trials when projected accrual is low. However, rare cancers may have driver mutations that can be targeted with potentially dramatic therapeutic effects. **Methods:** IND.206 is a multi-center, non-randomized phase II study of S or T in 11 rare tumor cohorts (< 100 eligible patients/year in Canada). Cohorts: 8 histologic, 2 genetic, 1 exploratory unspecified. Pts received S (50 mg PO daily x 28 days, q 6 weeks) or T (25 mg IV weekly, q 6 weeks). Each cohort and drug was evaluated separately using a 2 stage design targeting 5 versus 25% RECIST response rate. Blood and tumor were collected for genomic analyses. For trial efficiency, 1) pts could be re-entered to the alternate drug at progression; 2) data collection and SAE reporting were streamlined; 3) cohorts could be stopped early for activity, inactivity or failure to accrue. Central pathology review was performed. **Results:** The trial was activated in 7/2011. To date, 134 patients were enrolled, 156 registered (22 pts crossed over). 132 are evaluable for response, 134 are evaluable for toxicity. 4 cohorts failed meet the minimum accrual. Only the medullary thyroid cohort treated with S met the protocol defined activity level. Responses were seen in the following: medullary thyroid carcinoma (7/16 on S), clear cell carcinomas of ovary/endometrium (3/22 S; 3/22 T), pheochromocytomas and paragangliomas (1/4 S), 1 extraskeletal myxoid chondrosarcoma (ESMCS) on S, 1 perivascular epithelioid cell tumor on T. Responses were not seen in vascular sarcomas (n = 16 10 S, 6 T) Ewing's sarcoma family tumours (n = 10, T), adrenocortical (n = 12 S, 10 T) or thymic carcinomas (n = 5 S, 2 T) despite case reports in the literature. Toxicity was consistent with previously studies although quantity of grade 1-2 and expedited reports were reduced as per protocol. Genomic studies are underway. **Conclusions:** S and T induce responses in clear cell carcinomas of ovary and endometrium, medullary carcinoma of thyroid, paraganglioma and ESMCS. Case reports in the literature may overestimate activity. Our umbrella design is efficient for evaluating drug activity in rare cancers. Clinical trial information: NCT01396408.

2595 Poster Session (Board #311), Sat, 8:00 AM-11:30 AM

Activity of crizotinib in relapsed MET amplified malignancies: Results of the French AcSé Program. *First Author: Gilles Vassal, Institut Gustave Roussy, Paris, France*

Background: Crizotinib (crz) is registered only for the treatment of patients (pts) with ALK-translocated lung cancer. Crz is also a MET inhibitor. MET is amplified in several malignancies. Activity of crz in MET amplified (+) tumors was explored as part of the French National Cancer Institute (INCa) AcSé program, including both access to tumor molecular diagnosis and an exploratory multi-tumor 2-stage design phase II trial. We report here results in pts with MET + tumors. **Methods:** MET analysis on formalin-fixed, paraffin-embedded tumor samples was proposed in 170 investigating centers and performed in 28 regional INCa molecular genetic centers. MET+ was explored by FISH in tumor samples showing an IHC score of ≥2+. Pts with a tumor showing > 6 MET copies, whatever the MET/CEN7 ratio, were eligible, providing they were not eligible for any other academic or industry trial evaluating another MET inhibitor. Study treatment consisted in crz 250 mg BID. The objective response rate (ORR) and disease control rate (DCR) were assessed every 8 weeks, using RECIST v1.1. **Results:** From Aug. 2013 to Dec. 2014, MET was prospectively analyzed in the tumors of 3,044 pts, and amplification (median copy number=7) was found in 100/1,358 lung, 19/591 colon, 5/275 ovary, 13/218 glioblastoma, 10/180 gastric, 1/63 hepatocarcinoma, 1/50 kidney and 0/11 thyroid. 46 pts were enrolled in the trial. Median age: 59 yrs (range 30–92), 65% males and 95% metastatic disease at study entry. 23 pts were still on treatment at the cut-off date, 23 have stopped crz (18 PD, 2 adverse events, 1 death, 2 others reasons). Among the 30 pts evaluable for response at 8 weeks, we observed 4 PR and 8 SD, leading to DCR=40% [95% CI: 23-59]. At 6 months, DCR=15% achieved in 4/26 evaluable pts (3 lung, 1 gastric). Crz was well tolerated with only 8 grade ≥3 adverse events (AEs) or SAE. Most common AEs, mainly grade 1, were fatigue (64 % pts), anemia (53%), ALAT and ASAT increased (both 53%) and visual disorders (50%). **Conclusions:** Nationwide biomarker-driven access to crz for pts with MET+ malignancy is feasible. Crz showed responses in MET+ lung. No response was observed in MET+ colon cancer. Clinical trial information: NCT02034981.

2596 Poster Session (Board #312), Sat, 8:00 AM-11:30 AM

STARTRK-1: Phase 1/2a study of entrectinib, an oral Pan-Trk, ROS1, and ALK inhibitor, in patients with advanced solid tumors with relevant molecular alterations. *First Author: Manish R. Patel, Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, FL*

Background: Entrectinib (formerly RXDX-101), a potent and selective small molecule inhibitor of TrkA/B/C, ROS1, and ALK kinases, has demonstrated early clinical activity when orally administered intermittently under fasting conditions (ASCO 2014). In this abstract, we report a companion Phase 1/2a trial of entrectinib administered daily in the fed state. **Methods:** Pts with advanced solid tumors with molecular alterations in *NTRK1/2/3, ROS1* or *ALK* were treated daily with entrectinib in the fed state. Pts with asymptomatic untreated brain metastases were allowed; pts may have received prior TKI therapy. Endpoints include safety, RP2D, PK, and tumor response **Results:** Entrectinib was well tolerated across all dose levels. No DLTs or significant safety issues were reported from any cohort. Of 15 pts treated, the majority reported only G1 or G2 AEs. 3 pts reported > G3 AEs (each unrelated to entrectinib). 1 SAE (unrelated) has been reported. Entrectinib was readily absorbed with median T_{max} of 4 hr at steady state. Steady state was reached within 7 days of dosing and the estimated $t_{1/2}$ was approximately 17 hrs. There were dose proportional exposure increases with moderate accumulation (~2x or less) at steady state. 15 pts with various molecular alterations identified by local lab testing were treated in the following dose cohorts (mg/m^2): 100 (N = 5), 200 (N = 5), 400 (N = 5). Summary of alterations of enrolled pts: *NTRK* (point mutation = 5; amplification = 1; rearrangement = 1); *ROS1* (SNP = 1); *ALK* (SNP = 2; ampl = 1; rearr = 4). 3 pts with *ALK*-rearranged NSCLC failed at least 2 prior ALK inhibitors. No pts with *ROS1* rearrangements have been treated. No objective responses observed to date. **Conclusions:** Entrectinib, administered daily in fed condition, is well tolerated. In STARTRK-1, there have been no responses at doses ≤ 200 mg/m^2 (400 mg/m^2 cohort recently opened). Doses ≥ 400 mg/m^2 were associated with responses in the ALKA-372-001 Phase 1 study. Dose escalation will continue until the RP2D is identified. Thereafter, Phase 2a cohort expansion will begin enrolling pts with *NTRK1/2/3, ROS1*, or *ALK* molecular alterations to assess antitumor activity. Clinical trial information: NCT02097810.

2597 Poster Session (Board #313), Sat, 8:00 AM-11:30 AM

Phase I study of combination of crizotinib (C) and dasatinib (D) in patients (pts) with advanced cancer. *First Author: Shumei Kato, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although C and D both demonstrate activity resistance can develop. Preclinical studies demonstrated that activation of MET requires c-SRC. We hypothesized that a c-SRC inhibitor (D), in combination with a MET inhibitor (C), may overcome resistance and demonstrate activity. This study is the first in-human attempt to combine C and D. **Methods:** This is a 2 arm concurrent phase I study (3+3) to determine the safety of oral C and D (Table). Arm A: C fixed at 250mg BID with escalation of D. Arm B: D was fixed at 140mg QD with escalation of C. Endpoints included MTD, DLT, RP2D at least 10 evaluable pts at MTD of each arm and response (RECIST 1.1). **Results:** 47 pts were enrolled. Median age was 59 yrs (16- 76), 3 median prior therapies (1 - 11). Most common cancers were prostate (21%) and sarcoma (19%). 27 pts in Arm A were enrolled. 10 pts were not evaluable: consent withdrawal (n=3) primarily for G2 AEs, missed doses <15% (n=7) primarily for early progression. Among 17 pts evaluable for DLT/AE (dose level [DL] 1 [n=13], DL2 [n=4]), 7 pts (41%) had at least one G3 drug-related AE with diarrhea (n=3) the most common AE. 2/4 pts had DLTs at DL2 (all G3; dehydration, infection, nausea, vomiting [n=1 each]). We expanded Arm A DL1 to determine the MTD with 1/13 pts with DLT (G3 esophageal pain). Arm B, 20 pts were enrolled. 6 pts were not evaluable: consent withdrawal (n=1), missed doses (n=5). Among 14 pts evaluable for DLT/AE (DL1 [n=10], DL2 [n=4]), 5 pts (36%) had at least one G3 drug-related AE with fatigue (n=3) being the most common. 2/4 pts had DLT at DL2 (G3 renal failure, G3 fatigue, G3 anorexia [n=1 each]). We expanded Arm B DL1 to determine the MTD with 2/10 pts with DLT (G3 fatigue [n=2]). Based on number of DLTs in the MTDs of each arm, our preliminary RP2D is DL1 on Arm A. 2 pts had PR (prostate [-34%] and uterine carcinosarcoma [-27%]) and 2 pts had SD ≥ 6 months (NSCLC [10.1] and melanoma [(+)14.4]). **Conclusions:** Preliminary RP2D for the combination is C (250mg PO BID) + D (50 mg QD). Responses have been observed and specific tumor and molecular expansions are ongoing. Clinical trial information: NCT01744652.

Arm A Crizotinib 250 mg BID	Dasatinib (mg)

2598 Poster Session (Board #314), Sat, 8:00 AM-11:30 AM

A phase 1, open-label study to evaluate the safety and pharmacokinetics of the anti ErbB3 antibody, KTN3379, alone or in combination with targeted therapies in patients with advanced tumors. *First Author: Todd Michael Bauer, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: KTN3379 is a human monoclonal antibody against a unique epitope of human epidermal growth factor receptor-3 (ErbB3) blocking ligand (neuregulin (NRG)) dependent and independent activation. This trial assessed safety and pharmacokinetics (PK) of KTN3379 alone or with each of four targeted agents in advanced cancers and evaluated potential biomarkers of KTN3379 activity. **Methods:** Part I evaluated KTN3379 in a single agent dose escalation design. Part II evaluated KTN3379 with each of cetuximab, erlotinib, vemurafenib and trastuzumab in patients with refractory SCCHN, CRC, NSCLC, melanoma and HER2+ breast cancer (n = 6 each). Dose limiting toxicities (DLT) were evaluated in the first treatment cycle, RECIST tumor measurements every 3rd treatment cycle and PK and blood pharmacodynamic (PD) assessments each treatment cycle. Archival tumor tissue was evaluated for biomarkers and correlated with KTN3379 activity. **Results:** In Part I, no DLTs were observed in the 16 patients treated with KTN3379 at doses of 5 up to its maximally administered dose of 20 mg/kg IV every 3 weeks. PK parameters were linear, supported every 3-week dosing, and trough blood levels following dosing of KTN3379 at 10-20 mg/kg were consistent with maximum antitumor activity in preclinical models. Grade 3 or higher treatment related AE was reported in 1 patient (diarrhea). Other treatment related AEs were low grade diarrhea (n = 5), mucositis (n = 3), rash (n = 3), anemia (n = 2), and fatigue (n = 2). Patients in Part II to date had a similar profile, with low grade diarrhea, mucositis and rash being the most common AEs. In both Parts, elevations of soluble ErbB3 were noted after treatment. Other blood biomarkers and NRG expression are being evaluated. The best tumor response to date has been stable disease. **Conclusions:** Doses of 10-20 mg/kg exceed target blood concentrations. KTN3379 doses of 20 mg/kg with other targeted agents are safe and PK supports 3-week dosing. KTN3379 has the potential to benefit patients in combination with other targeted agents against ErbB family members, and NRG may be a predictive biomarker of response to KTN3379 in future studies. Clinical trial information: NCT02014909.

2599 Poster Session (Board #315), Sat, 8:00 AM-11:30 AM

Phase I study of temsirolimus in combination with cetuximab in patients with advanced solid tumors. *First Author: Antoine Hollebecque, Drug Development Department, Gustave Roussy, Cancer Campus, Grand Paris, Villejuif, France*

Background: Preclinical studies suggest that temsirolimus (T), an inhibitor of mammalian target of rapamycin (mTOR) combined with cetuximab (C), an anti-EGFR monoclonal antibody, may have synergistic antitumor effects. **Methods:** A dose escalation study was conducted to define the MTD and to characterize the pharmacokinetics and safety profile of T (30 min infusion) given 1 hour later after C (1 hour infusion) on a weekly schedule of a 28-day cycle. Five dose-levels were evaluated with dose range of T from 15 to 25 mg weekly and C from 150 to 250 mg/m^{2}weekly. Sequential biopsies were mandatory during the expansion cohort. **Results:** 39 patients (15M/24F), median age 57 years (range 38-76), previous number of lines 3 (range: 2-15) received the combination of T + C. The most common tumor types were colorectal (N = 6), breast (N = 5), uterine cervix SCC (N = 4) and NSCLC (N = 4). Three patients experienced dose limiting toxicities: grade 3 pulmonary embolism (at C 200 + T 20 level), grade 3 stomatitis (at C 250 + T 20 level) and grade 3 acneiform rash (at C 250 + T 25 level). The C 250 mg/m^{2}and T 25mg/week dose level was selected as the recommended dose. The most common treatment-related adverse events were (All grade/grade 3-4): rash acneiform (97%/15%), mucositis oral (82%/23%), fatigue (59%/13%), nausea (41%/0%) diarrhea (36%/0%), hypomagnesaemia (79%/5%), , and hyperglycemia (66%/10%). The median progression-free survival and overall survival were respectively 2.0 months 95%CI [1.8-3.5] and 7.5 months 95%CI [5.5-11.9]. Among all patients partial responses (PR) and stable diseases were observed in 2 (5.1%) and 18 pts (46.2%). Fifteen pts (38.5%) were treated because of a molecular aberration involving the EGFR and/or PIK3 pathways. Among molecularly selected patients (N = 16), 2 PR (12.5%) were observed (cervix scc with an EGFR amplification and head and neck cancer with a PIK3CA amplification) and 7 pts (44%) had a PFS upper 5.5 months. **Conclusions:** Tolerance of T + C was acceptable. Clinical activity was modest among all patients. Molecular selection increased the objective response rate. Pre and post-exposure biopsies are available in 20 patients and are currently been analyzed for pathway modulation and DNA structural changes. Clinical trial information: NCT02215720.

2600 Poster Session (Board #316), Sat, 8:00 AM-11:30 AM

A phase I study of temsirolimus plus erlotinib in patients with refractory solid tumors. *First Author: Andrea Wang-Gillam, Division of Oncology, Washington University in St. Louis, St. Louis, MO*

Background: Resistance to treatment with inhibitors of mammalian Target of Rapamycin (mTOR) is partially mediated by activation of epidermal growth factor receptor (EGFR). Based on pre-clinical evidence of synergy, we conducted a phase I study to determine the recommended phase II dose (RP2D) and dose-limiting toxicities (DLT) of temsirolimus (mTOR inhibitor) combined with erlotinib (EGFR inhibitor) in patients with refractory solid tumors. **Methods:** A classic 3+3 design was used for the dose escalation portion of the study. An expansion cohort at RP2D included only those with mutations that may contribute to PI3K or EGFR pathway activation or squamous histology. A cycle was defined as 28 days. Patients started daily erlotinib 7 days prior to starting temsirolimus on cycle 1. Intravenous temsirolimus was administered weekly. Starting dose levels were 15 mg temsirolimus and 100 mg erlotinib. **Results:** Forty-six patients were enrolled in this study (29 in dose escalation and 17 in the expansion cohort). Two patients experienced (DLTs) (grade 3 dehydration and grade 4 renal failure). The most common drug-related adverse events of all grades were rash, mucositis/stomatitis, diarrhea, nausea and fatigue. The RP2D is temsirolimus at a 25 mg weekly dose and 100 mg of daily erlotinib. No complete or partial responses were observed in the study. The median duration on this study was 77 days (range 15-770 days). Among 12 evaluable patients in the expansion cohort, 9 (75%) had stable disease and 3(25%) had progressive disease. The median duration on the study was 98 days (range 25- 243 days) for the expansion cohort. Clinical benefits were seen in patients with squamous cell histology; for example, a patient with refractory squamous cell cancer of the head and neck had durable disease control lasting 770 days. Stable disease was also observed in patients with specific genetic alternations; for example, a patient with refractory sarcoma with PTEN loss achieved stable disease of 194 days. **Conclusions:** The combination of temsirolimus and erlotinib at the RP2D is well tolerated, and the regimen resulted in prolonged disease stabilization in selected patients. Clinical trial information: NCT00770263.

TPS2601 **Poster Session (Board #317a), Sat, 8:00 AM-11:30 AM**

Pharmacodynamic study using FLT PET/CT in advanced solid malignancies treated with a sequential combination of X-82 and docetaxel. *First Author: Murtuza M. Rampurwala, University of Wisconsin, Madison, WI*

Background: Clinical experience has shown that despite resolution of tumor pain while on vascular endothelial growth factor receptor tyrosine kinase inhibitors (VEGFR TKI), pain not only returns, but increases during treatment break. We believe this is due to a *withdrawal flare* i.e. increased tumor proliferation after VEGFR TKI cessation driven by VEGF. We have previously demonstrated this *flare* using 18-Fluorothymidine (FLT) PET/CT. (Liu G et.al. Clin Cancer Res 2011;17:7634-44) A sequential approach synchronizing cell-cycle specific chemotherapy with this *withdrawal flare* may maximize therapeutic index of chemotherapy. Here we propose a novel sequential study using X-82, a VEGFR TKI with docetaxel using FLT PET/CT to measure change in vascular parameters and proliferation. We plan comparing low and high doses of X-82 to explore if low dose is preferable with chemotherapy. **Methods:** A phase 1 pharmacodynamic study in advanced solid malignancies is planned. Inclusion criteria include at least one lesion amenable to FLT PET/CT, ECOG performance status of $\leq$ 1 with normal organ and marrow function. 30 patients will be randomized 1:1 to low dose X-82 (200 mg) or high dose X-82 (400 mg) arm. In Cycle 1, X-82 is administered daily on days 2-15. FLT PET/CT (FLT 1) is obtained on day 1, once on day 12-15 (FLT 2) and day 19-21 (FLT 3). Comparison between FLT 1 and 2 will characterize response to X-82 and FLT 2 and 3 will characterize *withdrawal flare*. In Cycle 2, docetaxel (75 mg/m2) is administered on day 1, followed by X-82 on days 2-15. FLT PET/CT (FLT 4) once on day 12-15 will characterize response to X-82 and docetaxel. Sequential treatment is continued until progression or unacceptable toxicity. Correlative studies include VEGF levels and X-82 pharmacokinetics. Primary objectives are to evaluate safety, tolerability and FLT PET/CT changes with X-82 alone and with docetaxel. Secondary objectives include evaluating objective response rate to the combination. Toxicities will be monitored based on Pocock stopping boundaries with overall type I error of 0.10. At this time, 2 patients are enrolled on study. After establishing safety, we plan dose expansion cohorts in multiple disease sub-types. Clinical trial information: NCT02146222.

TPS2602 **Poster Session (Board #317b), Sat, 8:00 AM-11:30 AM**

A phase I study of a novel inhibitor of protein phosphatase 2A alone and with docetaxel. *First Author: Aaron Scott Mansfield, Mayo Clinc, Rochester, MN*

Background: Protein phosphatase (PP2A) is a multifunctional protein involved in regulation of cell cycle, DNA-damage response, and apoptosis. In pre-clinical studies, LB-100, a novel small molecule inhibitor of PP2A, inhibits the growth of a broad spectrum of leukemic and solid tumor cell lines. In cancer xenografts, LB100 potentiates the effectiveness of cytotoxic drugs (temozolomide, docetaxel, doxorubicin, cisplatin) and radiation without significant increases in toxicity. The predominant mechanisms responsible for potentiation are inhibition of mitotic exit and homologous recombination repair. PP2A inhibition also results in synthetic lethality of cancer cells overexpressing Mad2 (mitotic arrest deficiency protein 2) as a result of mutations in Rb and/or p53 pathways, suggesting that Mad2-overexpression may be a biomarker for LB100 responsiveness. In addition, cancers deficient in PP2A by somatic mutation such as (del)5q MDS are vulnerable to further PP2A inhibition, raising the possibility that other cancers with decreased PP2A resulting from increased endogenous PP2A inhibitors, CIP2A and SET, which include blast crisis CML, NSCLC (40%) and prostate cancers (60%), may also be vulnerable. PP2A has not been considered a practical target for anti-cancer therapy for concern of off-target effects. This trial seeks to determine appropriate doses of LB100 alone and LB100 plus docetaxel for phase II studies in (del)5q MDS and in cancers for which docetaxel is appropriate 2nd line treatment. **Methods:** This two-part phase I study aims to determine the MTD of LB100 alone given intravenously over 15 minutes daily for 3 days q3w and when given on the same schedule with docetaxel on day 2. In part 2, the starting dose of LB-100 is two levels lower than its single agent MTD combined with docetaxel at 60mg/m^2. LB100 is escalated to its MTD, and if tolerated, docetaxel is increased to 75mg/m^2 and LB-100 re-escalated. Eligible patients are $\geq$ 18 y with progressive or metastatic tumors having failed standard treatment. In part 2, patients are also docetaxel-naive. Enrollment through the 5th dose level of LB100 alone was completed in January 2015. Clinical trial: NCT01837667. Clinical trial information: NCT01837667.

TPS2603 **Poster Session (Board #318a), Sat, 8:00 AM-11:30 AM**

First-in-human, dose-escalation, safety, and PK study of a novel 5T4-ADC in patients with advanced solid tumors. *First Author: Geoffrey Shapiro, Dana-Farber Cancer Institute, Boston, MA*

Background: PF-06263507 is an anti-5T4 antibody drug conjugate (ADC) comprised of a humanized anti-5T4 IgG1antibody conjugated via cysteine residue to the microtuble disrupting agent monomethylauristatin F (MMAF) with a maleimidocaproyl (mc) linker. 5T4, also known as trophoblast glycoprotein (TPBG) is a cell surface protein, with over-expression observed in a variety of cancers as compared to normal adult tissue. PF-06263507 has demonstrated potent activity in human tumor xenograft models. **Methods:** PF-06263507 is being evaluated in an open-label study in patients with advanced solid tumors at increasing dose levels in cohorts of 2 to 4 patients. PF-06263507 is given intravenously once every 21 days. A modified continual reassessment method (mCRM) with a target dose limiting toxicity (DLT) rate of 25% is being utilized. Primary objectives include assessing the safety and tolerability of PF-06263507 in order to determine the maximum tolerated dose (MTD). Secondary objectives include evaluating the overall safety profile, characterization of pharmacokinetic (PK), evaluating the immunogenicity, and documenting any preliminary evidence of anti-tumor activity. Standard definitions are being used to classify hematological and non-hematological DLTs. Serum concentrations of ADC, total antibody, and unconjugated payload are measured with validated bioanalytical methods. Immunogenicity evaluation is performed with anti-drug antibody (ADA) assessment. Radiologic assessment of tumor burden is conducted every 6 weeks according to RECIST. Once the MTD is determined, expansion cohorts for patients with 5T4-expressing non-small cell lung cancer, breast cancer and ovarian cancer are planned. Accrual has completed in Cohort 1 (0.05 mg/kg) through Cohort 8 (5.4 mg/kg). The study is continuing to enroll patients at increasing dose levels. Clinical trial information: NCT01891669.

TPS2604 **Poster Session (Board #318b), Sat, 8:00 AM-11:30 AM**

A multicenter phase II basket clinical trial of lurbinectedin (PM01183) in selected advanced solid tumors. *First Author: Mariano Provencio Pulla, Hospital Puerta de Hierro, Madrid, Spain*

Background: PM01183 (lurbinectedin) is a new anticancer drug that binds to the DNA minor groove and blocks trans-activated transcription, inducing formation of double-strand DNA breaks leading to cell apoptosis. COMPARE analysis revealed that lurbinectedin's mechanism of action differs from the other 98 chemotherapy agents tested Advanced small cell lung cancer (SLCL), neuroendocrine tumors (NET), head and neck (H&N), biliary tract and endometrial carcinoma, BRCA1/2-associated metastatic breast cancer, carcinoma of unknown primary site, germinal cell tumors and Ewing family of tumors represent unmet medical needs. Cytotoxic chemotherapy remains a major component of their therapeutic armamentarium but new anticancer agents are needed to broaden clinical benefit. PM01183 has already shown clinical activity in BRCA1/2 breast cancer, SCLC, endometrial carcinoma, NET, H&N and in tumors with high proliferation index. This exploratory phase 2 trial has been designed to confirm the PM01183 anticancer activity, as a single agent, in several difficult-to-treat tumors. **Methods:** Primary objective: antitumor activity of PM01183 in terms of response rate by RECIST v.1.1, in the aforementioned indications. Secondary objectives: duration of response, clinical benefit, progression-free survival and 1-year overall survival in each tumor type. Pharmacokinetics, pharmacogenomic analyses of potential prognostic/predictive factors. Safety profile. Patients with each tumor type will be enrolled in nine cohorts. Up to 25 evaluable patients are planned to be recruited in each of them. To consider PM01183 active in the tumors analyzed, at least two confirmed responses in the 25 patients of each cohort are expected. If no responses are observed in the first 15 evaluable patients of each cohort, the accrual of this cohort will be stopped. If one confirmed response is observed in the first 15 evaluable patients, recruitment of this cohort will continue to 25 patients. Patients will receive PM01183 i.v. as a 1 hour infusion, every three weeks at a dose of 4 mg/m^2. In patients with ECOG PS = 2 or $>$ 70-years-old, dose will be 3 mg/m^2. Twenty six centers in 8 countries participate in this trial.

TPS2605 Poster Session (Board #319a), Sat, 8:00 AM-11:30 AM

A phase I study of RX-3117, an oral agent activated by uridine cytidine kinase 2, to treat subjects with advanced solid tumors. *First Author: Drew Warren Rasco, START Center for Cancer Care, San Antonio, TX*

Background: RX-3117 is an oral small-molecule antimetabolite, cyclopentyl pyrimidyl nucleoside that is activated by uridine cytidine kinase 2. RX-3117's efficacy in xenograft models (Colo-205, H460, H69 and CaSki), which are moderately sensitive or resistant to gemcitabine, indicates that RX-3117 may have the potential to treat tumors that do not respond to gemcitabine or have become gemcitabine resistant. **Methods:** This phase I, open-label, multicenter study evaluates the efficacy and safety of RX-3117 in subjects with solid tumors). RX-3117 is administered 3 times a week for 3 weeks with 1 week off during each 4 week cycle. Dose escalation starts with an accelerated design treating 1 subject per dose followed by a standard 3 + 3 design using a modified Fibonacci sequence after the occurrence of a single related Grade 2 or greater adverse event. The primary endpoint is the overall safety profile characterized by the type, frequency, severity, timing of onset, duration and relationship to study therapy of any adverse events, or abnormalities of laboratory tests or electrocardiograms, any dose limiting toxicities that occur during Cycle 1, serious adverse events, or adverse events leading to study treatment discontinuation. Secondary endpoints include pharmacokinetic parameters (e.g., time to maximum observed concentration [T_{max}], maximum observed plasma concentration [C_{max}], trough concentration [C_{trough}], area under the concentration-time curve [AUC]) and Indices of anti-tumor activity (e.g., overall response rate , time to response, duration of response, and progression-free survival). Exploratory endpoints are baseline biomarker expression/concentration, including (but not limited to) concentrative nucleoside transporter 2; equilibrative nucleoside transporter 1; uridine-cytidine kinase 1 and 2; DNA methyltransferase 1, 3a and 3b; and ribonucleotide reductases 1 and 2. Target recruitment is approximately 30 subjects. Eligible subjects must have confirmed histologic or cytologic evidence of metastatic or locally advanced solid neoplasm that has failed to respond to standard therapy, progressed despite standard therapy or for which standard therapy does not exist. Clinical trial information: NCT02030067.

TPS2606 Poster Session (Board #319b), Sat, 8:00 AM-11:30 AM

A phase I, dose-escalation, multi-center study of PFK-158 in patients with advanced solid malignancies explores a first-in-man inhbibitor of glycolysis. *First Author: Rebecca A. Redman, James Graham Brown Cancer Center, University of Louisville, Louisville, KY*

Background: In human cancers, activation of the MAP kinase and PI3K/PTEN/AKT pathways converge to increase the expression and activity of a potent regulator of glycolysis, 6-phosphofructo-2-kinase/fructose 2,6-bisphosphatase (PFKFB3). This enzyme synthesizes fructose-2,6-bisphosphate (F2,6BP), which is an activator of PFK-1, a key enzyme of glycolysis that is tightly controlled by multiple metabolic feedback mechanisms and dictates the overall rate of glycolytic flux to lactate and the TCA cycle. PFK158 is a potent small molecule inhibitor of PFKFB3 that is selectively cytotoxic to cancer cells and displays broad anti-tumor activity causing significant growth inhibition in preclinical models of breast, lung, glioblastoma, ovarian, pancreatic, melanoma and colon cancer. In addition, because resistance mechanisms frequently activate pathways that result in up-regulation of glycolysis, combination treatments with cytotoxic and targeted agents result in increased efficacy and tumor regressions. Importantly, IND-enabling safety and toxicity studies have demonstrated that PFK158 is well tolerated in rats and dogs resulting in an acceptable pre-clinical therapeutic index. **Methods:** The primary objective of this phase I clinical trial is to describe the dose limiting toxicity of PFK158 and to determine either the maximum tolerated dose or biological effective dose of PFK-158 in a "3+3" cohort-based dose escalation design that follows a modified Fibonacci scheme. Multiple secondary endpoints have been incorporated to assess the effects of PFK-158 on peripheral blood mononuclear cell F2,6BP activity, and on glucose uptake using FDG-PET imaging. This trial is currently enrolling at four US sites; Cohort 3 (96 mg/m^2) has been completed without dose-limiting toxicity and Cohort 4 (168 mg/m^2) has been enrolled as of February 2015. In conclusion, PFK158 is a first-in-human and first-in-class PFKFB3 inhibitor that is currently under evaluation in a phase I trial and is expected to have significant clinical utility either as a monotherapy or when combined with other targeted agents. Clinical trial information: NCT02044861.

TPS2607 Poster Session (Board #320a), Sat, 8:00 AM-11:30 AM

Phase I study of procaspase activating compound-1 (PAC-1) in the treatment of advanced malignancies. *First Author: Oana C. Danciu, University of Illinois at Chicago, Chicago, IL*

Background: Members of the caspase family of cysteine proteases are key players in both the initiation and execution of apoptosis; the activation of procaspase-3 to caspase-3 is a critical event in the apoptotic cascade. Procaspase-3 levels are elevated in: glioblastoma, breast cancer, colon cancer, lung cancer, lymphoma, neuroblastoma, melanoma, and liver cancer. As a consequence, caspase-3 levels are abnormally low in these tumors, allowing the tumors to avoid apoptosis. PAC-1 is a small molecule that activates procaspase-3 and induces apoptosis of cancer cells in culture. PAC-1 showed efficacy across a wide range of cancer cell lines, as well as in animal models of cancer, including brain cancer. This novel compound potently synergizes with chemotherapy agents (e.g.doxorubicin, temozolomide, etoposide, carboplatin). **Methods**: This is a Phase I dose escalation study with a modified- Fibonacci 3+3 design, consisting of two parts: to determine the maximum tolerated dose (MTD) of PAC-1 in advanced malignancies, and to determine the MTD of PAC-1 when combined with temozolomide in patients with primary brain tumors. For both parts the MTD dose level will expand to a total of 9 patients to ensure safety. Primary objectives: establish MTD, tolerability and toxicity. Secondary and correlative objectives: pharmacokinetics, pharmacodynamics, preliminary antitumor activity correlation with procaspase-3 expression in tumor, clinical response and adverse effects. Neurological symptoms of CNS toxicity will be assessed throughout the trial. Inclusion criteria: diagnoses of advanced malignancies (for part 1) and high grade glioma (for part 2), ECOG PS 0-2, adequate organ function. Exclusion criteria: received prior cytotoxic therapy in the last 3-6 weeks (duration based on prior therapy) or uncontrolled chronic illness. Administration and design: Part 1, PAC-1 (PO) will be dosed at 75-450 mg daily (up to 5 dose levels) on days 1-21 on 28 days cycle. In Part 2, the first PAC-1 dose will be 1 dose lower than the PAC-1 MTD established in Part 1 (up to 3 dose levels).Temozolomide (PO) will be dosed at 150 mg/m2 daily for 5 days starting on day 8 of each cycle. The study is open to enrollment. Clinical trial information: NCT02355535.

TPS2608 Poster Session (Board #320b), Sat, 8:00 AM-11:30 AM

A phase 1 study of RX-5902, an oral agent targeting phosphorylated p68, to treat subjects with advanced solid tumors. *First Author: S. Gail Eckhardt, University of Colorado School of Medicine, Anschutz Medical Campus, Aurora, CO*

Background: RX-5902 is a novel compound that targets phosphorylated p68 RNA helicase (also known as DDX5), a member of the DEAD box family of RNA helicases. Phosphorylated p68 may play a vital role in cell proliferation and tumor/cancer progression. As a single agent, RX-5902 inhibits tumor growth and enhances survival in a variety of in vivo animal xenograft tumor models (e.g., renal, ovarian, pancreatic, melanoma). **Methods:** This Phase 1, open-label, multicenter study evaluates the efficacy and safety of RX-5902 in subjects with solid tumors. RX-5902 is administered orally once weekly for 3 weeks with 1 week of rest in each 4 week cycle. Dose escalation starts with an accelerated design treating 1 subject per dose followed by a standard 3 + 3 design using a modified Fibonacci sequence after the occurrence of a single Grade 2 or greater adverse event that is considered at related to RX-5902. The primary endpoint is the overall safety profile characterized by the type, frequency, severity, timing of onset, duration and relationship to study therapy of any adverse events, or abnormalities of laboratory tests or electrocardiograms as well as the description of any dose limiting toxicities that occur during Cycle 1, serious adverse events, or adverse events leading to discontinuation of study treatment. Secondary endpoints include pharmacokinetic parameters (e.g., time to maximum observed concentration [T_{max}], maximum observed plasma concentration [C_{max}], trough concentration [C_{trough}], area under the concentration-time curve [AUC]) and Indices of anti-tumor activity (e.g., overall response rate , time to response, duration of response, and progression-free surviva during treatment. Exploratory endpoints are biochemical levels of drug targets in blood and tumor samples. Eligible subjects must have confirmed histologic or cytologic evidence of metastatic or locally advanced solid neoplasm that has failed to respond to standard therapy, progressed despite standard therapy or for which standard therapy does not exist. There is no limit on the number of prior treatment regimens. Clinical trial information: NCT02003092.

TPS2609 **Poster Session (Board #321a), Sat, 8:00 AM-11:30 AM**

A phase Ib study of investigational pan-RAF kinase inhibitor MLN2480 plus investigational TORC1/2 inhibitor MLN0128, investigational Aurora A kinase inhibitor alisertib (MLN8237), or paclitaxel in patients (pts) with advanced solid tumors. *First Author: Anthony J. Olszanski, Fox Chase Cancer Center, Philadelphia, PA*

Background: Signaling hyperactivation secondary to MAPK pathway aberrations are common. RAF kinases play key roles in the RAS/RAF/MEK/ERK signaling cascade, representing potentially valid therapeutic targets**.** In a phase 1 study, single-agent MLN2480 had an acceptable safety profile, expected pharmacodynamic effects and preliminary antitumor activity (Middleton et al, ENA 2014, Abstract 364). Preclinically, MLN2480 has shown synergistic/additive effects in xenograft models and cell lines when combined with MLN0128, alisertib or the taxane, docetaxel. Potential overlapping toxicities of each combination are expected to be manageable, with no apparent risks for clinically meaningful pharmacokinetic (PK) drug–drug interactions based on *in vitro* ADME data and exposures achieved clinically. **Methods:** This three-arm, open-label study (NCT02327169) is the first-in-human study for MLN2480 + MLN0128/alisertib/paclitaxel. Primary objective is to evaluate the safety, tolerability, and MTD of each combination. Secondary objectives are to characterize PK profiles and preliminary antitumor activity. An exploratory objective is to assess tumor samples and circulating tumor DNA for biomarkers of response/resistance. Pts aged ≥ 18 yrs with radiographically/clinically evaluable advanced solid tumors who failed standard therapies are eligible. Pts in the expansion phase require tumors measurable by RECIST v1.1. MAPK pathway aberrations are not required. Pts will receive MLN2480 100–200 mg (d 1, 3, 5 per week) in 28-d cycles plus: (A) MLN0128 2–9 mg (d 2, 3, 4 per week), (B) alisertib 30–50 mg twice daily (d 1–3, 8–10, 15–17) or (C) paclitaxel 80 mg/m^2 (d 1, 8, 15) for up to 12 cycles. Serial blood samples will be taken in cycle 1 for PK evaluation. A 3+3 dose escalation algorithm, based on cycle 1 DLTs, will be used, with up to 20/20/15 pts in groups A/B/C. Enrollment is ongoing. Once MTDs are established, ≥ 1 combination regimens will be selected for the expansion phase (~16 pts per group) based on safety, exposure and preliminary antitumor activity data. Clinical trial information: NCT02327169.

TPS2610 **Poster Session (Board #321b), Sat, 8:00 AM-11:30 AM**

STM-01: Phase I EFFTox study of aurora A kinase inhibitor alisertib (MLN8237) given in combination with selective VEGFR inhibitor pazopanib for therapy of solid tumors. *First Author: Arkadiusz Z. Dudek, University of Illinois at Chicago, Chicago, IL*

Background: Pazopanib is a potent and selective multi-targeted tyrosine kinase inhibitor targeting VEGF, PDGF and C-KIT and inhibits angiogenesis and tumor growth. Alisertib is a highly selective small molecule inhibitor of Aurora A kinase which may result in disruption of the assembly of the mitotic spindle apparatus and cell proliferation inhibition. At highest non-toxic concentrations, mitosis targeting agents may reduce endothelial activity and consequently, exhibit antiangiogenic activity. By this way they can enhance the antiangiogenic effects of VEGF inhibitors as well as complement anti-tumor activity, making combination therapy clinically useful to treat advanced refractory malignancies. **Methods:** This is a Phase I dose escalation study with a modified toxicity probability interval design to evaluate activity and safety of alisertib when given in combination with pazopanib to patient with advanced, previously treated solid tumors and hematologic malignancies. The primary objectives of this study are to determine the optimal tolerated dose, safety and toxicity. Secondary objectives are to establish PK/PD and preliminary antitumor activity. **Inclusion Criteria:** ECOG PS 0-2, good organ function and a rest period of 2-6 weeks fromprior systemic chemotherapy, immunotherapy, or biological therapy. **Administration and Design:** Alisertib is taken orally, twice a day for the first 7 days of a 21-day cycle. Pazopanib is taken orally, once a day, continuously. Since study opened in July 2013, 26 patients have been enrolled, so far 16 of them have been on treatment. Study is continuing accrual at dose of alisertib 30 mg twice a day for 7 days and pazopanib 600 mg daily for 21 days. Clinical trial information: NCT01639911.

TPS2611 **Poster Session (Board #322a), Sat, 8:00 AM-11:30 AM**

A randomized Phase 2a study to assess pharmacodynamics, antitumor activity and safety of intravenous BAL101553, a novel microtubule inhibitor, at two dose levels in adult patients with selected advanced solid tumors. *First Author: Rebecca Sophie Kristeleit, University College London, London, United Kingdom*

Background: BAL101553 is the pro-drug of BAL27862, a novel small-molecule microtubule-targeting agent with potent activity in drug-refractory tumor models. It exerts antiproliferative effects and dose-dependent vascular disruption, acting as a tumor checkpoint controller by modulating the spindle assembly checkpoint (SAC). In a Phase 1 dose escalation study pharmacodynamic (PD) effects were observed in post-treatment tumor biopsies[1]. The maximum tolerated dose (MTD) was determined at 60 mg/m^2 IV (intravenous), however clinical activity was observed at dose levels of 15-30 mg/m^2. A non small cell lung cancer (NSCLC) xenograft mouse model showed similar BAL27862 tumor exposure (AUC) at the MTD and a sub-MTD dose, with 11-fold higher peak intratumoral levels at the lower dose. Thus, enhanced vascular disruption at high BAL101553 doses may be associated with lower intratumoral drug disposition. The goal of this Phase 2a study is to assess the pattern of antivascular and antiproliferative effects and antitumor activity at two BAL101553 dose levels. **Methods:** This is an ongoing multicenter randomized, open-label Phase 2a study (NCT01397929) to assess PD, antitumor activity and safety of BAL101553. Eligible patients (pts) with advanced colorectal, gastric, pancreatic, ovarian, NSCLC or triple negative breast cancers are randomized to either 60 (MTD) or 30 mg/m^2 BAL101553 as a 2-h IV infusion on day(d) 1, 8 and 15 q28d. PD evaluations include serial collection of circulating tumor cells (CTCs), circulating endothelial cells and circulating endothelial progenitor cells. Pts with lesions amenable to biopsy will be asked to undergo pre- and post-dose biopsies. Biomarkers analyzed in CTCs and tumor biopsies include BubR1, a protein kinase involved in the SAC and a potential biomarker for BAL101553 activity. Antivascular effects will be quantified by dynamic-contrast enhanced MRI in a subset of pts. Tumor response will be assessed every 2 cycles using RECIST 1.1. Forty pts will be enrolled into this Phase 2a study, which started in June 2014. [1]Molife LR et al. J Clin Oncol 32:5s, 2014 (suppl; abstr 2562) Clinical trial information: NCT01397929.

TPS2612 **Poster Session (Board #322b), Sat, 8:00 AM-11:30 AM**

Phase I study of ADI-PEG 20 in combination with pemetrexed and cisplatin (TRAP) in patients with ASS1-deficient mesothelioma and non-squamous lung cancer. *First Author: Peter Wojciech Szlosarek, St Bartholomew's Hospital, London, United Kingdom*

Background: Loss of the metabolic tumor suppressor, argininosuccinate synthetase (ASS1), a rate-limiting enzyme in arginine biosynthesis, sensitizes mesothelioma and lung carcinoma cells to apoptosis following arginine withdrawal. Recently, we showed potentiation of the cytotoxic effect of pemetrexed by the arginine depletor pegylated arginine deiminase (ADI-PEG 20) in ASS1-negative tumor cells, which was accompanied by suppression of *de novo* pyrimidine synthesis and the pyrimidine salvage pathway (Allen et al, Cancer Res 2014). Consequently, we have initiated a phase I study (NCT02029690) to assess the maximum tolerated dose (MTD), safety and toxicity, and preliminary efficacy of ADI-PEG 20 combined with first-line pemetrexed and cisplatin chemotherapy in patients with ASS1-deficient mesothelioma or non-squamous non-small cell lung cancer (NSCLC). **Methods:** Up to 47 good performance (ECOG 0-1) patients are being enrolled in a 3+3+3 phase 1 design using tumoral ASS1 loss as a selection biomarker. Weekly ADI-PEG 20 is being dose escalated (18, 27 and 36 mg/m^2 IM), with pemetrexed 500 mg/m^2 and cisplatin 75 mg/m^2 both given every 3 weeks, for a maximum of 18 weeks of treatment. Cohorts 1 and 2 have been completed without dose-limiting toxicity and enrollment to cohort 3 began in January 2015 at the maximum ADI-PEG 20 dose of 36mg/m^2. A further 10 patients with mesothelioma and 10 patients with non-squamous NSCLC will be recruited at the MTD with pharmacodynamic monitoring of response using plasma arginine and citrulline, and assessment of tumor proliferation with [(18)F]-fluoro-L-thymidine (FLT)-positron emission tomography (PET). In summary, TRAP is the first triplet chemotherapy combination study to assess the role of arginine deprivation with ADI-PEG 20 in solid cancers using ASS1 as a selection biomarker. Patient accrual at the MTD cohort is nearing completion and ADI-PEG 20 in combination with cisplatin and pemetrexed will be evaluated further in the planned expansion cohorts. Clinical trial information: NCT02029690.

TPS2613 Poster Session (Board #323a), Sat, 8:00 AM-11:30 AM

A phase 1, dose-escalation, safety, pharmacokinetic, pharmacodynamic study of thioureidobutyronitrile, a novel p53 targeted therapy, in patients with advanced solid tumors. *First Author: Geoffrey Shapiro, Dana-Farber Cancer Institute, Boston, MA*

Background: Thioureidobutyronitrile, Kevetrin, induced apoptosis in wild type p53, mutant p53 and p53 null cell lines. In A549 lung carcinoma cells, wild type p53 was stabilized by Kevetrin. Kevetrin induced nongenotoxic activation of the p53 signaling pathway. Kevetrin also induced p21 and PUMA, known transcriptional targets of p53. Kevetrin caused accumulation of monoubiquitinated p53 and induced transcriptional independent apoptosis. In p53 mutant breast carcinoma cells (MDA-MB-231), Kevetrin induced degradation of hyperstable oncogenic mutant p53 and induced apoptotic cell death. Apoptotic cell death was also induced in K-562, a p53 null CML cell line. Consistent with *in vitro* data, Kevetrin showed potent antitumor activity in wild type p53 (A549), mutant p53 (MDA-MB-231), and p53 null (K-562) human tumor xenograft models. Kevetrin has the unique ability to target both wild type and mutant p53 tumors controlling tumor growth in various preclinical tumor models (ASCO 2013). Based on the pre-clinical data, a Phase I study was initiated at Dana-Farber/Harvard Cancer Center in 2012. **Methods:** Adults with refractory locally advanced or metastatic solid tumors, acceptable liver, kidney function, and hematologic status were eligible. Objectives include determination of DLT, MTD, pharmacokinetics, pharmacodynamics, and evaluating preliminary evidence of antitumor activity. Kevetrin is given as an intravenous infusion once weekly for 3 weeks in 28-day cycles. The starting dose was 10 mg/m^2. In a 3+3 design, groups of 3-6 patients are evaluated for toxicity at each dose level. Dose escalation is based upon the number and intensity of adverse events in cycle 1. Kevetrin PK is characterized for the first and last doses given in cycle 1. Kevetrin induced p21 in lymphocytes preclinically; therefore p21 expression in peripheral blood mononuclear cells is measured as a PD biomarker. Antitumor activity by RECIST 1.1 criteria and serum tumor markers is assessed. The p53 status of tumors of selected patients will be determined. The first nine cohorts were completed in December 2014. Enrollment in the tenth cohort at 450 mg/m^2 began January 2015. Clinical trial information: NCT01664000.

TPS2614 Poster Session (Board #323b), Sat, 8:00 AM-11:30 AM

Phase I trial of the combination of bortezomib and clofarabine in adults with refractory solid tumors. *First Author: Geraldine Helen O'Sullivan Coyne, Early Clinical Trials Development Program,, Bethesda, MD*

Background: We conducted a systematic combination drug screen across the NCI-60 cell line panel encompassing nearly all pairwise combinations of FDA-approved small-molecule cancer drugs ($>$ 5000) using multiple, clinically-achievable drug concentrations to discover efficacious combinations that could be advanced rapidly into clinical trials (Eur J. Cancer 2012 Nov;48, Suppl 6:11). The proteasome inhibitor bortezomib combined with the nucleoside inhibitor clofarabine was found to be supra-additive in multiple cell lines. Several solid tumor xenograft models were used to confirm enhanced responses to this combination than to the individual single agents at their Maximum Tolerated Doses (MTDs), with the combination displaying either prolonged tumor stasis or regression. Because both bortezomib and clofarabine have individually demonstrated to enhance tumor cell apoptosis *in vitro*, we investigated the role of alterations in the apoptotic pathway in producing the observed supra-additive efficacy for the bortezomib/clofarabine combination *in vivo*. We found that the combination significantly enhanced caspase-3 activation and decreased survivin levels in xenografts using our recently-validated 15-plex apoptosis ELISA. **Methods**: We are conducting an open label phase I trial (NCT02211755) of the bortezomib/clofarabine combination, following a 3+3 trial design, with Dose Limiting Toxicities (DLT) defined during cycle 1. Estimated enrollment: 35 patients. Bortezomib is administered subcutaneously on days 1 and 4 of a 21-day cycle. Clofarabine is administered intravenously over 1 hour on days 1-5 of a 21-day cycle. Patients must have histologically confirmed solid tumors that have progressed on standard of care therapy known to prolong survival or for which no standard treatment exists, an ECOG $\leq$ 2 and life expectancy $\geq$ 3 months. Exclusion criteria include a prolonged QTc interval (Fridericia formula) at study entry. Patients with treated brain metastasis whose disease is stable for $\geq$ 4 weeks without requiring steroids or anti-seizure medication are eligible. At this time, cohort 1 has enrolled 1 of 3 planned patients; accrual is ongoing with measurement of apoptosis biomarkers at the MTD. Clinical trial information: NCT02211755.

TPS2615 Poster Session (Board #324a), Sat, 8:00 AM-11:30 AM

First-in-human investigation of the oral first-in-class fatty acid synthase (FASN) inhibitor, TVB-2640. *First Author: Andrew Jacob Brenner, The University of Texas Health Science Center at San Antonio, Boerne, TX*

Background: FASN is a central mediator of neoplastic lipogenesis. It catalyzes the production of palmitate, the building block of long chain fatty acids needed to support cancer cell signaling and proliferation. Tumor cells have more dependence on *de novo* lipogenesis than normal cells, and express higher levels of FASN. Several studies have shown a correlation between high levels of FASN expression and both advanced disease stage and poorer prognosis in patients. The combination of these observations provides the rationale for FASN inhibition as an antitumor therapy. TVB-2640 is a potent, reversible and selective fatty acid synthase (FASN) inhibitor currently in its first Phase 1 study (3V2640-CLIN-002) in patients with refractory solid tumors (NCT02223247), EORTC 2014 Abstract number: 3 LBA. **Methods:** TVB-2640 is administered in monotherapy orally once daily continuously on a 21 day cycle to assess dose-limiting toxicities (DLT). An accelerated dose-escalation method was used initially with single-patient cohorts and 100% dose escalations planned until NCI-CTCAE toxicity $\geq$ Grade 2 was encountered. Thereafter, the classical "3 + 3" design was used. Additionally, exploration of combination therapy using TVB-2640 co-administered with a taxane has begun. Eligibility includes adult patients with adequate bone marrow, hepatic and renal function and other standard Phase I characteristics. Patients with significant cardiovascular, ophthalmological disease, or any conditions that might interfere with oral absorption are excluded. In addition to standard safety assessments and pharmacokinetic (PK) sampling (over 24 hours on Days 1 and 8), specialist ophthalmological examinations and 24-hour Holter monitoring for QTc assessments are required. Tumor tissue (archival and/or fresh) is being obtained to assess the consequences of FASN inhibition on neoplastic lipogenesis and a pharmacodynamic effect has been evaluated by measuring metabolite changes in patient sera. Clinical trial information: NCT02223247.

TPS2616 Poster Session (Board #324b), Sat, 8:00 AM-11:30 AM

Phase 1 dose-escalation study of EBC-46 given by intratumoral injection to patients with refractory cutaneous and subcutaneous tumors. *First Author: Jason D. Lickliter, Nucleus Network, Melbourne, Australia*

Background: EBC-46 is a novel protein kinase C (PKC) activator being developed for intratumoral treatment of cutaneous and subcutaneous tumors. Studies in syngeneic and xenograft mouse models showed that intratumoral injection of EBC-46 into subcutaneous tumors resulted in PKC-dependent hemorrhagic necrosis within 24 hours and complete loss of viable tumor cells. Immunostaining of tumor tissue for the endothelial marker CD31 showed marked vascular disruption at 24 hours after treatment (Boyle GM, et al. PLoS ONE 2014; 9: e108887). EBC-46 is also being studied in veterinary clinical trials in companion animals as an intratumoral treatment for spontaneous skin tumors. Notably, EBC-46 therapy leads to rapid healing at treated sites in animals and the mechanism of this is currently under investigation (Campbell J, et al. Proc ETRS 2014). **Methods:** This is a phase 1 first-in-human dose-escalation trial of intratumoral injection of EBC-46 in patients with cutaneous and subcutaneous tumors refractory to standard therapies. Other key eligibility criteria include an ECOG score of 0-2, adequate organ function, no involvement of major blood vessels by the tumor and no therapeutic anticoagulation or major abnormality of hemostasis. The starting dose of EBC-46 is 0.06 mg/m^2, which is prepared as a 0.25 mg/mL solution and infiltrated into a tumour volume 2-fold greater than the EBC-46 volume. Initial dose escalations are based on increasing the concentration of the EBC-46 solution until a maximum concentration is reached. Subsequent dose levels will inject higher volumes of EBC-46 solution into a correspondingly greater target tumour volume. Patients who tolerate the first dose, and who are deemed to be benefiting from treatment, will continue intratumoral injections in an extension protocol. Study endpoints include safety and tolerability parameters (local and systemic), pharmacokinetics of EBC-46 and preliminary efficacy assessments. Blood samples will be evaluated for biomarkers of vascular disruption and inflammation, and optional tumor biopsies will be performed pre- and post-treatment. Enrolment into the first dose level commenced in January 2015. Clinical trial information: ACTRN12614000685617.

TPS2617 **Poster Session (Board #325a), Sat, 8:00 AM-11:30 AM**

Phase II study of the PARP inhibitor talazoparib (BMN-673) in advanced cancer patients with somatic alterations in BRCA1/2, mutations/deletions in PTEN or PTEN loss, a homologous recombination defect, mutations/deletions in other BRCA pathway genes and germline mutation S in BRCA1/2 (not breast or ovarian cancer). *First Author: Sarina Anne Piha-Paul, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cancer cells deficient in BRCA1/2 and other components of the homologous recombination repair pathway are selectively sensitive to the double stranded DNA breaks whose repairs are inhibited by poly (ADP-ribose) polymerase (PARP) inhibitors, and in particular PARP inhibitors with "trapping" properties. Talazoparib tosylate, a potent oral "trapping" PARP1/2 inhibitor, exhibits selective anti-tumor cytotoxicity at far lower concentrations than other PARP inhibitors. Multiple ongoing trials are evaluating PARP inhibitor efficacy in patients with germline BRCA mutations. There is, however, a great need to define the spectrum of patients who may benefit. **Methods:** This is an investigator-initiated, single-center, non-randomized, multi-cohort trial of subjects >18 years old with measurable advanced solid tumors with no curative therapeutic options. Up to 180 patients will be treated with talazoparib at 1 mg PO daily following a two stage design with futility assessment at ten patients in each cohort with a maximum enrollment of thirty patients in each cohort. Patients will be enrolled in one of 6 cohorts: 1) Somatic mutations of BRCA1/ 2, 2) Somatic deletions of BRCA1/2, 3) Mutations or homozygous deletions in other BRCA pathway genes (e.g. ATM, PALB2, NBS1, Fanconi Anemia genes), 4) Mutations or homozygous deletions in PTEN and/or PTEN loss by IHC, 5) HR defects (Myriad HRD assay LOH >40), 6) Germline BRCA1/2 mutations (not breast or ovarian cancer). Primary endpoint is clinical benefit rate (CR, PR or SD>24 weeks). Secondary endpoints include baseline molecular and pharmacodynamics markers, concordance of BRCA1/2 alterations and HRD status, concordance of genomic alterations in tumor and circulating free DNA, progression free survival, duration of response, and overall survival. Statistical plan includes descriptive statistics, Kaplan Meier techniques and Cox proportional hazard modeling. Enrollment has already commenced. Clinical trial information: NCT 02286687.

TPS2618 **Poster Session (Board #325b), Sat, 8:00 AM-11:30 AM**

A phase I trial of veliparib, an inhibitor of poly(ADP-ribose) polymerase (PARP), and topotecan (TPT) in patients with solid tumors. *First Author: Andrea Elisabeth Wahner Hendrickson, Mayo Clinic, Rochester, MN*

Background: PARPs are a highly conserved family of enzymes whose predominant function is to preserve genomic integrity following DNA damage. Preclinical studies demonstrated that PARP inhibitors enhance the cytotoxicity of DNA damaging agents. Specifically, PARP inhibition sensitizes tumor cells to topotecan in vitro and in vivo by trapping PARP1 on damaged DNA and preventing repair of topo I-induced DNA damage (Patel *et al.*, J. Biol. Chem. 287:4198, 2012). Veliparib has been combined with daily topotecan but found to be quite myelosuppressive, requiring reduction in doses of both agents (Kummar *et al.*, Cancer Res. 71:5626, 2011). Based on these data, we sought to determine the maximum tolerated dose (MTD) of veliparib in combination with the less myelosuppressive weekly administration of topotecan in patients with solid tumors. Correlative studies were included to assess the impact of topotecan and veliparib on poly(ADP-ribose) levels in peripheral blood mononuclear cells as well as the pharmacokinetics of both agents. **Methods:** Eligible patients include any histologically confirmed solid tumor malignancy that is metastatic or unresectable with measurable disease (longest diameter > 2 cm with conventional CT) in patients 18 or older who have received < 2 chemotherapy regimens, ECOG PS < 2 and adequate bone marrow, renal and hepatic function. Using a standard 3+3 design, patients have been treated with veliparib PO twice daily on days 1-3, 8-10 and 15-17 and topotecan IV on days 2, 9 and 16 every 28 days. The trial is currently enrolling at veliparib 300 mg PO twice daily and topotecan 3 mg/m^2/dose. Once MTD is established, a phase II clinical trial in platinum resistant ovarian, peritoneal and fallopian tube malignancies is planned. Supported in part by UM1 CA186686 and P50 CA136393. Clinical trial information: NCT01012817 Clinical trial information: NCT01012817.

TPS2619 **Poster Session (Board #326a), Sat, 8:00 AM-11:30 AM**

A phase I trial of oral 5-azacitidine in combination with romidepsin in advanced solid tumors with an expansion cohort in virally mediated cancers and liposarcoma. *First Author: Kim Anna Reiss, Johns Hopkins Univ, Batimore, MD*

Background: Epigenetic alterations leading to silencing of tumor-suppressor genes play a key role in carcinogenesis and are reversible, therefore representing an appealing anti-cancer target. Hypermethylation of promoter regions by DNA methyltransferases (DNMTs) and deacetylation of histones by histone deacetylases (HDACs) are two mechanisms by which tumor suppressors are silenced. DNMT and HDAC inhibitors have been shown to reverse this process in multiple tumor types. Preclinically, combination DNMT and HDAC inhibition can synergistically re-express tumor suppressor genes and inhibit tumor growth in xenograft models. Emerging work shows that epigenetic agents modulate genes involved in viral response. We designed a phase I dose-escalation trial of oral 5-azacitidine (CC-486) and romidepsin in advanced solid tumors with an expansion cohort in virally mediated cancers and liposarcoma. **Methods:** We have enrolled 11 patients to date. Patients must have a metastatic or unresectable solid tumor or, for the expansion cohort, a known virally mediated cancer (e.g. EBV+ nasopharyngeal cancer, HPV+ head and neck, cervical, or anal cancer) or liposarcoma and must have failed at least one prior line of chemotherapy. Patients are enrolled in a standard 3+3 design. Toxicity is followed using the NCI CTCAE version 4.0 and disease response is followed using RECIST 1.1 criteria with serial imaging q8weeks. In the expansion cohort, patients will have paired biopsies as well as blood work for PK and PD analysis. Correlative work includes global and candidate gene methylation analysis of plasma samples and biopsy specimens. Potential candidate genes include: p16, SFRP1, TFP1, IGFBP3, EVL, CD109 and SOX17. Clinical trial information: NCT01537744.

TPS2620 **Poster Session (Board #326b), Sat, 8:00 AM-11:30 AM**

Phase I/II study of PF-06463922, an ALK/ROS1 tyrosine kinase inhibitor, in patients with advanced non-small-cell lung cancer harboring specific molecular alterations. *First Author: Todd Michael Bauer, Tennessee Oncology and Sarah Cannon Research Institute, Nashville, TN*

Background: Lung cancer is the most common cancer worldwide, with non-small cell lung cancer (NSCLC) occurring in 85% of cases. Oncogenic fusions of anaplastic lymphoma kinase (ALK) or c-ros oncogene 1 (ROS1)–receptor tyrosine kinase inhibitors (TKIs) define 2 distinct subsets of NSCLC patients (pts) and play essential roles in tumor cell survival, growth, and metastasis. While most biomarker-selected pts derive some clinical benefit from initial treatment with a TKI, most will eventually develop resistance. PF-06463922 is a selective TKI of ALK and ROS1 that preclinically demonstrated dose-dependent inhibition of mutations that confer resistance to treatment with other TKIs. As the central nervous system (CNS) is a common site of metastases in these pts and PF-06463922 is a brain-penetrant compound, it is hypothesized that PF-06463922 will also be active in pts with CNS metastases. **Methods:** This ongoing, single-arm, phase I/II trial (NCT01970865) is evaluating the safety, pharmacokinetics, and efficacy of PF-06463922 in pts with advanced ALK+ or ROS1+ NSCLC with or without CNS metastases. In all, 22 pts have been enrolled in Phase I and, thus far, PF-06463922 has demonstrated clinical activity in ALK+ and ROS1+ NSCLC pts, most of whom had CNS metastases and had received at least 1 prior TKI. Phase II was designed to assess efficacy across 4 distinct populations: ALK+ pts who are treatment-naïve, ALK+ pts with progression after crizotinib, ALK+ pts with progression after 1 or 2 prior TKI, and ROS1+ pts in any line of treatment. All pts must have at least 1 measurable extracranial lesion by RECIST v1.1. Pts with asymptomatic CNS metastases, leptomeningeal disease, or carcinomatous meningitis are eligible. The starting dose for phase II will be identified in phase I. Correlative biomarker studies on blood and tumor tissue (archival tissue and de novo biopsies) will be performed. Five of the 75 planned sites are open and recruiting. For more information, visit ClinicalTrials.gov or contact Pfizer Oncology at 1-800-718-1021. Clinical trial information: NCT01970865.

TPS2621 Poster Session (Board #327a), Sat, 8:00 AM-11:30 AM

A first-in-human phase I/Ib study of receptor tyrosine kinase (RTK) inhibitor, MGCD516, in patients with advanced solid tumors. *First Author: Gary K. Schwartz, Columbia University Medical Center, New York, NY*

Background: MGCD516, is an orally-available, potent small molecule inhibitor of a closely related family of RTKs including RET, TRK family, DDR2, MET, Axl family, KIT, as well as VEGFR and PDGFR family members. RTKs inhibited by MGCD516 are genetically altered in a variety of cancers, including non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC), functioning as oncogenic drivers promoting cancer development and progression. Alterations in these RTKs have also been implicated in tumor resistance mechanisms. MGCD516 has demonstrated broad antitumor activity including demonstration of tumor regression in preclinical models harboring genetic dysregulation of MGCD516 targets including MET amplification, METex14del, RET rearrangement and CHR4q12 amplification. **Methods:** This first-in-human, open label Phase 1/1b study is designed to evaluate the safety, pharmacokinetics, metabolism, pharmacodynamics and clinical activity of MGCD516 in patients with advanced solid tumors. Phase 1 is the dose escalation phase and uses the modified toxicity probability interval (mTPI) method to determine the MTD /Recommended Phase 1b Dose. Phase 1b is the expansion phase in which MGCD516 will be evaluated in patients with NSCLC, HNSCC, or any other solid tumor type harboring specific MGCD516 RTK target mutations of interest. Phase 1 and 1b are each anticipated to enroll 60 patients. Phase 1 enrollment started in September 2014, with patients receiving continuous daily dosing (QD) of 10mg MGCD516 in cycles of 21 days. Cohort 1 and Cohort 2 (QD 20mg) have been completed without DLTs and enrollment to Cohort 3 (QD 40mg) started in January 2015. Pharmacokinetics is evaluated after single and repeated administration. Pharmacodynamic biomarkers, including soluble (s)MET, sVEGFR2 and VEGFA will be explored in plasma samples for prognostic potential and possible relationship with clinical outcome. Clinical trial information: NCT02219711.

TPS2622 Poster Session (Board #327b), Sat, 8:00 AM-11:30 AM

A randomized, open-label, Phase II trial evaluating the clinical benefit of a maintenance treatment targeting tumor molecular alterations in patients with advanced solid tumors. *First Author: Maud Toulmonde, Institut Bergonié, Department of Medical Oncology, Bordeaux, France*

Background: Therapeutic decision for most cancers is mainly based on primary disease site, histological type and/or tumor burden. However, genotype-driven clinical trials where treatments are adapted to the molecular alteration supposed to drive tumor progression have recently emerged with promising early results (e.g. BATTLE, SAPHIR01/02, SHIVA, ...). **Methods:** MOST (My Own Specific Therapy) is a multicenter, randomized, open-label, adaptive phase II trial conducted in patients (pts) with progressive solid tumors (any subtype) after at least one prior therapy in the advanced setting. This trial aims to evaluate the clinical benefit of maintenance therapy targeting molecular alterations identified in the patient's tumor. Primary endpoint is progression-free survival. Secondary endpoints include toxicity, objective response rate (RECIST1.1) and overall survival. Based on the presence of molecular alterations detected by a previous tumor molecular profiling, pts are treated with one of the following targeted therapies: nilotinib (400 mg BID for ABL1, KIT, PDGFRA/B, DDR1/2, CSF1R mut/amp/transloc.); everolimus (10 mg QD for PIK3CA, PIK3R1, AKT1/2, mTOR mut/amp or TSC1/2 or PTEN loss); sorafenib (400 mg BID for VEGFR1-3, PDGFRB, FLT3, BRAF, CRAF, KRAS or RET mut/amp/transloc); lapatinib (1500 mg QD for HER2 mut/amp) or pazopanib (800 mg QD for VEGFR1-3, PDGFRA/B or KIT mut/amp). After 12 weeks of treatment, pts with objective response are proposed to continue the targeted therapy, while pts with stable disease are randomly assigned (1:1) to continuation (arm A) or interruption of treatment (arm B; reintroduction is allowed at disease progression). Statistical analysis will be carried out in each of the 5 treatment groups using a sequential Bayesian approach. Three interim analyses are planned after randomization of 10, 15 and 20 pts per arm. The trial will continue until the maintenance arm is shown with high posterior probability to be superior to the interruption arm according to a pre-defined stopping rule, or until the maximum sample size (i.e. 50 pts) is reached. To date, 66 of 400 planned patients have been enrolled. Clinical trial information: NCT02029001.

TPS2623 Poster Session (Board #328a), Sat, 8:00 AM-11:30 AM

First-in-human dose escalation study of oral ONC201 in advanced solid tumors. *First Author: Mark N. Stein, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: ONC201 is an orally active first-in-class small molecule with strong antitumor activity in preclinical models of advanced cancers. In cancer cell lines and patient samples ONC201 induces an integrated stress response (Ishizawa et al, 2014), late-stage inactivation of Akt and ERK, and downstream activation of the apoptotic TRAIL pathway as part of innate immune surveillance (Allen J et al, Sci Trans Med, 2013). Activity is independent of p53 status. ONC201 is well tolerated at efficacious doses in animal models, crosses the blood brain barrier, is particularly effective in refractory tumors, depletes cancer stem cells (Ishizawa et al, ASH 2014; Prabhu et al, Blood 2014; Zhao et al, ASCO 2014), and is effective with infrequent dosing preclinically. Based on the compelling efficacy and safety profile of ONC201 as well as the engagement of signaling pathways critical for many cancers, the clinical introduction ONC201 in advanced cancer patients is warranted. **Methods:** The first-in-human study of ONC201 (NCT02250781) began in January 2015 as an open-label single-site phase I trial enrolling adult patients with refractory advanced solid tumors and glioblastoma (GBM). Patients with symptomatic brain metastases or prior bevacizumab for treatment of GBM are excluded. The primary endpoint is determination of the recommended phase II dose (RP2D) of single agent ONC201 given orally once every 3 weeks (1 cycle). Secondary endpoints include assessment of pharmacodynamics using select biomarkers for ONC201 (Allen et al, 2015), pharmacokinetics, toxicity, and efficacy. The study employs an accelerated, single patient per cohort, dose escalation design with expansion to a standard 3+3 design if a subject has grade $>/=$ grade 2 toxicity or dose limiting toxicity within cycle 1. The maximum tolerated dose is the highest dose level in which 6 patients have been treated with $</=1$ instance of DLT. A subject in Cohort 1 (125mg) has completed the first cycle of treatment without any $>/=$ grade 2 toxicity. Cohort 2 (250mg) is currently enrolling. This phase I study will identify the RP2D to enable evaluation of the antitumor efficacy of ONC201 in select advanced cancer indications. Clinical trial information: NCT02250781.

TPS2624 Poster Session (Board #328b), Sat, 8:00 AM-11:30 AM

A first-in-human study of LOXO-101, a highly selective inhibitor of the tropomyosin receptor kinase (TRK) family. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: TheTRK family of neurotrophin receptors, TRKA, TRKB, and TRKC (encoded by *NTRK1, NTRK2,* and *NTRK3* genes, respectively) and their neurotrophin ligands regulate growth, differentiation and survival of neurons. Translocations involving the *NTRK1/2/3* kinase domain, mutations involving the TRK ligand-binding site, amplifications of *NTRK*, TRK splice variants, and autocrine/paracrine signaling have been described in a diverse number of tumor types and may contribute to tumorigenesis. Recently *NTRK1* fusions were described in a subset of adenocarcinoma lung cancer patients (Vaishnavi, 2013) and *NTRK2 and NTRK3* fusions have been described in multiple tumor types (Skalova, 2014; Ricarte-Filho, 2013; Vaishnavi, 2014). LOXO-101 is a potent, oral, ATP-competitive pan-TRK inhibitor with IC_{50} values in the low nanomolar range for inhibition of TRK family members in binding and cellular assays, with 100x selectivity over other kinases. LOXO-101 has demonstrated tumor inhibition in preclinical models. **Methods:** This study (NCT02122913) is an ongoing phase Ia/Ib dose escalation plus expansion trial in adults with advanced solid tumors. The phase Ia component is an open-label, multicenter, dose escalation trial. Patients with solid tumors refractory to standard therapy, with normal hematopoietic and major organ function are eligible for study. LOXO-101 is administered orally QD or BID for continuous 28-day cycles. This component of the trial will determine the MTD for LOXO-101. The phase Ib component is an open-label, multicenter, global, dose expansion study. In addition to the Phase Ia eligibility criteria, patients must have a demonstrated alteration in one of the three *NTRK* genes or three TRK proteins. The number of expansion cohorts will be determined by the molecular characteristics of the tumors in the patients enrolled. Data will provide initial evidence of tumor activity of LOXO-101, stratified by the type of *NTRK* or TRK alteration or tumor type, as well as further elucidation of the safety profile of LOXO-101 in cancer patients. Archival tissue is required for further characterization of molecular abnormalities. Clinical trial information: NCT02122913.

3000 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Atypical patterns of response in patients (pts) with metastatic melanoma treated with pembrolizumab (MK-3475) in KEYNOTE-001. *First Author: Jedd D. Wolchok, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune-related response criteria (irRC) were developed to better characterize the atypical response patterns observed with ipilimumab. Previously, we showed that 7.2% of melanoma pts treated with the anti–PD-1 monoclonal antibody pembrolizumab also demonstrate atypical response patterns and that irRC may better represent the clinical benefit of pembrolizumab than conventional RECIST. This updated analysis includes all 655 melanoma pts enrolled in KEYNOTE-001 (NCT01295827). **Methods:** Pts received pembrolizumab 2 mg/kg every 3 wk (Q3W), 10 mg/kg Q3W, or 10 mg/kg Q2W. Imaging was performed every 12 wk. Response was assessed centrally by irRC and RECIST v1.1. Investigator-assessed irRC was used for pt management. Early pseudoprogression was defined as ≥25% increase in tumor burden at first assessment that was not confirmed as progressive disease (PD) per irRC at the next assessment performed ~4 wk later. Delayed pseudoprogression was defined as ≥25% increase in tumor burden at any time point after the first assessment, followed by non-PD at the next assessment. **Results:** Of the 655 pts enrolled, 327 had ≥28 wk of follow-up by imaging at the time of analysis and were assessed for atypical responses. Overall, 29 pts (8.9%) experienced atypical response. Early pseudoprogression was observed in 15 (4.6%) pts. Late pseudoprogression was observed in 14 (4.3%) pts. In the 592 pts who survived ≥12 wk, 331 (56%) had best overall response of non-PD per RECIST and irRC, 177 (30%) had PD per both criteria, and 84 (14%) had PD per RECIST v1.1 but non-PD per irRC. OS was longer in pts with PD per RECIST but non-PD per irRC compared with those who had PD by both criteria (Table). **Conclusions:** Results of this expanded analysis are consistent with previous reports suggesting that pembrolizumab may result in atypical response patterns and that conventional response criteria may underestimate the therapeutic benefit of pembrolizumab in advanced melanoma. New standards such as irRC or irRECIST should be considered for assessing response to immunotherapy. Clinical trial information: NCT01295827.

	OS	
	12-mo Rate, %	24-mo Rate, %
Non-PD by RECIST and irRC (n = 331)	92.1	77.6
PD by RECIST, non-PD irRC (n = 84)	74.4	37.5
PD by RECIST and irRC (n = 177)	33.5	17.3

3001 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Association of response to programmed death receptor 1 (PD-1) blockade with pembrolizumab (MK-3475) with an interferon-inflammatory immune gene signature. *First Author: Antoni Ribas, David Geffen School of Medicine at the University of California, Los Angeles, Los Angeles, CA*

Background: Immunotherapy with anti–PD-1 monoclonal antibodies such as pembrolizumab shows robust, durable antitumor activity in patients with advanced melanoma. Examining gene expression related to the immune response within the tumor may provide new insights into the molecular features associated with clinical response to these agents. We evaluated immune-related gene expression patterns in patients with melanoma enrolled in the phase Ib KEYNOTE-001 study. **Methods:** Baseline tumor biopsy samples from 19 patients with melanoma enrolled in KEYNOTE-001 were used as a discovery set. Results were validated using samples from 62 additional patients from KEYNOTE-001, of whom 51 were evaluable for response per RECIST v1.1 by central review. RNA was extracted from formalin-fixed paraffin-embedded tissue sections and analyzed using the NanoString nCounter. Two signatures, the "Interferon-gamma [IFNγ] 10-gene" and the "Expanded-immune 28-gene," were pre-specified prior to linking NanoString data to clinical outcomes. **Results:** The overall response rate (ORR) was 47% in the validation cohort. Both the IFNγ and the expanded-immune signatures showed statistically significant associations with ORR ($P = 0.047$ and 0.027, respectively) and progression-free survival ($P = 0.016$ and 0.015). Analysis of top-ranked genes on the platform led to the discovery of two new signatures, "TCR-signaling" and "Denovo" that were enriched in T-cell markers and MHC Class I and II genes. **Conclusions:** Measuring immune-related biomarkers, including T-cell specific, antigen presentation–related, and IFNγ signaling–related genes, may allow for improved selection of patients likely to respond to anti–PD-1 therapy with pembrolizumab. Results are consistent with the hypothesis that clinical responses to PD-1 blockade occur in patients with a preexisting interferon-mediated adaptive immune response. Further confirmation of these new signatures in melanoma is required. Clinical trial information: NCT01295827.

3002 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Density of immunogenic antigens and presence or absence of the T cell-inflamed tumor microenvironment in metastatic melanoma. *First Author: Thomas Gajewski, The University of Chicago, Chicago, IL*

Background: Patients with melanoma can be categorized based on the presence or absence of a T cell-inflamed tumor microenvironment. The presence of baseline $CD8^+$T cells is associated with clinical benefit to immunotherapies, including anti-PD1 and anti-CTLA4. The molecular mechanism explaining lack of a T-cell infiltrate in a major subset are poorly understood, but differential expression of immunogenic antigens has been proposed as one explanation. **Methods:** Using the TCGA data set for malignant melanoma, the T cell-inflamed gene expression signature was used to segregate patients by immune phenotype. Three categories of antigens were examined: cancer-testis (CT) antigens, differentiation antigens, and somatic mutational antigens. **Results:** By transcriptional profiling, no difference was observed in levels of CT antigens or differentiation antigens. Using exome sequencing of tumor versus germline, a range of 18 to 3001 of non-synonymous mutations was observed in both cohorts. Using the syfpeithi algorithm for HLA-A*0201 patients, a median of 123 mutations having a high immunogenicity score were found in the T cell-inflamed cohort versus 176 in the non-T cell inflamed. To confirm actual immunogenicity, several synthesized peptides show positive HLA-A*0201 binding and can be recognized by human $CD8^+$T cells in vitro. **Conclusions:** Both the T cell-inflamed and non-T cell-inflamed subsets of melanoma show comparable expression of CT, differentiation, and mutational antigens. Lack of spontaneous immune infiltration in a major subset of tumors is unlikely to be due to lack of antigens. Strategies that improve spontaneous T-cell infiltration into tumors therefore could, in principle, render these patients response to immunotherapies once these antigens become recognized.

3003 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Phase I study combining anti-PD-L1 (MEDI4736) with BRAF (dabrafenib) and/or MEK (trametinib) inhibitors in advanced melanoma. *First Author: Antoni Ribas, UCLA, Los Angeles, CA*

Background: Inhibition of the MAPK pathway with dabrafenib (D) and trametinib (T) is efficacious in BRAF-mutant melanoma. MEK inhibitors have also shown activity in BRAF WT melanoma, particularly in NRAS-mutant tumors. However, most patients (pts) develop resistance to D and T. MEDI4736 (M), a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity, has shown clinical activity with durable responses and an acceptable safety profile in multiple tumor types. Combined therapy with these agents may lead to enhanced durable tumor responses. **Methods:** A phase I, multicenter, open-label study (NCT02027961) evaluating the safety and efficacy of M at 3 or 10 mg/kg IV every 2 weeks (q2w) in combination with D 150 mg twice daily + T 2 mg daily, or T alone in pts with stage IIIc/IV melanoma. Pts enroll by BRAF status into dose escalation cohorts (3+3 design), followed by dose expansion: BRAF mutant in Cohort A (M+D+T); BRAF WT in Cohort B (M+T) or Cohort C (sequential T→M). Prior BRAF/MEK inhibitors were prohibited; prior immunotherapy was allowed, including anti-PD-1/anti-PD-L1 therapy. **Results:** As of December 5, 2014, 50 pts were treated. DLTs were observed in 1 pt in Cohort A1 (reversible grade [G] 3 thrombocytopenia) and 1 pt in Cohort B (reversible G3 choroidal effusion). No MTD was identified; M 10 mg/kg q2w was selected for expansion in all cohorts. The most frequent drug-related adverse events (AEs) by cohort were: pyrexia (63%) and fatigue (54%) (Cohort A); diarrhea (30%) and rash (25%) (Cohort B); and vomiting (67%) (Cohort C). 2 pts discontinued due to drug-related AEs (DLTs above). Clinical activity to date is shown below. Most responses are ongoing (range of duration: 0.1+ - 32+ wk). **Conclusions:** M can be combined with T ± D at full doses with a manageable safety profile, and evidence of clinical activity in BRAF-mutant and WT melanoma. Clinical trial information: NCT02027961.

Cohort	n	Any AE (%)	Related AE (%)	Related G ≥ 3 AE (%)	CR/PR (n/n)[a]	SD (n/n)[a]
A1 (3 mg/kg M + D + T)	6	100	100	17	6/6	0/6
A2 (10 mg/kg M + D + T)	18	94	94	39	10/15	5/15
B (10 mg/kg M + T)	20	90	85	40	3/14	6/14
C (sequential T + 10 mg/kg M)	6	100	100	17	3/6	1/6

[a]Includes pts with ≥ 1 follow up scan or discontinuation due to PD or death prior to first scan (confirmed and unconfirmed CR/PR).

3004 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

A phase I study of PF-05082566 (anti-4-1BB) + rituximab in patients with CD20+ NHL. *First Author: Ajay K. Gopal, University of Washington, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: 4-1BB agonists enhance cytotoxic T-cell and NK cell responses, including antibody-dependent cellular cytotoxicity, resulting in anti-tumor activity in preclinical models. PF-05082566 (PF-566), a fully humanized IgG2 monoclonal antibody, activates 4-1BB while blocking binding to endogenous 4-1BBL. **Methods:** This Phase I study evaluated PF-566 in doses ranging from 0.03-10 mg/kg in combination with 375 mg/m^2 rituximab (R) in patients (pts) with relapsed or refractory CD20+ NHL. Patients were treated using a Time-To-Event Continuous-Reassessment-Method design. Pts received PF-566 from D1 Q4 weeks up to 24 mo. and R from D-7 Q1W X4. The 1° endpoint was first 2-cycle DLT with PK/PD, safety, and anti-tumor activity as 2° endpoints. **Results:** 35 pts with CD20 + NHL were treated with PF-566 combined with R: Follicular (FL) (n = 22), mantle cell (MCL) (n = 5), diffuse large B cell (n = 3), marginal zone (n = 2), small lymphocytic (n = 2) and nodular lymphocyte predominant Hodgkin's (n = 1), 34 (97%) with prior R, and 20 (57%) with R-refractory disease. The median number of prior regimens was 3 (range of 1 - 9). No DLTs were observed and no pts discontinued treatment due to treatment-related AEs. The MTD was estimated as ≥ 10 mg/kg. No severe immune-related AEs were observed. PK data show a dose proportional increase in exposure and a half-life of ~10 days. Increases in soluble 4-1BB, memory T cells, and activated NK cells were observed. For pts up to 2.4 mg/kg (higher doses under evaluation for efficacy), the ORR was 21% (6/28), and in R-refractory pts the ORR was 29% (4/14), with 2 CR (0.03 and 0.12 mg/kg, both FL) with a duration of response > 2 years and 2 PR (FL and MCL). Enrollment into an expansion cohort is ongoing. The PFS for all of the R-refractory responders was > 6 mo and for all R-refractory pts the 6 mo PFS rate was 66% by Kaplan-Meier. **Conclusions:** PF-05082566 in combination with rituximab was well tolerated, with anti-tumor activity in R-refractory NHL patients, along with biomarker modulation consistent with 4-1BB agonist activity. In these R-refractory patients, the durability of anti-tumor activity appeared greater than their previous therapy. Further clinical studies of this combination in R-refractory indolent NHL patients are warranted. Clinical trial information: NCT01307267.

3005 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Phase I study of RG7155, a novel anti-CSF1R antibody, in patients with advanced/metastatic solid tumors. *First Author: Carlos Alberto Gomez-Roca, Institut Claudius Regaud, Department of Medicine, Toulouse, France*

Background: Tumor associated macrophages (TAM) suppress anti-tumor immunity and have been associated with poor prognosis in several types of cancer. CSF-1 is a critical survival and differentiation factor for TAM. Preclinically, TAM depletion has been shown to enhance/restore the activity of several clinically established treatment modalities and also novel immunotherapies. Here, we report on the phase I study of a monoclonal antibody (RG7155) that blocks the dimerization interface of the CSF1 receptor (CSF1R). **Methods:** In this dose-escalation and extension study, patients with advanced solid tumors or locally advanced pigmented villonodular synovitis (PVNS, a CSF1-driven "model disease" for clinical investigation of CSF1R targeting approaches) received RG7155 IV at dose levels between 100 – 3000mg Q2W. Primary objectives were to assess safety, tolerability, pharmaco-kinetics and –dynamics. Clinical activity was evaluated using FDG-PET (at 4 weeks after treatment start; EORTC criteria) and CT/MRI (every 6 weeks; RECIST 1.1). PD markers in pre- and on-treatment biopsies of tumor and surrogate skin tissue as well as peripheral blood were analyzed. **Results:** To date, data is available for 44 patients with solid tumors and 29 patients with PVNS. RG7155 treatment led to significant reduction of CSF1R$^+$ and CD68/CD163$^+$ macrophages in tumor and surrogate skin tissue and rapid elimination of CD14^{Dim}CD16^{Bright} peripheral monocytes. In solid tumors, partial metabolic responses (FDG-PET) and disease stabilization were observed in 5/44 and 6/40 patients, respectively. 24/28 patients with PVNS experienced an objective response (best time point response). RG7155 was well tolerated. The MTD was not reached. Grade 3/4 AEs assessed as related to RG7155 were reported in 18% of patients (21/114). Most frequent AEs (any grade) were asthenia (70% of patients), peripheral edema (44%) and pyrexia (27%). **Conclusions:** RG7155 was well tolerated and biologically highly active. RG7155 is now being tested as a promising combination partner with immunotherapies (e.g. Phase Ib study (NCT02323191) in combination with Mab-PDL1 (MPDL3280A) is ongoing). Clinical trial information: NCT01494688.

3006 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Immunotherapy with CD19-specific chimeric antigen receptor (CAR)-modified T cells of defined subset composition. *First Author: Cameron John Turtle, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Genetically modified T cells derived from distinct T cell subsets differ in the capacity to persist after adoptive transfer. We are conducting the first phase I/II clinical trial in which patients (pts) with CD19$^+$ B cell malignancies receive T cells comprised of a defined composition of CD8$^+$ T$_{CM}$ and CD4$^+$ T cells engineered to express a CD19 CAR. **Methods:** CD8$^+$ T$_{CM}$ and CD4$^+$ T cells were separately enriched from each patient, transduced with a CD19 CAR lentivirus and expanded in vitro. The cell product for infusion was formulated in a 1:1 ratio of CD8$^+$:CD4$^+$ CAR$^+$ T cells and infused at one of three dose levels ($2x10^5$ – $2x10^7$ CAR-T cells/kg) after lymphodepleting chemotherapy. **Results:** Thirty-seven pts with ALL (n = 20), NHL (n = 14) or CLL (n = 3) have been treated and 33/37 received a product that conformed to a prescribed CD8$^+$:CD4$^+$ composition. There was no serious acute infusional toxicity. Severe cytokine release syndrome (sCRS) consisting of fever, hypotension, coagulopathy and neurotoxicity associated with elevated serum IFN-γ and IL-6 was only observed in ALL pts with high tumor burden. One ALL patient treated at the highest cell dose died of complications associated with sCRS. No NHL or CLL pts had sCRS. Eighteen of 20 ALL pts were evaluated for response, with 15 (83%) achieving complete marrow remission by high resolution flow cytometry. Clinical responses in NHL included complete (n = 1) or partial (n = 6) remission in 7/13 pts. Two of 3 CLL pts achieved marrow remission by flow cytometry. The peak level and duration of persistence of both CD4$^+$ and CD8$^+$ CAR-T cells were associated with clinical response. We are investigating the impact of distinct lymphodepletion regimens on CAR-T cell proliferation and persistence in vivo. A T cell immune response to the murine CD19-specific scFv component of the CAR transgene was detected in a subset of pts with limited CAR-T cell persistence. **Conclusions:** Adoptive immunotherapy with CD19 CAR-T cells of defined subset composition is feasible and safe in a majority of heavily pretreated pts with refractory B cell malignancies and has potent anti-tumor activity at low cell doses. CAR-T cell doses for phase II studies in ALL and NHL cohorts have been determined. Clinical trial information: NCT01865617.

3007 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Safety and antitumor activity of chimeric antigen receptor modified T cells in patients with chemotherapy refractory metastatic pancreatic cancer. *First Author: Gregory Lawrence Beatty, Hosp of the Univ of Pennsylvania, Philadelphia, PA*

Background: Pancreatic ductal adenocarcinoma (PDAC) is characterized by an immunosuppressive microenvironment with a scarcity of effector T cells. Adoptive T cell therapy to restore anti-tumor immunity has demonstrated promise in several advanced malignancies. However, its role in PDAC remains to be established. This Phase I study was performed to determine the safety and feasibility of administering autologous T cells genetically modified with a chimeric antigen receptor (CAR) that recognizes mesothelin overexpressed on PDAC. **Methods**: Patients (ECOG 0-1; adequate organ function) with chemotherapy refractory metastatic PDAC (> 1 prior chemotherapy) were treated with autologous T cells engineered using *in vitro* transcribed mRNA to transiently express a mesothelin-specific CAR that includes both CD3-zeta and 4-1BB co-stimulatory domains. CAR T cells were infused 3 times per week for 3 weeks. The primary endpoint was to determine safety and manufacturing feasibility. Secondary endpoints were to measure clinical and immune responses. **Results**: 10 patients were enrolled (6 treated, 2 withdrew due to progressive disease prior to treatment, 1 manufacturing failure, 1 did not complete apheresis necessary for manufacturing). 53 of 54 (98%) planned CAR T cell infusions were administered without dose limiting toxicity. Infusions were well tolerated without evidence of cytokine release syndrome, pleuro-pericarditis or peritonitis. Treatment-related grade > 3 toxicities included abdominal pain (1) and back pain (1). CAR T cells were transiently detected in the peripheral blood after infusion. Two of six patients experienced stable disease by RECIST 1.1 with disease control off therapy seen in one patient for > 4 months. The change in SUV$_{max}$ of all lesions for each patient detected on ^{18}FDG-PET/CT imaging performed before and 1 month after beginning treatment was -1.9% (95% CI: -25.5% to 21.7%). In one patient, abnormal ^{18}FDG avidity seen in liver metastases at baseline was no longer detected at 1 month after therapy. **Conclusions**: Mesothelin-redirected CAR T cell therapy is well tolerated and shows preliminary evidence of antitumor efficacy in PDAC. Clinical trial information: NCT01897415.

3008 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Autologous HER2 CMV bispecific CAR T cells for progressive glioblastoma: Results from a phase I clinical trial. *First Author: Nabil M. Ahmed, Texas Children's Hosp Baylor Coll Of Medcn, Houston, TX*

Background: Glioblastoma (GBM) remains virtually incurable. T-cell therapy holds the promise to improve outcomes for GBM patients since it does not rely on the cytotoxic mechanisms of conventional therapies. We have shown in preclinical studies that HER2 and CMV are potential T-cell therapy targets for GBM. **Methods:** We report the initial results of the phase I clinical study, NCT01109095, administering autologous CMV.pp65 T cells grafted with a second generation HER2 chimeric antigen receptor (CAR; with a CD28.zeta signaling domain) to patients with progressive GBM. **Results:** Sixteen CMV-seropositive patients with HER2-positive GBM and radiological evidence of progression aged 11-70 (median age 49) were enrolled. Autologous HER2-CAR CMV T cells were successfully generated for all patients from a peripheral blood draw (maximum 90mL). T-cell products contained HER2-CAR expressing T cells as judged by FACS analysis (median: 67% (range: 46-82) %), and CMV.pp65-specific T cells as judged by IFN-gamma Elispot assays (median 985.5 (range 390 to 1292) SFC/10^5 T cells). Infusions of $1x10^6/m^2$, $3x10^6/m^2$, $1x10^7/m^2$, $3x10^7/m^2$ or $1x10^8/m^2$HER2-CAR.CMV-T cells were well tolerated without systemic side effects and no dose limiting toxicity was observed. HER2-CAR CMV T cells were detected in the peripheral blood for up to 12 weeks post infusion as judged by real-time PCR of a CAR-specific amplicon. Out of fifteen evaluable patients, 10 had progressive disease. Five out of fifteen patients had objective responses: 1 patient had a partial response with a ~62% reduction in tumor volume lasting 8 months, 1 patient had stable disease lasting 4 months and 3 patients have stable disease and are currently alive with a follow up of 18 to >24 months, after T cell infusion. **Conclusions:** This initial evaluation of the safety and efficacy of autologous HER2-CAR CMV bispecific T cells in patients with progressive GBM shows that infusions are safe and that cells could persist for up to 12 weeks in the peripheral blood. Clinical benefit was observed in 33% of patients setting the stage for studies that combine HER2-CAR CMV T cells with other immunomodulatory approaches to enhance their expansion and anti-GBM activity. Clinical trial information: NCT01109095.

3009 Poster Discussion Session; Displayed in Poster Session (Board #335), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Pembrolizumab (MK-3475) plus low-dose ipilimumab (IPI) in patients (pts) with advanced melanoma (MEL) or renal cell carcinoma (RCC): Data from the KEYNOTE-029 phase 1 study. *First Author: Michael B. Atkins, Georgetown-Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Pembrolizumab is a potent, highly selective, humanized monoclonal antibody against PD-1 that has shown robust antitumor activity against several advanced malignancies. In phase 1 testing, combination therapy with the anti–PD-1 antibody nivolumab and full-dose IPI (3 mg/kg) was seemingly associated with improved response rates but also increased toxicities (*NEJM* 2013;369:122-33). Here, we report the phase 1 data of concurrent administration of pembrolizumab and low-dose IPI in pts with advanced MEL or RCC. **Methods:** KEYNOTE-029 (NCT02089685) is a phase 1/2 study of pembrolizumab plus IPI or pegylated interferon alfa-2b (PEG-IFN). Assessment of the safety and tolerability of pembrolizumab plus PEG-IFN is ongoing. Safety and tolerability of pembrolizumab 2 mg/kg plus low-dose IPI 1 mg/kg every 3 weeks (Q3W) for 4 doses, followed by pembrolizumab 2 mg/kg Q3W for up to 2 years, were assessed. Dose confirmation continued until 18 pts completed the 6-wk observation period (Cycle 1). DLTs were evaluated in pts who completed the first cycle of combination therapy or who discontinued due to a treatment-related AE. The dose would be considered tolerable if ≤6 pts experienced DLTs. Toxicities were graded by CTCAE v4.0. Response is assessed at wk 12, every 6 wk thereafter until wk 30, and every 12 wk thereafter. **Results:** DLTs were observed in 6 of 19 evaluable pts (2 of 9 RCC pts, 4 of 10 MEL pts). All DLTs were of grade 3 severity. Two pts experienced 2 DLTs each: elevation of pancreatic enzymes and hyperthyroidism in 1 patient and lipase elevation and pneumonitis in another patient. The remaining DLTs were ALT/AST elevation (n = 2), colitis (n = 1), and uveitis (n = 1). Responses have been observed in MEL and RCC pts. Additional safety and preliminary efficacy data will be available for presentation. **Conclusions:** Pembrolizumab and low-dose IPI combination therapy was considered to have an acceptable safety profile in this initial safety run-in period. Based on these results, we have initiated a protocol-specified, single-arm expansion cohort to further evaluate the safety, tolerability, and preliminary efficacy of this combination in advanced MEL pts. Clinical trial information: NCT02089685.

Preliminary safety and activity of nivolumab and its combination with ipilimumab in recurrent glioblastoma (GBM): CHECKMATE-143. *First Author: John H. Sampson, Duke University Medical Center, Durham, NC*

Background: GBM has a grim prognosis despite current first-line therapies. Immune checkpoint inhibitors have shown antitumor activity in both solid tumors and preclinical glioma models. This study evaluates the safety/tolerability of the checkpoint inhibitors nivolumab (NIVO) and ipilimumab (IPI) in patients (pts) with a first recurrence of GBM. **Methods:** Pts were randomized to NIVO 3 mg/kg Q2W or NIVO 1 mg/kg + IPI 3 mg/kg (NIVO+IPI) Q3W followed by NIVO 3 mg/kg Q2W. Eligible pts had first recurrence of primary GBM, no prior bevacizumab treatment and KPS ≥70. The primary endpoint was safety/tolerability. This analysis reports the preliminary experience after all pts had the opportunity to complete ≥6 months (mo) of follow-up after first dose. **Results:** 20 pts were treated, 10 in each arm. All pts had prior surgical resection, radiation, and temozolomide. Median age was 57 years (range: 37-73), KPS=90 (n=13), 80 (n=2) and 70 (n=5). Median time from first GBM diagnosis was 9 mo. The median number of doses (range) received in NIVO arm was 6 (3-23). In NIVO+IPI, pts received 3 (2-8) doses of NIVO and 2 (2-4) of IPI. Drug-related adverse events (AE) in ≥3 pts were fatigue (n=3) and nausea (n=3) with NIVO and fatigue (n = 8), diarrhea (n = 7), AST and lipase increased (n = 5 each), vomiting and ALT increased (n=4 each), and amylase increased, headache, hyperthyroidism, nausea and maculo-papular rash (n=3 each) with NIVO+IPI. All NIVO AEs were grade 1 or 2. Eight (80%) NIVO+IPI pts had grade 3 or 4 AEs. Drug-related AEs leading to discontinuation occurred only in NIVO+IPI pts (n = 5; 50%), including colitis, cholecystitis, diabetic ketoacidosis, confusion, and increased lipase. There were no drug-related deaths. Among 20 treated pts, OS at 6 mo. was 75%, including 7/10 NIVO pts (70%) and 8/10 NIVO+IPI pts (80%). ORR, PFS, and biomarker analysis are being evaluated. **Conclusions:** This is the first randomized study to report the safety/tolerability of checkpoint inhibitors in GBM. The AE profile of NIVO ± IPI was consistent with studies in other tumors. OS at 6 mo. is encouraging relative to comparable historical controls. Updated safety, efficacy, and biomarker data including on-treatment histopathology will be presented. Clinical trial information: NCT02017717.

3011 Poster Discussion Session; Displayed in Poster Session (Board #337), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Safety and efficacy of MEDI4736, an anti-PD-L1 antibody, in patients from a squamous cell carcinoma of the head and neck (SCCHN) expansion cohort. *First Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Outcomes are poor for patients (pts) with recurrent/metastatic (R/M) SCCHN, and new treatments are needed. An ongoing phase I/II, multicenter, open-label study (NCT01693562) is evaluating the safety and efficacy of MEDI4736 (M), a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity, in multiple solid tumor types including SCCHN. PD-L1 is expressed in SCCHN tumors and may be associated with response to anti-PD-L1 treatment. **Methods:** Pts with R/M SCCHN, an ECOG of 0 or 1, without prior anti-PD-1/PD-L1 exposure are eligible. M is administered IV every 2 weeks at 10 mg/kg for 12 months. Retreatment is permitted upon progression after 12 months. PD-L1 expression is assessed by IHC using the Ventana SP263 clone. Prior documented HPV status is collected at study entry. Response is based on investigator assessment per RECIST v1.1. Data included represent a larger population with more mature follow up than previously reported (Fury M, et al. Poster presented at ESMO 2014, 988PD). **Results:** As of 31 Oct 2014, 62 pts (mean age 58 years [range 24–96]; 86% male; 64% current/prior smokers; ECOG 0/1: 38%/62%; HPV pos/neg/unk: 40%/39%/21%), with a median of 3 prior systemic treatments (1–10), received a median of 6 doses (1–26). Drug-related AEs were observed in 60% of pts; the most frequent were fatigue (11%), diarrhea, (8%), and nausea (7%). Grade ≥ 3 related AEs were reported in 7% of pts: rash (2 pts), and increased GGT, fatigue, and tumor inflammation (1 pt each). No drug-related AEs led to discontinuation or death. No colitis or grade ≥ 3 pneumonitis was observed. Overall, 51 pts were evaluable for response with ≥ 24 weeks of follow up; ORR was 12% (25% in PD-L1+ pts), and DCR at 24 weeks was 16% (25% in PD-L1+ pts). Responses are ongoing in 5/6 responding pts, with response durations ranging from 4+ to 43+ weeks. Median duration of response has not been reached. **Conclusions:** With more mature follow up, the safety profile of M in SCCHN is manageable and consistent with previous reports. Responses are durable; ORR and DCR are higher in PD-L1+ pts. A registration program is underway in pts with SCCHN for M alone and in combination with tremelimumab. Clinical trial information: NCT01693562.

3012 Poster Discussion Session; Displayed in Poster Session (Board #338), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Efficacy based on tumor PD-L1 expression in KEYNOTE-002, a randomized comparison of pembrolizumab (pembro; MK-3475) versus chemotherapy in patients (pts) with ipilimumab-refractory (IPI-R) advanced melanoma (MEL). *First Author: Igor Puzanov, Vanderbilt University Medical Center, Nashville, TN*

Background: Pembro is an anti–PD-1 antibody approved for treating advanced MEL that progressed following IPI and, if *BRAF*^{V600} mutant, a BRAF inhibitor. In KEYNOTE-002 (NCT01704287), pembro doses of 2 mg/kg and 10 mg/kg every 3 wk (Q3W) significantly improved PFS compared with investigator-choice chemotherapy in IPI-R MEL ($P < .0001$), with no difference between pembro doses ($P = .44$). Data from KEYNOTE-001 showed that PD-L1 positivity was correlated with a higher ORR and longer PFS in MEL pts. We evaluated efficacy in PD-L1$^+$ and PD-L1$^-$ MEL pts enrolled in KEYNOTE-002. **Methods:** 540 pts with advanced IPI-R MEL were randomized 1:1:1 to pembro 2 or 10 mg/kg every 3 wk (Q3W) or chemotherapy. PD-L1 expression was assessed centrally by IHC using the 22C3 antibody. The cut point for positivity was staining in ≥1% of tumor cells. Response was assessed at wk 12 and every 6 wk thereafter (RECIST v1.1, central review). Primary end points were PFS and OS (final analysis planned after 370 deaths occur). ORR and the relationship between PD-L1 expression and efficacy were secondary end points. Data for the pembro arms were pooled. **Results:** 421/540 pts enrolled (78%) had tumors evaluable for PD-L1 expression; 291 (69%) were PD-L1$^+$, 130 (31%) were PD-L1$^-$. Pembro prolonged PFS and increased ORR compared with control in PD-L1$^+$ and PD-L1$^-$ pts (Table). Among pembro-treated pts, ORR was higher in PD-L1$^+$ pts, but the CIs were overlapping, and there was no difference in duration of response (DOR) based on PD-L1 expression. There was no prognostic effect in the control arm. **Conclusions:** Pembro improved efficacy over chemotherapy in both PD-L1$^+$ and PD-L1$^-$ IPI-R advanced MEL. These data indicate that in IPI-R MEL pts, pembro therapy should not be limited to pts with PD-L1$^+$ tumors. Clinical trial information: NCT01704287.

	Total		PD-L1$^+$		PD-L1$^-$

An ongoing phase IIIb/IV safety trial of nivolumab (NIVO) in patients (pts) with advanced or metastatic non-small-cell lung cancer (NSCLC) who progressed after receiving 1 or more prior systemic regimens. *First Author: Todd Michael Bauer, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: NIVO, a fully human IgG4 programmed death-1 (PD-1), immune checkpoint inhibitor antibody, has demonstrated durable responses and tolerability in heavily pretreated pts with advanced NSCLC. Conducted mostly in community-based oncology centers, this ongoing trial explores the safety of NIVO in previously treated NSCLC pts. **Methods:** Eligible pts are enrolled in 4 subgroups: 1) squamous cell (SQ), performance status (PS) 0–1, ≥2 prior therapies; 2) SQ, PS 0–1, 1 prior therapy; 3) nonsquamous (NSQ), PS 0–1, ≥1 prior therapy; and 4) SQ or NSQ, PS 2, ≥1 prior therapy. Pts receive NIVO 3 mg/kg IV (60 min) Q2W either until progressive disease (PD)/unacceptable toxicity (Cohort A) or for 1 year with the possibility of retreatment upon disease progression (Cohort B). Primary objective is to estimate incidence of high grade (CTCAE v4.0 Grade 3–4 and 5) select treatment-related adverse events (TRAEs); exploratory efficacy assessments include ORR, PFS and OS. **Results:** From 4/16/14 to 8/15/14, 226 pts were treated and have demographic and safety data available; 179 remain on study as of 8/15. 51 pts had evaluable radiographic tumor assessments at week 9. **Conclusions:** Safety and tolerability are consistent with prior NIVO experience and no new safety signals have been identified in this trial. Immune-related toxicities are manageable in a community practice setting using previously developed safety algorithms. Early data from this large multicenter trial suggests that pts with pretreated advanced NSCLC benefit from NIVO therapy. Clinical trial information: NCT02066636.

[a]1 fatal drug-related respiratory failure was reported in the setting of known lymphangitic tumor spread, recurrent pulmonary embolus, bacteremia, pleural effusion and tumor progression; death classified as "Other-Multifactorial" by investigator.

3014 Poster Discussion Session; Displayed in Poster Session (Board #340), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Phase Ib study of MEDI4736, a programmed cell death ligand-1 (PD-L1) antibody, in combination with tremelimumab, a cytotoxic T-lymphocyte-associated protein-4 (CTLA-4) antibody, in patients (pts) with advanced NSCLC. *First Author: Scott Joseph Antonia, Moffitt Cancer Center, Tampa, FL*

Background: The inhibitory PD-L1 and CTLA-4 pathways control T-cell activation. MEDI4736 (M) is a human IgG1 mAb that blocks PD-L1 binding to programmed cell death-1 and CD80 with high affinity and selectivity. Tremelimumab (T) is a selective human IgG2 mAb inhibitor of CTLA-4. M and T have demonstrated acceptable safety profiles and clinical activity as single agents. M and T block distinct interactions contributing to immunosuppression and the combination may provide greater antitumor activity versus either agent alone. **Methods:** A Phase 1, open-label dose escalation and expansion study (NCT02000947) is assessing the safety/tolerability and antitumor activity of M + T combinations in pts with advanced NSCLC. **Results:** As of 4 Dec 2014, 61 pts have been treated during the dose escalation phase (table). An MTD has not yet been defined; the Cohort 5a dose exceeded the MTD (n=2 with dose-limiting toxicities; Grade [G] 3 increased AST/ALT, G4 increased lipase). 64% of pts had ≥1 drug-related AE; the most frequent were fatigue (26%), diarrhea (21%), and increased amylase (13%). 31% of pts had ≥1 G3/4 related AE; the most frequent (>5%) were diarrhea (8%) and colitis (7%). Increasing doses of T with a constant dose of M were associated with greater severity and frequency of AEs. 18% of pts had drug-related AEs leading to discontinuation; the most frequent was colitis (7%). All AEs were manageable with standard therapy, including steroids, except G4 myasthenia gravis and G5 polymyositis in 1 pt in Cohort 2a. Of 31 pts with ≥18-week scan, 8 (26%) had partial response (PR) and 11 pts (35%) had stable disease. PRs occurred in 3 of 10 pts with PD-L1-negative tumors. **Conclusions**: The combination has a manageable safety profile with evidence of clinical activity, including in PD-L1-negative disease. These data support continued study of the combination; recruitment is ongoing. Clinical trial information: NCT02000947.

Molecular, immune and histopathological characterization of NSCLC based on PDL1 expression on tumor and immune cells and association with response to the anti-PDL1 antibody MPDL3280A. *First Author: Scott N. Gettinger, Yale School of Medicine, New Haven, CT*

Background: Programmed death ligand-1 (PD-L1) expression on tumor cells (TC) or tumor-infiltrating immune cells (IC) is associated with OS, PFS and ORR in patients with advanced NSCLC treated with MPDL3280A (Spigel et al, Spira et al, ASCO 2015, pending). In a phase I study, high PD-L1 expression on TC or IC (TC3 or IC3) was associated with a 45% ORR (RECIST v1.1) compared to a 14% ORR in patients without TC3 or IC3 NSCLC (Horn et al, ASCO 2015, pending). **Methods:** NSCLC specimens from both pre-treatment tumor samples across MPDL3280A trials (n = 498) and a non-trial cohort (n = 706) were evaluated for PD-L1 expression in TC and IC using the SP142 IHC assay. The specimens were scored as TC 0-3 and IC 0-3 based on increasing PD-L1 expression. A subset of samples was further characterized by histopathologic review, gene expression and epigenetic modifications. **Results:** TC3 or IC3, TC2/3 or IC2/3, and TC1/2/3 or IC1/2/3 tumors represented ≈ 20%, ≈ 40% and ≈ 65% of NSCLC, respectively. TC3 and IC3 tumors represented 2 distinct populations, with < 1% overlap. IC3 tumors demonstrated a high frequency of immune infiltrates within the tumor, stroma and tumor/stroma interface, with higher expression of B- and NK-cell signatures compared to TC3 tumors. In contrast, TC3 tumors featured distinct histopathologic characteristics, with a dense desmoplastic and sclerotic tumor microenvironment. TC3 tumors had a lower frequency of immune infiltrates, which when present were primarily located in the surrounding stroma. In addition, an inverse correlation was seen with PD-L1 promoter methylation and PD-L1 expression in TC, suggesting that PD-L1 may be influenced in part by epigenetic events in TC. Tumors that were TC0 and IC0 (≈ 35% of NSCLC) showed little to no evidence of immune infiltration or activation, consistent with immunologic ignorance. **Conclusions:** NSCLC can be classified into previously unrecognized, distinct molecular and histopathologic subsets that define sensitivity to treatment with PD-L1 targeted therapy. While expression of PD-L1 on TCs and/or ICs may confer sensitivity to MPDL3280A, the immunologic context and response to treatment may differ.

CEA-targeted engineered IL2: Clinical confirmation of tumor targeting and evidence of intra-tumoral immune activation. *First Author: Jan H. M. Schellens, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: CEA-IL2v (RG7813) is an engineered IL-2 variant (IL-2v) with abolished IL-2Rα (CD25) binding fused to an antibody targeting Carcinoembryonic Antigen (CEA). The molecule was designed to improve the pharmacological and safety profile of IL-2 and enable tumor targeting. **Methods:** In an ongoing Phase I trial of CEA-IL2v (ranges 0.1 – 40 mg flat dose IV; schedule q1W and q2W) in patients (pts) with advanced and/or metastatic solid CEA+ tumors, extensive pharmacodynamic monitoring in peripheral blood as well as immunohistochemical (IHC) and flow cytometric (FC) analysis of pre- and on-treatment biopsy specimens (day + 4) were performed, including tests for effector (CD8+) and helper T cell (CD4+) percentage and density. In a sub-study, biodistribution was analyzed using PET imaging of ^{89}Zr-CEA-IL2v at doses of 6 and 30 mg. **Results:** Of the 11 pts treated at 30 mg, 4 had sequential tumor biopsies evaluable both by IHC and FC. An increase in the median density (IHC) of CD8+ T cells from 62.5 (7 - 90) [median (range)] to 104.2 (7 - 255) cells/ mm^2 was observed in 3/4 subjects after the 1st dose. No relevant change in the density of CD4+ T cells was detected. FC analysis confirmed the increase in CD8:CD4 ratio in the same 3/4 patients: from 0.88 (0.57 - 1.24) to 4.54 (0.36 - 7.47). Effects in peripheral blood included strong lymphocyte expansion that was mostly driven by Natural Killer (NK) and CD8+ T cells. Medians and ranges for the 11 pts before and 4 days after dosing were: NK: 168 (range: 52 - 337) vs. 655 (206 - 1569) cells/μl; CD8+: 340 (19 - 464) vs. 831 (78 – 3754) cells/μl. While there was no clear evidence of CEA-mediated tumor accumulation at 6 mg in the first 6 pts, intra-tumoral accumulation of ^{89}Zr-CEA-IL2v was observed in 2/2 pts at 30 mg. Additional studies are ongoing. **Conclusions:** Collectively, these data support the concept that reduced affinity of CEA-IL2v for IL2R-alpha together with high-affinity binding to CEA enables tumor targeting. These findings suggest that CEA-IL2v is the first tumor-targeted cytokine, which increases immune infiltration and activates NK and T cells both in the periphery and within tumors. Clinical trial information: NCT02004106.

A first-in-human dose escalation study of PEGylated recombinant human IL-10 (AM0010) in advanced solid tumors. *First Author: Jeffrey R. Infante, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: PEGylated IL-10 induces the expansion of tumor reactive CD8 T cells both in the periphery and within the tumor. In mice, PEG-IL-10 but not non-PEG-IL-10 induces the rejection of tumors and establishes immunological memory. Primary objectives of this FIH study were to establish the safety, tolerability and the MTD of AM0010. Secondary objectives were to assess anti-tumor-activity, pharmacokinetics, immunogenicity and induced immune activation. **Methods:** Patients with advanced melanoma (4), non-small cell lung cancer (1), renal cell cancer (6), colorectal cancer (16), prostate cancer (1), ovarian cancer (1) and pancreatic cancer (4) were enrolled in escalating cohorts of 3-6 patients each followed by expansion cohorts. AM0010 was self-administrated daily subcutaneously at doses of 1 to 40 μg/kg. PK, anti-drug antibodies and immune responses were monitored. **Results:** Since November 2013, 33 patients were enrolled in cohorts of 1, 2.5, 5, 10, 20, and 40 μg/kg. An MTD was not defined through the planned maximally administered dose. Common treatment related adverse events included injection site reaction, rash, fatigue, thrombocytopenia and anemia. Most adverse events were low grade. Eight G3 adverse events were observed including anemia (3), thrombocytopenia (1), rash (1), increased lipase (1), dyslipidemia (1), transaminitis (1). The half-life of AM0010 half-life is ~20 hrs and exposures increased linearly with increasing doses. IL-18 was dose dependently increased in the serum of all patients, IFNg, IL-4, GM-CSF and IL-7 were elevated at doses $>$ 20 μg/kg. Activation of CD8 T cells was observed. Ongoing immune related partial responses (irPR) were observed in one RCC patient (20 μg/kg; -71% at 22 weeks) and one ocular melanoma patient (40 μg/kg; -57% at 14 weeks). Additional 9 patients had stable disease at 8 weeks (1 melanoma (duration 24+ weeks); 2 RCC (21/13); 1 CRC (40+); 3 CRC, 1 pancreatic, 1 ovarian (13)). **Conclusions:** AM0010 has a manageable safety profile and leads to sustained and systemic Th1 immune stimulation. The pharmacodynamics and clinical activity observed support the ongoing monotherapy expansions and future combination development in a variety of advanced malignancies. Clinical trial information: NCT02009449.

A phase I study of intratumoral injection of ipilimumab and interleukin-2 in patients with unresectable stage III-IV melanoma. *First Author: Randy Christopher Bowen, University of Utah, Salt Lake City, UT*

Background: Intratumoral (IT) IL-2 is highly effective and well tolerated, but does not generate systemic immunity or response in untreated lesions. Intravenous (IV) ipilimumab (Ipi) lowers the threshold for T cell activation leading to a durable clinical response in a minority of melanoma patients, but is associated with potentially severe toxicities. Since IV Ipi doesn't have tissue distribution, circulating anti-tumor T cells activated by this drug may differ greatly from tumor-infiltrating lymphocytes (TILs) activated by IT Ipi in terms of quantity and quality. Therefore, we hypothesized that a combination of IT IL-2 and IT Ipi would effectively hyperactivate and expand TILs to engender systemic immunity with minimal toxicity. **Methods:** This was a phase I dose escalation study for Ipi with fixed dose IL-2 in patients with unresectable stage III/IV melanoma and at least one injectable lesion. A single lesion (0.5-2.0 cm) in each patient was treated with IL-2 (3 mIU) IT TIW x 2 weeks, then BIW x 6 weeks, with escalating doses of Ipi IT weekly x 8 wks. A minimum of 3 patients were enrolled at each dose level. Endpoints included safety, tumor responses, and changes in systemic T cells. **Results:** 12 patients were treated at 3 Ipi dose levels (0.5, 1, 2 mg). Treatments were well tolerated. The only grade 3 toxicity observed was injection/tumor site ulceration/necrosis, not a DLT per protocol. Other toxicities were grade 1 in nature. An abscopal effect (response in at least 1 non-injected lesion) was seen in 9/12 patients (75%). 10 patients were evaluable for response by immune-related response criteria: 4 PR (40%) and 6 PD. 1 PD was later found to be a CR by resection. The 2 nonevaluable patients had regression of multiple skin lesions. An increase in the frequency of total peripheral IFN-γ-producing CD8+ T cells was detected in 6/8 abscopal responders. Tbet+ and granzyme-B + CD8+ T cells were observed in 4/5 and 3/5 responders tested, respectively. **Conclusions:** IT injection with the combination of Ipi/IL-2 is well tolerated and generates responses in both injected and non-injected lesions in the majority of patients. We plan to conduct a phase II trial using IT Ipi/IL-2 in conjunction with systemic immunotherapy. Clinical trial information: NCT01672450.

Immunogenomics-based development of personalized immunotherapy for lung cancers. *First Author: Yataro Daigo, Research Hospital, Institute of Medical Science, The University of Tokyo, Tokyo, Japan*

Background: Oncoantigens are oncogenic and high immunogenicity proteins specifically expressed in cancers, and are promising targets for personalized immunotherapy. **Methods:** We have established a strategy to identify new oncoantigens; i) screening of genes expressed in the majority of 120 lung cancers with cDNA microarray covering 27,648 genes, ii) verification of no expression of these genes in normal tissues, iii) validation of the clinicopathological significance of their expression with tissue microarray covering 400 lung cancers, iv) characterization of their role in the growth or invasiveness of cancer cells by RNAi and cell growth/invasion assays, v) screening of the epitope peptides recognized by HLA-A*0201- or A*2402-restricted cytotoxic T lymphocyte (CTL) for clinical trials. **Results:** We identified dozens of 10-amino-acid peptides from 45 oncoantigens, each of which was a candidate to be presented on the surface of HLA-A*0201 or HLA-A*2402 that induced CTL response. We conducted a phase I study for HLA-A*2402-positive, advanced non-small cell lung cancer patients who failed to standard therapy, using the combination of three peptides from LY6K, CDCA1, and KIF20A mixed with adjuvant once a week. 20 evaluable patients have been enrolled, and this cancer vaccine therapy demonstrated tolerability and had very high immunogenicity to induce antigen-specific CTLs in cancer patients. Disease control rate including one complete response was 50%. The patients showing LY6K-specific CTL responses demonstrated a longer overall survival than those without CTL induction. The patients with CTL induction for multiple peptides were likely to show better clinical outcomes. We are also screening predictive and monitoring biomarkers for peptide vaccine therapy through immunogenomics approach by analyzing pattern of CTL response, genomic/proteomic profiles of CTLs, cancer tissues and serum, as well as genetic variation of patients and identified various candidate biomarkers detectable in cancer tissues and/or serum. **Conclusions:** Current data of the cancer vaccine therapy coupled with screening of companion diagnostics warrants further clinical studies to develop more personalized and effective immunotherapy. Clinical trial information: NCT01069575.

Vaccination of MSI-H colorectal cancer patients with frameshift peptide antigens: A phase I/IIa clinical trial. *First Author: Matthias Kloor, University of Heidelberg, Heidelberg, Germany*

Background: High level microsatellite instability (MSI-H) occurs in 15% of colorectal cancers as a consequence of DNA mismatch repair deficiency. MSI-H colorectal cancers are characterized by a dense immune cell infiltration. They are characteristic of the inherited HNPCC (hereditary non-polyposis colorectal cancer) or Lynch syndrome, but can also develop sporadically. DNA mismatch repair deficiency causes insertion or deletion mutations at coding microsatellites, which leads to the generation of frameshift peptide (FSP) antigens. FSP antigens are attractive targets for vaccination, because they are highly immunogenic shared antigens, which directly result from driver mutations in MSI-H cancers. To evaluate safety and immunological efficacy of FSP vaccination, we have initiated a clinical phase I/IIa vaccination trial (Micoryx). **Methods:** The protocol comprised 3 cycles of 4 subcutaneous applications of FSP antigens (frameshift variants of the coding microsatellite-containing genes AIM2, HT001, TAF1B) mixed with Montanide ISA-51 VG over a 6 month period. Inclusion criteria were history of colorectal cancer (UICC stage III or IV) who received standard chemotherapy. Phase I of the trial evaluated safety and toxicity as the primary endpoint (6 patients), phase IIa addressed the induction of cellular and humoral immune responses (16 patients). **Results:** No FSP antigen-associated severe adverse events have been observed. Significant induction of FSP-specific immune responses against one or more FSP antigens was observed in all patients vaccinated per protocol. Few patients had stage IV disease and were evaluable according to RECIST. One heavily pretreated patient with bulky metastases showed a stable disease and stable CEA levels over 7 months under the study treatment. **Conclusions:** Vaccination with FSPs is well tolerated and leads to the induction of humoral and cellular immune responses. FSP vaccination represents a promising novel approach for treatment of MSI-H colorectal cancer patients and for tumor prevention in Lynch syndrome, allowing the evaluation of the concept of preventive cancer vaccines in an ideal model scenario of a defined high-risk patient population. Clinical trial information: NCT01461148.

Phase I, first-in-human trial of LV305 in patients with advanced or metastatic cancer expressing NY-ESO-1. *First Author: Neeta Somaiah, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Generation of tumor-specific cytotoxic T cells (CTLs) in vivo is a major goal of cancer immunotherapy. LV305 is a replication-incompetent, integration-deficient, hybrid viral vector based on the ZVex platform designed to target dendritic cells (DC) in vivo via CD209 (DC-SIGN) and induce the full-length expression of the cancer testis antigen, NY-ESO-1, in order to generate and expand anti-cancer CTLs. In preclinical models, LV305 is a potent inducer of CTLs and anti-tumor immunity. In this first-in-human study, the safety, immunogenicity and efficacy of LV305 are being examined in patients (pts) with cancer. **Methods:** Adults with previously treated, advanced or metastatic melanoma, sarcoma, breast, lung or ovarian cancers expressing the NY-ESO-1 protein by IHC were eligible. Following a 3+3 dose escalation design, 3 pts were enrolled into 4 cohorts to receive 3 or 4 intradermal injections every 3 weeks of 10^8, 10^9 or 10^{10} vector genomes (vg) per dose. Expansion of up to 53 pts at the 10^{10}dose is underway. **Results:** During dose escalation, 12 pts with NY-ESO-1 positive sarcomas were treated. No DLT or SAEs were observed and all related AEs were CTCAE grade 1 or 2. Common AEs were fatigue (58%), injection site reaction (33%), and myalgia (33%). After review by an independent DSMB, the highest dose, 10^{10} vg, was determined to be safe. Immunogenicity data from the initial 6 pts at the low dose (10^8 vg) demonstrated increased NY-ESO-1-specific CD8 and/or CD4 T cells in 3 pts by ELISPOT, tetramer assay of unstimulated blood, and/or TCR sequencing of blood and TILs. Data indicate the induction of T cells to new epitopes and boosting of TIL TCR sequences in blood. Of these initial 6 pts, 4 had a best response of SD (range 12-34+ weeks) with 1 pt achieving regression of 13.8%, and 2 had PD. The 6 pts dosed at 10^9 and 10^{10}vg are completing therapy. **Conclusions:** LV305 demonstrated acceptable safety at all doses up to 10^{10} vg. At the lowest dose, LV305 generated strong T cell responses and preliminary evidence of anti-tumor effect. Data from the mid and high dose are pending. These encouraging results will be followed by studies of LV305 (10^{10} vg) alone, in prime/boost with G305 (NY-ESO-1 protein-TLR4 agonist) and with anti-PD-1 therapy. Clinical trial information: NCT02122861.

3022 Poster Session (Board #348), Sat, 8:00 AM-11:30 AM

Utility of FDG-PET/CT in lymphoma patients undergoing immunotherapy with autologous CTL019 T-cells. *First Author: Nirav Niranjan Shah, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Molecular imaging with FDG-PET/CT (PET/CT) is an established modality for response assessment in lymphoma patients (pts) undergoing treatment (Tx). However, pts treated with novel immunotherapies may have false positive PET/CT findings due to tumor site and systemic inflammation. In particular, Tx with CTL019cells(autologous chimeric antigen receptor modified T-cells redirected at CD19) can be complicated by 'cytokine release syndrome' (CRS) due to a severe systemic inflammatory reaction. Infiltration of tumors by activated CTL019 cells may impact radiographic and functional imaging findings. The role of PET/CT in pts treated with CTL019has not previously been described. **Methods:** We performed a pilot, single arm, prospective study to explore the utility of early PET/CT in pts with diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL) undergoing Tx with CTL019 T-cells. Pts had PET/CT prior to CTL019infusion and then early PET/CT at 1 month (m) post-Tx. The primary outcome was the amount/change in metabolically active tumor volume (MTV) and FDG uptake. Secondary outcomes included the association of early PET/CT with formal response assessment by 3 m CT scan and the effect of CRS on PET/CT results. **Results:** We enrolled 6 pts (DLBCL 4; FL 2). 5 of 6 had baseline PET/CT with active disease. 4 of 6 pts developed CRS but all resolved symptoms prior to the 1 m scan. On the 1 m PET/CT, 3 had response (CR or PR) and 3 had disease progression (PD). There was 100% correlation of early PET/CT result with 3 month CT response assessment (Table). Development of CRS did not confound PET/CT findings. **Conclusions:** In DLBCL and FL pts on Tx with CTL019, early PET/CT may predict response to this novel immunotherapy. The development of CRS did not influence image assessment at 1 m. We plan to include early PET/CT in future CTL019 lymphoma studies to better define its role in this setting.

Subject	Disease	CRS N=No Y=Yes	Pre-Tx Total MTV (cc)	Post-Tx Total MTV (cc)	Absolute change in MTV(cc)	Post-Tx PET/CT Deauville Score/Response	3 m CT response
13	FL	N	54.7	0	-54.7	1/CR	CR
16	DLBCL	Y	0	32.7	+ 32.7	5/PD	PD
12	DLBCL	Y	91.2	22.9	-68.3	4/PR	PR
22	DLBCL	Y	255.9	1625.3	+ 1369.4	5/PD	PD
19	FL	Y	451.6	0	-451.6	2/CR	CR
25	DLBCL	N	121.3	369.8	+ 248.5	5/PD	PD

3023 Poster Session (Board #349), Sat, 8:00 AM-11:30 AM

Phase I, open-label, multi-ascending dose trial of avelumab (MSB0010718C), an anti-PD-L1 monoclonal antibody, in Japanese patients with advanced solid tumors. *First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in phase I/II trials. Here we report on the safety and tolerability of avelumab in a phase I dose escalation study (NCT01943461) in Japanese patients (pts) with advanced solid tumors. **Methods:** Dose escalation (3+3 design) was performed for 3 dose levels (DL 3, 10, and 20 mg/kg). The dose limiting toxicity (DLT) evaluation period was 3 weeks. **Results:** A total of 17 pts (4 gastric, 4 melanoma, 3 NSCLC, 2 CRC, 2 GIST, 1 esophageal, 1 MBC) were enrolled, with 5, 6, and 6 pts treated with avelumab at 3, 10, and 20 mg/kg, Q2W, respectively. Median age was 62 years (range 30–74) and all had ECOG PS 0 or 1, with a median of 4 prior lines of therapy (range 1–9). Treatment-emergent adverse events (TEAEs) occurred in 16/17 pts (94.1%), of which 11 (64.7%) were treatment-related. The most frequent related TEAEs ($\geq$ 10%) were infusion-related reactions (5, 29.4%), stomatitis (4, 23.5%), maculopapular rash (4, 23.5%), decreased white blood cell count (3, 17.6%), pyrexia (2, 11.8%), headache (2, 11.8%), and anemia (2, 11.8%). Two pts had grade 3 TEAEs (not related). No pt experienced a DLT. Two pts had confirmed partial responses (1 melanoma, 1 esophageal), and 5 had stable disease for $>$ 3 months. To date, 12 pts (70.6%) have discontinued treatment: 10 (58.8%) for progression, 1 (5.9%) for death, and 1 (5.9%) for other reason. Five pts (29.4%) remain on treatment. All 17 pts were evaluable for PK analysis. Half-life was 88.6, 121.8, and 114.0 h for dose levels 3, 10, and 20 mg/kg, respectively. The parameters C_{max} and AUC were approximately proportional with dose, showed low variability, and were similar to those previously obtained in Caucasian pts. **Conclusions:** Avelumab can be safely administered to Japanese pts in doses up to 20 mg/kg Q2W. Additional phase II/III studies to evaluate the clinical activity of avelumab at 10 mg/kg Q2W in select tumor types are currently being planned. *Proposed INN. Clinical trial information: NCT01943461.

3024 Poster Session (Board #350), Sat, 8:00 AM-11:30 AM

Phase I study of MEDI0639 in patients with advanced solid tumors. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: MEDI0639 is an investigational monoclonal antibody that selectively binds to Delta-like ligand 4 (DLL4) and blocks its ability to bind to and activate signaling through the Notch receptors, potentially inhibiting tumor growth by multiple mechanisms. **Methods:** This study (NCT01577745) included patients (pts) with advanced solid tumors who had ECOG performance status 0–1 and adequate organ function. MEDI0639 10–200 mg was given every 21 days with a 3+3 dose-escalation design. Primary objective was to determine maximum tolerated dose (MTD) and safety. Other objectives included pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity (IG), and antitumor activity. **Results:** As of Jan 7, 2015, 20 pts were enrolled (median age 61y [range 40–83y]; median number of prior therapies: 5). The most common tumors were colorectal (n = 5), small cell lung cancer (n = 4), and melanoma (n = 4). No dose-limiting toxicities were identified through the 150 mg dose; the 200 mg dose is currently being evaluated. Of 20 safety-evaluable pts, the most common treatment-related adverse events (trAEs) were increased aspartate aminotransferase, increased brain natriuretic peptide (BNP), and fatigue (n = 3 each). Grade 3/4 trAEs were observed in 3 pts (acute myocardial infarction [AMI], atrial fibrillation [AF], ventricular dilatation [VD], and ventricular hypokinesia [VH] in 1 pt; lower abdominal pain in 1 pt, and hypertension in 1 pt), and 3 pts had serious trAEs (AMI, AF, VD, VH in 1 pt; diplopia in 1 pt; hemorrhagic diarrhea (HD), chest discomfort, and back pain in 1 pt). One pt discontinued due to a trAE (AMI). The trAEs of interest consistent with the mechanism of action included AMI (n = 1), hypertension (n = 2), increased BNP (n = 3), and HD (n = 1). No treatment-related deaths occurred. Of 19 efficacy evaluable pts, partial response was observed in 1 pt with melanoma; 7 pts had stable disease lasting ≥ 12 weeks. Preliminary PK was nonlinear at doses < 100 mg, and PD showed target engagement at the doses tested. IG has not been observed. **Conclusions:** MEDI0639 150 mg did not exceed the MTD. Enrollment at the 200 mg dose level is ongoing. The safety profile is consistent with the mechanism of action and appears to be manageable. Preliminary evidence of antitumor activity was observed. Clinical trial information: NCT01577745.

3025 Poster Session (Board #351), Sat, 8:00 AM-11:30 AM

Baseline serum predictors of clinical response to CTLA4 inhibitor therapy in melanoma patients. *First Author: Krisztian Homicsko, University Hospital Lausanne, CHUV, Lausanne, Switzerland*

Background: A CTLA4 specific antibody (Ipilimumab, Yervoy) has been approved as first line therapy for metastatic melanoma. Despite long-term benefit for a subpopulation (~20%) of patients, the majority will unfortunately not benefit. To date, only VEGFA levels have been suggested as a potential predictive marker in serum. In the current study we set out to identify serum protein marker/s that could identify patients benefiting from ipilimumab. **Methods:** We performed a retrospective discovery analysis of serum samples obtained before melanoma patients started Ipilimumab treatment. We selected 5 responder and 5 non-responder patients. Response was evaluated based on the first CT scan (W12) after the first course of Ipilimumab therapy. The protocol was approved by the local IRB. Samples were analyzed for 440 proteins using the RayBio Quantibody Multiplex ELISA platform. Results are being verified in a validation cohort of 12 patients. **Results:** Out of 440 proteins, 29 showed a statistically significant difference ($p < 0.05$, two-tailed Student t-test), with 7 proteins upregulated and 22 downregulated in responders. VEGFA levels were not predictive ($p = 0.4246$). One particular protein showed the most significant difference and was undetectable in 5 out of 5 responders, while 4 out of 5 non-responders in the discovery cohort had the protein expressed. In this cohort, this protein showed a positive predictive value (PPV) of 83% and also a negative predictive value of 100%. We will also present the ongoing analyzes of 12 additional pretreatment samples as a validation cohort. We generated a 10-protein signature, which we are comparing with the single protein predictor. Multivariate analyzes of markers and clinical parameters are ongoing to confirm that protein B alone or the 10-protein signature is a better predictor of response and survival. Recruitment of additional patients in this translational protocol is ongoing. **Conclusions:** The finding that a serum protein or a protein signature predicts clinical response to ipilimumab warrants further validation in larger prospective studies. (The use of protein B and/or the 10-protein signature as predictors of response to anti-CTLA4 therapy is pending patent application).

3026 Poster Session (Board #352), Sat, 8:00 AM-11:30 AM

Correlation of gene expression signatures and clinical outcomes in patients with advanced gastric cancer treated with pembrolizumab (MK-3475). *First Author: Veena Shankaran, University of Washington, Seattle, WA*

Background: Pembrolizumab, an anti–PD-1 monoclonal antibody, has shown antitumor activity in advanced gastric cancers. Hypothesis testing of 4 prespecified multigene immune expression signatures enriched for T-cell mediated interferon signaling and antigen presentation genes was used to evaluate associations with clinical outcomes in patients with gastric cancer enrolled in KEYNOTE-012, a multicohort, phase 1 study of pembrolizumab in patients with PD-L1$^+$tumors. **Methods:** 33 of 39 pembrolizumab-treated advanced gastric cancer patients had RNA expression profiling data of sufficient quality. RNA was extracted from formalin-fixed, paraffin-embedded samples and analyzed using the NanoStringnCounter system. Hypothesis testing was conducted on 4 prespecified signatures ("Interferon-gamma," "TCR-signaling," "Expanded-immune," and "Denovo") that were constructed based on analyses in patients with melanoma and prior to linking any NanoString data to clinical outcome data. **Results:** In the patients with NanoString data, ORR was 30%. For ORR, all 4 signatures showed a P value <0.10 (Table). For PFS, all signatures achieved $P<$ 0.05. All signatures showed a general pattern such that pts with very low signature scores did not respond. ROC analyses suggest that cutoffs with high sensitivity and a resultant high negative predictive value (NPV) can readily be achieved. The cutoff associated with the Youden Index of the ROC curve for the Interferon-gamma signature yielded a positive predictive value (PPV) of 45% with a NPV at 92%. **Conclusions:** Immune response signatures were associated with clinical benefit from anti–PD-1 therapy with pembrolizumab in patients with advanced gastric cancer enrolled in KEYNOTE-012. Clinical trial information: NCT01848834.

3027 Poster Session (Board #353), Sat, 8:00 AM-11:30 AM

TCR use and cytokine response in PD-1 blockade. *First Author: Jesse M Zaretsky, UCLA, Los Angeles, CA*

Background: PD-1 blockade releases effector T-cells in the tumor microenvironment, but little is known on the effects in peripheral blood. We used T cell receptor (TCR) sequencing and multiplex serum cytokine analysis to assess treatment-induced changes and correlation with clinical response. **Methods:** Patients with metastatic melanoma were administered PD-1 inhibitor pembrolizumab (MK-3475) across three clinical trials at UCLA (NCT01295827, NCT01704287, NCT01866319). Among those consenting to blood collection (UCLA IRB#10-000870), we selected cases with paired samples (baseline and at second dose), yielding 19 responders and 22 non-responders per irRECIST. Peripheral TCRs were sequenced by immunoSEQ assay (Adaptive Biotechnology). Serum cytokines were analyzed by Milliplex 38 Cytokine kit (HCYTMAG-60K-PX38). Mann-Whitney and Wilcox signed-rank tests evaluated group differences and treatment effects. **Results:** Unlike previous reports with CLTA4 blockade, anti-PD-1 treatment itself did not cause a net expansion in unique TCR repertoire size ($p = 0.42$). However, post treatment samples in responders had significantly more unique TCRs compared to non-responders ($p = 0.022$). Fold change in the number of clones comprising the top 25% of total TCR reads, a metric which minimizes noise from rare clonotypes, differed significantly between groups ($p = 0.015$, MW), showing a net decrease in non-responders but no net change in responders ($p = 0.013$ vs $p = 0.77$, WSR). Among serum cytokines, higher FGF-2 ($p < 0.01$) and eotaxin ($p = 0.04$) levels at baseline correlated with response, as did a post treatment decrease in relative levels of IL-8 ($p < 0.01$), MCP-1 ($p < 0.01$) and FGF-2 ($p = 0.01$). Changes in FGF-2 correlated with IL-8 and MCP1 (Spearman rho $\sigma = 0.35$, $p = 0.03$ and $\sigma = 0.70$, $p < 0.0001$). Among all study patients there was a mean increase in IP-10 ($p < 0.001$), IL-12.p40, IL-10, and TNF-a (all $p < 0.05$), and decrease in MDC ($p = 0.037$). **Conclusions:** Greater diversity of post-treatment peripheral T-cell repertoire favorably correlates with response to PD-1 inhibition, and differs from the non-specific increase observed with CTLA4 blockade. Of 38 circulating cytokines analyzed, 8 showed treatment induced changes, of which a decrease in FGF-2, MCP1, and IL-8 correlated with response.

3028 Poster Session (Board #354), Sat, 8:00 AM-11:30 AM

Biomarker analysis of patients treated with anti-CD19 chimeric antigen receptor (CAR) T cells. *First Author: Adrian Bot, Kite Pharma Inc, Santa Monica, CA*

Background: CAR engineered autologous T cell therapy has shown promising efficacy in B cell malignancies in an ongoing phase 1 study (Kochenderfer et al. J Clin Oncol 2014, ASH 2014). Anti-CD19 CAR T cell product characteristics and pharmacodynamic markers from patients in this study were correlated with clinical results. **Methods:** Patients with relapsed/refractory B cell malignancies received conditioning with fludarabine and cyclophosphamide, then anti-CD19 CAR T cells engineered with a CAR comprising CD28 and CD3-zeta signaling domains. Product T cells were characterized as such, or upon co-culture with CD19+ tumor cells, by flow cytometry and multiplex cytokine analysis. Pre- and post-CAR T cell infusion peripheral blood mononuclear cells (PBMCs) and sera were also evaluated. **Results:** To date, 11 anti-CD19 CAR T cell products, and PBMCs and serum samples from 7 patients have been evaluated. Five had an objective response to anti-CD19 CAR T cell treatment. Product T cells comprised central memory, peripheral memory and effector T cells. Upon co-culture with CD19+ tumor cells, these CAR T cells produced T_1, T_2, pro-inflammatory, homeostatic and effector cytokines, and chemokines. The treated patients showed induction of key homeostatic and inflammatory cytokines upon conditioning, as well as increased levels of immune effector molecules (granzymes, perforin) during the first 2 weeks after CAR T cell treatment. Additionally, the clinical responders showed *in vivo* expansion of CAR+ T cells to a range of 15-300 CAR+ PBMC/μL within 14 days after T cell treatment. Further analyses are ongoing. **Conclusions:** Detailed biomarker analysis from patients treated with anti-CD19 CAR T cells, may provide insight to clinical outcomes and guide the design of T-cell therapies.

3029 Poster Session (Board #355), Sat, 8:00 AM-11:30 AM

Immunological long-term follow-up of neuroblastoma stage IV patients after anti-GD2 CH14.18 antibody treatment. *First Author: Simone Kayser, University Children's Hospital, Tübingen, Germany*

Background: Neuroblastoma stage IV is associated with low cure rates. Treatment with the GD2 antibody ch14.18 could improve the long-term overall survival. Apart from GD2 other tumor antigens (TA) are expressed in neuroblastoma and studies implicated that T-cell responses to TA are associated with a better outcome. For the present study we analyzed the immune response in long term neuroblastoma survivors treated with anti GD2 ch14.18. **Methods:** Blood and serum of 17 neuroblastoma long-term survivors after GD2 therapy with $>$ 5 years follow up (patients group) and 17 age and gender matched healthy donors (control group) were analyzed. Serum was analyzed for antibodies binding to neuroblastoma cell lines and antibodies to a nominal antigen GD2. T cells were stimulated with overlapping peptides of the tumor antigens (TA) NY-ESO-1, WT-1, Survivin, MAGE-A1 and two mimotope peptides to GD2 for 10 days and analyzed for IFN-γ secretion in flow cytometry. **Results:** T-cell responses to at least one TA could be found in 82% of healthy and in 93% of patients with no significant difference in the number of TA responders between the two groups to any of these TA (Fisher´s exact test). In contrast, T-cell responses to at least one of the GD2 mimotopes were found in 53% of neuroblastoma survivors but in 0% of healthy donors. Moreover, even priming with GD2 mimotope loaded dendritic cells did not induce a T-cell response in healthy donor cells. No differences between patient and control group could be detected in binding of antibodies to neuroblastoma cell lines and no GD2-specific antibodies were detected in patients and controls. **Conclusions:** Survivors of neuroblastoma treated with anti-GD2 ch14.18 demonstrated robust T-cell responses to neuroblastoma associated TA that was comparable to healthy donors. This could enable patients to attack minimal residual disease efficiently. Moreover more than half of the patients had T-cell responses to GD2 which could be an effect of the GD2 antibody therapy. Our results show that involvement of the cellular immune system might have an impact on the better outcome of this treatment in stage IV neuroblastoma patients.

3030 Poster Session (Board #356), Sat, 8:00 AM-11:30 AM

Association of epithelial-mesenchymal transition with an immunosuppressive, inflammatory tumor microenvironment with elevated levels of checkpoint inhibitors in lung adenocarcinoma. *First Author: Yanyan Lou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Promising results in the treatment of NSCLC have been seen with agents targeting immune checkpoints, such as programmed cell death 1 (PD-1) or programmed cell death 1 ligand (PD-L1). However, only a select group of patients respond to these interventions. The identification of biomarkers that predict clinical benefit to immune checkpoint blockade is critical to successful clinical translation of these agents. Epithelial-mesenchymal transition (EMT) is a key process driving metastasis and drug resistance. Previously we have developed a robust EMT gene signature, highlighting differential patterns of drug responsiveness for epithelial and mesenchymal tumor cells. **Methods:** We conducted an integrated analysis of gene expression profiling from three independent large datasets, including The Cancer Genome Atlas (TCGA) of lung and two large datasets from MD Anderson Cancer Center, Profiling of Resistance patterns and Oncogenic Signaling Pathways in Evaluation of Cancers of the Thorax (PROSPECT) and the Biomarker-integrated Approaches of Targeted Therapy for Lung Cancer Elimination (BATTLE-1). Comprehensive analysis of mRNA gene expression, reverse phase protein array (RPPA), immunohistochemistry and in vivo mouse models were analyzed. **Results:** EMT is highly associated with an inflammatory tumor microenvironment in lung adenocarcinoma, independent of tumor mutational burden. We found immune activation co-existent with elevation of immune checkpoint molecules, including PD-L1, PD-L2, PD-1, TIM-3, BTLA and CTLA-4, along with increases in tumor infiltration by Foxp3+ regulatory T cells in lung adenocarcinomas that displayed an EMT phenotype. Similarly, IL-6 and indoleamine 2, 3-dioxygenase (IDO) were elevated in these tumors. Furthermore, we demonstrate that in murine models, many of these changes are recapitulated by modulation of the miR-200/ZEB1 axis, a known regulator of EMT. **Conclusions:** This study demonstrates EMT might represent a potential biomarker to select the patients who will benefit from immune checkpoint blockade agents and other immunotherapies in NSCLC and possibly other cancers.

3031 Poster Session (Board #357), Sat, 8:00 AM-11:30 AM

Exploratory analysis of clinical and translational factors associated with the inflamed phenotype in HNSCC. *First Author: Narendiran Rajasekaran, Center for Clinical Sciences Research Stanford, Stanford, CA*

Background: Immunotherapy with PD-1/PD-L1 axis blockade shows encouraging activity in head and neck squamous cell carcinoma (HNSCC). T-cell inflammation and gamma interferon driven gene expression patterns delineate a group of tumors that are most likely to benefit from anti-PD-1 therapy (Seiwert ASCO 2015, Keck CCR 2015). We examined two large, genetically annotated cohorts (TCGA & CHGC) in order to identify putative clinical and translational biomarkers that may predict benefit from anti-PD-1/anti-PD-L1 therapy in patients with HNSCC. **Methods:** 424 HNSCC tumors from the TCGA cohort were used to calculate a continuous score for tumor inflammation/inflamed mesenchymal phenotype (Keck CCR 2015). Respective scores were then correlated with available clinical, and translational characteristics. We used a second cohort, the Chicago Head and Neck Cancer Genomics cohort (CHGC) N = 132 for validation. In particular we focused on HPV status, tobacco use, anatomic site, stage, gender, race, and mutational burden for discovery of novel biomarkers/associations for HNSCC immunotherapy. **Results:** HPV status was moderately associated with inflamed phenotype in both cohorts (58/55) of HPV-positive tumors showed a high degree of inflammation, which only 30%/34% of HPV-negative tumors showed this. Smoking status, race, gender, anatomic site (controlling for HPV status), and stage did not correlate with the inflamed phenotype. The highest mutational burdens were seen in inflamed tumors, however correlation was weak. **Conclusions:** 'Inflamed phenotype' is a candidate predictive biomarker of clinical benefit from anti-PD-1 treatment and HPV status correlates with inflamed phenotype. In this study none of other the examined clinical or pathologic features including mutational burden demonstrated predictive characteristics of a therapeutic biomarker to PD-1/PD-L1 blockade.

3032 Poster Session (Board #358), Sat, 8:00 AM-11:30 AM

A phase I dose-escalation clinical trial of a peptide-based human papillomavirus therapeutic vaccine with *candida* skin test reagent as a novel vaccine adjuvant for treating women with biopsy-proven cervical intraepithelial neoplasia 2/3. *First Author: Mayumi Nakagawa, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Non-surgical treatments for cervical intraepithelial neoplasia 2/3 (CIN2/3) are needed as surgical treatments have been shown to double preterm delivery rate. An investigational human papillomavirus (HPV) therapeutic vaccine, PepCan, consists of four current good manufacturing production-grade peptides covering the HPV type 16 E6 protein and *Candida* skin test reagent as a novel adjuvant. **Methods:** The study was a single-arm, single-institution, dose-escalation Phase I clinical trial, and patients with biopsy-proven CIN2/3 were eligible for vaccination. Four injections were administered intradermally every 3 weeks in limbs, and loop electrical excision procedure (LEEP) was performed 12 weeks after the last injection for treatment and histological analysis. Six subjects were enrolled at each dose level, and dose escalation was allowed as long as less than two subjects demonstrated dose-limiting toxicities. **Results:** Six subjects at each of four dose levels (50, 100, 250, and 500 mcg per peptide) were accrued, and none of the subjects experienced any dose-limiting toxicities. The most common adverse events were injection site reactions. Vaccine-induced immune responses to E6 were detected in 65% of recipients (significantly in 43%), and systemic T-helper type 1 (Th1) cells were significantly increased after 4 vaccinations ($p = 0.02$). The best histological response was seen at the 50 mcg dose level with a regression rate of 83% (n = 6), and the overall rate was 52% (n = 23). **Conclusions:** PepCan has been shown to be safe, and able to induce HPV-specific immune responses and Th1 cells. *Candida*, which has been shown *in vitro* to induce interleukin-12 secretion, is likely responsible for the increased Th1 cells, and should be considered as a candidate adjuvant for other vaccines. A Phase II clinical trial to assess the full effect of PepCan is warranted using the 50 mcg per peptide dose. Clinical trial information: NCT00569231.

3033 Poster Session (Board #359), Sat, 8:00 AM-11:30 AM

Immunotoxin therapy in animal model of HuD antigen positive small cell lung cancer. *First Author: Bo Wang, Albert Einstein College of Medicine, New York, NY*

Background: Small cell lung cancer (SCLC) is a highly aggressive form of lung cancer. Most patients exhibit clinically detectable metastases at diagnosis and have an extremely poor prognosis despite combined modality therapy. HuD-antigen is a neuronal RNA-binding protein that is expressed in 100% of SCLC tumor cells. High levels of circulating anti-HuD antibodies in patients appear to be linked to spontaneous remission of their SCLC. This suggests that the HuD-antigen might be a potential molecular target for SCLC immunotargeting therapy. **Methods:** We constructed a new antibody-toxin compound (BW-2) comprised of mouse-anti-human-HuD mAb bound to saporin and tested the compound in vitro in the NCI-H69 SCLC cell line. In vivo SCLC experiments utilized male athymic nude mice (NCRNUM) xenografted with NCI-H69 cells. Tumor xenografted mice received a single intravenous or intratumoral injection of BW-2, while control tumor xenografted mice were treated with either anti-HuD antibody or saporin alone. Normal C57BL/6 mice were used to test for potential neurological side effects from BW-2. **Results:** In vitro experiments showed a high level of HuD+ tumor cell specific cytotoxicity in the presence of BW-2 immunotoxin and minimal HuD- cell cytotoxicity only at much higher concentrations of BW-2. Immunotoxin therapy in a nude mouse model of human SCLC demonstrated clear tumor shrinking while control tumor xenografted mice demonstrated rapid tumor volume expansion. Tumor volume in immunotoxin treated mice regressed for several weeks. Neurological testing revealed no manifestations of neurological disease in normal C57BL/6 mice even at doses of BW-2 as high as 10mg/kg. **Conclusions:** Our findings demonstrate in vitro and in vivo effectiveness of anti-HuD immunotoxin therapy for HuD+ SCLC. This approach to tumor antigen specific immunotargeting therapy may one day provide an additional treatment for SCLC.

3034 Poster Session (Board #360), Sat, 8:00 AM-11:30 AM

Results of the phase IIb part of TIME study evaluating TG4010 immunotherapy in stage IV non-small cell lung cancer (NSCLC) patients receiving first line chemotherapy. *First Author: Elisabeth A. Quoix, Hôpitaux Universitaires de Strasbourg, Strasbourg, France*

Background: TG4010 is an immunotherapy using an attenuated and modified poxvirus (MVA) coding for MUC1 and interleukin-2. A previous study showed that the baseline level of Triple Positive Activated Lymphocytes (TrPAL, CD16+CD56+CD69+) might be a predictive biomarker for TG4010 efficacy in NSCLC. **Methods:** TIME is a double blind, placebo-controlled phase IIb/III study. The phase IIb part compared first line chemotherapy combined with TG4010 or placebo and further assessed the predictive value of baseline level of TrPAL. Eligibility criteria included stage IV NSCLC not previously treated, MUC1+ tumor by immunohistochemistry (IHC), PS $\leq$ 1. TG4010 10^8pfu or placebo was given SC weekly for 6 weeks (w), then every 3w up to progression in immediate combination with chemotherapy. Primary endpoint was progression-free survival (PFS). **Results:** 222 patients (pts) were randomized 1:1. In pts with normal TrPAL the study met the primary endpoint of having a Bayesian probability for HR < 1 being $> 95\%$. PFS was significantly improved in the TG4010 arm in pts with low TrPAL (152 pts HR = 0.66 [CI95% 0.46-0.95] p = 0.013) while it was not the case in pts with high TrPAL (70 pts HR = 0.97 [CI 95% 0.55-1.73] p = 0.463). In addition, PFS was also significantly improved in pts with non-squamous tumors (196 pts HR = 0.69 [CI95% 0.51-0.94] p = 0.009) as well as in pts with non-squamous tumors and low TrPAL (131 pts HR = 0.61 [CI95% 0.42-0.89] p = 0.005). In this last group PFS at 9 months was 37% with TG4010 versus 18% with placebo. Overall survival (OS) data show an improvement in line with that observed for PFS and will be presented at the time of the meeting. Preliminary data on the effect of PDL1 expression by IHC in the tumor support the activity of TG4010 whether the tumor is positive or negative for PDL1 expression. Frequency and severity of adverse events were similar in both treatment arms. **Conclusions:** These results provide additional data supporting the efficacy of TG4010, particularly in patients with non-squamous tumors and/or a low level of TrPAL at baseline. The phase III part of the TIME study will continue in patients with non-squamous tumors and with OS as primary endpoint. Clinical trial information: NCT01383148.

3035 Poster Session (Board #361), Sat, 8:00 AM-11:30 AM

Comprehensive analysis of variation of tumor infiltrating lymphocytes during neoadjuvant chemotherapy in triple-negative breast cancer. *First Author: Carlos Castaneda Altamirano, Instituto Especializado De Enfermedades Neoplasicas, Lima, Peru*

Background: Tumor infiltrating lymphocytes(TIL) have a predictive and prognostic role in Triple Negative Breast Cancer (TNBC).There is little data regarding specific lympohcyte subsets. In this study we evaluated the association between clinicopathologic variables and TIL identified by either H&E (total TIL) or immunohistochemistry (TIL subsets) in TNBC patients receiving neoadjuvant chemotherapy (NAC). **Methods:** We evaluated stromal TIL in whole sections and in 5 HPF of a 0.6 cm tumor cylinder before and after NAC in a cohort of 100 TNBC patients. **Results:** Median age:49y,inflammatory(29%),pCR(30%),recurrences(42%),death(45%) and median follow-up(37.5m).TIL percentage by H&E is similar in the whole slide and in the 0.6 cylinder in post NAC homogeneous tumor(ICC = 0.731) but not in post NAC heterogeneous(ICC = 0.065) or preNAC tumor(ICC = 0.017). Quantitative counting and percentage calculating of TIL was significantly correlated in every subset(IHC):CD3,CD4,CD8 and FOXP3 in Pre(r:0.4982-0.6918,$p < 0.05$) and PostNAC(r:0.5387-0.7733,$p < 0.05$). The median percentage of total TIL in pre- and post-NAC specimens were 40 and 20%($p < 0.0001$), respectively. DFS $>$ 32 m and OS $>$ 41m are associated to higher preNAC TIL by H&E(40 vs 20%,p = 0,007)(40 vs 30%,p = 0.033). Media H&E TIL was not associated with age(40 vs 20%,p = 0.14), inflammatory features of pre-NAC(40 vs 35%,p = 0.64) or pCR in PostNAC samples(20 vs 20%,p = 0.63).TIL in PostNAC samples was not associated to DFS(p = 0.24) nor OS(p = 0.59).The CD4/CD3 ratio tend to be lower in pre-NAC samples with pCR(0.14 vs 0.24, p = 0.06) and lower in post-NAC samples with pCR(0.33 vs 0.07,p = 0.009).The CD8/CD4 ratio was higher in pre-NAC samples with pCR(2.75 vs 0.99,p = 003) and lower in post-NAC samples with pCR(2.09 vs 3.66,p = 0.008). **Conclusions:** TIL in PreNAC predicts pCR and Survival.TIL in 0.6 cm cylinder differs from whole slide and percentage correlates with absolute TIL calculation.CD4/CD3 and CD8/CD4 ratio evaluated by counting technique appears to predict pCR.

3036 Poster Session (Board #362), Sat, 8:00 AM-11:30 AM

Phase I/II study of tecemotide cancer immunotherapy for Japanese patients with unresectable stage III non-small cell lung cancer (NSCLC). *First Author: Hiroshi Nokihara, National Cancer Center Hospital, Tokyo, Japan*

Background: Tecemotide is a MUC1 antigen-specific cancer immunotherapy. We report results from a phase I/II study of tecemotide in Japanese patients (pts) with no disease progression (PD) after primary chemoradiotherapy (CRT) for stage III NSCLC. **Methods:** The phase II part of the study evaluated efficacy using the treatment schedule and dose confirmed in the phase I part. Eligible pts had unresectable stage III NSCLC with no PD after CRT (platinum-based chemotherapy and ≥ 50 Gy radiotherapy). In the phase II part, pts were randomized (2:1, double-blind) to tecemotide (930ug lipopeptide) or placebo (PBO) via subcutaneous administration weekly x8 then q6 weeks until PD or withdrawal. Cyclophosphamide 300–600mg/m^2 x1 or saline was given 3 days before first tecemotide or PBO dose, respectively. The primary endpoint was overall survival (OS). **Results:** A total of 172 pts were enrolled in the phase II part from Feb 2010 to Feb 2012, with 114 randomized to tecemotide and 58 to PBO. In the ITT population, baseline characteristics were well balanced between both arms. The majority (94%) of pts received concurrent CRT. Median OS was 32.4 vs 32.2 months with tecemotide vs PBO (HR 0.95, 95% CI 0.61–1.48, p = 0.828). Secondary endpoints were progression-free survival: 11.6 vs 8.0 months (HR 0.95, 95% CI 0.66–1.37, p = 0.773); time to progression: 11.3 vs 7.0 months (HR 0.94, 95% CI 0.65–1.35, p = 0.723); time to treatment failure: 8.0 vs 6.2 months (HR 1.07, 95% CI 0.75–1.54; p = 0.700). A predefined subgroup analysis showed no OS improvement with tecemotide vs PBO in the subgroups examined. Tecemotide was associated with a higher incidence of grade 3/4 adverse events vs PBO, but no new safety concerns were identified. No treatment-related grade 3/4 injection site reactions were detected. **Conclusions:** In this study, the design of which was comparable to the global phase III START trial, tecemotide maintenance therapy did not improve OS compared with PBO in Japanese patients with stage III NSCLC; in addition, no improvement in secondary endpoints was observed. Tecemotide was well tolerated, with no clinically relevant increase in adverse events. Clinical trial information: NCT00960115.

3037 Poster Session (Board #363), Sat, 8:00 AM-11:30 AM

Pharmacokinetics and myeloid effector cell engagement of an engineered IgA antibody against the epidermal growth factor receptor. *First Author: Thomas Valerius, Division of Stem Cell Transplantation and Immunotherapy, 2nd Department of Medicine, Kiel, Germany*

Background: IgA antibodies play an important role in bridging adaptive and innate immunity. There is increasing evidence that FcαRI-dependent engagement of myeloid cells appears to be crucial to activate mechanisms like phagocytosis or antibody-dependent cell-mediated cytotoxicity and that myeloid cells constitute important effector cells in cancer and cancer immunotherapy. Here, we describe an Fc engineering approach to further improve the immunotherapeutic potential of IgA antibodies. **Methods:** Recombinant IgA antibodies against the epidermal growth factor receptor (EGFR) were produced by co-transfecting CHO-K1 cells with vectors encoding the 225 variable and Igα heavy and κ light chain constant regions, respectively. An Fc engineered IgA2 antibody was generated by mutating two N-glycosylation sites and by removing two free cysteines. The resulting antibody was compared to wild type IgA2 regarding biochemical characteristics as well as Fab and Fc-mediated effector functions. Additionally, serum half-life and in vivo efficacy in a xenogeneic FcαRI-transgenic tumor model were evaluated. **Results:** Rational engineering of an IgA2 antibody resulted in monomeric molecules with improved biochemical characteristics, identical Fab- and Fc- mediated effector functions, but with significantly lower levels of terminal galactose. This molecule demonstrated lower asialoglycoprotein-receptor (ASGPR) binding and subsequently improved pharmacokinetics in mice. Compared to wild type IgA, this novel molecule displayed enhanced therapeutic efficacy against A431 tumor cells in vivo, which required human FcαRI-dependent myeloid effector cell engagement. **Conclusions:** These results demonstrate that an Fc engineered IgA antibody against EGFR displayed improved immunotherapeutic efficacy, which may overcome limitations (stability, pharmacokinetics, in vivo efficacy) of wild type IgA antibodies. Thus, these results promote the concept of FcαRI-dependent engagement of myeloid effector cells as a promising approach for antibody-based tumor immunotherapy.

3038 Poster Session (Board #364), Sat, 8:00 AM-11:30 AM

Antibody dependent cellular cytotoxicity activity of a novel anti-PD-L1 antibody, avelumab (MSB0010718C), on human tumor cells. *First Author: Kwong-Yok Tsang, Laboratory of Tumor Immunology and Biology, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. In addition to disruption of immune suppressive signaling induced by the binding of PD-L1 on tumor cells with PD-1 on tumor infiltrating immune cells, avelumab was designed to mediate antibody dependent cellular cytotoxicity (ADCC). Other anti-PD-1/anti-PD-L1 monoclonal antibodies (mAbs) undergoing clinical evaluation are either of the IgG1 isotype and modified to remove ADCC activity or of the IgG4 isotype, which does not mediate ADCC. We present data from preclinical studies examining the ability of avelumab to induce ADCC and factors affecting tumor cell sensitivity to this mechanism. **Methods:** The ability of avelumab to induce lysis of human carcinoma cells was assessed using whole peripheral blood mononuclear cells (PBMCs) or purified natural killer (NK) cells as effectors. PD-L1 expression was reported as % positive tumor cells and mean fluorescence intensity (MFI) as determined by flow cytometry. **Results:** Using PBMCs as effectors, avelumab induced ADCC in 8/18 human carcinoma cell lines; tumor cell lysis positively correlated with the percentage of PD-L1 positive tumor cells and PD-L1 MFI. Lysis was increased when NK cells were used as effectors. Pretreating tumor cell lines with IFN-γ increased PD-L1 expression, but augmented lysis in only 4/10 cell lines. Preactivating NK cells with IL-12, however, increased lysis, suggesting a potential for synergy by combining avelumab with IL-12–based therapy. Little or no lysis was observed in NK-mediated ADCC assays vs whole PBMCs or dendritic cells isolated from PBMCs. A tumor cell line insensitive to lysis by CD8$^+$T cells was lysed by ADCC using NK cells and avelumab. **Conclusions:** Avelumab induced lysis of many human tumor cell lines via ADCC. Further clinical trials are necessary to determine whether the additional mechanism of inducing tumor lysis by ADCC will result in enhanced clinical activity compared with similar agents without ADCC activity.

3039 Poster Session (Board #365), Sat, 8:00 AM-11:30 AM

Phase I study to evaluate the safety and tolerability of MEDI4736, an anti-programmed cell death ligand-1 (PD-L1) antibody, in Japanese patients with advanced solid tumors. *First Author: Haruo Iguchi, Clinical Research Institute, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan*

Background: Immune-suppressing molecules can be exploited by tumor cells to suppress immune responses to cancer. Programmed cell death-1 (PD-1) is an inhibitory regulator of T-cell activation. The ligand to PD-1, PD-L1, is upregulated in several tumor types. MEDI4736 is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity. **Methods:** This Phase 1, multicenter, open-label study (NCT01938612) is evaluating the safety, PK, and clinical activity of MEDI4736 in Japanese patients (pts) with advanced solid tumors. Pts (≥ 20 years) with ECOG performance status 0–1 who are refractory or intolerant to standard treatment or for whom no standard treatment exists are eligible. MEDI4736 was given IV every 2, 3, or 4 wks (q2/3/4w) using a 3+3 dose escalation, followed by a dose-expansion phase that includes further pts at or below the maximum tolerated dose. Treatment continues for up to 12 months; retreatment is possible upon progression after 12 months. Disease response was assessed by RECIST v1.1. **Results:** As of 27 November 2014, 22 pts were enrolled across 5 dose levels. Drug-related adverse events (AEs) ≥ Grade (G) 2 were pneumonitis (G2; 3 mg/kg q2w), oral stomatitis (G2; 3 mg/kg q2w), constipation (G2; 3 mg/kg q2w), hypothyroidism (G2; 15 mg/kg q3w), eruption (G2, 20 mg/kg q4w), skin atheroma (G2, 1 mg/kg q2w), mucositis (G2; 3 mg/kg q2w), and serum-free triiodothyronine decreased (FT3; G3; 10 mg/kg q2w); all n = 1. There were no G4 drug-related AEs. G2 pneumonitis and G3 low serum FT3 were considered serious drug-related AEs. 1 pt discontinued due to an AE; G1 pneumonitis. No drug-related deaths or dose-limiting toxicities (DLTs) were reported. Of 19 evaluable pts with ≥ 1 post-baseline CT assessment, 1 pt (10 mg/kg q2w) had a partial response, and 6 pts had stable disease (n = 2 at 1 mg/kg q2w, and n = 1 each at 3 mg/kg q2w, 10 mg/kg q2w, 15 mg/kg q3w, and 20 mg/kg q4w). **Conclusions:** Initial results indicate no DLTs, 7 G2- and 1 G3-related AEs, and clinical activity for MEDI4736 in Japanese pts with advanced solid tumors. Based on these data, an expansion phase, including biliary tract cancer, SCCHN, and esophageal tumors, is underway. Clinical trial information: NCT01938612.

3040 Poster Session (Board #366), Sat, 8:00 AM-11:30 AM

Strategies for clinical development of monoclonal antibodies beyond first-in-man trials: Tested doses and rationale for dose selection. *First Author: Marie Vinches, Institut régional du Cancer de Montpellier - Val d'Aurelle, Montpellier, France*

Background: We conducted a comprehensive survey (*J. Clin. Oncol.*, in press) on the design, implementation and outcome of first-in-human trials (FIHT) of monoclonal antibodies (mAbs) over the last decade. We showed that, due to the limited observed toxicity, the maximum tolerated dose was infrequently reached and therefore the recommended phase II dose (RP2D) for subsequent clinical trials was only tentatively defined. **Methods:** In order to evaluate strategies of mAb development beyond FIHT, we performed a MEDLINE search to identify articles reporting single agent trials of mAbs whose FIHT was published between April 1, 2003 and April 1, 2013. For each mAb, we examined the doses tested in these non-FIH trials (NFIHT) with regard to the corresponding FIHT results, as well as the rationale for dose selection in NFIHT. **Results:** Sixty-nine NFIHT of 36 mAbs were selected for analysis, of which 30 were phase I, 37 phase II and 2 phase III trials. For each mAb, the number of trials ranged from 1 to 8. In phase I NFIHT, the maximum administered dose (MAD) coincided with the FIHT MAD for the tested mAb in 12 cases (40%), and the ratio between the NFIHT and FIHT MAD ranged from 0.28 to 2. An RP2D was indicated in only 14 phase I NFIHT (47%) and coincided with the FIHT RP2D or MAD for the tested mAb in 2 and 8 trials, respectively. The ratio between the phase I NFIHT RP2D and the FIHT RP2D or MAD ranged from 0.33 to 2 and from 0.28 to 2, respectively. While a FIHT RP2D was available for the tested mAb in 22 phase II-III NFIHT (56%), the dose actually administered was the FIHT RP2D in only 11 trials (28%) and the FIHT MAD in 12 other trials (31%). In the 16 phase II-III NFIHT (41%) in which the tested dose was different from FIHT RP2D or MAD, a rationale for dose selection was indicated in few cases, reporting former pharmacokinetics data (4 trials) or safety issues (1 trial). **Conclusions:** The RP2D and the MAD determined in FIHT is infrequently used in the subsequent clinical development of mAbs. The rationale beyond dose selection in phase II and III trials of mAbs is often unclear in published papers, a fact that represents a weakness in the development of this class of drugs, and may lead to wrong-dosing.

3041 Poster Session (Board #367), Sat, 8:00 AM-11:30 AM

Adoptive immunotherapy of acute myeloid leukemia (AML) with allogenic CAR t-cells targeting CD123. *First Author: Roman Galetto, Cellectis, Paris, France*

Background: Chimeric antigen receptor (CAR)-redirected T-cells have given rise to long-term durable remissions and remarkable objective response rates in patients with refractory leukemia, raising hopes that a wider application of CAR technology may lead to a new paradigm in cancer treatment. A limitation of the current autologous approach is that CAR T-cells must be manufactured on a "per patient basis". We have developed a standardized platform for manufacturing T-cells from third-party healthy donors to generate allogeneic "off-the-shelf" engineered CAR+ T-cell–based frozen products. **Methods:** Allogeneic CAR+ T cell products have been generated using Transcription Activator-Like Effector Nuclease (TALEN) gene editing technology to inactivate the TCRa constant (TRAC) gene, eliminating the potential for T-cells bearing alloreactive TCR's to mediate Graft versus Host Disease (GvHD). Editing of the TRAC gene can be achieved at high frequencies, up to 80% of TCRab negative cells. This allows the efficient production of TCR-deficient T-cells that no longer mediate alloreactivity in a xeno-GvHD mouse model. In addition, T-cells are engineered to co-express the RQR8 gene as a safety feature, with the aim of rendering them sensitive to the monoclonal antibody rituximab. **Results:** In this work we present the adaptation of this allogeneic platform to the production of T cells targeting CD123, the transmembrane alpha chain of the interleukin-3 receptor, which is expressed on tumor cells in patients with Acute Myeloid Leukemia (AML). To identify an effective CAR, we have screened multiple antigen recognition domains in the context of different CAR architectures to identify candidates displaying activity against cells expressing variable levels of the CD123 antigen. Furthermore, experiments in an orthotopic AML mouse model using UCART123 cells demonstrate important anti-tumor activity *in vivo*. **Conclusions:** The ability to carry out large scale manufacturing of allogeneic, non alloreactive CD123 specific T-cells from a single healthy donor can offer the possibility of an off-the-shelf treatment that would be immediately available for administration to a large number of AML patients.

3042 Poster Session (Board #368), Sat, 8:00 AM-11:30 AM

Tremelimumab, a fully human anti-CTLA-4 monoclonal antibody, optimal dosing regimen for patients with unresectable malignant mesothelioma (MM). *First Author: Rajesh Narwal, MedImmune, Gaithersburg, MD*

Background: Tremelimumab (T) is a selective human IgG2 mAb inhibitor of CTLA-4 that promotes T-cell activity though CTLA-4 inhibition. The primary objective of this analysis was to project the optimal T dosing regimen for a Phase (Ph) 2b study in MM. **Methods:** Retrospective population PK (N = 654; Ph 1–3; 0.01 to 15 mg/kg single dose/Q90D/Q4W) and exposure-OS (N = 293; Ph3; 15 mg/kg Q90D) analyses were performed using data from metastatic melanoma studies (A3671001/NCT00086489/NCT00254579/NCT00257205). PK (N = 40) and efficacy (N = 58) data were collected from a Ph2 study of T (NCT01649024/NCT01655888) following 2 dosing regimens: 15 mg/kg Q90D and 10 mg/kg Q4W. Modeling and simulations were performed in NONMEM and CTS software. **Results:** PK profiles were adequately described in the population model, resulting in parameters similar to a typical mAb with modest variability and indicating no need for dose adjustments. The exposure-OS analysis of a Ph3 study in melanoma showed better OS in patients with higher exposure compared to lower exposure (mOS of 18.4 vs 9 months). T did show clinical benefit in the Ph3 melanoma study; however, the primary endpoint was not met. One potential reason could be the sub-optimal dose of 15 mg/kg Q90D. Following 15 mg/kg Q90D, exposure was below the target trough level of ~30 μg/mL for about half of the dosing interval, with almost all patients below the LLOQ at the end of dosing interval. PK simulations indicated more frequent dosing of 10 mg/kg Q4W could maintain exposure at or above the target trough level in > 90% patients over the entire dosing interval and could yield higher OS. Based on these evaluations, a 10 mg/kg Q4W regimen extension arm was added in an ongoing ISS study exploring 15 mg/kg Q90D. Data from this ISS study confirmed similar PK for both schedules in melanoma and MM. A 10 mg/kg Q4W dose yielded higher exposure and could be associated with better clinical outcome in MM. The dosing regimen of 10 mg/kg Q4W for 6 months followed by 10 mg/kg Q12W is currently being tested. **Conclusions:** An optimal dosing regimen of 10 mg/kg Q4W T was identified based on integrated data analysis. This dosing regimen is currently being evaluated in an ongoing Ph2b study in MM. Clinical trial information: A3671001/NCT00086489/NCT00254579/NCT00257205/NCT01649024/NCT01655888.

3043 Poster Session (Board #369), Sat, 8:00 AM-11:30 AM

T-cell therapy in metastatic melanoma: TIL 1383I TCR transduced T cells after infusion and activity in vivo. *First Author: Courtney Regan, Loyola University Medical Center, Maywood, IL*

Background: Studies in adoptive T-cell transfer have suggested that persistence of the transduced T-cells is central to the viability of this therapeutic option. The objectives of this phase I clinical trial using TCR TIL 1383I transduced T cells in stage IV melanoma patients include measuring of persistence and monitoring the behavior of tumor-reactive T-cells in vivo. **Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from three melanoma patients, activated with anti-hCD3 with rhIL2 and rhIL15, transduced with lentivirus encoding the TIL 1383I TCR, and expanded to treatment numbers. The transduced cells were suspended in 5% human albumin and infused over 30 minutes. The infusion was preceded by lymphodepletion with fludarabine and cyclophosphamide and followed with low dose IL-2 for one week. A modified CD34 cassette in the vector enabled monitoring of the transduced T cells in the patient's PBMC post-infusion. PBMCs were collected from patients on days 1, 3, 5, 7, 14, 25, 35 and monthly up to 3 months and then every 1-3 months as clinically indicated. The presence of transduced T-cells at each time point was measured by staining with anti-CD34 mAb and analyzed using a BD LSRFortessa flow cytometer. **Results:** Transduced T-cells were detected in the blood of all three patients post infusion. Clinical activity was demonstrated in two patients – one in the form of tumor shrinkage and another with development of progressive vitiligo. **Conclusions:** Previous studies with TIL suggest better T-cell engraftment, persistence, and therapeutic efficacy with homeostatic proliferation after lymphodepletion. Out results confirm that the infused TIL 1383I TCR transduced T-cells could be detected up to 6 months after infusion and demonstrate activity. Clinical trial information: NCT01586403.

3044 Poster Session (Board #370), Sat, 8:00 AM-11:30 AM

Avelumab (MSB0010718C), an anti-PD-L1 antibody, in patients with metastatic or locally advanced solid tumors: assessment of safety and tolerability in a phase I, open-label expansion study. *First Author: Karen Kelly, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. The primary objective of this phase I, open-label, parallel-group expansion study (NCT01772004) was to assess the safety and tolerability of avelumab in patients (pts) with metastatic or locally advanced solid tumors. **Methods:** Pts with advanced or metastatic disease (including NSCLC, gastric, ovarian, breast, and melanoma; ECOG PS 0-1 at trial entry) were treated with avelumab at 10 mg/kg Q2W until confirmed complete response (CR), progression, unacceptable toxicity, or withdrawal. Adverse events (AEs) were evaluated by CTCAE v4.0. **Results:** In total, 480 pts treated with avelumab were followed-up for at least 4 weeks (wks) by Nov 5, 2014 and assessed in this interim analysis (median age, 60 years [range 29-85]; ECOG PS 0 [40.6%], 1 [59.0%], 3 [0.2%], or unknown [0.2%]; median of 2 prior treatments [range 1-≥ 4]). Drug-related treatment-emergent AEs (TEAEs; all grades) occurred in 68.8% of pts, with the most frequent being fatigue (20.2%), nausea (12.9%), infusion-related reaction (IRR) (9.8%), diarrhea (6.9%), chills (6.9%), decreased appetite (6.3%), pyrexia (5.6%), influenza-like illness (5.2%), and arthralgia (5.0%). Drug-related TEAEs resulted in treatment discontinuation in 34 pts; of these, 8 were due to an IRR. Drug-related grade ≥ 3 TEAEs were reported in 12.3% (n = 59); the most common of these were anemia (5), fatigue (5), increased GGT (4), IRR (4), increased lipase (4), and decreased lymphocytes (3). AEs that were potentially immune-related were observed in 11.7% of pts, with the most common being hypothyroidism (4.0%) and pneumonitis (1.5%). **Conclusions:** Avelumab demonstrated an acceptable safety profile in a heavily pretreated population across a range of tumor types. Development of avelumab as a monotherapy and in combination is ongoing. *Proposed INN. Clinical trial information: NCT01772004.

3045 Poster Session (Board #371), Sat, 8:00 AM-11:30 AM

A phase II study of novel three peptides combination with gemcitabine as a first-line therapy for advanced pancreatic cancer (VENUS-PC study). *First Author: Hiroaki Tanaka, Department of Surgical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan*

Background: The novel HLA-A*2402-binding peptides derived from KIF20A (RAB6KIFL) belong to the kinesin superfamily of motor proteins, which play critical roles in the trafficking of molecules and organelles during the growth of pancreatic cancer. A phase I cancer vaccination trial using KIF20A determined its safety and immunogenicity in advanced pancreatic cancer (PC) patients (J Immunother 2014;37:36-42). We further performed a phase II trial using not only KIF20A but also an antiangiogenic cancer vaccine targeting VEGFR1 (vascular endothelial growth factor receptor 1) and VEGFR2. This revealed the safety and immunogenicity in advanced colorectal cancer as presented at the 2011 ASCO Oral Abstract Session (J Transl Med. 2014; 12:63). We try to evaluate the benefit of the cancer vaccination in combination with gemcitabine (GEM) as first-line therapy in advanced PC patients. **Methods:** Sixty-eight chemotherapy naïve PC patients were enrolled to evaluate primarily the one year survival rate, and secondarily overall survival. Each of the three peptides was mixed with 1ml of Incomplete Freund's adjuvant and subcutaneously administered weekly. GEM was administered at a dose of 1000 mg/m^2 on days 1, 8, and 15 in a 28-day cycle. All enrolled patients received the therapy without knowing the HLA-A status, and the HLA genotypes were revealed at analysis point and then, the endpoints were evaluated between the HLA-A*2402 positive and HLA-A*2402 negative group. **Results:** Between June 2012 and May 2013, a total of 68 patients were enrolled in this study. No severe adverse effects of grade 3 or higher related to these three peptides were observed. The one year survival rate was 30.3%. Median survival time was 9.2months. Response rate was 11.8% and disease control rate was 73.5%, respectively. The HLA genotype will be revealed in March 2015 and the endpoints compared between HLA-A*2402 positive and negative group will be presented at this meeting. **Conclusions:** These results suggest that this combination therapy will be feasible and promising for the treatment of advanced pancreatic cancer. Clinical trial information: UMIN000008082.

3046 Poster Session (Board #372), Sat, 8:00 AM-11:30 AM

Effect of denileukin diftitox (DD) on vaccine-induced T-cell responses and depletion of Tregs in melanoma. *First Author: Jason John Luke, University of Chicago, Chicago, IL*

Background: Depletion of CD25+ Tregs improves anti-tumor immunity in preclinical models. DD is a recombinant fusion protein of hIL-2 and diptheria toxin fragment that also kills CD25+ T cells. Prior clinical trials of DD suggested reduction of FoxP3+ Tregs, improved immune responses, and some clinical responses. We evaluated the effect of DD prior to vaccination in patients (pts) with metastatic melanoma. **Methods:** Pts were randomized to 4-peptide vaccine (250 mcg of Melan-A, gp100, MAGE3 and NA17 with GM-CSF 125 mcg emulsified in Montanide) alone or after single dose of DD (18 mcg/kg). Vaccine was given every 2 weeks for 3 doses and absent progression continued every 2 weeks. Toxicity was evaluated by CTCAE and response by RECIST. Pts were HLA-A2+ with stage IIIC/IV melanoma. Any prior therapy, standard biochemical parameters and no history of autoimmunity were allowed. Blood and tissue biopsy (when possible) were obtained pretreatment and after 3 vaccinations for immunologic assessments. **Results:** 17 pts were enrolled (7 receiving DD, 41%). Characteristics included (median) age:63, M:14; ECOG:1; cutaneous: mucosal (15:2), M status A:B:C% (6:29:65), pretreated 83%. There were no drug-related G3-4 adverse events. 9 pts (4 DD: 5 vaccine only) showed clinical benefit (1 PR, 8 SD). Time to progression was 4.9 months for DD, 4.4 mo for non-DD. Flow cytometry showed that DD did not affect total Tregs in peripheral blood (p = 0.76). ELISPOT assays revealed that in some pts peptide vaccination augments the number of Ag-specific CD8 T cells in the blood but DD did not increase Ag-specific CD8 T cell response. On-treatment biopsy from DD and non-DD treated pts showed no depletion of intratumoral Foxp3+ T cells by RT-PCR. ELISA for IL2R-alpha demonstrated that outcomes were not impacted by soluble CD25 level (p = 0.13). **Conclusions:** In contrast with previous studies,DD did not effectively deplete Tregs, augment T cell responses or improve clinical activity in pts with melanoma. Clinical trial information: NCT00515528.

3047 Poster Session (Board #373), Sat, 8:00 AM-11:30 AM

Safety and tolerability results from a phase I study of MEDI4736, a human IgG1 anti-programmed cell death-ligand-1 (PD-L1) antibody, combined with gefitinib in patients (pts) with non-small-cell lung cancer (NSCLC). *First Author: Ben C. Creelan, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: MEDI4736 is a human IgG1 monoclonal antibody which blocks PD-L1 binding to PD-1 and CD-80 with high affinity and selectivity. A Phase I open-label multicenter study was initiated to evaluate MEDI4736 combined with the EGFR tyrosine kinase inhibitor (TKI) gefitinib in NSCLC (NCT02088112). Dose escalation phase data are reported. **Methods**: Key eligibility criteria included: locally advanced/metastatic NSCLC of any *EGFR* mutation status, relapsed/refractory/intolerant of standard treatment; ≤ 4 prior therapies. Cohort A received MEDI4736 3 mg/kg (starting dose) every 2 weeks plus gefitinib 250 mg once-daily (QD). If no dose-limiting toxicities were observed, Cohort B received MEDI4736 at a higher dose of 10 mg/kg every two weeks plus gefitinib 250 mg QD. Primary endpoint: safety/tolerability and recommended dose of the MEDI4736 plus gefitinib combination. Secondary endpoints included: tumor response (RECIST 1.1); pharmacokinetics (PK); immunogenicity. **Results**: Of 10 pts (Cohort A = 3; Cohort B = 7): 4 male; 4 Asian; median age 58.5 years. Maximum tolerated dose was not reached, and no dose limiting toxicities were observed. Adverse events (AEs) were observed in all pts; treatment-related CTC Grade 3-4 AEs in 3 pts led to study discontinuation: dyspnea/hypoxia (Cohort A; 1 pt), myalgia/fatigue and elevated ALT (Cohort B; 1 pt each). These AEs resolved upon discontinuation and standard management guidelines. Two unrelated deaths occurred in Cohort B. No PK interactions were observed nor anti-drug antibodies detected with the drug combination. Of 7 pts with ≥ 1 8-week tumor assessment; 3 pts had reduction in tumor size (Cohort A = 2; Cohort B = 1). **Conclusions**: MEDI4736 (3 and 10 mg/kg) plus gefitinib was generally well tolerated in pts with NSCLC in the escalation phase, with early clinical activity observed in these heavily pre-treated pts. Preliminary data support continued evaluation of MEDI4736 10 mg/kg with gefitinib 250 mg as the recommended expansion phase dose in pts with *EGFR* sensitized mutation-positive/TKI naïve NSCLC. **Sponsored by MedImmune, global biologics R&D arm of AstraZeneca** Clinical trial information: NCT02088112.

3048 Poster Session (Board #374), Sat, 8:00 AM-11:30 AM

Phase II randomized trial of autologous tumor lysate dendritic cell vaccine (ADC) plus best supportive care (BSC) compared with BSC, in pre-treated advanced colorectal cancer patients. *First Author: Joan Maurel, Hospital Clinic, Barcelona, Spain*

Background: No treatments are available for patients (pts) with metastatic colorectal cancer (mCRC) that progresses after all approved therapies. Autologous tumor lysate dendritic cell vaccine (ADC) has T-cell stimulatory capacity and therefore potential antitumor activity. We designed a phase II randomized trial of ADC plus BSC (arm A) compared with BSC (arm B), in pre-treated mCRC patients. **Methods:** Pts with documented mCRC and progressive disease at least to two chemotherapy regimens and ECOG performance status (PS) of 0-2, were randomized (1:1 ratio) to arm A vs B. Stratification was done by ECOG PS (0,1 vs 2) and LDH ($<$ ULN vs $>$ ULN). Arm A was administered subcutaneously days 0,10,20,40,120 and thereafter every 6 months (m) till progressive disease (PD). Radiological evaluation was planned with multidetector computed tomography (MDCT) every 2 m the first 6 m and then every 3 m till PD in both arms. Primary endpoint was progression free rate (PFR) at 4 m. Accordingly, sample size was established in 76 pts to detect differences at month 4 in the PFR of $>$ 30% (40% in the ADC arm and 10% in BSC arm) with an a error = 0.05 and a power = 0.8. **Results:** From 08/2011 to 10/2013, 61 pts were screened and 52 pts were included (28 arm A and 24 arm B). An interim analysis recommended early termination for futility. Pts characteristics were well balanced between arms. No ADC-related adverse events were reported. Immunization induces an autologous tumor-specific T-cell response in 21 of 25 (84%) treated pts. Pts with evidence of a vaccine-induced, tumor-specific immune response has a markedly higher overall survival than non-responders (220 days (d) versus 113d); p = 0.026). No objective radiological response was observed in ADC arm. Median PFS and 4 m PFR in arm A was 2.7 m (95%CI 2.3-3.2m) and 15% vs 2.3 m (95%CI 2.1-2.5m) and 21% in arm B (p = 0.628). Median overall survival was 6.2m (95%CI 4.4-7.9m) in arm A vs 4.7m (95%CI 2.3-7m) in arm B (p = 0.41). **Conclusions:** Our trial, the first randomized clinical trial comparing ADC plus BSC vs BSC in mCRC, demonstrates that ADC generates a tumor-specific immune response, but not benefit on PFR, PFS and OS compared with BSC. Clinical trial information: NCT01413295.

3049 Poster Session (Board #375), Sat, 8:00 AM-11:30 AM

A subgroup with improved overall survival from the phase 2 IMPACT study: Maintenance therapy of metastatic colorectal cancer patients with the TLR-9 agonist MGN1703. *First Author: Jorge Riera-Knorrenschild, Universitätsklinikum Giessen und Marburg, Marburg, Germany*

Background: The double-blind placebo-controlled phase 2 IMPACT trial aimed to assess the clinical efficacy, safety, and immunological effects of the potent TLR9 agonist MGN1703, given at the dose of 60 mg subcutaneously twice weekly as switch maintenance after disease control due to first-line induction chemotherapy +/- bevacizumab in patients with metastatic colorectal cancer (mCRC). **Methods:** After randomization of 59 patients the trial was prematurely closed and final analysis showed a superior effect of MGN1703 compared to placebo with hazard ratios (HR) for the primary endpoint PFS on maintenance of 0.55 (p = 0.041) and 0.56 (p = 0.070) by local investigator assessment or independent radiological review, respectively. Exploratory PFS analyses of pretreatment characteristics identified patients with normalized CEA, objective response, and the presence of activated NKT cells at the end of induction chemotherapy to benefit the most from maintenance with MGN1703. The impact of these factors on the secondary endpoint overall survival (OS) is presented here. **Results:** OS data were not mature at time of final study analysis, since only 35% of MGN1703 patients and 50% of placebo patients had an event. The HR for OS of the whole study population was 0.63 (median 22.6 vs. 15.1 months). The subgroup of patients randomized into the study with confirmed RECIST response had a HR of 0.40 (median 24.5 vs. 15.1 months), suggesting this may be the population with greater benefit. HR for patients with normalized CEA or with activated NKT cells were 0.69 and 0.43, respectively. Based on this evidence, patients with mCRC and objective response after standard induction therapy are randomized in the phase 3 IMPALA study to standard treatment or switch maintenance with MGN1703. CEA and activated NKT cells are stratification factors for the study and will be prospectively assessed. **Conclusions:** The pretreatment characteristics predictive of a PFS benefit in the IMPACT study seem to retain their value also in exploratory analyses for OS. This information has been used to design the phase 3 IMPALA study, currently recruiting patients. Clinical trial information: NCT01208194.

3050 Poster Session (Board #376), Sat, 8:00 AM-11:30 AM

CD137 co-stimulation and blocking PD-1 enhances NK cell-mediated target cell lysis by CD30/CD16A TandAb AFM13. *First Author: Xing Zhao, Tissue Engineering and Stem Cells Research Center, Department of Immunology, Guiyang Medical University, Guiyang, China*

Background: The CD30/CD16A bispecific tetravalent TandAb antibody AFM13 recruits and activates NK cells by specific binding to CD16A for targeted lysis of $CD30^+$ tumor cells. Given promising clinical activity and safety profile of AFM13 and proof-of-mechanism demonstrating dependence on the immune response, potential synergy of AFM13 and checkpoint inhibitors was evaluated. **Methods:** Efficacy was assessed by in vitro cytotoxicity with human PBMCs, enriched NKs, and $CD30^+$ target cells as well as cell line and patient-derived xenograft in vivo models with AFM13, anti-CTLA-4, anti-PD-1, or anti-CD137 antibodies. **Results:** AFM13 demonstrated higher potency and efficacy toward target and effector cells relative to other $CD30^+$ antibody formats (EC50 = 15pM). These favorable properties resulted in superior cytotoxicity when AFM13 was incubated with $CD30^+$ tumor cells and enriched NK cells. Single treatment with AFM13 at suboptimal concentrations (1 pM) induced effector-to-target cell-dependent lysis of $CD30^+$ lymphoma cells up to 40% using enriched NK cells. Immune-modulating antibodies alone mediated substantially lower lysis ($<$ 25%). However, the addition of anti-PD-1 or anti-CD137 to AFM13 strongly enhanced specific lysis up to 70%, whereas the addition of anti-CTLA-4 to AFM13 showed no beneficial effect. The most impressive increase of efficacy was observed when AFM13 was applied together with a combination of anti-PD-1 and anti-CD137. In vivo, synergy of AFM13 and CPI combination was observed with each CPI tested and augmented with anti-PD1 (regression in 9/10 tumors), ant-CTLA-4 (3/10), and anti-CD137 mAb (3/10) and influenced by presence of regulatory T cells, NK cells, and Th1 cytokines. **Conclusions:** Our findings support engagement of NK cells using CD30/CD16A TandAbs by binding to CD16A does not completely exploit the efficacy of NK cells. Therefore combination trials performed with companion intratumoral assessment may personalize dual-Ab therapy and augment the efficacy of AFM13 and CPIs.

3051 Poster Session (Board #377), Sat, 8:00 AM-11:30 AM

Long term survival in IMAGE 1 (Immune Modulation And Gemcitabine Evaluation 1), a randomized, open-label phase II trial comparing gemcitabine with and without IMM-101 in advanced pancreatic cancer. *First Author: Angus George Dalgleish, St. George's University of London, London, United Kingdom*

Background: Immunotherapy may produce durable responses in some patients. IMM-101, a systemic immunomodulator containing heat-killed *Mycobacterium obuense* (NCTC13365), can be combined with various forms of chemotherapy and has shown survival benefits in cancer patients. **Methods:** In IMAGE 1, survival, safety and tolerability were assessed in advanced pancreatic cancer patients (n = 110) with a WHO score of 0-2 receiving IMM-101 (0.1 mL, 10 mg/mL intradermally) + Gemcitabine (Gem) (1000 mg/m^2 q7d3) (n = 75) or Gem alone (n = 35) for a 12-cycle maximum. Patients who completed IMAGE 1 were invited to enter a follow-up study to monitor long term survival, and received IMM-101 and, at the investigator's discretion, adjunctive chemotherapy. **Results:** As previously reported, IMM-101 was associated with clinically meaningful increases in OS and PFS, with no additional burden of adverse events above those relating to chemotherapy or the underlying disease. Patients in the ITT set with metastatic disease (n = 92) benefited most with a significant increase in median OS from 4.4 months in the Gem group (n = 28) to 7 months in the IMM-101 + Gem group (n = 64) (p = 0.01; HR 0.54, 95% CI 0.33-0.87). We now report an increase in survival probability at 12 months from 11.5% in the Gem group to 22.4% in the IMM-101 + Gem group. Consistent with an increasing separation of the K-M curves, this is amplified at 18 months when the figures are 2.3% and 18.3% in the respective groups. The times corresponding to 25% probability of survival are 7.2 and 11.5 months for the Gem and IMM-101 + Gem group, respectively, an extension of 4.3 months. Of 11 metastatic patients in the ongoing follow-up study, all from the IMM-101 + Gem group, 8 survived for 18 months from randomization and 4 of these remained alive at 2 years. The longest period on study is currently 34 months. **Conclusions:** First line IMM-101 with adjunctive chemotherapy produced significant survival benefits in patients with metastatic disease. The durable responses seen in a proportion of patients are consistent with immunotherapy for other cancers but were not predicted in advanced pancreatic cancer. Clinical trial information: NCT01303172.

3052 Poster Session (Board #378), Sat, 8:00 AM-11:30 AM

Effect of human OX40 ligand fusion protein (MEDI6383) on immune cells of the humoral and cell-mediated immune response in a non-human primate model. *First Author: Michael D Oberst, MedImmune, Gaithersburg, MD*

Background: MEDI6383 is a human OX40 ligand fusion protein currently in clinical development for the treatment of advanced solid malignancies. In vitro, this OX40 agonist binds and activates the human OX40 receptor to potently induce activation and proliferation of OX40-expressing human T cells. Given that MEDI6383 binds and signals through non-human primate OX40 with similar potency as human OX40, we hypothesized that the fusion protein would mediate T cell activation in vivo in a non-human primate model. **Methods:** To test this hypothesis, a PK/PD study was conducted wherein non-human primates were administered MEDI6383, a vehicle control, or an agonist mouse anti-human OX40 monoclonal antibody (mAb). Pharmacodynamic changes in the peripheral blood were measured using flow cytometry-based immunophenotyping. **Results:** Peripheral CD4 and CD8 memory T cell activation and proliferation were observed after administration of MEDI6383, and differed quantitatively and qualitatively from that following treatment with the OX40 mAb. Likewise, MEDI6383 also induced the proliferation of peripheral B cells, suggesting an effect on T cell-to-B cell crosstalk in vivo. Other pharmacodynamic changes observed with OX40 agonism will also be presented. **Conclusions:** These findings suggest that MEDI6383 activates both humoral and cellular immune responses, activities that have the potential to boost anti-tumor immunity in the setting of human cancer.

3053 Poster Session (Board #379), Sat, 8:00 AM-11:30 AM

A retrospective analysis of high-dose aldesleukin (HD IL-2) following immune checkpoint blockade (ICB) in metastatic melanoma (MM) and metastatic renal cell carcinoma (mRCC). *First Author: Anasuya Gunturi, Beth Israel Deaconess Medical Center, Boston, MA*

Background: HD IL-2 received FDA-approval for the front-line treatment for MM and mRCC based on its ability to produce durable responses in a subset of pts. Recently, agents targeting CTLA-4 (ipilimumab, ipi) and PD-1/PD-L1 (aPD-1) have been developed and tested in these settings. As more pts are treated with ICB as front-line therapy, it becomes increasingly important to understand if HD IL-2 is safe and efficacious as salvage therapy. **Methods:** PROCLAIM (www.proclaimregistry.com) is a IL-2 observational registry with $>$ 40 participating sites consisting of a retrospective ($n = 170$, locked) and prospective cohort ($n > 343$, on-going). We queried this database to identify pts treated with HD IL-2 after receiving ipi or aPD-1 and report their safety and efficacy outcomes, compared to those who received HD IL-2 alone. **Results:** Within the database, there are 112 pts who received HD IL-2 without any prior or post ICB, 47 pts who received HD IL-2 after ipi and 4 who received HD IL-2 after aPD-1. The most common toxicities were hypotension, thrombocytopenia, and diarrhea in the HD IL-2 alone and prior ipi groups, while hypotension, nausea/vomiting, and pulmonary edema were most common in the prior aPD-1 group. In pts evaluable for AEs, 1.9% of the HD IL-2 alone group, 6.4% of the prior ipi group and none of the prior aPD-1 group developed immune-related adverse events. None of these events were grade 3/4. The ORR was 22.9% for pts treated with HD IL-2 alone, while the ORR for pts treated with HD IL-2 after ipi or aPD-1 was 17.7%. Median OS was 14 mos for HD IL-2 alone group, 16 mos for prior ipi group and 14.5 mos for prior aPD-1 group. **Conclusions:** Early patient data from the PROCLAIM database suggest that HD IL-2 is a safe treatment option for pts who have had progressive disease after prior ICB. Outcomes from additional pts as well as updated survival data will be reported. Further exploration through prospective studies is needed to determine the optimal sequence of these immunotherapies. Clinical trial information: NCT00686959.

3054 Poster Session (Board #380), Sat, 8:00 AM-11:30 AM

Targeting the Wnt5a-β-catenin pathway in the melanoma microenvironment to augment checkpoint inhibitor immunotherapy. *First Author: Brent Allen Hanks, Duke University Medical Center, Durham, NC*

Background: While checkpoint inhibitor immunotherapy has demonstrated recent success in patients with advanced melanoma, a significant fraction of these patients continue to fail therapy. The β-catenin signaling pathway plays a role in dendritic cell (DC) tolerization and regulatory T cell (Treg) differentiation however the factors responsible for inducing this pathway are unknown. **Methods:** We utilized a $BRAF^{V600E}PTEN^{-/-}$ autochthonous model of melanoma to identify melanoma-derived factors capable of driving local Treg development and the generation of an immunotolerant microenvironment. Primary human melanoma specimens were examined for expression of these candidate factors by immunohistochemistry while sentinel lymph node-derived DCs were analyzed for expression of downstream mediators of the identified signaling pathway. Based on this data, a small molecule inhibitor of the candidate signaling pathway was tested to augment the anti-tumor immune response of checkpoint inhibitors in a murine melanoma model. **Results:** We identified the Wnt5a ligand as a critical mediator β-catenin signaling in DCs and of Treg generation in the $BRAF^{V600E}PTEN^{-/-}$model. We further determined Wnt5a to be associated with expression of the Treg marker, FoxP3, in human melanoma tissues and for Wnt5a expression by primary melanomas to be associated with an improved objective response to anti-CTLA-4 antibody therapy. In addition, our work suggests that activation of the β-catenin signaling pathway in sentinel lymph node derived DCs correlates with higher tumor burden and inferior clinical outcome. Finally, we show that suppressing Wnt ligand secretion and downstream signaling by targeting the Porcn acyl transferase enzyme functions to enhance the anti-melanoma immune response and suppress melanoma growth when administered in combination with anti-CTLA-4 antibody therapy. **Conclusions:** The Wnt5a-β-catenin signaling pathway represents a novel pharmacological target within the melanoma microenvironment that is worthy of further investigation in combination immunotherapy clinical trials.

3055 Poster Session (Board #381), Sat, 8:00 AM-11:30 AM

Pharmacokinetic profile and receptor occupancy of avelumab (MSB0010718C), an anti-PD-L1 monoclonal antibody, in a phase I, open-label, dose escalation trial in patients with advanced solid tumors. *First Author: Christopher Ryan Heery, Laboratory of Tumor Immunology and Biology, NCI, NIH, Bethesda, MD*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. Reported here is the pharmacokinetic (PK) profile of avelumab and receptor occupancy (RO) from a phase I dose escalation trial (NCT01772004). Previous in vitro experiments spiking anti-PD-L1 into human whole blood samples from healthy donors confirmed that 1 mcg/mL was sufficient for $>$ 95% RO. **Methods:** In this study, dose escalation (3+3 design) was performed for 4 dose levels (DL 1, 3, 10, and 20 mg/kg). The dose limiting toxicity (DLT) evaluation period was 3 weeks. After DL safety was determined, accrual of additional patients (pts) was allowed for the purpose of generating additional safety, PK, and RO data. **Results:** 50 pts with advanced solid tumors were enrolled and treated with avelumab, Q2W. 4, 13, 13, and 20 pts were accrued to DL 1-4, respectively. Median pt age was 59 yrs (range 29-77); 19 had an ECOG PS of 0 and 29 had an ECOG PS of 1 (2 unknown).The median number of prior lines of therapy was 3 (range 1- $\geq$ 4). Data from 45 pts were evaluable for PK analysis. $C_{max}$and AUC increased linearly with dose. Half-lives were 66, 86, 92, and 115 h for DL 1, 2, 3 and 4, respectively, with no statistically significant differences between the 3 higher DLs. Trough levels at 10 mg/kg, but not at 1 and 3 mg/kg, were sufficient for $>$ 95% RO at all dosing occasions. Population PK analysis showed that a 2-compartment model with linear elimination best described the data. Covariate analysis did not demonstrate significant correlation between body-size metrics and clearance. There was no significant change in absolute lymphocyte count or in additional multiple immune cell subsets evaluated. **Conclusions:** The PK and RO data indicate the 10 mg/kg dose of avelumab achieves excellent RO with a predictable PK profile. Based on these data and the safety profile reported separately, the 10 mg/kg dose is being tested in ongoing phase II trials. *Proposed INN. Clinical trial information: NCT01772004.

3056 Poster Session (Board #382), Sat, 8:00 AM-11:30 AM

Human OX40 ligand fusion protein (MEDI6383) as a potent OX40 agonist and immuno-modulator in vitro and in vivo. *First Author: Scott A Hammond, MedImmune, Gaithersburg, MD*

Background: OX40 is a tumor necrosis factor receptor found primarily on activated T effector (Teff) cells and regulatory T (Treg) cells including lymphocytes infiltrating mouse and human tumors. Costimulation of OX40 by agonist molecules is hypothesized to improve antitumor immunity by enhancing Teff cell activity and inhibiting Treg cell suppression. MEDI6383 is a novel, agonist, human OX40 ligand fusion protein currently undergoing early phase clinical testing for the treatment of advanced solid malignancies. **Methods:** Preclinical pharmacological properties of MEDI6383 were assessed using in vitro and in vivo models. **Results:** MEDI6383 bound specifically and with high affinity to human and monkey OX40 expressed on the cell surface of T cells, and did not bind to OX40 expressed on the cell surface of either rat or mouse T cells. The OX40 signaling pathway was activated by MEDI6383, as measured by NFκB signaling in human OX40-expressing Jurkat T reporter cells. Co-culture of reporter cells with cells that express Fcγ receptors enhanced OX40 signaling, demonstrating that clustering of MEDI6383 by Fcg receptors increased the OX40 intracellular signaling strength and magnitude of response. MEDI6383 enhanced T cell receptor mediated (co-stimulatory) activation of primary human CD4+ T cells as demonstrated by the induction of cell proliferation and cytokine release, and reduced Treg cell suppression in T cell co-cultures. MEDI6383 showed no such activity in the absence of concomitant CD3/T cell receptor complex signaling. MEDI6383 demonstrated potent in vivo antitumor activity that was dependent on the addition of alloreactive human T cells in a xenograft mouse model of human cancer. Intravenous administration of MEDI6383 to rhesus monkeys in the absence of a define antigen challenge resulted in the proliferation of both CD4+ and CD8+ total memory T-cell populations as measured by induction of the cell-proliferation marker Ki67, and by an increase in absolute numbers of these T cell populations. **Conclusions:** These results demonstrate that MEDI6383 is a potent, soluble agonist of the OX40 pathway that may be utilized to boost anti-tumor immunity in patients with cancer.

3057 Poster Session (Board #383), Sat, 8:00 AM-11:30 AM

In vitro and in vivo killing of AML using tetravalent bispecific CD33/CD3 TandAbs. *First Author: Linda G. Eissenberg, Washington University School of Medicine, St. Louis, MO*

Background: Antibody-based targeting agents specific for CD33 and CD3 are evolving as promising strategies for treating AML. T550, T564, and T589 are TandAbs that are bispecific as well as tetravalent with high affinity for CD33 (McAleese and Eser, 2012, Future Oncol. 8: 687-695). **Methods:** TandAbs were incubated with purified human T cells and a VPD-450-labeled human $CD33^+$ leukemia cell line, KG-1, or the $CD33^-$ human ALL cell line, G2 (E:T = 5:1). Flow cytometry was used to evaluate target cell lysis by TandAbs (10^{-15} to 10^{-8}M for 24h at 37°C). A primary $CD33^+$ AML patient sample (5 x 10^6 PBMC; 98% blasts, 2% T cells) engrafts robustly when injected iv into NSG mice. TandAb T550 and T564 were administered iv at 5 or 50 ug/mouse qd starting 4 h after injection of primary AML cells and daily thereafter for 5 days (n = 8). On day 38 human leukemic blasts and human T cells in the blood, spleen, and bone marrow (BM) were enumerated by flow cytometry (human CD33, CD34, CD45, CD45, CD14, CD3, CD4, CD8, and 7AAD). **Results:** Incubation of TandAbs T550, T564, and T589 with human T cells efficiently lysed KG-1 cells (IC50 ~0.01, 0.5, and 5 pM respectively). Up to 40% of T cells were activated ($CD25^+$), rising with cytotoxic activity. A control TandAb with an irrelevant target, T151 ($> 10^{-7}$ M), did not cause significant killing of KG-1 in vitro. T564 induced lysis of KG-1 cells (IC50 = 5 x 10^{-12}M) but had no effect on $CD33^-$ G2 cells (1 x 10^{-8}M). In mice injected with AML cells alone $>$ 40% of spleen cells and $>$ 45% of BM cells were confirmed by FACS to be AML blasts by day +38. No human AML was detected in the peripheral blood. In contrast, after treatment with $\geq$ 5 ug of either T550 or T564, $<$ 0.1% of cells in the spleen and $<$ 1% in the BM were leukemic blasts, representing an ~3 log reduction in leukemic blasts by day +38. Treated and untreated mice had equivalent T cell numbers on day 38. **Conclusions:** T cells become activated and potently lyse tumor cells only when targeted to CD33+ leukemic cells (KG-1) and primary CD33+ AML blasts by CD33/CD3 TandAbs. In spite of the protective environments of the BM and spleen and the extremely low number of T cells infused, nearly all primary AML blasts could be eliminated in vivo.

3058 Poster Session (Board #384), Sat, 8:00 AM-11:30 AM

Population pharmacokinetic (popPK) model of pembrolizumab (pembro; MK-3475) in patients (pts) treated in KEYNOTE-001 and KEYNOTE-002. *First Author: Tara C. Gangadhar, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: The anti–PD-1 antibody pembro has efficacy in advanced cancer pts. We characterized pembro PK properties and quantified the effect of clinical factors on exposure. Immunogenicity was also assessed. **Methods:** Pooled popPK analysis was performed to characterize pembro serum concentrations over time in pts with melanoma (n = 1077), non-small cell lung cancer (n = 46), and other advanced cancers (n = 16) treated in KEYNOTE-001 and KEYNOTE-002. Simulations were performed to evaluate the magnitude of the effects of several clinical covariates on exposure. To investigate the immunogenicity potential of pembro, the development of antidrug antibodies (ADA) was determined. **Results:** A 2-compartment model with linear clearance from the central compartment adequately describes the clinical pharmacokinetics of pembro over the 1-10 mg/kg dose range (Table). No significant differences in efficacy have been observed for pembro 2 and 10 mg/kg Q3W and 10 mg/kg Q2W and Q3W. The PK profile is similar to other monoclonal antibodies, with a low clearance (0.2 L/day), limited central volume of distribution (3.8 L), and low to moderate variability (22-41%). The effect of age, sex, geographic location, baseline ECOG PS, eGFR, AST, bilirubin, albumin, glucocorticoid coadministration, tumor type and burden, and prior ipilimumab on pembro exposure is limited, as alterations of 20% or less are predicted by the popPK model. Of 268 pts evaluable for ADA, 1 ($<$1%) developed confirmed treatment-emergent ADA with no impact on efficacy or safety. **Conclusions:** The pembro PK profile indicated a low clearance and limited volume of distribution, consistent with other monoclonal antibodies. There was no clinically meaningful effect of baseline clinical factors on pembro exposure. Pembro has limited potential to elicit the formation of ADA. Clinical trial information: NCT01295827 and NCT01704287.

Median (90% prediction interval) PK parameters of pembro at steady state based on popPK model.

	Pembro Dose Regimen		
PK Parameter	**2 mg/kg Q3W**	**10 mg/kg Q3W**	**10 mg/kg Q2W**
C_{max} (μg/mL)	64.6 (43.9; 99.2)	318 (215; 488)	393 (261; 691)
C_{trough} (μg/mL)	22.3 (8.84; 50.1)	110 (40.8; 257)	185 (82; 395)
AUC_{ss}, 6 wk (μg•day/mL)	1398 (713; 2730)	6859(3403; 13712)	10353 (5308; 20137)

3059 Poster Session (Board #385), Sat, 8:00 AM-11:30 AM

Phosphatidylserine targeting antibody in combination with anti-PD-1 antibody treatment activates infiltrating T lymphocytes of the spleen and tumor microenvironment in pre-clinical models of melanoma and breast cancer. *First Author: Xianming Huang, The University of Texas Southwestern, Dallas, TX*

Background: Despite substantial progress, only a select subset of patients benefit from anti-PD-1/PD-L1 therapies. The underlying cause for these failures of immune checkpoint blockade therapy is the overwhelming, persistent and multifocal immune suppression within the tumor microenvironment. As phosphatidylserine (PS) becomes externalized to the outer leaflet of the cell's plasma membrane within the tumor microenvironment, it serves as a signaling ligand for PS receptors on immunosuppressive myeloid-derived suppressor cells (MDSCs), regulatory T cells and M2 macrophages that can occupy up to 50% of the tumor mass. Bavituximab is a chimeric monoclonal antibody that targets and inhibits PS mediated immunosuppressive signaling, supporting immune activation and reducing levels of MDSCs, re-polarizing tumor-associated macrophages from M2 to M1 phenotype, promoting the maturation of dendritic cells (DCs) and inducing potent antitumor T-cell immunity. **Methods:** A combination of bavituximab and anti-PD-1 therapy was compared in syngeneic, pre-clinical models of melanoma and breast cancer. **Results:** Our results show that the combination induces a statistically significant activation of lymphocytes in the spleen and the tumor microenvironment as well as decreases MDSCs and PD-L1 expression. In the spleen, increases were noted in T-cells producing IFN-g and IL-2 and DCs in association with decreased MDSCs over single anti-PD-1 treatment alone. Similarly, in the tumor microenvironment, the combination treatment demonstrates increases in TILs producing IFN-g, TNFα, IL-2, Granzyme B, PD-1, increased Lag-3 positive CD8 cells, CD137 (41BB) positive CD4 cells as well as a decrease in MDSCs and PD-L1 expressing TILs compared to anti-PD-1 treatment alone. **Conclusions:** Our pre-clinical results support the use of bavituximab as an immunomodulatory treatment in PD-1 sensitive and anti-PD-1 resistant/unresponsive tumors. This effect involves enhancing the activation of CD8+ TIL correlating with increased immune stimulatory components in the spleen and the tumor microenvironment.

3060 Poster Session (Board #386), Sat, 8:00 AM-11:30 AM

Activation of CD8+ tumor infiltrating lymphocytes by bavituximab in a 3D ex vivo system of lung cancer patients. *First Author: Soner Altiok, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Bavituximab is a chimeric monoclonal antibody that targets the membrane phospholipid phosphatidylserine (PS) exposed on endothelial cells and cancer cells in solid tumors. Bavituximab blocks PS-mediated immune suppression in the tumor microenvironment. **Methods:** Fresh tumor tissues from consented patients with adenocarcinoma of the lung extracted at the time of surgical resection were utilized in a proprietary 3D *ex vivo* tumor miscrosphere assay to assess the immunomodulatory effects of bavituximab and potential immunosuppressive mechanisms such as expression of PD-1, CTLA-4, LAG3, TIM3, BTLA, and adenosine A2A receptor on the CD4+ and CD8+ tumor infiltrating T-cells. 3D tumor microspheres were prepared and cells were treated *ex vivo* with $f(ab)'_2$version of bavituximab, bavituximab, docetaxel, and a combination of bavituximab and docetaxel for 36 hours within an intact tumor microenvironment. Flow cytometry analysis evaluated treatment-mediated activation of TILs and changes in CD4, CD8 and Treg (CD25+/CD127-) subpopulations. A multiplex human cytokine assay was used to simultaneously analyze the differential secretion of cytokines. Additionally, a NanoString platform containing probes to quantitate 770 immune function genes was used to determine potential positive or negative associations between expression of immune function genes and TIL activation by bavituximab. **Results:** Bavituximab induces activation of TILs in 3D *ex vivo* tumor microsphere model of lung cancer, as evaluated by a significant increase in IFNgamma, TNF-a, and GM-CSF secretion. Flow cytometry analysis revealed that this effect was associated with low PD-1 expression on CD8 cells, but did not correlate with expression of other immune inhibitory molecules. **Conclusions:** Our preliminary data support the use of bavituximab as an immunomodulatory treatment in adenocarcinoma of the lung by enhancing the activation of CD8+ TIL that correlates with increased cytokine production by lymphoid and myeloid cells. We identified PD-1 expression as a potential biomarker of response to bavituximab treatment, suggesting that the interruption of the PD-1/PD-L1 axis may enhance the bavituximab effect in lung cancer.

3061 Poster Session (Board #387), Sat, 8:00 AM-11:30 AM

A phase I/II study of ipilimumab in women with metastatic or recurrent cervical carcinoma: A study of the Princess Margaret and Chicago N01 Consortia. *First Author: Stephanie Lheureux, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Response to second-line therapy in cervical cancer (CC) is infrequent. Based on evidence of HPV-induced immune evasion, immunotherapy is an attractive strategy in CC. Ipilimumab (Ipi) is a fully humanized monoclonal antibody that blocks cytotoxic T-lymphocyte antigen-4, a molecule that acts to downregulate the T cell immune response. **Methods:** A multicenter trial was designed to evaluate Ipi IV in metastatic/recurrent cervical cancer (NCT01693783). Eligibility requirements included measurable disease progression and prior exposure to platinum therapy. A run-in phase I safety cohort was scheduled using Ipi 3mg/kg every 21 days for four cycles in 6 patients (pts). The phase II was planned in 32 pts with Ipi 10mg/kg every 21 days for four cycles; followed by four cycles of maintenance therapy (same dose) every 12 weeks for pts demonstrating radiologic response/stabilization. Primary objectives were safety and response rate at the end of cycle 4. Immune correlative studies were performed on peripheral blood pre- and post-Ipi therapy, on archival tissue, on fresh tumor obtained prior to registration and 7 days post cycle 2. **Results:** From Dec/12 to Sept/14, a total of 42 pts with a median age of 49 (23-78) were enrolled; 29 pts had squamous CC and 13 pts had adenocarcinoma. Thirty five pts had prior radiation completed $>$ 3 months prior to enrollment and 21 pts had received 2/3 prior regimens. Toxicities were manageable and Grade 3 toxicities included diarrhea (4 pts) and colitis (3 pts). Best response (RECIST 1.1) for the 34 evaluable pts (2 pts awaiting results) included: 3 PR (1 PR and 2 uPR), 8 SD and 23 PD. The median PFS was 2.5 months (95% CI: 2.3-3.2). HPV testing was positive in 33 tumors. Intratumoral CD3, CD4, CD8, FoxP3, IDO and PD-L1 expression pre and post treatment are pending. Multicolor flow cytometry on peripheral lymphocytes revealed a treatment dependent increase of ICOS, HLA-DR, CCR4, and PD-1 during initial treatment which returned to baseline during maintenance. **Conclusions:** Ipi was well tolerated in cervical cancer pts. There is a signal of activity of immunotherapy in cervical cancer. Following Ipi treatment, an immune activation has been observed. Clinical trial information: NCT01693783.

3062 Poster Session (Board #388), Sat, 8:00 AM-11:30 AM

Second generation antihistamines after breast cancer diagnosis to improve prognosis both in patients with ER+ and ER- breast cancer. *First Author: Hakan Lars Olsson, Department of Oncology, Lund, Sweden*

Background: Subgroups of patients with breast cancer (BC) could be candidates for immunological interventions. In the present investigation the role of antihistamines on prognosis of breast cancer has been studied, especially comparing first and second generation H-1 receptor antagonists due to their possible different effects on cytokines. **Methods:** The study includes all women with BC diagnosed in Sweden 2000 through 2008 (n = 54406). Dates of birth, BC diagnosis and TNM-stage were directly extracted from the cancer registry. Therapy with antihistamines was gathered from the Swedish Prescription Registry. Other registries utilised were the Cause of Death Registry, Population Registry, and the in patient or out patient registries. BC and overall survival was compared between users of antihistamines and non users. Analyses were adjusted for TNM-stage, receptor status and age at diagnosis. A late entry model was used for different types of antihistamines. **Results:** The HR for BC specific survival for the combined group of antihistamine users (n = 9777) was 0.70 (0.66-0.75). All the effect was seen for use after BC diagnosis. Results remained after adjusting for out or in patient diagnoses of allergy. In late entry models women using desloratadine (n = 1895) had a HR of 0.69 (0.52-0.91). Loratadine users (n = 2132) HR of 0.74 (0.60-0.93). Cetirizine users (n = 3001) HR of 1.13 (0.96-1.33) and Klemastine users (n = 2278) had a HR of 0.98 (0.80-1.19). Ebastin users (n = 326) had a HR of 0.50 (0.22-1.12) and Fenofexadine users (n = 145) had a HR of 0.73 (0.30–1.76). The analyses was also stratified for ER-status, but the results did not differ noticeably. Results were similar when overall survival was analysed. **Conclusions:** This population based registry study shows that women treated with second generation antihistamines have a better overall and BC specific survival compared with non users regardless of age, history of allergy, ER status and tumor stage. The results are strongest for desloratadine use and use after BC diagnosis. Second generation antihistamines could offer a nontoxic therapy for both receptor positive and negative BC. The mechanism behind this effect is presently unknown.

3063 Poster Session (Board #389), Sat, 8:00 AM-11:30 AM

A phase I study of the toll-like receptor 5 (TLR5) agonist, entolimod in patients (pts) with advanced cancers. *First Author: Hatoon Bakhribah, Roswell Park Cancer Institute, Buffalo, NY*

Background: Entolimod is a specific, TLR5 agonist derived from salmonella flagellin, with immunotherapeutic effects in preclinical cancer models. Entolimod activates innate and adaptive immune responses and mobilizes immunocytes to organs such as liver and bladder, with functional TLR5. A phase 1 trial was undertaken to evaluate entolimod's safety, tolerability, pharmacokinetics, immunoactivity, and preliminary antitumor activity. **Methods:** Pts with advanced cancers and ECOG PS of 0-1 were treated at 5 subcutaneous doses (5, 10, 15, 20, 30, 40 μg/day) over a 2-week period. PK/PD samples were obtained pre, and 2, 4, 6, 8, 24 hrs post-dose. Immune function samples were obtained pre and 24 hrs post-dose on days1, 8, 11 and 22. **Results:** 26 pts (38.4% colorectal cancer [CRC] and 19% NSCLC) were enrolled. Common toxicities were transient hypotension (9 grade 1/4, 7 grade 2/4), hyperglycemia (8 grade 1/4, 6 grade 2/4), and fever (10 grade 1/4, 3 grade 2/4). Three DLTs were observed at 40 μg/day. One pt developed grade 3 rigors and pyrexia, a 2nd pt had grade 3 transaminitis; a 3rd had grade 3 hypotension. T_{max} was 2 to 6 hrs and $t_{1/2}$ was 3 to 7 hrs with little change between 1st and subsequent doses. Pharmacogenetic analysis revealed that 6 SNPs in the TLR5 gene were associated with LFT elevations ($p < 0.05$) Induced plasma cytokines included G-CSF, IL-6, IL-8 and IL-10 with no indications of cytokine storm. Pts exhibited immune cell activation with a stable or decrease in the levels of suppressive immune cells, accompanied by increased immunostimulatory and decreased immunosuppressive cytokines. Stable disease (SD) for $>$ 6 weeks was observed in 8 pts, with 3 pts (anal, CRC and urothelial cancer) maintaining SD for $>$ 12 weeks. Neutralizing antibodies developed by the 2nd week in most pts, indicating immune memory for flagellin. **Conclusions:** The recommended phase II dose of entolimod was30 μg/day on days 1, 4, 8, 11. The clinical results corroborated pre-clinical findings and support entolimod's potential as an immunotherapeutic agent. The safety profile suggests that entolimod can be combined with chemotherapeutic, targeted, or other immunotherapeutic agents. Clinical trial information: NCT01527236.

3064 Poster Session (Board #390), Sat, 8:00 AM-11:30 AM

MyD88/CD40-based costimulation to enhance survival and proliferation of chimeric antigen receptor (CAR)-modified T cells. *First Author: Aaron E Foster, Bellicum Pharmaceuticals, Houston, TX*

Background: Treatment of B cell malignancies with CAR-modified T cells has shown remarkable efficacy, but clinical responses in solid tumors have been limited due to poor T cell persistence and expansion. We examined whether incorporation of unconventional signaling elements, derived from the "universal" toll-like receptor adaptor molecule, MyD88, and the TNF family member, CD40, into CARs could improve T cell survival, proliferation and antitumor efficacy. **Methods:** Bicistronic vectors encoding inducible Caspase-9 (iCasp9) and CD19- or Her2-targeted CARs incorporating various costimulatory domains (e.g., CD28, 4-1BB, MyD88/CD40) were generated and used to transduce T cells. CAR-T cells were assessed for antitumor function in tumor coculture assays using $CD19^+$ (Raji and Daudi) cells or $Her2^+$ (SK-BR-3) tumor cells. Efficacy was monitored in immunodeficient (NSG) mice engrafted with tumor cell lines followed by i.v. CAR-T cell injection. *In vivo* T cell proliferation, as well as elimination via iCasp9 after i.p. injection of rimiducid, was measured using bioluminescent imaging (BLI). Tumor burden was also assessed by BLI or caliper measurements. **Results:** All CAR constructs could be stably expressed in T cells (30-90% CAR expression). MC costimulation resulted in greatly increased IL-2 production compared to CARs with alternative costimulation (~2500 pg/mL and ~200 pg/mL for MC and CD28.41BB, respectively). This correlated with enhanced T cell proliferation and corresponded to better tumor elimination in coculture assays (99% elimination at a 1:1 E:T ratio within 14 days). MC costimulation also enhanced the efficacy of CAR-T therapy in $CD19^+$ and $Her2^+$ tumor models, respectively, compared to control CARs. Furthermore, T cells transduced with MC-encoding CARs could be rapidly eliminated *in vivo* (within 1 day) via iCasp9 following rimiducid administration. **Conclusions:** MyD88/CD40 represents a potent, new T cell costimulatory molecule for CAR-T cells, resulting in robust IL-2 production, improved survival and proliferation, increased antitumor activity against $CD19^+$ and $Her2^+$ tumors *in vitro* and *in vivo,* while retaining a high safety profile through the iCasp9 suicide gene.

3065 Poster Session (Board #391), Sat, 8:00 AM-11:30 AM

A phase 1 dose-escalation study of IPH2102 (lirilumab, BMS-986015, LIRI), a fully human anti KIR monoclonal antibody (mAb) in patients (pts) with various hematologic (HEM) or solid malignancies (SOL). *First Author: Norbert Vey, Institut Paoli-Calmettes, Marseille, France*

Background: Inhibitory Killer Immunoglobulin-like receptors (KIRs) negatively regulate the killing, by NK cells, of tumors expressing their HLA class I ligands. We showed safety of 1st generation mAb targeting the major inhibitory KIRs (Vey et al Blood 2012).LIRI is a 2nd generation anti KIR mAb. The objectives of this study were to evaluate the safety and PK/PD of LIRI in pretreated pts with HEM or SOL with no or slowly progressive disease. **Methods:** In the dose escalation 3+3 phase 1 part, six dose levels of LIRI were evaluated: 0.015, 0.3, 1, 3, 6, and 10 mg/kg administered q4w x 4; the time between the first 2 infusions was adjusted to KIR desaturation (KIR occupancy $<$ 30%). In a cohort expansion, pts were treated at 0.015 and 3 mg/kg q4w x 4 **Results:** Twenty and 17 patients were treated in the dose escalation and cohort expansion parts, respectively Overall median age was 62 years (33-73); 22 had HEM (5 AML, 6 CLL and 11 NHL) and 15, SOL (7 ovarian [OC], 6 breast [BC], and 2 others cancers). LIRI was generally well tolerated with no DLT in the dose-escalation; MTD was not reached. Related AEs observed in $>$ 10% of the pts included fatigue/asthenia (30% of pts), pruritus (20%), infusion related reaction (14%), headache (11%). Only one SAE (G3 urticaria, at 0.015 mg/kg) was reported as treatment-related. Release of cytokines in serum was rare and mild to moderate. Eighteen patients (49%) discontinued the study prematurely including 13 because of disease progression, 3 for AE's and 2 for other reasons. Full KIR occupancy ($>$ 95%) was sustained during $>$ 4 weeks for dose-levels $\geq$ 0.3 mg/kg. **Conclusions:** LIRI was generally well tolerated up to the highest tested dose of 10 mg/kg which was associated with prolonged KIR occupancy. Based on these results, LIRI is currently investigated in a randomized phase 2 trial as maintenance therapy for elderly pts with AML in CR1 and in several phase 1 studies in combination with other immune checkpoints inhibitors or a cytotoxic mAb.

3066 Poster Session (Board #392), Sat, 8:00 AM-11:30 AM

Preclinical efficacy studies using HuMax-Axl-ADC, a novel antibody-drug conjugate targeting Axl-expressing solid cancers. *First Author: Esther CW Breij, Genmab, Utrecht, Netherlands*

Background: HuMax-Axl-ADC is an antibody-drug conjugate (ADC) that specifically targets Axl-expressing tumor cells. Aberrant expression of Axl, a receptor tyrosine kinase, has been described in solid and hematological malignancies, in both primary tumors and metastasis. Expression and activation of Axl is associated with poor clinical prognosis in cancers of the lung, pancreas, esophagus and breast. Moreover, Axl expression has been implicated in resistance to both chemotherapy and targeted therapy. Although the mechanism behind Axl activation in cancer is not fully understood, activation through the Axl ligand Gas6 has been implicated in at least some cancers. At the cellular level, Axl is involved in tumor cell adherence, migration and epithelial-to-mesenchymal transition. **Methods:** A panel of Axl-specific ADCs was generated by conjugating human Axl antibodies with the microtubule disrupting agent monomethyl auristatin E (MMAE), through a protease-cleavable linker. Axl-ADCs were functionally characterized *in vitro*, and the anti-tumor activity was tested *in vivo* using xenograft models. **Results:** Axl-ADCs demonstrated high affinity binding to Axl and efficiently induced cytotoxicity *in vitro,* which was dependent on both Axl expression and conjugation with MMAE. In a lung cancer xenograft model, Axl ADCs were shown to have potent anti-tumor activity *in vivo*. The most potent Axl-ADCs, including HuMax-Axl-ADC, induced complete tumor regression upon treatment with a single dose of 1 mg/kg. HuMax-Axl-ADC also strongly inhibited tumor growth in a xenograft model that showed high endogenous expression of Gas6. This is in line with our observation that HuMax-Axl-ADC does not compete with Gas6 for Axl binding. Importantly HuMax-Axl-ADC was able to induce tumor regression in PDX models that, similar to many human tumor biopsies, showed Axl expression in only a subpopulation of tumor cells **Conclusions:** HuMax-Axl-ADC is a novel ADC that shows potent anti-tumor activity in solid cancer xenograft models. The results obtained in preclinical studies support further development of HuMax-Axl-ADC for the treatment of solid cancers.

3067 Poster Session (Board #393), Sat, 8:00 AM-11:30 AM

Significance of PD-L1, IDO-1, and B7-H4 expression in lung cancer. *First Author: Kurt Alex Schalper, Yale University, New Haven, CT*

Background: Expression of immune inhibitory signals such as co-regulatory ligands/receptors and tolerogenic enzymes by cancer cells limits the effectiveness of the immune surveillance. Blockade of such signals (e.g. CTLA-4 and PD-1/PD-L1) can reinvigorate the anti-tumor immune response and induce clinical benefit in a proportion of patients with advanced cancer. **Methods:** Using multiplexed quantitative immunofluorescence**,** we measured the levels of CD3 (E272-Novus), CD8 (C8/144B-DAKO), PD-L1 (E1L3N-CST), IDO-1 (1F8.2-Millipore) and B7-H4 (D1M8I-CST) in 554 stages I-IV lung carcinomas represented in two tissue microarrays, one from Yale U. (TM79 n = 204) and one from Greece (TM140 n = 350). The markers were measured in different tumor compartments based on their colocalization with pancytokeratin and DAPI. Associations between the marker levels, clinico-pathological variables and survival were determined. **Results:** PD-L1 was detected in 16.9% of cases in the Yale set and 20% of cases in the Greek collection. IDO-1 was expressed in 42.6% and 49.8%; and B7-H4 in 12.8% and 22.6% of cases, respectively. The levels of PD-L1 and IDO-1 were not consistently associated with sex, age and tumor histology. B7-H4 expression was significantly associated with squamous tumors in both collections ($P = 0.041$ and $P < 0.0001$, respectively). Elevated PD-L1 or IDO-1 was consistently associated with prominent CD3 and CD8+ T cells ($P < 0.05$), but B7-H4 was not. In univariable analysis, IDO-1 expression was significantly associated with longer overall survival in the Yale set (HR = 0.572 [CI:0.368-0.871], P = 0.009), but not in the Greek (HR = 0.883 [CI:0.636-1.220], P = 0.452). Expression of PD-L1 and B7-H4 were not significantly associated with survival. Tumors with prominent levels of one of the markers had typically low levels of the others, suggesting predominance of only one immune inhibitory pathway. **Conclusions:** PD-L1, IDO-1 and B7-H4 are differentially expressed in human lung carcinomas and have limited prognostic value. While the expression of PD-L1 and IDO-1 are associated with increased T-cells, B7-H4 is not. The high frequency of IDO-1 expression in lung tumors (~45%) suggests its potential for therapy, perhaps in combination with checkpoint inhibitors.

3068 Poster Session (Board #394), Sat, 8:00 AM-11:30 AM

Model-based analysis of the relationship between pembrolizumab (MK-3475) exposure and efficacy in patients with advanced or metastatic melanoma. *First Author: Richard Wayne Joseph, Mayo Clinic Cancer Center, Jacksonville, FL*

Background: Optimization of antibody dosing in oncology drug development is an area of growing interest. We have previously demonstrated that the dose and schedule of pembrolizumab does not correlate with clinical outcomes in melanoma. Here, we assess the relationship between steady state plasma exposure and tumor growth dynamics in patients enrolled in the KEYNOTE-001 and KEYNOTE-002 studies. **Methods:** Patients received pembrolizumab 2 mg/kg every 3 weeks (Q3W) to 10 mg/kg Q2W or Q3W. Exposure was defined as the area under the serum concentration curve (AUC) over 6 weeks. Response was defined as the change in tumor size per standard rules for measuring target lesions (ie, sum of the longest diameters). We assessed the extent of tumor growth and its reduction under pembrolizumab treatment using nonlinear mixed effects modeling; specifically, we tested whether individual exposures predict patterns of tumor response. **Results:** In this initial analysis, we found that reduction in tumor growth was best characterized by an exponential decline, with an estimated halving time of approximately 4 months. The 90th percentile of pembrolizumab exposures ranged from 0.8 to 14 g×day/L. In agreement with the flat dose-efficacy relationship observed per objective response criteria, the observed individual pembrolizumab exposures do not significantly correlate with extent of tumor reduction or overall growth patterns over time. **Conclusions:** The significant and prolonged reductions in tumor size under pembrolizumab treatment were well characterized by the tumor size dynamics model. Tumor size reductions were independent of a wide (15-fold) range of exposure to pembrolizumab, supporting 2 mg/kg Q3W as an effective dosage that achieves a level of exposure sufficient to saturate tumor response. This examination of a wide exposure range and analysis via dynamic tumor size modeling demonstrates a framework for identifying an optimally efficacious dose in oncology. Clinical trial information: NCT01295827 and NCT01704287.

3069 Poster Session (Board #395), Sat, 8:00 AM-11:30 AM

UCART19, an allogeneic "off-the-shelf" adoptive T-cell immunotherapy against CD19$^+$ B-cell leukemias. *First Author: Julianne Smith, Cellectis, Paris, France*

Background: Autologous T-cells engineered to express chimeric antigen receptors (CARs) that target specific tumor antigens are of high potential in treating different kinds of cancer. However, they must be generated on a "per patient" basis, thereby limiting the population of patients that could benefit from this approach. **Methods:** We have developed a standardized platform for manufacturing T-cells from third-party healthy donors to generate allogeneic "off-the-shelf" engineered CD19-CAR+ T-cell–based frozen products. Our platform involves the use of transcription activator-like effector nucleases (TALEN), which mediate the simultaneous inactivation of two genes through genome editing. The knockout of the TCR alpha gene eliminates TCR expression and is intended to abrogate the donor T-cell's potential for graft-versus-host disease (GvHD), while knocking out the CD52 gene makes donor T-cells resistant to the lymphodepleting agent alemtuzumab. In addition, our T-cells are engineered to co-express the RQR8 gene as a safety feature, with the aim of rendering them sensitive to the monoclonal antibody rituximab. **Results:** We have obtained proof-of-concept by manufacturing TCR/CD52-deficient RQR8+ and CD19-CAR+ T-cells (UCART19) using a good manufacturing practice–compatible process and have demonstrated that UCART19 cells were functional using in vitro assays. Furthermore, we have demonstrated that the ability of UCART19 cells to engraft into an orthotopic human CD19+ lymphoma xenograft immunodeficient mouse model. UCART19 cells exhibited antitumor activity equivalent to that of standard CD19 CAR T-cells. We also demonstrated that UCART19 cells did not mediate alloreactivity in a xeno-GvHD mouse model. Finally, the effectiveness of the rituximab-induced depletion mechanism of RQR8$^+$cells was shown in an immunocompetent mouse model. **Conclusions:** This valuable dataset supports the development of allogeneic CAR T-cells, and UCART19 will be investigated in an exploratory, first-in-human, clinical trial where refractory/relapsed CD19+ B-cell leukemia patients are to be enrolled.

3070 Poster Session (Board #396), Sat, 8:00 AM-11:30 AM

Durability and characteristics of objective tumor responses with the innate immune cell modulator Imprime PGG in combination with standard of care frontline treatment for patients (Pts) with metastatic non-squamous NSCLC. *First Author: Walburga Engel-Riedel, Hospital Cologne-Merheim, Lung clinic, University Witten/Herdecke, Cologne, Germany*

Background: Recently, we reported numeric improvements in objective tumor response (OTR) and overall survival (16.1 vs 11.6 months median; HR = 0.66) with Imprime PGG (PGG) in a randomized (2:1) phase 2 study in 92 patients (pts) with stage IV non-squamous NSCLC receiving standard of care carboplatin/ paclitaxel (C/P) and bevacizumab (B) treatment first line (Engel-Riedel W et al, Ann Onc 2014, 25(5):1-41). Here, we report on the durability and characteristics of tumor regressions. **Methods:** The impact of treatment on the burden of malignant lesions was evaluated by modified RECIST v1.0. Imaging assessments (CT of chest and abdomen every 6 wks) were reviewed centrally in an independent, blinded facility. Pts were removed from treatment upon disease progression. **Results:** PGG (vs ctrl) in combination with C/P/B achieved a 60.4% (vs 43.5%) OTR rate. Time to OTR was short (12 wks vs $>$ 18 wks) and responses were durable: median duration of response was 10.3 mos vs 5.6 mos (KM), with OTR lasting $\geq$ 12 mos in 7% vs 0% of pts in the PGG vs ctrl groups. Following completion of C/P chemotherapy, there was continued regression of lesions on maintenance treatment with PGG+B but not B alone: 6 pts (20%) in the PGG group vs 0 in the ctrl group had further $>$ 1 cm reductions in target lesions' sum of longest diameters (SLD), incl. 1 CR at 47 wks; this pt remains on treatment 2 yrs post randomization. In the PGG group, OTR were observed regardless of baseline tumor burden (up to $>$ 30cm SLD) or lesion location (incl. lung, lymph nodes, adrenals, liver). Change from baseline in target lesions (SLD) over time will be presented for each pt. 1-yr survival was 62.8% vs 42.7% with PGG vs ctrl, and 13 (vs 1) pts remained in survival follow-up at primary analysis. Safety results have been reported previously and were favorable overall. **Conclusions:** Combined use of chemotherapy, B and PGG mediated rapid and durable responses of metastatic NSCLC regardless of baseline tumor burden or lesion location. There was further regression of lesions on maintenance PGG+B. Innate immune cell modulation with PGG holds promise for pts with metastatic non-squamous NSCLC. Clinical trial information: NCT00874107.

3071 Poster Session (Board #397), Sat, 8:00 AM-11:30 AM

Safety of Imprime PGG, a novel innate immune cell modulator, in adults with stage IV non-small cell lung cancer: an integrated analysis of two randomized phase 2 studies. *First Author: Folker Schneller, Policlinic of the Klinikum rechts der Isar, Technical University Munich, Muenchen, Germany*

Background: Imprime PGG (IPGG; beta-1,3/1,6 glucan), a yeast-derived pathogen-associated molecular pattern (PAMP), can prime innate immune effector cells to kill cancer cells opsonized by therapeutic antibodies. In two recent, identically designed phase 2 trials in patients (pts) with stage IV NSCLC, IPGG in combination with frontline carboplatin/paclitaxel (C/P) chemotherapy and bevacizumab (bev) or cetuximab (cet), respectively, was associated with numeric increases in objective tumor response rates and survival. This analysis evaluates the safety of IPGG across these studies. **Methods:** Patient-level data from two identically designed, randomized phase 2 trials of patients (pts) with stage IV NSCLC were combined for safety analyses. **Results:** A total of 177 pts were enrolled (118 IPGG, 59 Control [Ctrl]) and evaluable for safety. Overall (IPGG vs Ctrl), 99.2% (vs 100%) of pts experienced at least 1 treatment-emergent adverse event (AE) over the course of the study. Grade (Gr) III/IV AEs occurred in 85.6% vs 76.3% of pts, and serious AEs in 51.7% vs 42.4% of pts, respectively. Most common Gr III/IV AEs (occurring in at least 10% of pts in either arm) included neutropenia (35.6%, 37.3%), leukopenia (10.2%, 16.9%) and thrombocytopenia (11%, 11.9%). Gr III/IV AEs occurring at a $\geq$ 2% higher frequency in the IPGG arm included nausea (4.2%, 1.7%), abdominal pain (3.4%, 0%), fatigue (4.2%, 1.7%), hypersensitivity (2.5% vs 0%), polyneuropathy (5.9%, 3.4%) and pleural effusion (2.5%, 0%). Fatal AEs were experienced by 11% vs 3.4% of pts; no event occurred in $>$ 1 pt in either arm, except general physical health deterioration (2.5%, 0%); all fatal AEs were deemed unrelated or unlikely related to IPGG. In the IPGG arm, 72% of pts experienced AEs reported as related to IPGG; of these, 10.2% were considered unlikely related and 61.9% were considered possibly or probably related to IPGG. AEs of specific interest (e.g. infusion-related reactions; immune-mediated AEs) as well as subset analyses by histology will be presented. **Conclusions:** IPGG was generally well tolerated in pts with stage IV NSCLC receiving C/P chemotherapy and cet or bev therapy frontline. Clinical trial information: NCT00874107 and NCT00874848.

3072 Poster Session (Board #398), Sat, 8:00 AM-11:30 AM

Safety, immunogenicity, and clinical activity of the immunotherapeutic vaccine, DPX-Survivac, in a Phase 1/1b trial of women with ovarian, fallopian tube, or peritoneal cancer. *First Author: Jeannine A. Villella, Winthrop-University Hospital, Mineola, NY*

Background: Survivin is important in apoptosis, proliferation, and angiogenesis. High expression has been linked to progression and drug resistance. DPX-Survivac vaccine (DPX) contains a mix of survivin HLA class I peptides designed to evoke a cytotoxic T cell response against survivin. This trial reports the safety and immune response profiles of DPX in combination with metronomic low dose oral cyclophosphamide (CPA) in ovarian cancer (OC). **Methods:** 40 Stage IIc-IV OC patients with no evidence of disease progression post-platinum chemotherapy were enrolled. Adverse events and dose limiting toxicities (DLT) were defined by CTCAE v4.03. Immune correlates (MDSCs; T regs; B cells) and vaccine induced T cell immunity (ELISpot; tetramer analysis) was assessed in purified PBMC and blood. Clinical response was assessed by CT and CA125. **Results:** 34/40 pts had an HLA match with the vaccine. Local injection site reactions (ISR) were the main DLT with 2 grade 3 skin ulcerations in cohort C. One hematological grade 3 DLT was seen in cohort 2. Immune response increased with dose (B vs C $p = 0.01$) and use of CPA (A vs C $p = 0.02$). Subsequent cohorts (Table) were de-escalated to find a dose with similar immunogenicity and reduced ISR. Skin ulcerations were not seen in Cohort 3, with a slightly lower immune response (non-significant). CD4 T cell immune responses were also seen in HLA unmatched pts. A radiological and biochemical response was confirmed in 1 pt with residual disease post-platinum therapy and correlated to a robust immune response. **Conclusions:** DPX-Survivac is well tolerated with proven immunogenicity and preliminary evidence of clinical activity. The recommended phase 2 dose is based on tolerance for localized ISR and immune response. A randomized phase 2 in consolidation/maintenance OC and open label studies in recurrent DLBCL and OC are planned. Clinical trial information: NCT01416038.

3073 Poster Session (Board #399), Sat, 8:00 AM-11:30 AM

A first-in-human phase 1 dose-escalating trial of G305 in patients with solid tumors expressing NY-ESO-1. *First Author: Amit Mahipal, Moffitt Cancer Center, Tampa, FL*

Background: A major way to expand *in vivo* tumor antigen-specific CD8 cytotoxic T cells (CTLs) is to induce and enhance the presence of CD4 helper T cells that are specific for the same antigen. G305 is recombinant full-length NY-ESO-1 protein mixed with a proprietary formulation of the synthetic TLR4 agonist, glucopyranosyl lipid A (GLA). GLA, when administered with other recombinant antigens in healthy volunteers, induces antigen-specific CD4 T and B cells and activates innate immunity. **Methods:** Adults with advanced or metastatic melanoma, sarcoma, ovarian, breast, bladder, or NSCLC expressing NY-ESO-1 by IHC were enrolled using a 3+3 dose-escalation design. Patients were dosed i.m. every three weeks for three doses. NY-ESO-1 was fixed at 250 μg and GLA was increased from 2 to 5 to 10 μg. Safety, immunogenicity, and clinical responses were assessed prior to, during, and at the end of therapy. **Results:** 12 patients were treated; mild local reactogenicity was most common (92%) and all related adverse events were CTCAE Grade 1 or 2, with no DLTs or related SAEs. Serology results show that G305 was immunogenic at all doses; 8 of 12 patients had preexisting antibody titers at baseline, 5 of which increased with treatment, and 3 of 4 with no baseline titer seroconverted. 4 of 6 patients tested to date had high baseline CD4 T cells that increased in 2 with G305 treatment; 1 of 8 tested developed antigen-specific CD8 T-cell responses. 6 of 12 patients (50%) have had SD for 2.5 to 8+ months and 6 patients progressed after a mean of 99 days with no relationship between dose, reciprocal antibody titers, or efficacy. One patient had decreasing CA125 titers and SD for 8 months, and subsequently developed brain metastases. **Conclusions:** G305 was shown to be safe and well-tolerated at doses up to 10 μg GLA and was associated with a satisfactory clinical response. Anti-NY-ESO-1 titers suggest that a 5 μg dose of G305 is suitable for subsequent trials. The immunogenicity results support the mechanism of action for G305, which is planned to complement LV305, a hybrid novel DC-tropic viral vector expressing NY-ESO-1, in a sequential prime-boost regimen to generate and expand NY-ESO-1-specific CTLs that target solid tumors. Clinical trial information: NCT02015416.

3074 Poster Session (Board #400), Sat, 8:00 AM-11:30 AM

A sugar engineered non-fucosylated anti-CD40 antibody, SEA-CD40, with enhanced immune stimulatory activity alone and in combination with immune checkpoint inhibitors. *First Author: Shyra Jane Gardai, Seattle Genetics, Bothell, WA*

Background: SEA-CD40 is a non-fucosylated, humanized IgG1 monoclonal antibody directed against human CD40. It is derived from dacetuzumab, a humanized IgG1 previously developed for B-lineage malignancies. Antibody glycosylation is essential for Fc receptor-mediated activity and nonfucosylated antibodies may show improved efficacy via increased binding to FcγRIIIa (CD16). **Methods:** Enhanced functionality of SEA-CD40 was determined through FcγRIIIa binding, immune activation, and induction of antigen-specific T-cells **Results:** While SEA-CD40 and the parent antibody dacetuzumab bind to CD40 with similar affinity, the non-fucosylated SEA-CD40 has a higher affinity for both low (158F) and high (158V) affinity FcγRIIIa. The consequence of enhanced SEA-CD40/FcγRIIIa binding is potent ADCC activity and improved agonistic signaling to antigen presenting cells (APCs). SEA-CD40 treatment of human PBMCs elicits a robust immune response consisting of proinflammatory cytokine production, APC maturation and up-regulation of co-stimulatory receptors on APCs with activity at antibody concentrations as low as 10 ng/ml. Utilizing a surrogate antibody against mouse CD40, the immune stimulatory properties of nonfucosylated anti-CD40 were confirmed *in vivo* in syngeneic tumor models. SEA-CD40 induction of antigen specific T-cells was assessed using human peripheral blood mononuclear cells (PBMCs) exposed to the M1 influenza antigen. SEA-CD40 stimulated the expansion of influenza specific T-cells and elevated their production of IFNγ. Likewise, SEA-CD40 also stimulated T-cell proliferation and IFNγ production in PBMCs from melanoma, pancreatic, or breast cancer patients in response to a mixture of the tumor-associated antigens MAGE-A1/A3. Interestingly, antigen-specific T-cell responses to both the influenza and tumor antigens were enhanced in the presence of blocking antibodies to CTLA4 or PD1. **Conclusions:** These observations demonstrate the potential of combining the non-fucosylated agonistic SEA-CD40 with immune check point inhibitors to generate more effective adaptive antitumor immune responses.

3075 Poster Session (Board #401), Sat, 8:00 AM-11:30 AM

Effect of CD137 stimulation on ibrutinib antagonism of GA101 dependent NK cell-mediated cytotoxicity. *First Author: Narendiran Rajasekaran, Center for Clinical Sciences Research Stanford, Stanford, CA*

Background: The clinical successes of BTK inhibitor Ibrutinib and Ofatumumab (GA101), a humanized, glycoengineered mAb against CD20, suggests that a combination therapy may have clinical potential. Our previous study demonstrated that Ibrutinib antagonizes ADCC in $CD20^+$ B-cell lymphoma due to Ibrutinib's irreversible binding to interleukin-2 inducible tyrosine kinase (ITK), which is required for FcR-stimulated NK cell function. (Kohrt *et al* Blood 2014, 123;12:1957). As GA101 is superior to Rituximab in induction of NK cell mediated ADCC, we hypothesized that-Ibrutinib may not antagonize GA101 and inhibition of NK cell function by Ibrutinib could be overcome by CD137 agonistic mAb enhanced NK cell function. **Methods:** Purified NK cells were isolated from healthy peripheral blood mononuclear cells and cultured with Ibrutinib for 4 hours together with GA101-coated DHL4 lymphoma cells. For NK cell activation studies, the cells were primed with GA101 coated cells for 20 hours prior to CD137 mAb addition. Secretion of IFN-gamma, CD107a mobilization and cytotoxicity were assessed. **Results:** The results showed that Ibrutinib inhibited GA101 induced NK cell mediated lysis of lymphoma target cells and degranulation, although IFN gamma release was unaffected. Anti-CD137 mAb enhanced functional GA101 induced NK cell IFN gamma release, restored and enhanced degranulation and lysis of target cells that was impaired by Ibrutinib. Similar results were obtained when autologous peripheral blood mononuclear cells were cultured with CLL cells obtained from circulating tumor cells. The therapeutic efficacy of Ibrutinib and GA101 with anti-CD137 mAb was evaluated in a xenotransplant model of DHL4 lymphoma. Following tumor inoculation, athymic mice received GA101 on day 14 and oral dose of Ibrutinib twice daily and anti-CD137 mAb on day 15 with each treatment repeated weekly for a total of three weeks. Our results demonstrate that GA101 retains its potency in vivo in combination therapy with Ibrutinib and anti-CD137 mAb. **Conclusions:** Our results support a novel approach to overcome Ibrutinib inhibition of NK cell function by activation of the host immune system by CD137 stimulation that warrants clinical investigation.

3076 Poster Session (Board #402), Sat, 8:00 AM-11:30 AM

Transfer of anti-breast cancer immunity induced by infusions of bispecific antibody armed T cells and boosted with ex vivo primed T cells after stem cell transplant in metastatic breast cancer patients. *First Author: Archana Thakur, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

Background: In a recent phase I immunotherapy (IT) study in 23 women with metastatic breast cancer (MBC), 8 infusions of activated T cells (ATC) armed with anti-CD3 x anti-HER2Bi bispecific antibody (HER2Bi) given in combination with IL-2 and GM-CSF induced specific anti-SK-BR-3 breast cancer (BrCa) cytotoxicity and increased Th_1 cytokines and in IL-12 in the serum. This study investigated whether specific cellular and humoral anti-BrCa immunity is induced by infusions of HER2Bi **a**rmed **T** cell**s** (BATs) could be transferred after high dose chemotherapy (HDC) and stem cell transplant (SCT). **Methods:** BATs were cryopreserved in 8 doses for twice weekly infusions for 4 weeks along with IL-2 (3.0×10^5 IU/m^2/day) and GM-CSF (250μg/m^2 twice per week). Seven to 14 days after the last infusion of BATs, the patient was leukapheresed to obtain 8-20 x 10^9 PBMC for expansion of immune ATC. Immune ATC were harvested and cryopreserved for multiple infusions after the HDC and SCT. **Results:** Six of 8 MBC patients enrolled in the protocol completed the protocol were evaluable for transfer of cellular and humoral immunity. Five of 6 evaluable patients exhibited 2 to 40% CTL activity after vaccination with BATs and 2.5-45% up to 12 months post SCT. One of 6 evaluable patients showed poor immune responses and no evidence of transfer. Serum anti-SK-BR-3 IgG levels increased from 1 to 11μg/ml post IT and 1 and 8 μg/ml after SCT. *In vitro* antibody synthesis showed gradual increases in antibody levels after SCT. Serum cytokine profile showed changes in IL-2, IL-12, IFN-γ, MIP-1β and IP-10. No dose-limiting events for the infusions, delays in engraftment, and life-threatening infections were observed. In the one patient who rapidly progressed after SCT, CTL and IFN-γ EliSpots were absent and the serum had high levels of Th_2 cytokines. **Conclusions:** This pilot study suggests that optimal adoptive transfer of cellular and humoral immunity, induced by BAT infusions, by immune anti-breast cancer T cells after SCT accelerates not only immune reconstitution but, more importantly, enhances reconstruction of anti-tumor cellular and humoral immunity after HDC and SCT. Clinical trial information: NCT0002780 and NCT00020722.

3077 Poster Session (Board #403), Sat, 8:00 AM-11:30 AM

First interim exploratory analysis of immune response in patients with advanced non-small cell lung cancer receiving viagenpumatucel-l (HS-110) in combination with low-dose cyclophosphamide in an ongoing phase II trial. *First Author: Roger B. Cohen, University of Pennsylvania, Jenkintown, PA*

Background: Viagenpumatucel-L (HS-110), consists of an allogeneic NSCLC cell line, selected for high expression of a series of tumor antigens shared by NSCLC patients, which has been stably transfected with gp96-Ig. Cell-secreted gp96-Ig then delivers these cell-derived antigens directly to a patient's own antigen presenting cells, and shuttles those antigens to MHC-I via the cross-presentation pathway, leading to the preferential trafficking to MHC-I and exclusive activation of CD8+ cytotoxic T cells with limited or no activation of CD4+ helper T cells. Viagenpumatucel-L is currently being evaluated in a randomized phase II trial in combination with low-dose cyclophosphamide versus physician's choice chemotherapy. **Methods:** In support of the first planned exploratory analysis in this trial, the peripheral blood immune response was evaluated for the initial cohort of patients randomized to the treatment arm and treated for at least 9 weeks of therapy. Peripheral blood mononuclear cells were evaluated by flow cytometry for detection of circulating leukocyte subsets, regulatory T cells, myeloid derived suppressor cells, activated T cells and expression of immune checkpoint molecules on T cells. Cytokine and chemokine arrays from patient serum samples were also evaluated. **Results:** The combination of viagenpumatucel-L and low-dose cyclophosphamide was well tolerated in this first cohort of patients. Increased PD-1, Tim-3 and Ki67 was observed on CD8+ T cells isolated from peripheral blood over the treatment period, which may indicate CD8+ T cell activation and proliferation in response to HS-110. **Conclusions:** If these trends are observed in the full cohort of patients, the data may provide mechanistic evidence of HS-110 and support combination therapy with anti-PD-1/L1 antibodies. Clinical trial information: NCT02117024.

3078 Poster Session (Board #404), Sat, 8:00 AM-11:30 AM

An analysis of phase II and III therapeutic cancer vaccine trials and review of the successes and failures behind 10 different vaccine modalities. *First Author: Holbrook Edwin Kohrt, Stanford University, Stanford, CA*

Background: Between 1996-2014, the FDA approved 175 drugs for the treatment of various indications of oncology and despite the progress that has been made in other forms of cancer therapy, Provenge (Sipuleucel-T) is the only therapeutic vaccine that has received FDA approval for the treatment of cancer. To understand the current landscape of therapeutic oncology vaccines, an analysis of cancer vaccines under in phase 2 and phase 3 investigation was performed. **Methods:** A search of the terms "vaccine" and "cancer" or "oncology was performed on the clinicaltrials-.gov. registry and medtrack. A literature review was also performed to identify factors that have impacted the perceived success or failure of 10 different vaccines. **Results:** Database analysis of 451 phase 2 and phase 3 therapeutic cancer vaccine trials identified the most targeted indications, vaccine modalities, adjuvant and vaccine-treatment combinations and highlighted the shift in trends between studies completed prior to 2014 and those with completion scheduled after 2014. Despite the lower number of phase 3 compared to phase 2 trials, the registration of phase 3 trials between 2010 and 2014 appeared stable indicating continued investment in the development of immunotherapeutic vaccines at this stage. The review of vaccine trials revealed that patient characteristics (disease stage, HLA-type, MGMT status, antigen signature) and combination treatments had an impact on on vaccine success while the detection of immune responses was found to be important, provided parameters such as tumour antigen expression, breadth and magnitude of the response and correspondence to intra-tumour responses were considered. **Conclusions:** Identification of factors that can impact on vaccine success and their implementation into study design could ensure vaccine trials are best matched to patients most likely to benefit from the selected mode of vaccination, improving the outlook for both the patient and the development of therapeutic cancer vaccines.

3079 Poster Session (Board #405), Sat, 8:00 AM-11:30 AM

Anti-tumor efficacy and PD-L1 expression in the tumor microenvironment after poxvirus-based active immunotherapy and PD-1 blockade. *First Author: Stefanie J Mandl, Bavarian Nordic Inc., Mountain View, CA*

Background: Treatment with poxvirus-based active immunotherapies shows evidence of robust immune responses against a variety of tumor-associated antigens in preclinical and clinical studies. These active immunotherapies are in clinical trials to treat tumors expressing PSA (PROSTVAC/Phase 3), CEA and MUC-1 (CV-301/Phase 2), HER-2 (MVA-BN-HER2), and Brachyury (MVA-BN-Brachyury). Because these immunotherapies drive IFNγ-producing T cells to the tumor, we hypothesized that the tumors would upregulate PD-L1 in an attempt to evade the immune response. Thus, combination treatment of poxvirus-based immunotherapy with PD-1 axis blockade has the potential to yield therapeutic synergy against tumors in preclinical and clinical regimens. **Methods:** In therapeutic MC38-CEA and CT26-HER2 tumor models, mice were treated with CV-301 or MVA-BN-HER2, respectively, in combination with anti-PD-1 antibody. PD-L1 expression was evaluated in the tumor microenvironment by immunofluorescence and FACS. **Results:** Poxvirus-based immunotherapies induced activation and trafficking of antigen specific T cells that produce high levels of IFNγ in the tumor microenvironment.TumorPD-L1 expression was upregulated following CV-301 and MVA-BN-HER2 immunotherapy *in vivo* as measured by immunofluorescence. The PD-L1 expression was significantly elevated on tumor cells ($p < 0.01$) and infiltrating immune cells ($p < 0.05$) as measured by FACS. Combining poxvirus-based immunotherapy with PD-1 blockade in therapeutic mouse tumor models demonstrated synergistic anti-tumor efficacy. **Conclusions:** In preclinical studies, CV-301 and MVA-BN-HER2 poxvirus-based immunotherapies drive a robust, tumor-infiltrating T cell response that provokes tumor PD-L1 expression. Synergistic anti-tumor efficacy in mice resulted from combining active immunotherapy with PD-1 immune checkpoint inhibition. The potential of active immunotherapy to drive productive antigen specific T cell immunity could provide patients with PD-L1$^{neg/low}$ tumors an opportunity to benefit from PD-1/PD-L1 axis blockade when given in combination with poxvirus-based immunotherapies.

3081 Poster Session (Board #407), Sat, 8:00 AM-11:30 AM

Effect of alphavirus vaccine encoding HER2 during concurrent anti-HER2 therapies on induction of oligoclonal T cell and antibody responses against HER2. *First Author: William Rayford Gwin, Duke University, Durham, NC*

Background: Advanced HER2-overexpressing breast cancer eventually develops resistance to standard therapies; however, the HER2 receptor persists and may serve as a target for immunotherapy. We tested an immunization strategy with a novel alphaviral based vaccine encoding the extracellular and transmembrane domains of HER2 (VRP-HER2), alone and in conjunction with standard anti-HER2 agents, in patients with predominantly metastatic treatment refractory HER2-overexpressing breast cancer to determine safety, immunogenicity, and clinical activity. **Methods:** Cohort 1 (n = 4) enrolled patients not receiving any other anticancer therapy. Cohort 2 (n = 10) enrolled patients receiving either concurrent trastuzumab +/- pertuzumab, TDM-1, or Lapatinib. VRP-HER2 was given at 4 x 10^8 IU intramuscularly, every 2 weeks for three doses. Immune response specific for HER2 was determined by ELISPOT and ELISA. Progression-free survival (PFS) was defined as time to disease progression or death. Median length of follow-up for survival was calculated in patients still alive. **Results:** VRP-HER2 immunizations were well tolerated in these heavily pre-treated cohorts (median 4.5 prior therapies). There were no dose limiting toxicities or significant decreases in cardiac ejection fraction. Adverse events were predominantly grade 1 and 2, with one grade 3 AE, hyponatremia, felt not attributable to the VRP-HER2 vaccine. T cell responses specific for HER2 were detected by ELISpot in patients from cohort 1. The magnitude of the immune response was not altered by prior anti-HER2 therapy. In cohort 1, median PFS was 57 days, median overall survival (OS) was not reached, and median follow-up for OS was 26 months. In cohort 2, median PFS was 58 days, with one partial response and stable disease in two patients, median OS was not reached, and median follow-up for OS was 7 months. **Conclusions:** VRP-HER2 was safe and immunogenic alone or with concurrent anti-HER2 therapy. Future studies will combine the vaccine in prime boost strategies alone and in combination with other therapies. Clinical trial information: NCT01526473.

3082 Poster Session (Board #408), Sat, 8:00 AM-11:30 AM

Allogeneic myeloma GVAX with lenalidomide in near complete remission to enhance progression free survival. *First Author: Ivan Borrello, Johns Hopkins Univ, Baltimore, MD*

Background: We have previously shown that lenalidomide (Len) can augment vaccine efficacy to the pneumococcal conjugate vaccine (PCV), Prevnar. We now examine if vaccinating patients on Len in a near complete remission (nCR) (negative M-spike, IFE+) could improve the clinical response and generate myeloma specific immunity. **Methods:** Patients on a Len-containing regimen were eligible for enrollment if: 1) in stable nCR for at least 4 months; 2) converting from IFE negative to IFE positive; or 3) relapsing from a nCR to an M-spike <0.3g/dL. Patients continued only on single agent Len and received 4 GVAX vaccinations consisting of two allogeneic MM lines: H929, U266 admixed with K562-GM-CSF and PCV (Prevnar). Patients received 3 monthly vaccines and a boost at 6 months. **Results:** To date 34 patients have been screened. 16 patients initially in a nCR were ineligible for vaccination: 5 (31%) had disease progression and 11 (69%) became IFE negative during the 4 month observation period. 15 patients have enrolled. The table contains patient characteristics. Median follow-up is 33.9 months. Median progression free survival (PFS) of the cohort of vaccinated patients has not been reached. In contrast, PFS in the observation arm that remained on a multidrug Len-containing therapy was 10 months (p=0.0146). Vaccination with a rising M-spike was less likely to induce a durable remission. Laboratory analysis showed that patients achieving a CR had more central memory CD8 T cells at baseline in the BM and blood and greater tumor specific IFNg production in the BM. **Conclusions:** Vaccination in combination with Len appears to significantly extend the PFS in patients with a minimal disease burden. This enhanced clinical response correlates with the development of myeloma-specific immunity with the bone marrow compartment. Vaccination of MM patients with a poly-antigenic approach such as GVAX in combination with Len in nCR shows promising early clinical activity that warrants further investigation as an approach to maintaining durable clinical remissions. Clinical trial information: NCT01349569.

	Vaccination (n=15)	Observation (n=16)
Age	69 (55-81)	66 (40-83)
FISH (high risk)	0%	0%
ISS Stage III	2 (13%)	3 (19%)
IFE negative	0 (0%)	11 (69%)

3083 Poster Session (Board #409), Sat, 8:00 AM-11:30 AM

Pilot study of intratumoral G100, toll-like receptor-4 (TLR4) agonist, therapy in patients with Merkel cell carcinoma (MCC). *First Author: Shailender Bhatia, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: MCC is an aggressive skin cancer with suboptimal therapeutic options. Despite persistent expression of Merkel cell polyomavirus (MCPyV) proteins in ~80% of cases, these tumors are able to evade host immunity. G100 consists of a specific formulation of glucopyranosyl lipid-A (GLA), a TLR4 agonist, and is capable of directly activating dendritic cells (DCs), T cells and other effector cells and stimulating anti-tumor responses in preclinical models. Intratumoral (IT) G100 may overcome immune suppression mechanisms prevalent in MCC tumors and lead to effective local and systemic anti-tumor responses. **Methods:** 10 MCC patients (pts) with accessible tumor will be enrolled for G100 treatment. Pts with locoregional MCC (Cohort A) receive 1 cycle of G100 (5 mcg/day) IT on days 1, 8 followed by definitive surgery and/or radiation (RT) starting in week 4. Pts with metastatic disease (Cohort B) receive G100 (5 mcg/day) IT on days 1, 8 and 22 of a 6-week treatment cycle. For cycles 2-4, pts receive palliative RT to the injectable tumor on day 0 followed by G100 IT weekly for 6 doses. All pts have pre- and post-treatment tumor biopsies and blood samples collected for immune monitoring. **Results:** 8 pts have been enrolled to date (2 cohort A; 6 cohort B); all 8 pts have completed one or more cycles of G100. Treatment-related AEs have all been grade 1 (inflammation, pain and bruising at the injection site) or transient grade 2 (inflammation). 2/2 Cohort A pts with stage IIIB MCC are recurrence-free at 11+ and 4+ months; the first of whom had a pathologic CR after two G100 IT injections. Of 6 pts with stage IV MCC in Cohort B, 2 pts have SD after cycle 1 (one with 28% regression) and 4 pts had PD. MCPyV-specific CD8 and CD4 T cells have been isolated from tumors and peripheral blood, and correlative immune studies of frequency and functional status are in progress. **Conclusions:** In this pilot study in MCC pts, G100 has demonstrated acceptable safety and encouraging preliminary clinical efficacy. RT was recently added to cohort B and may further enhance immune and clinical responses by increasing the release of endogenous tumor antigens. G100 IT studies in other cancers and in combination with anti-PD-1 therapy are planned. Clinical trial information: NCT02035657.

3084 Poster Session (Board #410), Sat, 8:00 AM-11:30 AM

First-in-human dose-escalating trial of *E.coli* purine nucleoside phosphorylase and fludarabine gene therapy for advanced solid tumors. *First Author: Thomas Kenwise Chung, University of Alabama at Birmingham, Birmingham, AL*

Background: The use of *E. coli* purine nucleoside phosphorylase (PNP) to activate fludarabine was safe and demonstrated robust antitumor activity in preclinical studies. The regimen demonstrated cytotoxicity within neighboring tumor cells that did not incorporate PNP, an effect known as bystander killing. Given the potential of this novel therapeutic, the FDA approved this clinical trial. **Methods:** A first-in-human multi-site Phase I clinical trial (NCT 01310179; IND 14271) was initiated to evaluate the safety and efficacy of intratumoral administration of a replication-deficient adenoviral vector expressing *E. coli* PNP in combination with intravenous fludarabine. Escalating doses of fludarabine comprised the first three cohorts (15, 45, and 75 mg/m^2) and escalating virus in the fourth (10^{12} versus 10^{11} viral particles) with 75 mg/m^2 fludarabine. Primary endpoints included adverse event rates and tumor volume change from baseline to final measurement on day 56. **Results:** All 12 study subjects completed therapy without any dose limiting toxicities. Change in tumor size from baseline to final measurement demonstrated a dose-dependent response, with 5 of 6 patients in Cohorts 3 and 4 achieving tumor regression compared to 0 of 6 patients in Cohorts 1 and 2 (p = 0.018). The overall adverse event rate was not dose-dependent. Most common adverse events included pain at the viral injection site (92%), drainage/itching/burning (50%), fatigue (50%), and fever/chills/flu-like symptoms (42%). Four patients experienced decreased peripheral blood counts and three patients experienced transient liver enzyme elevations that resolved spontaneously. Analysis of serum confirmed lack of systemic exposure to fluoroadenine, the active agent generated by E. coli PNP. Antibody response to adenovirus was detected in 2 patients, suggesting that neutralizing immune response is not a barrier to efficacy. **Conclusions:** This first-in-human clinical trial found that localized generation of fluoroadenine within tumor tissues using *E. coli* PNP and fludarabine is safe and effective. The pronounced effect on tumor volume after a single treatment cycle suggests phase II studies are warranted. Clinical trial information: NCT01310179.

3085 Poster Session (Board #411), Sat, 8:00 AM-11:30 AM

An evaluation of local and systemic immune markers following intratumoral administration of a chimeric adenovirus Ad5/3-D24-GMCSF in refractory cancer patients with solid tumors. *First Author: Sari Anneli Pesonen, Oncos Therapeutics, Helsinki, Finland*

Background: Clinical studies consistently show how adenovirus, unlike other viral vectors, can both prime and boost immune responses. Consequently, adenovirus is used to develop vaccines against various human diseases, such as cancer. Adenoviruses can be armed with transgenes for further enhancement of a tumor-specific immune reaction. We present results from a phase I study describing both local and systemic immune activation following administration of ONCOS-102, a chimeric oncolytic adenovirus, in patients with refractory solid tumors. **Methods:** A total of 12 patients were treated with up to 9 intratumoral injections of ONCOS-102. Biopsies were collected at baseline, 1 and 2 months after treatment initiation to analyze tumors for the presence of tumor infiltrating lymphocytes (TILs), expression of PD-L1, and gene expression profiles. Peripheral blood mononuclear cells (PBMCs) were collected to assess antigen specificity of CD8+ T cells by IFN-gamma ELISPOT. **Results:** No dose limiting toxicity was identified. An immediate short-term increase in systemic pro-inflammatory cytokines and an infiltration of innate immune cells into tumors was seen following ONCOS-102. Furthermore, increase in tumor infiltrating $CD8^+$ T cells was seen in 11 out of 12 patients. 10 out of 12 patients showed an increase in PD-L1+ tumor and/or lymphoid cells. Two patients showing the most striking post-treatment increase in TILs showed also a systemic induction of tumor-specific CD8+ T cells (MAGE-A1, MAGE-A3, NY-ESO-1, mesothelin) while none of these tumor-recognizing T cell populations were detected at baseline. These two patients showed high expression levels for genes associated with activated Th1 cells (perforin, granzyme B, granulysin, IFN-gamma) and Th1 type immunoprofile (IRF-1, X3CL1, CXCL9, CXCL10, CCL5, CCL2) in post-treatment biopsies. **Conclusions:** Concomitant increase in CD8+ TILs and PDL1 expressing cells in tumors suggests that local ONCOS-102 treatment is able to break the immunological ignorance towards tumors by activating the immune system in advanced refractory tumors which were immunologically silent before treatment. Clinical trial information: NCT01598129.

3086 Poster Session (Board #412), Sat, 8:00 AM-11:30 AM

Immunomodulatory effects of OX40 agonists in a defined antigen challenge in cynomolgus macaques. *First Author: Stacie L Lambert, MedImmune, Mountain View, CA*

Background: Immunomodulatory antibodies targeting specific T cell costimulatory pathways have shown great potential as cancer therapeutics. OX40 agonists can enhance T cell proliferation and survival and cause tumor regressions in mouse models. While initial evaluations of pharmacodynamic activity of these compounds in non-human primate models have relied on non-specific T cell proliferation readouts (Ki67), additional sensitive biomarkers of pharmacodynamic activity would add value in evaluating optimal dosing and timing of candidate therapeutics. **Methods:** In this study, we compared the *in vivo* activity in cynomolgus macaques of intravenously infused OX40 agonist MEDI6469 (9B12, a murine IgG1 antibody) and MEDI6383, a human OX40 ligand fusion protein consisting of a dimer of OX40L trimers held together by Fcγ domains that also agonizes the OX40 receptor. Antigen-specific responses were evaluated to respiratory syncytial virus soluble F (sF) protein, which was administered intramuscularly on the same day as OX40 agonist treatment. Ki67 proliferation was additionally measured in whole blood. **Results:** Enhancement of F-specific T cell responses, serum anti-F IgG responses and functional antibodies was observed in animals that received the OX40 agonists. In addition, OX40 agonism resulted in a temporal enhancement of cellular proliferation (Ki67 staining) in CD4 and CD8 T cell memory subsets, as well as in NK cells and B cells. The strongest antigen-specific and Ki67 responses were observed in response to MEDI6383, with the exception of responses observed for NK cell proliferation which were similar between MEDI6469 and MEDI6383. **Conclusions:** Our study indicates that antigen-specific cellular and humoral responses may be useful biomarkers of OX40 agonist activity. Additionally, our study confirms that Ki67 readouts are informative in cynomolgus macaques, which was also demonstrated in separate studies using rhesus macaques.

TPS3087 Poster Session (Board #413a), Sat, 8:00 AM-11:30 AM

Phase I, open-label study of MEDI0680, an anti-programmed cell death-1 (PD-1) antibody, in combination with MEDI4736, an anti-programmed cell death ligand-1 (PD-L1) antibody, in patients with advanced malignancies. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: The PD-1/PD-L1 pathway plays a key role in controlling T-cell activation and may be utilized by tumor cells to evade antitumor responses. Anti-PD-1 and anti-PD-L1 antibodies have shown acceptable safety profiles and clinical activity across a range of tumor types. MEDI0680 is a humanized IgG4κ mAb specific for human PD-1 that blocks PD-L1 and programmed cell death ligand-2 (PD-L2). Blocking both PD-L1 and PD-L2 may have more efficient blockade and may be more specific for different tumor groups in comparison to blocking either one alone. MEDI4736 is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity. Anti-PD-1 and PD-L1 agents block distinct interactions contributing to immunosuppression, suggesting potential additive or synergistic effects. Preclinical data, including mouse models, support potential benefit for anti-PD-L1 and anti-PD-1 in combination. **Methods:** This phase I, multicenter, open-label study evaluates the safety of MEDI0680 in combination with MEDI4736 in patients with advanced malignancies (NCT02118337). Eligible patients ($\geq$ 18 years) will have an Eastern Cooperative Oncology Group performance status of 0-1. The primary objectives are to assess safety and tolerability, and determine the maximum tolerated dose of MEDI0680 in combination with MEDI4736. Secondary objectives include assessment of antitumor activity (including objective response rate, disease control rate, duration of response, progression-free survival, and overall survival), pharmacokinetics, and immunogenicity of the combination. Exploratory objectives include an evaluation of biomarkers within the tumor microenvironment and their relationship to tumor response, identification of genetic predictors of response or resistance, and an assessment of patient-reported outcomes. Recruitment is ongoing, with a target enrollment of approximately 150 patients across 3 centers in the United States. Clinical trial information: NCT02118337.

TPS3088 Poster Session (Board #413b), Sat, 8:00 AM-11:30 AM

A phase I, multicenter, open-label, first-in-human study to evaluate MEDI0680, an anti-programmed cell death-1 antibody, in patients with advanced malignancies. *First Author: Jeffrey R. Infante, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Programmed cell death-1 (PD-1) is an inhibitory regulator or checkpoint of T-cell activation. Recent data from several large phase I studies have shown that targeting the PD-1/programmed cell death ligand-1 (PD-L1) axis has an acceptable safety profile, can enhance antitumor responses, and provide clinical benefit. MEDI0680 is a humanized immunoglobulin gamma 4, kappa monoclonal antibody specific for human PD-1 that blocks PD-L1 and programmed cell death ligand-2 (PD-L2). Blocking both PD-L1 and PD-L2 may provide more efficient pathway inhibition and may be more specific for different tumor groups in comparison to blocking either one alone. As well as blocking interactions between PD-1 and its ligands, MEDI0680 also improves the intrinsic functionality of T cells by triggering internalization of PD-1, thereby reducing the surface levels of PD-1 and membrane-proximal tyrosine phosphatase SHP2. **Methods:** This is an ongoing, phase I, multicenter, open-label, first-in-human, dose-escalation study (NCT02013804) evaluating MEDI0680 in patients with advanced malignancies. Eligible patients ($\geq$ 18 years) will have an Eastern Cooperative Oncology Group performance status of 0 or 1, histologically- or cytologically-confirmed melanoma or clear-cell renal cell carcinoma that is refractory to standard treatment or for which no standard treatment exists, $\geq$ 1 measurable lesion per RECIST v1.1, with prior treatment toxicities of $\leq$ grade 1. The primary objectives of the study are to assess the safety and tolerability and define the maximum tolerated dose of MEDI0680. Secondary objectives include an evaluation of the pharmacokinetic and antitumor effects of MEDI0680. Recruitment is ongoing, with a target enrollment of approximately 48 patients across 5 centers in the United States. Clinical trial information: NCT02013804.

TPS3089 Poster Session (Board #414a), Sat, 8:00 AM-11:30 AM

First-in-human study assessing safety and tolerability of REGN1979, a novel CD20xCD3 bispecific antibody, in patients with CD20+ B-cell malignancies previously treated with anti-CD20 therapy. *First Author: Carrie M. Brownstein, Regeneron Pharmaceuticals Inc, Tarrytown, NY*

Background: REGN1979 is a human bispecific antibody based on an IgG4 isotype modified to reduce Fc binding, designed to bridge CD20-expressing cells to cytotoxic T-cells by binding to the CD3 subunit of the TCR complex. Bridging results in targeted killing of CD20+ cells by T-cells that is independent of typical requirements for specific TCR recognition of a target cell. T-cell activation requires CD20, a well-validated surface target for B-cell malignancies. This MOA is distinct from that of other available anti-CD20 antibodies, and may provide additional therapeutic benefit to patients with CD20+ malignancies, including those who have relapsed after anti-CD20 therapy. REGN1979 has been shown to specifically kill CD20+ tumor cells *in vitro*, and has shown potent *in vivo* anti-tumor activity in several mouse models (established Raji tumors and B16_hCD20)(Varghese B et al. ASH 2014. Abstract 4501). In cynomolgus monkeys, REGN1979 at doses ≥ 0.01 mg/kg depleted peripheral and tissue CD20+ B-cells to similar levels achieved with significantly higher doses of rituximab (30 mg/kg). At ≥ 0.1 mg/kg, REGN1979 depleted B-cells in spleen, mesenteric lymph nodes, and thymus to undetectable levels. **Methods:** This open label, multicenter, Phase 1, FIH study (NCT02290951) uses a 3+3 dose-escalation design with a 28-day DLT observation period to assess both acute and late toxicity. Each dose level (DL) has an initial dose followed by a second and subsequent higher dose, if the initial dose was tolerated. Patients receive REGN1979 IV weekly during a 4-week induction period at their assigned DL, then monthly for 5 additional doses. There will be parallel independent dose escalation cohorts for patients with NHL and CLL at each DL. After determining the recommended dose for further study, there will be an expansion phase with independent cohorts for patients with indolent NHL, aggressive NHL, and CLL. The primary objective is to assess the safety, tolerability, and DLTs of REGN1979. Secondary objectives include characterization of the PK profile, immunogenicity, and preliminary anti-tumor activity of REGN1979. Enrollment is ongoing. Clinical trial information: NCT02290951.

TPS3090 Poster Session (Board #414b), Sat, 8:00 AM-11:30 AM

Phase I study to evaluate the safety and efficacy of MEDI4736 in combination with tremelimumab in patients with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN). *First Author: Lillian L. Siu, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Despite advances in the treatment of SCCHN, the outlook for patients (pts) with R/M disease remains poor. Development of immunotherapies to treat this disease may hold promise. High mutational burden due to tobacco and expression of human papilloma virus (HPV)-associated viral antigens is linked to immunogenicity in SCCHN tumors. Despite this immunogenicity, tumors can evade immune detection by exploiting inhibitory checkpoints. PD-L1 is up-regulated on SCCHN tumors and is associated with antitumor T-cell response inhibition. MEDI4736 (M), a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity, has shown a manageable safety profile and promising antitumor activity in R/M SCCHN (ORR 24% in PD-L1+ pts, phase I)(Fury M, et al. Poster presented at ESMO 2014, 988PD). Tremelimumab (T), a selective human IgG2 mAb inhibitor of CTLA-4, has also shown antitumor activity in several tumor types (Tarhini AA. Immunotherapy 2013;5:215–29). Preclinical data suggest that combining anti-PD-L1 and anti-CTLA-4 provides non-redundant immune checkpoint blockade and synergistic antitumor activity. Preliminary data for M + T in NSCLC show encouraging clinical activity in both PD-L1-positive and PD-L1-negative pts (Antonia S, et al. Poster presented at ESMO 2014, 1327P). Here we describe a study assessing the safety, efficacy, and potential biomarkers of response to M + T, in pts with R/M SCCHN. **Methods:** This is a phase I, multicenter, open-label study (NCT02262741) in pts (N~164) with R/M SCCHN deemed incurable by local therapy. The dose exploration phase will evaluate the combination of M + T, followed by dose expansion in treatment-naive or pretreated R/M pts. Pts will have PD-L1 status determined prior to dosing with M IV + T IV or T IV alone. The primary objective is to assess safety/tolerability of M + T and T alone. Secondary objectives are to assess antitumor activity via RECIST (including ORR, DCR, DoR, PFS, and OS), PK/PD, immunogenicity, and if clinical activity correlates with potential biomarkers, including PD-L1 expression, HPV status, and tobacco use. Recruitment is ongoing. Clinical trial information: NCT02262741.

TPS3091 Poster Session (Board #415a), Sat, 8:00 AM-11:30 AM

A phase 1b/2, open-label study to evaluate the safety and tolerability of MEDI6469 in combination with immune therapeutic agents or therapeutic mAbs in patients with selected advanced solid tumors or aggressive B-cell lymphomas. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: Anti-CTLA-4 and anti-PD-1/PD-L1 have shown antitumor activity in 10–30% of patients (pts) with select tumors. Combinations of co-stimulatory agonists, such as OX40, and antagonist Abs against the T-cell checkpoints CTLA-4 or PD-L1 could synergize to yield higher response rates. Additionally, nonclinical models show OX40 cell surface expression is induced following activation of NK cells. OX40 ligation promotes enhanced NK cell activity, suggesting greater antitumor activity could be achieved with an OX40 agonist in combination with an anti-CD20 antibody engaging NK cells for antitumor activity. Depleting B cells with rituximab could decrease immunogenicity of murine MEDI6469 by decreasing anti-drug Ab production. MEDI6469, an agonist human OX40 receptor murine mAb, showed clinical activity in a Phase 1 study and is being evaluated as monotherapy and in combination with tremelimumab (anti-CTLA-4) or MEDI4736 (anti-PD-L1) in pts with select advanced solid tumors, or with rituximab (anti-CD20) in relapsed diffuse large B cell lymphoma (DLBCL) pts. **Methods:** This is a Phase 1b/2, multicenter, open-label study (NCT02205333) in adult pts with select advanced solid tumors refractory to standard therapy or for which no standard therapy exists, or with histologically confirmed aggressive DLBCL. The dose-escalation phase includes single-dose IV MEDI6469 monotherapy (6+3 design) and 3 combination therapies (3+3 design): single-dose IV MEDI6469 Day 1 + repeated IV doses of (1) tremelimumab, or; (2) MEDI4736 up to 12 months or until PD, or; (3) repeated IV doses of MEDI6469 and rituximab until confirmed CR plus 1 cycle or PD. The dose-expansion phase will examine MEDI6469 combination treatments at the dose levels determined during dose escalation in pts with select advanced solid tumors or DLBCL. The primary endpoints are safety and determination of the maximum tolerated dose. Secondary endpoints are PK, immunogenicity, and antitumor activity. Enrollment of up to ~212 pts (66, dose escalation; 146, dose expansion) is ongoing. Clinical trial information: NCT02205333.

TPS3092 Poster Session (Board #415b), Sat, 8:00 AM-11:30 AM

A phase Ib study of neoadjuvant immune biomarker modulation with cetuximab and motolimod in head and neck cancer (HNC). *First Author: Benjamin Alexander Kansy, University of Pittsburgh; University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: HNC is an immunosuppressive disease, with low absolute lymphocyte counts, impaired activity of effector cells such as natural killer cells (NK), and poor antigen-presenting function. The anti-EGFR monoclonal antibody cetuximab (CTX) prolongs survival in HNC, but only in a subset of patients. This limited efficacy may be due to immunosuppressive cells such as myeloid derived suppressor cells and suppressive macrophages. The clinical efficacy of CTX may be augmented by immune stimulation. Motolimod (formerly VTX-2337) is a novel Toll-like receptor 8 (TLR8) agonist which stimulates myeloid dendritic cells, monocytes, and NK cells. Preclinical data have demonstrated enhanced CTX and NK cell-mediated lysis of HNC cells and dendritic cross-priming of EGFR-specific CD8+ T cells. CTX and motolimod in HNC patients was tolerable and active in a phase Ib study, with enhanced mobilization and activation of NK cells. Our hypothesis is that the differential clinical response of HNC to treatment with CTX and motolimod reflects the role of cellular immune activation, immune escape mechanisms, and TLR8 stimulation enhancement of the immune response in the circulation and in the tumor microenvironment. **Methods:** This is a prospective phase Ib clinical trial (NCT02124850) of preoperative treatment with CTX and motolimod. The primary objective is to determine the extent to which the administration of neoadjuvant CTX plus motolimod modulates immune biomarkers in peripheral blood and HNC tumors. An exploratory objective of the study is to assess whether this modulation of biomarkers can predict anti-tumor response. Subjects must have HNC stage II–IVA and be surgical candidates. CTX and motolimod will be administered for a 3–4 week preoperative period. Immune biomarkers will be quantitatively assessed. The biomarker modulation and biopsies of skin/acneiform rash will be studied in correlation with clinical response by CT or MRI scan. Tumor apoptosis/proliferation will be assessed by biopsy pre- and post- treatment with CTX /motolimod. All patients will receive definitive surgical resection. Enrollment target is fifteen complete specimens (tumor, peripheral blood mononuclear cells and serum). Clinical trial information: NCT02124850.

TPS3093 Poster Session (Board #416a), Sat, 8:00 AM-11:30 AM

A phase I study of MEDI6383, an OX40 agonist, in adult patients with select advanced solid tumors. *First Author: Todd Michael Bauer, Sarah Cannon Research Institute / Tennessee Oncology, PLLC., Nashville, TN*

Background: Enhancing T-cell function in cancer patients (pts) through T-cell co-stimulatory pathways such as OX40 has the potential to overcome cancer-induced immune suppression. MEDI6469, a human OX40 agonist murine antibody, administered for a single cycle in a phase I clinical study showed both an acceptable toxicity profile and regression of ≥ 1 metastatic lesion in 12 of 30 treated pts(Curti B, et al. Cancer Res 2013;73:7189–98). Humanized OX40 agonists are expected to have reduced immunogenicity relative to murine antibody, which may allow for repeat-dose administration, potentially enhancing biologic and antitumor activity. MEDI6383 is a human OX40 ligand fusion protein that in preclinical models initiates an intracellular signaling cascade to enhance T-cell survival, proliferation of T cells and macrophage lineage cells, and cytokine production. **Methods:** This is a phase I, multicenter, open-label study of MEDI6383 (NCT02221960) in adult pts with select recurrent or metastatic solid tumors. In the dose-escalation phase, sequential cohorts of pts will receive 1 of up to 6 dose levels (3+3 design) of MEDI6383 IV every 2 weeks for up to 48 weeks or until progressive disease (PD). In the dose-expansion phase, tumor-type specific cohorts will be treated at the MEDI6383 dose level and treatment schedule determined during dose escalation for up to 48 weeks or until PD. Pts who achieve a response and then have PD in follow-up may have 1 round of MEDI6383 retreatment. All pts will be followed for survival through end of study. The primary endpoint is safety and determination of the maximum tolerated dose; secondary endpoints are antitumor activity (objective response and disease control by immune-related RECIST, duration of response, progression-free survival, overall survival), pharmacokinetics, immunogenicity, and pharmacodynamics. Enrollment of up to 122 pts (42 pts, dose escalation; 80 pts, dose expansion) is ongoing. Clinical trial information: NCT02221960.

TPS3094 Poster Session (Board #416b), Sat, 8:00 AM-11:30 AM

KEYNOTE-055: A phase II trial of single agent pembrolizumab in patients (pts) with recurrent or metastatic head and neck squamous cell carcinoma (HNSCC) who have failed platinum and cetuximab. *First Author: Steven Francis Powell, Sanford Health, Sioux Falls, SD*

Background: Treatment options are limited for pts with recurrent and/or metastatic HNSCC whose disease has progressed after platinum and cetuximab therapy. Pembrolizumab (MK-3475) is a humanized IgG4 monoclonal antibody designed to block interaction between activated T-cell-specific programmed death receptor 1 (PD-1) and its ligands PD-L1 and PD-L2. Preclinical studies have shown that blocking PD-1/PD-L1 interaction promotes infiltration of activated tumor-specific effector T cells, leading to tumor cell death. In KEYNOTE-012, a phase 1b clinical study, pembrolizumab exhibited antitumor activity in patients with recurrent or metastatic, PD-L1–positive HNSCC. Treatment with intravenous pembrolizumab 10 mg/kg every 2 weeks resulted in an objective response rate (ORR) of 19.6% (confirmed and unconfirmed responses) by investigator review, and the magnitude of response was positively correlated with PD-L1 expression in the tumor tissue (P= 0.018). **Methods:** KEYNOTE-055 (NCT02255097) is a multicenter, open-label, nonrandomized phase 2 trial with the primary objective to evaluate the efficacy and safety of pembrolizumab in 150 pts with recurrent and/or metastatic HNSCC resistant to platinum and cetuximab. Pembrolizumab will be administered intravenously for up to 24 months at a dose of 200 mg every 3 weeks until disease progression or unacceptable toxicity. Eligible pts must undergo a core or excisional biopsy prior to treatment for evaluation of PD-L1. The primary efficacy parameter is ORR, with response to treatment assessed every 6-9 weeks by central radiology review using RECIST v1.1. Secondary efficacy end points include: duration of response, ORR per modified RECIST v1.1 (to account for the unique tumor response profile of pembrolizumab), ORR for HPV^+ pts, progression-free survival (PFS), and overall survival (OS). For the ORR analyses, a 97.5% confidence interval and 1-sided P value will be provided using exact binomial distribution. Kaplan-Meier statistics will assess PFS and OS. Adverse events (AEs) will be monitored and graded using CTCAE v4.0. Clinical trial information: NCT02255097.

TPS3095 Poster Session (Board #417a), Sat, 8:00 AM-11:30 AM

A Phase II multicenter trial to evaluate combination ipilimumab and high-dose IL-2 in patients with unresectable stage III and IV melanoma. *First Author: Howard Kaufman, Rush University Medical Center, Chicago, IL*

Background: High-dose (HD) IL-2 (600,000 IU.kg) and ipilimumab (3 mg/kg) are approved immunotherapy agents for selected patients with advanced melanoma and both are associated with durable responses in a small number of patients. Previous studies in a pre-clinical melanoma tumor models and in a small phase I/II dose escalation clinical trial suggested that concurrent combination treatment was associated with improved response rates, including a 17% complete response rate in the clinical trial, without an increase in toxicity. Data has also suggested that higher doses of ipilimumab may improve response rates as shown in clinical trials comparing 3 to 10 mg/kg dosing. To better define the potential benefit of this combination in patients with melanoma, this phase II multicenter, open-label, single arm trial, is being conducted (NCT02203604). **Methods:** The primary goal of this trial is to determine the clinical OR rate within the first 24 weeks. Secondary end points include safety, feasibility, overall survival, one- and two-year survival, progression-free survival, best overall response, and frequency of effector CD8+ T cells and CD4+FoxP3+ regulatory T cells in peripheral blood, and when possible in the tumor microenvironment. Adults with advanced unresectable stage III and IV melanoma and who meet criteria for high-dose IL-2 therapy are eligible. Main exclusion criteria are active brain metastases, active autoimmune diseases, concurrent systemic immunosuppressive therapy as well as prior immunotherapy with IL-2 or impilimumab. Up to 82 patients will be enrolled and receive ipilumimab (10 mg/kg) for 4 cycles (Days 1, 22, 43, 64) and high-dose IL-2 (600,000 IU/kg) for 2 cycles (Days 22-26, 43-47) followed by maintenance ipilimumab. Preliminary safety assessment will be performed on the first 6 patients before other patients are allowed to enter the study. If significant toxicity occurs in the first 6 patients ipilimumab will be dose reduced to 3 mg/kg. As of Feb 4, 2015 3 patients have been enrolled. Clinical trial information: NCT02203604.

TPS3096 Poster Session (Board #417b), Sat, 8:00 AM-11:30 AM

Phase I study evaluating high dose ADXS11-001 treatment in women with carcinoma of the cervix. *First Author: Sharad A. Ghamande, Georgia Regents Univ, Augusta, GA*

Background: This is a phase I, dose-escalation, open-label, single-center study, in subjects with carcinoma of the cervix who have failed conventional therapy. ADXS11-001 is a live attenuated *Listeria monocytogenes* (*Lm*)-LLO immunotherapy bioengineered to secret an antigen-adjuvant fusion protein (fused to HPV16 E7). The primary objective of the study is to evaluate the tolerability and safety of ADXS11-001. Secondary objectives are tumor response, progression-free survival and correlative immunologic studies. **Methods:** Subject eligibility: Women ≥ 18 years of age with histologically-confirmed, measurable and/or evaluable (defined by RECIST 1.1) persistent, metastatic, or recurrent squamous or adenocarcinoma of the cervix with documented disease progression that is not amenable to surgery or standard radiotherapy. Subjects must have received ≤ 2 prior regimens for treatment of their metastatic disease. Planned sample size is approximately 6-12 subjects. Subjects will receive ADXS11-001 every 3 weeks during a 12- week treatment cycle. Doses will be escalated in the standard 3 + 3 fashion, in two doses, starting with 5×10^9 colony forming units (cfu) to a maximum dose level of 1×10^{10} cfu. If DLT is seen in one of 3 subjects, another 3 subjects will be treated at that same dose. If DLT is seen in 2 of 6 subjects, then that dose level will be considered maximum tolerated dose (MTD) and the previous dose level will be selected as the recommended phase II dose (RP2D). Blood samples will be evaluated for immunologic effects in cycle 1 only. Treatment cycles can be repeated at the RP2D (or less) for an individual subject until a discontinuation criterion is met, including documented disease progression, intolerable side effects. The end of study will be defined as 1 year after the last subject's first treatment or until that subject has met a discontinuation criterion. Assessment of the RP2D level may be further explored in an expansion cohort of 15 subjects. Clinical trial information: NCT02164461.

TPS3097 Poster Session (Board #418a), Sat, 8:00 AM-11:30 AM

Phase I study of AMG 211/MEDI-565 administered as continuous intravenous infusion for relapsed/refractory gastrointestinal (GI) adenocarcinoma. *First Author: Elisabeth De Vries, University Medical Center Groningen, Groningen, Netherlands*

Background: The bispecific CD19-directed CD3 T-cell engager (BiTE$^{(R)}$) blinatumomab was recently approved by FDA as single-agent immunotherapy for patients with Philadelphia chromosome-negative relapsed or refractory B-cell precursor ALL. The clinical activity of blinatumomab seen with 4-week infusion regimen provides rationale for BiTE administration as continuous intravenous infusion (cIV). Experience with an EpCAM-directed BiTE first-in-human study (FIH) suggests that in solid tumor indications dose levels achieving exposure comparable to 50% or even 90% of the maximal effective concentration in in vitro might be needed to observe substantial anti-tumor activity translating into objective response (Fiedler et al, J Clin Oncol 30, 2012, abstr 2504). The CEA-directed BiTE (MEDI-565, AMG 211) inhibited the growth of CEA-expressing cancer cells in various cancer models in the presence of CD3+ T-cells and has been explored as an intermittent 3-hour infusion for 5 subsequent days in a FIH study (NCT01284231). The present study aims at cIV AMG 211 administration that will result in lower C_{max} concentrations compared to intermittent infusions. The steady state levels with potential effective exposure should range above a threshold level required for anti-tumor activity for a prolonged period of time. The therapeutic index may be improved by reduction of adverse events attributable to a higher $C_{max}$of discontinuous administration but other adverse events due to prolonged exposure will need to be assessed. **Methods:** Approximately 34 patients with relapsed/refractory GI adenocarcinomas will be treated with AMG 211 for 7, 14 or 28 days at 200-6,400 μg/day cIV infusion in repeated cycles with 2-week breaks until confirmed disease progression, occurrence of a dose-limiting toxicity (DLT) or discontinuation for other reasons. A toxicity probability interval Bayesian model will guide dose escalation after a first DLT. Study objectives include evaluation of safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy. Cohort 1 has been completed without DLT and cohort 2 started enrollment in January 2015. **ClinicalTrials.gov Identifier**: NCT02291614 Clinical trial information: NCT02291614.

TPS3098 Poster Session (Board #418b), Sat, 8:00 AM-11:30 AM

A randomized multicenter phase Ib/II study to assess the safety and the immunological effect of chemoradiation therapy (CRT) in combination with pembrolizumab (anti-PD1) to CRT alone in patients with resectable or borderline resectable pancreatic cancer. *First Author: Matthew H. G. Katz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tumor-infiltrating lymphocytes (TILs) play a major role in anti-tumor immune responses, and their presence is correlated with survival in a variety of tumors. These TILs do not reach the pancreatic cancer (PC) cells in significant numbers due to the presence of stroma and a suppressive microenvironment. One of the leading causes for immune suppression is elevated expression of PD-L1 either by the tumor cells or the surrounding regulatory cells, resulting in dysfunction of TILs. There is recent evidence to suggest that CRT can increase the presence of TILs in the PC microenvironment (PCME), leading to production of interferon-γ (IFN-γ), which could increase the expression of PD-L1 through a negative feedback loop. **Methods:** This is a prospective multicenter randomized trial that will accrue subjects with resectable or borderline resectable PC who had not received prior treatment. The primary objectives of the study are: (1) to determine the safety of neoadjuvant CRT in combination with pembrolizumab. (2) To estimate the difference in the number of TILs in PC subjects receiving neoadjuvant CRT in combination with pembrolizumab to the number of TILs in subjects receiving neoadjuvant CRT alone. This study will also investigate the effect of CRT+/- anti-PD-1 on the other effector and suppressive immune cells. Eligible subjects will be randomized 2:1 to the investigational treatment (Arm A) to receive pembrolizumab administered IV every 3 weeks on days 1, 22, and 43 during concurrent CRT with capecitabine (825 mg/m2 orally twice daily on days of radiation only) and radiation (50.4 Gy in 28 fractions over 28 days) or Arm B to receive only concurrent CRT with capecitabine. Patients without local or distant disease progression will be taken to the operative room for planned surgery (within 2 weeks of imaging). Postoperatively, resected patients will receive off study standard of care adjuvant gemcitabine (1000mg/kg IV weekly for 3 out of 4 weeks for 6 months). Post operatively resected patients will be followed for up for PFS and OS for up to 2 years. Clinical trial information: NCT02305186.

TPS3099 Poster Session (Board #419a), Sat, 8:00 AM-11:30 AM

A phase I study to evaluate the safety and tolerability of MEDI4736, an anti- programmed cell death-ligand-1 (PD-L1) antibody, in combination with tremelimumab in patients with advanced solid tumors. *First Author: Patrick Alexander Ott, Dana-Farber Cancer Institute, Boston, MA*

Background: Programmed cell death-1 (PD-1) and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) are regulators or checkpoints of T cell activation, utilized by tumor cells to evade antitumor immune responses. MEDI4736 (M) is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD-80 with high affinity and selectivity. Tremelimumab (T) is a selective human IgG2 mAb inhibitor of CTLA-4. Blocking each of these checkpoints is associated with antitumor effects. The mechanisms for activating PD-1 and CTLA-4 are non-redundant, suggesting the potential for additive or synergistic effects; clinical studies have shown synergistic antitumor activity of anti-PD-1/anti-PD-L1 and anti CTLA-4 as combination therapy. **Methods:** An ongoing, phase 1, multicenter, open-label study (NCT01975831) is evaluating the safety/tolerability, pharmacokinetics (PK), immunogenicity and antitumor activity of M in combination with T in patients with advanced solid tumors. The study comprises a dose-escalation phase (3+3 design) and a subsequent dose-expansion phase. Patients with non-small cell lung, cervical, head and neck, colorectal, ovarian cancers, or renal cell carcinoma are eligible. M is administered at escalating doses starting at 0.3 mg/kg (up to 10 mg/kg) every 2 wks and T is administered at escalating doses starting at 3 mg/kg (up to 10 mg/kg) every 4 wks for the first 6 cycles, then every 12 wks. Treatment may continue for up to 12 months or until progressive disease or unacceptable toxicity. The primary endpoints are safety/tolerability and identification of the maximum tolerated dose of the combination. Secondary objectives include clinical activity (tumor response by RECIST v1.1 and Immune-related Response Criteria (irRC), PFS, and OS). The study will also assess PK and pharmacodynamic parameters, serum and tissue PD-L1 expression, immune cell phenotypes, cytokine profiling, and flow. Pharmacogenomic analysis of blood and tumor samples may be performed to examine gene expression patterns following treatment. Cohort 1 has been completed without DLT. Enrollment to cohort 2 began in March 2014. Clinical trial information: NCT01975831.

TPS3100 Poster Session (Board #419b), Sat, 8:00 AM-11:30 AM

"ARMY": First-in-human study of the humanized, defucosylated monoclonal antibody (mAb) MEN1112/OBT357 targeting CD157 antigen, in relapsed or refractory (R/R) acute myeloid leukemia (AML). *First Author: Adriano Venditti, Fondazione Policlinico Tor Vergata, Rome, Italy*

Background: Defucosylated mAbs enhance antibody dependent cell-mediated cytotoxicity (ADCC) through an improved affinity for Fc receptors. MEN1112/OBT357 is a humanized, defucosylated mAb targeting Bst1/CD157, a GPI-anchored transmembrane protein highly expressed on blasts of AML patients either at primary diagnosis or relapse. Preclinical findings show that MEN1112/OBT357 has the potential to exert powerful ADCC against AML (Aud et al ASH 2014; Venditti et al ASH 2014). **Methods:** Multi-center, non-randomized, 3+3 dose escalation/expansion cohort trial of MEN1112/OBT357 intended to recruit approximately 50 adult patients (pts) with R/R AML. Refractory pts must have failed $\geq$ 1 cycle of cytotoxic chemotherapy or hypomethylating agents. A baseline WBC count $\leq$ 10 x 10^9/L is required (pre-treatment with hydroxyurea is permitted). Main exclusion criteria are acute promyelocytic leukemia, hematopoietic stem cell transplant within 3 months prior to screening and active central nervous system involvement. MEN1112/OBT357 is given intravenously at 5 incremental doses on Days 1, 8, and 15 in a 21-day cycle for a total of 2 cycles; monthly maintenance is allowed in pts achieving clinical benefit. Primary objective is to identify dose limiting toxicities and maximum tolerated dose of MEN1112/OBT357 in pts with R/R AML; secondary objectives include (1) clinical pharmacokinetics, (2) potential immunogenicity, (3) clinical activity (complete- and composite complete remission rate, best response rate, overall survival) in treated pts and (4) its correlation with target expression/saturation, natural killer cells status, ex vivo activity at baseline and clinical/biological AML features. AEs will be graded according to NCI CTCAE v. 4.03 guidelines. Study variables will be presented by dose-cohort and overall using appropriate descriptive statistics. Efficacy will be evaluated in each cohort in pts completing the first cycle and with $\geq$ 1 post-cycle assessment using modified IWG 2003 criteria. The individual study duration is 6 months. The enrolment began on December 2014. Clinical trial information: NCT02353143 Clinical trial information: NCT02353143.

TPS3101 Poster Session (Board #420a), Sat, 8:00 AM-11:30 AM

Phase I expansion cohort trial to investigate the safety and clinical activity of avelumab (MSB0010718C) in patients with metastatic or locally advanced solid tumors. *First Author: Christopher Ryan Heery, Laboratory of Tumor Immunology and Biology, NCI, NIH, Bethesda, MD*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. **Methods:** This is a parallel group expansion trial of avelumab in patients (pts) with selected tumor indications following the determination of dose and regimen in a phase I, open label, dose escalation study. The dose escalation cohort has been completed (n = 53). Pts in 11 separate cohorts of advanced solid tumors will receive avelumab at 10 mg/kg as a 1h infusion, Q2W. Treatment will continue until disease progression, unacceptable toxicity, or if any criterion for withdrawal of investigational medicinal product occurs. In addition to evaluating tolerability, specific objectives for the expansion cohorts include: assessment of best overall response (BOR) and progression-free survival (PFS) according to RECIST 1.1; assessment of immune-related BOR and immune-related PFS using the modified Immune-Related Response Criteria; and assessment of overall survival. Association between tumor PD-L1 expression and efficacy will be evaluated and the PK/PD profile of avelumab characterized. This trial is in progress: recruitment for 2nd-line non-small cell lung cancer (n = 184), metastatic breast cancer (n = 168), colorectal cancer (n = 21), and ovarian cancer cohorts (n = 75) is complete. Recruitment for gastric/gastroesophageal junction cancer (n = 150), melanoma (n = 50), castration-resistant prostate cancer (n = 20), adrenocortical carcinoma (n = 50), mesothelioma (n = 50), urothelial carcinoma (n = 50), and 1st-line NSCLC (n = 150) is ongoing (target enrollment provided for each tumor type). Overall, > 700 pts have been enrolled across the dose escalation and current expansion cohorts (start Jan 2013, estimate end Oct 2016). NCT01772004. *Proposed INN. Clinical trial information: NCT01772004.

TPS3102 Poster Session (Board #420b), Sat, 8:00 AM-11:30 AM

Genetically engineered NY-ESO-1 specific T cells in HLA-A201+ patients with advanced cancers. *First Author: Melinda S. Merchant, Natl Cancer Inst, Bethesda, MD*

Background: NY-ESO-1 (CTAG-1B) is a cancer testis antigen associated with spontaneous and vaccine-induced immunity that can lead to improved clinical outcomes. NY-ESO-1 is not expressed in vital tissues, and is expressed in approximately 40% of ovarian, 60% of advanced myeloma, and 70% of synovial sarcoma tumors. Expression is correlated with tumor proliferation and high risk features. A human-derived affinity-optimized TCR that recognizes the NY-ESO-1 derived SLLMWITQC peptide in complex with HLA-A*0201 (NY-ESO^{c259}) has been generated, and clinically tested as previously described using adoptive T cell transfer with supportive IL-2[1] **Methods:** Multiple clinical studies were initiated in HLA-A201+ patients with NY-ESO-1 expressing tumors. NY-ESO-1^{c259}-engineered autologous T-cells are manufactured centrally, using a 12 day commercial-grade closed system, and are administered without supportive IL-2. 40 patients have been infused: 25/26 on a phase I/II study in adults with systemic or multifocal myeloma requiring autologous stem cell transplantation, and who have incompletely responded to prior therapy or have high risk features (NCT01352286); 10/30 on a pilot study in patients ≥4 years old with unresectable, metastatic or recurrent synovial sarcoma (NCT01343043); 5/20 on a phase I study in adults with refractory or platinum resistant ovarian cancer and/or that have received ≥2 lines of chemotherapy (NCT01567891). Pre-infusion lymphodepleting chemotherapy is administered, and varies in intensity across studies. Primary objectives include safety and tolerability. Secondary objectives include evaluation of gene modified cells persistence in blood and tumor biopsies, lineage and functionality of these cells over time, and monitoring for serum cytokine levels and NY-ESO-1 antigen on tumor post infusion. Response assessments are performed using RECIST (sarcoma), IMWR criteria (myeloma), or immune-related response criteria (irRC; ovarian). 1. Robbins PF, Morgan RA, Feldman SA, et al: Tumor Regression in Patients With Metastatic Synovial Cell Sarcoma and Melanoma Using Genetically Engineered Lymphocytes Reactive With NY-ESO-1. Journal of Clinical Oncology 29:917-924, 2011 Clinical trial information: NCT01343043.

TPS3103 Poster Session (Board #421a), Sat, 8:00 AM-11:30 AM

Phase I/II study of stereotactic body radiation therapy (SBRT) to metastatic lesions in the liver or lung in combination with monoclonal antibody to OX40 in patients with progressive metastatic breast cancer (mBC) after systemic therapy. *First Author: Marka Crittenden, Earle A. Chiles Research Institute, Portland, OR*

Background: Focal radiation mediates tumor regression not only through direct cell killing, but also by influencing adaptive immune responses. We and others have investigated pre-clinical murine tumor models using the combination of high dose per fraction radiation (SBRT) given in conjunction with T-cell checkpoint and co-stimulatory molecules. For instance, in established 3LL tumor in C57BL/6 mice, the combination of radiation (3 doses of 20 Gy over 10 days) followed by an agonistic OX40 antibody administered within 24 hours of the last dose of radiation cured 60% of mice. There were no cures using radiation or OX40 alone. The combination increased the percent of activated CD8+CD25+ T cell infiltrating the tumor and tumor-draining lymph nodes. We designed a translational study for patients with progressive metastatic breast cancer after systemic therapy. **Methods:** Patients with mBC, at least one liver or lung metastatic site amenable to SBRT and at least one other metastatic site that is evaluable are eligible. Patients with hormone receptor positive mBC must have received one prior anti-hormonal therapy and have progressed. Patients with hormone receptor negative mBC must have received at least one prior chemotherapy regimen. SBRT will be administered in consecutive cohorts of 3-6 patients at doses of 15 Gy x 1, 20 Gy x 1 and 20 Gy x 2 with the first dose on day 1 of anti-OX40. Anti-OX40 is administered at a dose of 0.4 mg/kg IV on days 1, 3 and 5 of a single treatment cycle. Patients are accruing to the 20Gy x 2 radiation dose presently. The primary objective is to determine the maximum tolerated dose of SBRT administered in combination with anti-OX40. Secondary objectives include response of radiated and non-irradiated tumor sites, the influence of anti –OX40 on circulating CD4+ and CD8+ T cells and the proliferation of and activity of effector and memory T cells. Exploratory studies of serum markers of cell lysis, immunogenicity and T-cell responses to breast cancer antigens are also planned. Clinical trial information: NCT01642290.

TPS3104 Poster Session (Board #421b), Sat, 8:00 AM-11:30 AM

Study of hTERT and IL-12 DNA immunotherapy using electroporation in patients with solid tumors after definitive surgery and adjuvant therapy. *First Author: Robert H. Vonderheide, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: hTERT, the human catalytic reverse transcriptase subunit of telomerase, is highly expressed in breast, lung, and pancreatic cancers. Peptides derived from hTERT can be recognized on MHC by cytotoxic T cells and mediate tumor death. In preclinical studies, TERT DNA delivered with electroporation (EP) triggered an immune response in vivo that slowed tumor growth in HPV16-associated tumor-bearing mice. The advantages of DNA-based immunotherapy include (1) strong immunogenicity exceeding those achieved by viral vectors; (2) non infectiousness of the immunogen; (3) ability for repeated dosing; and (4) relatively low cost. EP can be used to optimally and safely deliver DNA in vivo by creating a transient electric field to enhance the cellular uptake of large molecules such as DNA. Addition of IL-12 to hTERT significantly enhanced immune responses in preclinical models. We hypothesized that generation of robust T-cell immunity by immunotherapy with hTERT + IL-12 can be clinically used to reduce the risk of relapse in high-risk cancer patients in the adjuvant setting. **Methods:** This hypothesis is being tested in a phase 1 clinical trial (NCT02327468) sponsored by Inovio and opened at Abramson Cancer Center of the University of Pennsylvania. INO-1400 is a plasmid encoding *hTERT*. INO-9012 is a dual promoter plasmid encoding human *IL-12* subunits p35 and p40. INO-1400 and INO-9012 are delivered IM followed by EP with the CELLECTRA device. This is an open-label, dose escalation study in patients with lung, pancreas, or breast carcinomas at high risk of relapse. Eligible patients must have early stage ER+ or HER2+, or any stage triple negative breast cancer; or Stage IB-IIIA NSCLC; or Stage I-III pancreatic cancer. Patients will enroll ≥ 4 and ≤ 16 weeks from completion of definitive surgery and adjuvant therapy into 1 of 6 cohorts (total N = 54): dosing INO-1400 at 2 or 8 mg ± INO-9012 at 0.5 or 2 mg, with EP, once every 4 weeks for 4 total treatments. Primary Endpoints:Safety and tolerability. Secondary Endpoints:(1) Time to progression; (2) Antigen-specific T cell response by IFN-γ ELISpot and flow cytometry; (3) antigen-specific humoral responses by ELISA. Clinical trial information: NCT02327468.

TPS3105 Poster Session (Board #422a), Sat, 8:00 AM-11:30 AM

***In situ* vaccine for low-grade lymphoma: Combination of intratumoral FIt3L and poly-ICLC with low-Dose radiotherapy.** *First Author: Thomas Urban Marron, Mount Sinai Hospital, New York, NY*

Background: Lymphomas are the 5th most incident cancer in the U.S. and indolent non-Hodgkin's lymphoma (iNHL) are incurable with standard therapy. We previously completed three trials of '*in situ* vaccination' - combining low-dose radiotherapy (XRT) with intratumoral administration of a TLR9 agonist (CpG). We demonstrated induction of tumor-specific CD8 T cell responses and clinical remissions of patients' untreated sites of disease, lasting up to > 4 years. One limitation may have been the scarcity of intratumoral dendritic cells (DC). DC are uniquely able to endocytose dying (e.g. irradiated) tumor cells for cross-presentation to anti-tumor CD8 T cells. **Methods:** FIt3L– the predominant DC differentiation factor– induces tumor leukocyte infiltration and regression of lymphoma tumors pre-clinically and a new formulation of this cytokine -CDX-301- was shown to mobilize BDCA-1 and BDCA-3 DC subsets in an early phase trial. These DC subsets respond to several TLR agonists and cross-present antigens more effectively than plasmacytoid DC (the CpG-responsive DC subset). We initiated a phase I/II study of a new iteration of the *in situ* vaccine, adding FIt3L-priming and replacing the prior TLR9 agonist with the TLR3 agonist poly-ICLC (Fig 1A). The vaccine consists of: -**intratumoral FIt3L** administration to increase DC within the tumor -**low-dose XRT** to induce immunogenic tumor cell death and release tumor-associated antigens, and -**intratumoral poly-ICLC** administration to *activate* tumor antigen-loaded DC. The current study will assess two cohorts of patients (n = 15, each) with either previously untreated or relapsed/refractory iNHL to test the hypothesis that *in situ* vaccination will induce clinical remissions at distant (untreated) tumor sites. Eligibility: iNHL, either previously untreated or relapsed/refractory. Treatment: Intratumoral CDX-301 25ug/kg x 9 days. Local radiotherapy 2Gy x 2. Intratumoral poly-ICLC 2mg weekly x 8 weeks. Patients will have tumor (FNA) and blood collected for immune monitoring at weeks 0, 2, 4, 6, 8, 12 as well as pre treatment biopsy. Restaging CT scans will be done pretreatment and at week 12. Clinical trial information: NCT01976585. Clinical trial information: NCT01976585.

TPS3106 Poster Session (Board #422b), Sat, 8:00 AM-11:30 AM

Phase I study of safety and immunogenicity of ADU-623, a live-attenuated *Listeria monocytogenes* vaccine (Δ*actA*/Δ*inlB*) expressing EGFRvIII and NY-ESO-1, in patients with WHO grade III/IV astrocytomas. *First Author: Marka Crittenden, Earle A. Chiles Research Institute, Portland, OR*

Background: The neo-antigen EGFRvIII is expressed in multiple tumor types, including high-grade astrocytomas. It is associated with a poor prognosis and resistance to conventional therapies such as chemotherapy and radiation that are part of the standard treatment. We propose that immunization with a live-attenuated *Listeria*-based vaccine, ADU-623, expressing EGFRvIII and NY-ESO-1 will elicit robust tumor-specific immune responses capable of killing EGFRvIII and/or NY-ESO-1-expressing tumor cells and improve survival of the patients. In addition, ADU-623 induces a potent innate immune response that can kill transformed cells even in the absence of neo-antigens. We designed a translational vaccine study to evaluate the safety and immunogenicity of this vaccine in patients with high-grade astrocytomas after standard of care therapy or at progression. **Methods:** Patients with a pathologic diagnosis of WHO Grade III/IV astrocytic tumors that have completed standard of care external beam radiation therapy and concurrent temozolomide followed by adjuvant temozolamide or with radiographic evidence of progression following standard of care radiation and chemotherapy treatment, including those who have gone on to a second surgical resection are eligible. Patients are enrolled and assigned consecutively to one of the following ADU-623 dose level cohorts: Cohort 1 $3x10^7$ cfu, Cohort 2 $3x10^8$ cfu, or Cohort 3 $1x10^9$ cfu, each administered IV on Days 0, 21, 42 and 63. Adverse events are monitored throughout the treatment and patients are followed for up to 24 months. Patients are currently accruing to Cohort 3. The primary objective is to determine the maximum tolerated dose and characterize the safety profile of ADU-623 in patients with treated and recurrent WHO Grade III/IV astrocytomas. Secondary objectives include progression free survival, time to progression and overall survival rates in patients vaccinated with ADU-623. Exploratory studies of EGFRvIII-, NY-ESO-1-, vector-specific and innate immune responses will be performed. Clinical trial information: NCT01967758.

3500 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

A multi-center randomized controlled trial of mFOLFOX6 with or without radiation in neoadjuvant treatment of local advanced rectal cancer (FOWARC study): Preliminary results. *First Author: Yanhong Deng, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: The FOWARC study investigates whether peri-operative mFOLFOX6 chemotherapy (CT) improves disease-free survival (DFS) in locally advanced rectal cancer. **Methods:** Between 01/2011-02/2015, patients with rectal cancer within 12 cm from the anal verge, clinical stage II-III were randomly assigned to received 5-FU with radiation(RT) (control arm), or receive mFOLFOX6 with RT (FOLFOX-RT arm), or receive 4-6 cycles of mFOLFOX6 alone (FOLFOX arm), post-operative RT is allowed if needed. Primary endpoint is DFS. Here we report the preliminary results. **Results:** 495 patients were randomized (165 in each arm). 92% of patients accomplished at least 46 Gy of RT in FOLFOX-RT arm compared to 86.8% in control arm. 5% of FOLFOX arm patients received post-op RT. R0 resection rate was 90.1%, 88.2%, and 91.2%, respectively in control arm, FOLFOX-RT arm and FOLFOX arm. The pCR rate was 12.5%, 31.3% and 7.4% respectively (P = 0.001). Good down staging (ypTNM 0-1) was achieved in 34.7%, 57.8%, and 37.9% of patients respectively. Higher toxicity and post-op complications were observed in patients received RT. Similar results were seen in subgroup of patients with lesions located within 5cm from the anal verge. **Conclusions:** mFOLFOX6 concurrent with RT resulted in higher pCR rate, neoadjuvant mFOLFOX6 alone achieved similar down staging rate with less toxicity and post-op complications, compared to preoperative 5-FU with RT. Clinical trial information: NCT01211210.

3501 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Radiofrequency ablation (RFA) combined with chemotherapy for unresectable colorectal liver metastases (CRC LM): Long-term survival results of a randomized phase II study of the EORTC-NCRI CCSG-ALM Intergroup 40004 (CLOCC). *First Author: Theo Ruers, The Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: This study evaluates the benefit of combining systemic chemotherapy (CT) with local tumor destruction by RFA in patients with unresectable CRC LM up to 9 lesions and without extrahepatic disease. Overall survival (OS) at 30 months and progression free survival (PFS) results were reported (Ann Oncol. 23(10): 2619-26, 2012). We now report on OS results, after a long term median follow-up of 9.7 years. **Methods:** Between 2002 and 2007, 119 pts were randomized between CT alone (59) or RFA+CT (60). In both arms, CT consisted of 6 months FOLFOX (oxaliplatin 85mg/m2 and LV5FU2) plus, since October 2005, bevacizumab. In the CT arm resection was allowed when unresectable disease was converted by CT to resectable disease. Primary objective was a 30-months OS rate > 38% for the combined treatment group. OS and PFS were secondary endpoints. **Results:** In the RFA+CT arm, 56 pts (93.3%) received RFA which was combined with resection in 27 pts (45%), 1 pt had all metastases resected (ineligible), 2 pts were not treated at all, in 1 pt no local treatment data were available. 51 patients (85%) in the RFA+CT arm received CT compared to all 59 in the CT arm. 6 pts in the CT arm eventually underwent hepatic resection. The primary endpoint was met, 30-months OS rate was 61.7% (95% CI: 48.2-73.9) for combined treatment. However, 30-month OS for systemic treatment only was 57.6% (95% CI: 44.1-70.4), higher than anticipated. At a median follow-up of 9.7 years, 92 deaths were reported, 53 in the CT arm and 39 in the RFA+CT arm. Causes of death in the CT arm were progressive disease (49 pts), and unknown for 4 pts, and in the RFA+CT arm, progressive disease (35 pts), other causes (2 pts) and unknown (2 pts). There was a significant difference in OS in favor of the RFA+CT arm (HR = 0.58, 95% CI: 0.38-0.88, p = 0.01). Observed median OS was 45.6 months (95% CI: 30.3 – 67.8) in the RFA+CT arm vs. 40.5 months (95% CI: 27.5 - 47.7) in the CT arm. **Conclusions:** This is the first study that prospectively investigated the efficacy of RFA +CT in pts with unresectable CRC LM. In this phase II trial, RFA+CT was associated with improved long-term OS compared to CT alone. Clinical trial information: NCT00043004.

3502 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

SIRFLOX: Randomized phase III trial comparing first-line mFOLFOX6 ± bevacizumab (bev) versus mFOLFOX6 + selective internal radiation therapy (SIRT) ± bev in patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Peter Gibbs, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Background: The SIRFLOX study was designed to assess the efficacy and safety of combining FOLFOX chemotherapy (± bev) with SIRT using yttrium-90 (Y-90) resin microspheres as first-line treatment of pts with liver metastases from mCRC. **Methods:** SIRFLOX was an international, multicenter, open-label, RCT in chemotherapy-naïve pts with non-resectable, liver only or liver dominant (liver plus lung and/or lymph node metastases) mCRC. Arm A: mFOLFOX6 ± bev was compared to arm B: mFOLFOX6 + SIRT (SIR-Spheres; Sirtex) administered once with cycle 1 ± bev until disease progression. The primary endpoint was progression free survival (PFS) using RECIST v1.0. Stratification variables included presence of extra hepatic disease (EHD; liver only *v* liver dominant), degree of liver involvement (≤ 25% *v* > 25%), and treatment with bev (at clinician discretion). **Results:** From Oct 2006 to Apr 2013,530 pts were randomised (arm A, n = 263; arm B, n = 267), 212 (40%) had EHD. Median follow-up was 36.1 months. The median overall PFS was 10.2 *v* 10.7 months in arms A *v* B respectively (hazard ratio [HR]: 0.93; 95% CI 0.77–1.12; p=0.428) by Kaplan Meier analysis. The median PFS in the liver was 12.6 *v* 20.5 months in arm A *v* B (HR: 0.69; 95% CI 0.55–0.90; p = 0.002) by competing risk analysis. Overall response rate (PR + CR) was 68.0% *v* 76.4% in arm A *v* B, respectively (p = 0.113). Hepatic response rate was 68.8% *v* 78.7% in arm A *v* B (p = 0.042), including CR rate 1.9% *v* 6.0% (p = 0.02). The liver resection rate was 13.7% *v* 14.2% in arm A *v* B (p = 0.857). Adverse events ≥ grade 3 were noted in 73.3% *v* 85.4% of pts in arm A *v* B. Most common toxicities were hematologic; 32.9% *v* 51.2% and gastrointestinal; 21.2% *v* 32.9%, including gastric ulcer 0.0% *v*2.4%. **Conclusion:** In first-line treatment of pts with non-resectable CRC liver metastases, the addition of SIRT to standard chemotherapy failed to improve overall PFS. However, median liver PFS was significantly extended. The addition of SIRT was associated with acceptable toxicity. Overall survival analyses, combining data from SIRFLOX and two other ongoing studies in this disease setting, are awaited. Clinical trial information: NCT00724503.

3503 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Vitamin D status and survival of metastatic colorectal cancer patients: Results from CALGB/SWOG 80405 (Alliance). *First Author: Kimmie Ng, Dana-Farber Cancer Institute, Boston, MA*

Background: Prospective epidemiologic data suggest that higher levels of 25-hydroxyvitamin D [25(OH)D] are associated with improved survival in patients with colorectal cancer, however the relationship between 25(OH)D and outcome in metastatic CRC (mCRC), specifically, is unknown. **Methods:** We prospectively assessed the association between plasma 25(OH)D and overall survival (OS) in previously untreated mCRC patients enrolled in CALGB/SWOG 80405, a randomized phase III trial of chemotherapy + bevacizumab, cetuximab, or both, prior to the *KRAS* wild type amendment. Progression-free survival (PFS) was a secondary endpoint. Plasma 25(OH)D levels were measured at baseline by radioimmunoassay, and dietary and lifestyle behaviors collected from self-administered questionnaires. Cox proportional hazards models were used to calculate hazard ratios (HR) adjusted for other prognostic variables. **Results:** Among 1,043 patients, median plasma 25(OH)D was 17.2 ng/mL (range 2.2-72.7). Male and black patients, those living in the northeast, patients with lower dietary and supplemental vitamin D intake, ECOG performance status 1 (vs. 0), tumoral *RAS* mutation, higher body-mass index, lower physical activity, and blood draw during the winter and spring had significantly lower levels of 25(OH)D. Patients in the highest quintile of 25(OH)D had significantly improved OS compared to those in the lowest after adjusting for pathologic and clinical prognostic factors (median 32.6 vs. 24.5 months; HR 0.65, 95% CI, 0.51-0.83; *P* trend = 0.001). Increasing concentrations of 25(OH)D were also significantly associated with improved PFS (median 12.2 vs. 10.1 months; HR 0.79, 95% CI, 0.63-0.99; *P* trend = 0.01). The results were consistent across subgroups of patient characteristics, including *RAS* status, and remained unchanged after excluding patients who died within 3 or 6 months of blood draw. **Conclusions:** Higher concentrations of plasma 25(OH)D are associated with significantly improved survival in mCRC patients treated with chemotherapy + biologics. Randomized trials of vitamin D supplementation are warranted and ongoing, and effect modification by SNPs in vitamin D pathway genes is currently being explored.

3504 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Impact of aspirin as secondary prevention in an unselected cohort of 25,644 patients with colorectal cancer: A population-based study. *First Author: Simer Bains, 1The Biotechnology Centre and Centre for Molecular Medicine Norway, Nordic EMBL Partnership, University of Oslo, Oslo, Norway, Oslo, Norway*

Background: Regular use of aspirin (acetylsalicylic acid) has been associated with reduced incidence and mortality of colorectal cancer (CRC). However, the use of aspirin as primary prevention in the general population is still being debated due to the risk of serious hemorrhagic side effects. In contrast, the use of aspirin as secondary prevention in patients with CRC may be more justified from a risk-benefit prospective, and also as we have observed that aspirin reverses tumor immune evasion mechanisms in established colorectal cancer. This study was conducted to examine the association between aspirin use after diagnosis of CRC with CRC-specific survival (CSS) and overall survival (OS) in the largest cohort ever examined. **Methods:** An observational population-based retrospective cohort study was undertaken by linking patients diagnosed with CRC from 2004 through 2011 (Cancer Registry of Norway) with the use of aspirin in the same patients (The Norwegian Prescription Database). The registries used cover more than 99% of the Norwegian population, and include all cases in an unselected manner. Exposure was defined as having received prescription for more than 6 months of aspirin after diagnosis of CRC. Multivariate Cox proportional hazard and competing risk analyses were used to model survival. The main outcome measures of the study were CSS and OS. **Results:** In total, 25,644 patients were diagnosed with CRC in the study period and 6,109 of them were defined as exposed to aspirin after the diagnosis of CRC. The median follow-up was 2.2 years. Among aspirin exposed cases (n = 6,109), a total of 2,088 (34.2%) deaths were recorded of which 1,172 (19.2%) were CRC-specific. Among non-exposed aspirin cases (n = 19,535), a total of 7,595 (38.9%) deaths were recorded of which 6,356 (33.5%) were CRC-specific. In multivariate analysis, aspirin exposure after the diagnosis of CRC was independently associated with improved CSS (hazard ratio [HR], 0.53; 95% confidence interval [CI], 0.50-0.57; $p < 0.001$) and OS (HR, 0.71; 95% CI, 0.68-0.75; $p < 0.001$). **Conclusions:** Exposure to aspirin after the diagnosis of CRC is independently associated with improved CSS and OS.

3505 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Comprehensive molecular characterization of colorectal cancer reveals genomic predictors of immune cell infiltrates. *First Author: Marios Giannakis, Dana-Farber Cancer Institute, Boston, MA*

Background: Colorectal cancer (CRC) is a molecularly heterogeneous disease that arises and progresses in the context of a complex microenvironment. Tumor immune cell infiltrates have been shown to be associated with an improved CRC-specific and overall survival. However, the genomic features of CRC that determine the number and types of immune infiltrates remain largely uncharacterized. **Methods:** We performed Whole Exome Sequencing and microsatellite instability (MSI) analysis on primary CRCs from 689 patients (pts) identified from two large prospective cohorts, the Nurses' Health Study and the Health Professionals Follow-Up Study. We also immunohistochemically characterized the immune infiltrate (peritumoral, intratumoral periglandular, Crohn's-like, tumor-infiltrating, and total lymphocyte score) and conducted tissue microarray imaging analysis for T-cell subsets (CD3+, CD8+, CD45RO+, FoxP3+). We utilized a novel computational pipeline to calculate tumor neoantigen load (peptides resulting from somatic mutations and recognized by the immune system as foreign) and subsequently correlated the tumor neoantigen load with the aforementioned immune variables and with pt survival. **Results:** When compared to microsatellite-stable cancers, MSI-high tumors expressed significantly more neoantigens ($P < 2e\text{-}16$). Tumor neoantigen load significantly correlated with total lymphocytic score in the primary CRCs ($P = 4.9e\text{-}9$) and was most significantly associated with tumor infiltrating lymphocytes ($P = 1.6e\text{-}15$). Among T-cell subsets, tumor neoantigen load was only significantly associated with the CD45RO+ T-cell subset ($P = 0.0003$). Higher tumor neoantigen load predicted significantly improved CRC-specific and overall survival ($P = 0.014$ and $P = 0.048$, respectively). **Conclusions:** In the large prospective study of molecularly characterized CRCs, tumor neoantigen load predicts greater tumor-infiltrating lymphocytes and memory T-cell infiltration and represents a novel genomic predictor of CRC survival. Our findings link tumor genomics to specific immune response elements and have implications for the therapeutic manipulation of the latter in CRC.

3506 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Analysis of DNA mismatch repair (MMR) and clinical outcome in stage III colon cancers from patients (pts) treated with adjuvant FOLFOX +/- cetuximab in the PETACC8 and NCCTG N0147 adjuvant trials. *First Author: Aziz Zaanan, Mayo Clinic and Mayo Cancer Center, Rochester, MN*

Background: The prognostic impact of deficient (d) MMR, including sporadic and familial types, in stage III colon cancer pts receiving standard adjuvant FOLFOX therapy remains unknown. We examined the association of MMR status with clinical outcome in two phase III clinical trials of adjuvant FOLFOX +/- cetuximab. **Methods:** Prospectively collected tumors from both studies were separately analyzed for MMR protein (MLH1, MSH2, MSH6) expression and mutations in *BRAF* (*V600E*). Loss of any MMR protein indicated dMMR. Methylation of the *MLH1* gene promoter was studied in tumors with loss of MLH1 and wild-type (WT) *BRAF*. Associations of MMR status with time-to-recurrence (TTR), disease-free survival (DFS) and overall survival (OS) were analyzed using a stratified Cox proportional hazards model. Multivariate models were adjusted for treatment and covariates (age, sex, tumor grade, T/N stage, tumor location, ECOG PS, *BRAF/KRAS*). **Results:** The frequency of dMMR in the overall cohort was 10.7% (499/ 4674). 3-year (yr) DFS for dMMR *vs* proficient (p) MMR pts was 75% *vs* 74% (HR = 0.87; 95% CI, 0.71-1.07; $p_{adustedj} = .196$). Among pts with complete biomarker data (N = 4339), there were 405 dMMR tumors of which 265 (65.4%) were categorized as sporadic (*BRAF* mutation or WT with *MLH1* methylation) and 140 (34.6%) as familial (*BRAF* WT and unmethylated *MLH1* or loss of MSH2 or MSH6). DFS rates of pts with sporadic and familial dMMR tumors were similar (HR, 1.15; 95% CI, 0.73-1.81; $p_{adjusted} = .54$). Pts with dMMR tumors had similar DFS rates as did pts with pMMR tumors without *BRAF* or *KRAS* mutations (Table). Consistent results were found for biomarkers and TTR and OS. **Conclusions:** In this large cohort of stage III colon cancer pts enrolled in two adjuvant trials testing FOLFOX +/- cetuximab, MMR status was not prognostic. Similar outcomes were found for sporadic and familial dMMR cases, and when each of these dMMR subtypes was compared to pMMR tumors WT for both BRAF and KRAS genes. Clinical trial information: NCT00079274.

Variable	N	3-yr DFS %	HR (95% CI)	Adjusted P value
WT *KRAS*, WT *BRAF*, pMMR,	2205	78.1	Ref	---
Sporadic dMMR	265	77.3	0.99 (0.73,1.32)	0.9263
Familial dMMR	140	77.6	0.86 (0.58,1.26)	0.4342

3507 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Prognostic value of *BRAF* V600E and *KRAS* exon 2 mutations in microsatellite stable (MSS), stage III colon cancers (CC) from patients (pts) treated with adjuvant FOLFOX+/- cetuximab: A pooled analysis of 3934 pts from the PETACC8 and N0147 trials. *First Author: Julien Taieb, Paris Descartes University, Georges Pompidou European Hospital, Paris, France*

Background: The prognostic value of BRAF and KRAS mutations in resected CC pts remains controversial due to published studies that include stage II & III, microsatellite instability (MSI) and MSS, colon and rectal tumors, and variable treatment regimens. We examined this question in prospectively collected biospecimens from MSS stage III CC pts receiving adjuvant FOLFOX +/- cetuximab. **Methods:** Tumors were analyzed for BRAF V600E and KRAS exon 2 mutations, only MSS tumors were included. Three groups were defined: BRAF Mutant, KRAS Mutant and double wild-type (WT). The analytic strategy estimated study- and arm-specific prognostic effects to assess homogeneity of results, and then analysis of pooled data. Associations of mutations with time-to-recurrence (TTR), survival after relapse (SAR) and overall survival (OS) were analysed using a stratified Cox proportional hazards model. Multivariate models were adjusted for treatment and covariates (age, sex, tumor grade, T/N stage, tumor location, ECOG PS). **Results:** Of the 5,577 pts enrolled, 3,934 tumors were MSS and evaluable for BRAF and KRAS; 279 pts were BRAF Mutant, 1,450 KRAS Mutant, and 2,205 WT. Both mutations were linked to shorter TTR and OS vs WT, and results were confirmed in multivariate analyses (table). Median SAR was 2.57, 2.09 and 1.0 year in WT, KRAS Mutant (HR: 1.20- 95%CI: 1.01-1.44, $p < 0.0001$) and BRAF mutant (HR: 3.01-95%CI: 2.32-3.93, $p < 0.0001$), respectively. No interaction was found between treatment (with or without cetuximab) and KRAS/BRAFmutations for TTR ($p = 0.38$) or OS ($p = 0.16$). **Conclusions:** In a large pooled analysis of pts with resected stage III MSS colon cancers receiving adjuvant FOLFOX, BRAFV600E or KRAS exon 2 mutations, including codons 12 or 13, are independent predictors of significantly shorter TTR, SAR and OS. Future clinical trials in the adjuvant setting should consider these mutations as important stratification factors.

	TTR			OS		
	3 y rate	HR (95% CI)	p	3 y rate	HR (95% CI)	p
WT	80.0%			91.4%		
BRAF V600E	69.7%	1.49 [1.19,1.87]	0.0005	73.9%	1.72 [1.33,2.22]	< .0001
KRAS Exon 2	69.5%	1.60 [1.40,1.83]	< .0001	86.3%	1.52 [1.29,1.79]	< .0001

3508 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Trastuzumab and lapatinib in HER2-amplified metastatic colorectal cancer patients (mCRC): The HERACLES trial. *First Author: Salvatore Siena, Niguarda Cancer Center, Ospedale Niguarda Ca' Granda, Milan, Italy*

Background: We conducted a phase II of trastuzumab (T) and lapatinib (L) in HER2-amplified, KRAS exon 2 wild-type, mCRC pts resistant to standard therapies (HERACLES Trial EudraCT 2012-002128-33). **Methods:** Pts progressing after fluoropyrimidines, oxaliplatin, irinotecan, bevacizumab, cetuximab or panitumumab were eligible if tumor was HER2+ [IHC3+ or 2+ and FISH positive (HER2:CEP17 $>$ 2) in $>$ 50% cells]. L was given po qd, T iv qw at standard doses. Response was assessed q 8 wks. The primary end-point was objective response (OR, RECIST v1.1). To consider the study positive 6/27 ORs had to be observed (α = 0.05; β = 85%; H1 = 30%). Serial liquid biopsies for HER2 ctDNA (ddPCR/NGS) and ectodomain (ECD) plasma levels (ELISA) were collected until progression. **Results:** As of Jan 31 2015, 913 pts were screened, 44 found HER2+ (4.8%), and 23 eligible and evaluable: 2F/21M, median age 63 (r = 40-86), ECOG PS $\leq$ 1, median prior regimens 5 (r = 3-8). Primary endpoint was met with 8/23 ORs [7 PR, 1 PRunc (too early); ORR = 35% (95% CL 20-55)]; 7/8 ORs were observed in HER2 IHC3+ pts. Responses lasted: 8+, 12+, 14+, 24, 24.5+ 32, 54+ and 55+ weeks. Median time to progression was 5.5 months (95% CL 3.7-9.8). Toxicity was limited to G2 diarrhea, fatigue, and rash (1 G3). HER2+ ctDNA and ECD levels decreased in 2/3 ORs and 0/2 non responders and in 2/2 ORs 0/6 with SD or PD, respectively. Exploratory correlative analyses of HER2 gene dosage will be presented together with exome analysis of index cases. **Conclusions:** HER2 is amplified in 5% of WT exon 2 KRAS mCRC patients. The HERACLES trial met its primary endpoint with 8/23 objective responses in pts heavily pretreated with standard therapies, including EGFR-targeted agents, indicating that the dual anti HER2 therapy is effective and deserves further clinical assessment in earlier lines of treatment of HER2+ mCRC patients. HERACLES is funded by Associazione Italiana Ricerca Cancro. Clinical trial information: 2012-002128-33.

Exploring the poor outcomes of *BRAF* mutant (*BRAF* mut) advanced colorectal cancer (aCRC): Analysis from 2,530 patients (pts) in randomized clinical trials (RCTs). *First Author: Jenny F. Seligmann, University of Leeds, Leeds, United Kingdom*

Background: *BRAF*-mut aCRC pts have poor overall survival (OS). To investigate this phenomenon, we have examined individual patient data from pts treated with chemotherapy alone in 3 RCTs to identify the points on the treatment pathway at which their outcomes are inferior to *BRAF*-wt pts. **Methods:** *BRAF* was assessed in tumors of 2530 pts in 3 RCTs: COIN (n = 1284), FOCUS (n = 787) and PICCOLO (n = 459). End-points were progression free survival (PFS), response rate (RR), post progression survival (PPS) and OS. Treatments received were 1st line OxFU (COIN), 1st line FU (FOCUS) or 2ndline Irinotecan (Ir) (PICCOLO). Analyses were performed using Cox proportional hazards models and logistic regression. **Results:** 231 pts (9.1%) were *BRAF*-mut. *BRAF*-mut status conferred worse OS in both 1st-line studies (FOCUS HR = 1.55, p = 0.002; COIN HR = 1.77, p $<$ 0.001). Compared with wt, *BRAF*-mut pts treated with 1stline OxFU had inferior RR (32% vs 48%; OR = 0.51,p $<$ 0.001) and PFS (unadjusted HR = 1.34, p = 0.041, but p = 0.19 after adjustment). Following progression on 1st-line chemotherapy, *BRAF*-mut pts had shorter PPS (COIN HR = 1.99, p $<$ 0.0001; FOCUS HR = 2.13, p $<$ 0.001). However, *BRAF*-mut did not confer a disadvantage among pts pausing chemo without progression for planned chemo-free intervals (COIN, OS HR 0.97, p = 0.75; PFS HR = 1.09, p = 0.33). In COIN, *BRAF*-mut pts were less likely to receive 2nd-line treatment after 1st-line progression (39% *vs* 60%, p = 0.002). However, once started, the outcomes during or after 2nd-line chemo were not significantly inferior in *BRAF*-mut pts: in PICCOLO: RR OR = 0.75, p = 0.65; PFS HR = 1.06, p = 0.72; PPS HR = 1.13, p = 0.57). **Conclusions:** The poor survival of *BRAF*-mut pts is driven by accelerated decline following progression, and a lower probability of receiving further lines of therapy, so clinicians need extra vigilance. However, *BRAF*-mut pts may still enjoy treatment breaks when not progressing, and if treated with 2nd line chemotherapy are no less likely to benefit.

FOLFOXIRI plus bevacizumab versus FOLFIRI plus bevacizumab as initial treatment for metastatic colorectal cancer (TRIBE study): Updated survival results and final molecular subgroups analyses. *First Author: Fotios Loupakis, U.O. Oncologia Medica 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: The phase III TRIBE study met its primary endpoint by demonstrating that first-line FOLFOXIRI plus bev significantly prolongs PFS, as compared to FOLFIRI plus bev (*Loupakis et al, N Eng J Med 2014*). At a median follow-up of 32.2 months a preliminary OS analysis indicated a borderline OS improvement with FOLFOXIRI plus bev (HR = 0.79, p = 0.054) with a consistent effect across *RAS* (*KRAS* and *NRAS* codons 12, 13, 61) and *BRAF*V600E molecular subgroups. **Methods:** 508 pts were randomized to either FOLFIRI plus bev (Arm A, N = 256) or FOLFOXIRI plus bev (Arm B, N = 252). On available samples from *RAS* and *BRAF* wild-type (wt) pts (N = 129), also *KRAS* and *NRAS* codons 59, 117 and 146 were analysed by means of Sequenom MassArray, identifying a new "all wt" population (N = 93). **Results:** At a median follow-up of 48.1 months, in the ITT population, updated median OS for Arm B vs Arm A was 29.8 vs 25.8 months (HR = 0.80, 95%CI, 0.65-0.98, p = 0.030). Estimated 5-years OS rate were: Arm B, 24.9% vs Arm A, 12.4%. Molecular results were informative for 357 pts (70.3%). All wt patients had longer OS as compared to *RAS* mutant (HR = 0.70, p = 0.006) and to *BRAF* mutant (HR = 0.24, p $<$ 0.001). The benefit from FOLFOXIRI plus bev was consistent across all molecular subgroups (Table 1). All wt pts treated with FOLFOXIRI plus bev reported a median OS of 41.7 months as compared to 33.5 months in the FOLFIRI plus bev group (HR = 0.75, 95%CI, 0.45-1.24). **Conclusions:** FOLFOXIRI plus bev significantly improves survival of metastatic colorectal cancer pts and the OS advantage increases over time. Benefit from FOLFOXIRI plus bev is independent of *RAS* and *BRAF* mutational status. All wt pts have a better outcome independently from the treatment arm. Notable results with FOLFOXIRI plus bev are achieved in all wt pts. Clinical trial information: NCT00719797.

	Arm A FOLFIRI+bev Median PFS (mos)	Arm B FOLFOXIRI+bev Median PFS (mos)	HR [95%CI]	Arm A FOLFIRI+bev Median OS (mos)	Arm B FOLFOXIRI+bev Median OS (mos)	HR [95%CI]
All wt (N = 93)	12.2	13.7	0.82 [0.53-1.26]	33.5	41.7	0.75 [0.45-1.24]
***RAS* mut (N = 236)**	9.5	12.0	0.82 [0.63-1.07]	23.9	27.3	0.95 [0.71-1.27]

Phase Ib study of vemurafenib in combination with irinotecan and cetuximab in patients with *BRAF*-mutated metastatic colorectal cancer and advanced cancers. *First Author: David S. Hong, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *BRAF* V600 mutations, present in 5-10% of patients (pts) with metastatic colorectal cancer (mCRC), are poor prognostic markers and are associated with a low response to the combination of cetuximab (C) and irinotecan (I). Vemurafenib (V), an oral kinase inhibitor specific to mutated V600 BRAF, demonstrated a 5% response rate in a phase I trial of pts with *BRAF*-mutated mCRC. In vitro data in CRC cell lines has shown that blockade of mutated BRAF by vemurafenib triggers compensatory activation of EGFR. Inhibition of EGFR combined with vemurafenib results in synergistic cytotoxicity in preclinical models, which is further augmented by irinotecan. The safety and efficacy of the combination in pts with *BRAF*-mutated advanced malignancies have not been defined. **Methods:** In this 3+3 phase I study, pts with *BRAF*-mutated cancers received escalating doses of V in combination with C and I over a 14-day cycle. Responses were evaluated every 4 cycles by RECIST 1.1. Adverse events (AEs) were assessed by CTCAE 4.0. **Results:** Among 19 total pts treated on study, 18 pts have mCRC: 6 at dose level 1(DL) (V- 480mg PO BID, C-250 mg/m^2 weekly and I- 180mg/m^2 every 14 days), 6 at DL 2 (increased to V-720mg PO BID), and 6 at DL3 (V-960mg PO BID). Median age was 63 yrs (42-73yrs). One DLT was observed at each DL (arthralgia in 2 pts, diarrhea in 1 pt). The MTD was determined to be DL3 (V-960 mg PO BID, C-250 mg/m^2 weekly, I-180mg/m^2 every 14 days). The most common AEs were fatigue (94%), diarrhea (89%), nausea (83%), and rash (78%). Six of the 17 evaluable mCRC pts achieved a partial response (RR 35%). Median best response was a reduction of -20% (+21% to -100%) with median duration of response of 12.5 cycles (IQR, 5-17 cycles). Seven mCRC pts remain on study. Median PFS is 7.7 months. One pt came off study due to diarrhea before restaging. Preliminary PKs and PDs will be reported. **Conclusions:** The combination of V with I and C is well tolerated in pts with *BRAF*-mutated mCRC with the MTD at V-960 mg PO BID, C-250 mg/m^2 weekly, I-180mg/m^2 every 14 days. Responses were seen in 35% of evaluable mCRC pts. A US cooperative group randomized phase II trial of I and C with or without V in *BRAF*-mutated mCRC (SWOG 1406) is ongoing. Clinical trial information: NCT01787500.

Randomized phase III study of adjuvant chemotherapy with S-1 versus capecitabine (cape) in patients with stage III colon cancer (CC): Results of Japan Clinical Oncology Group study (JCOG0910). *First Author: Tetsuya Hamaguchi, Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan*

Background: We previously reported the results of the JCOG0205 study, which indicated that D2/D3 lymph node dissection followed by adjuvant fluoropyrimidine (F) monotherapy resulted in better disease-free survival (DFS) and overall survival (OS) in Japan than in Western countries (*EJC 2014*). Cape is one of standard adjuvant chemotherapy for stage III CC (*NEJM 2005*). Recently, S-1 was demonstrated to be non-inferior to uracil and tegafur plus leucovorin in DFS (*Ann Oncol 2014*). This is the first report of JCOG0910, which compared S-1 with cape. **Methods:** Key eligibility criteria were: stage III, colorectal adenocarcinoma except for lower rectal cancer, R0 with D2/3 lymph node dissection, 20-80 years old. Patients were randomized to 8 courses of cape (2,500 mg/m^2/day, days 1–14, q3w) or 4 courses of S-1 (80 mg/m^2/day, days 1–28, q6w). Primary endpoint was DFS. Planned sample size was 1,550 to provide 80% power with a non-inferiority margin of hazard ratio (HR) of 1.24 and 1-sided α = 0.05; with interim analyses after 50% of the planned accrual and 1 year after completion of accrual. **Results:** Between Mar 2010 and Aug 2013, 1,564 pts were randomized to cape (n = 782) or S-1 (n = 782). Median age was 66; male/female: 52%/48%, colon/rectum: 68%/32%, number of positive nodes $\leq$ 3/4 $\leq$: 84%/16%. At the second interim analysis on Sep 2014, 48% of required events (258/535) were observed, and JCOG Data and Safety Monitoring Committee recommended early publication because S-1 was apparently inferior to cape in DFS. With median follow-up of 23.7 months for all randomized pts, 3-year DFS was 82.0% in cape and 77.9% in S-1. The HR of DFS was 1.23 (99.05% CI, 0.887–1.70) and the non-inferiority of S-1 was not demonstrated (P = 0.111). The incidence of grade 3/4 adverse events was 21.2% in cape and 12.1% in S-1. Hand-foot syndrome was common in cape, whereas diarrhea and anorexia were common in S-1. **Conclusions:** This study failed to demonstrate the non-inferior of adjuvant S-1 to cape in DFS. Adjuvant cape remains the standard treatment and S-1 should not be used for stage III CC. Clinical trial information: UMIN000003272.

3513 Poster Discussion Session; Displayed in Poster Session (Board #5), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Cochrane systematic review and meta-analysis of adjuvant therapy for stage II colon cancer. *First Author: Brandon Matthew Meyers, Juravinski Cancer Centre McMaster Univ, Hamilton, ON, Canada*

Background: Stage III disease is associated with a high risk of relapse after surgery, and adjuvant 5-fluorouracil chemotherapy (5FUc) has been shown to improve overall (OS) and disease-free survival (DFS). Whether adjuvant 5FUc confers a similar benefit in stage II colon cancer is unclear. A previous Cochrane review demonstrated that adjuvant therapy improved DFS, but not OS. An updated systematic review of the literature was undertaken, including all forms of adjuvant therapy. **Methods:** We searched Cochrane Central Register of Controlled Trials, MEDLINE(R), and EMBASE from 1/1987 - 7/2014. We scanned ASCO and ESMO annual meeting proceedings. Randomized controlled trials (RCTs) containing data on stage II colon cancer patients undergoing adjuvant therapy *vs.* observation were included. Pooled results were expressed as risk ratios (RR), with 95% confidence intervals using a random effects model. Treatments were evaluated using *a priori* defined categories, and sub-groups, of systemic chemotherapy, regional chemotherapy, and immunotherapy. **Results:** 25 RCTs met the inclusion criteria. Overall, adjuvant systemic chemotherapy did not improve OS (RR 0.93; 0.81 - 1.07). Sub-group analysis demonstrated that newer 5FUc improved OS (RR 0.85; 0.75 - 0.96) and DFS (RR 0.82; 0.72 - 0.93). Portal vein infusion (PVI), a sub-group of regional chemotherapy, improved OS (RR 0.74; 0.55 - 0.99) but not DFS (RR 0.93; 0.74 - 1.16). Heterogeneity was low for systemic chemotherapy (I^2 = 0% for all analyses), but moderate-high for PVI (I^2= 41% for OS). Tumour vaccines and edrecolomab immunotherapy resulted in OS similar to observation (RR 0.94; 0.79 - 1.12). The estimated 'optimal information size' was only reached for the category of systemic chemotherapy. **Conclusions:** 5FUc bolus injections demonstrated an improvement in OS and DFS in stage II colon cancer. Although the PVI sub-group showed a statistical benefit to OS, significant heterogeneity, and a failure to reach 'optimal information size' indicates these results are not robust. Immunotherapy had no demonstrated benefits. Further investigation is required to determine whether subsets of stage II colon cancer patient might derive additional benefit from adjuvant chemotherapy.

3514 Poster Discussion Session; Displayed in Poster Session (Board #6), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Toxicity and quality of life data from SCOT: An international phase III randomized (1:1) noninferiority trial comparing 3 vs 6 months of oxaliplatin-based adjuvant chemotherapy. *First Author: Timothy Iveson, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom*

Background: Oxaliplatin/Fluoropyrimidine combination chemotherapy is an established adjuvant treatment for colorectal cancer (CRC). Neurotoxicity from Oxaliplatin is cumulative, dose limiting, and potentially irreversible. **Methods:** SCOT is designed to determine whether 3 months of adjuvant chemotherapy with OxMdG or XelOX (physician/patient choice) in Stage III /high risk Stage II CRC is as effective as 6 months, with less toxicity. In the initial 867 patients toxicity was graded during treatment using NCI-CTCAE. Quality of life was assessed using EORTC QLQ-C30/EQ-5D (n = 1681) and neuropathy using GOG-Ntx4 (n = 1776). **Results:** From May 2008 to Nov 2013, 6087 patients were randomized from 237 centers/6 countries. Median age was 65 years. 4972 (82%) were Stage III, 4983 (82%) had colon cancer and 4105 (67%) received XelOx. There were 31 toxic deaths (0.5%) equally distributed between the randomized arms. Toxicity profiles depended on the FU backbone with more grade 3/4 neutropenia on OxMdG (23% v 5%) and more grade 3/4 diarrhea (9% v 15 %) on XelOx. 16% overall did not complete 3 months of treatment mainly citing toxicity (56%). Peripheral neuropathy was *cumulative*, (24% grade 2/3 toxicity by 3 months; 56% by 6 months) and as measured by GOG-NTX4 persisted and was much higher at 1 year on the 6 month compared to the 3 month randomized arm (mean difference = 19 [se = 1.3]). QLQ-C30 global health status worsened during treatment and stayed more depressed in months 4-6 in the 6 month arm. By12 months the mean difference between the arms was small (2.2[0.9]); a similar pattern was seen with the QLQ-C30 functional scales. The pattern for the EQ-5D health score were also similar with small differences at 12 months (.03 [.02] respectively). **Conclusions:** Both OxMdG and XelOx were safe and well tolerated. As expected, the main toxicities did vary according to FU backbone (but this was not randomized). Quality of life worsened while patients were on treatment but recovered by 1 year despite persistent peripheral neuropathy, suggesting that current quality of life tools may not adequately capture the morbidity associated with this toxicity. Clinical trial information: ISRCTN59757862.

3515 Poster Discussion Session; Displayed in Poster Session (Board #7), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

A randomized phase III trial comparing S-1 versus UFT as adjuvant chemotherapy for stage II/III rectal cancer (JFMC35-C1: ACTS-RC). *First Author: Akihiko Murata, Department of Gastroenterological Surgery, Hirosaki University Graduate School of Medicine, Hirosaki, Japan*

Background: The ACTS-RC trial is a phase III trial designed to superiority of S-1 (tegafur, 5-chloro-2,4-dihydropyrimidine, and potassium oxonate) to UFT (uracil and tegafur), a standard treatment in Japan as adjuvant chemotherapy for curatively resected stage II/III rectal cancer. **Methods:** 20-80 aged patients (pts) with stage II/III rectal cancer who underwent curative surgery without preoperative therapy randomly assigned to receive UFT (500, or 600mg/day according to BSA on days 1 to 5 days, followed by 2 days rest) for 1 year or S-1 (80, 100, or 120mg/day according to BSA on days 1 to 28, followed by 14 days rest) for 1 year. The primary endpoint was Relapse-free survival (RFS). The 5-year RFS rate in the UFT group was assumed to be 70%. We calculated that a total enrollment of 800 pts was needed for a hazard ratio (HR) of 0.70 in the S-1 group as compared with the UFT group, with the use of the log-rank test, two-sided alpha of 0.05, and power of 0.80. **Results:** A total of 959 pts were randomly assigned between April 2006 and March 2009 (480 pts in UFT group, 479 pts in S-1 group). Median age: 63 years, upper/lower rectum: 52%/48%. The groups were balanced. At a median follow-up of 5.02 years, 5-year RFS rate was 61.7%(95%CI: 57.1-65.9%)in the UFT group and 66.4%(95%CI: 61.9-70.5%) in the S-1 group. The HR of RFS was 0.773(95%CI: 0.625-0.955) and superiority of S-1 was demonstrated (p = 0.0165). The completion rate of the protocol treatment was 61.8% in UFT group and 61.3% in S-1 group. 5-year overall survival rate was 80.2%(95%CI: 76.3-83.5%)in the UFT group and 82.0%(95%CI:78.3-85.2%) in the S-1 group. The overall incidence of grade $\geq$ 3 adverse events in UFT group and S-1 group were 11.7% and 13.4%: anemia(1.3% v 1.3%), diarrhea(2.3% v 2.6%), anorexia(1.0% v 2.6%), nausea(0.4% v 1.3%), hyperbilirubinemia (1.0% v 1.3%), AST(1.5% v 0.9%) and ALT(2.3% v 0.9%), respectively. **Conclusions:** Adjuvant chemotherapy using S-1 demonstrated improved 5-year RFS in pts with curatively resected stage II/III rectal cancer. S-1 is an additional adjuvant treatment option for these pts. Clinical trial information: C000000385.

3516 Poster Discussion Session; Displayed in Poster Session (Board #8), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

S0713: A phase II study of cetuximab (CET) added to induction chemotherapy (ICT) of oxaliplatin (OX) and capecitabine (CAP), followed by neoadjuvant chemoradiation (NACR) for locally advanced rectal cancer (LARC). *First Author: Cynthia G. Leichman, New York Univ, New York, NY*

Background: NACR for LARC has been standard for 2 decades. Pathologic complete response (pCR) associates with improved survival and is an outcome surrogate in NACR clinical trials. In modern phase III trials of NACR in LARC, pCR ranges 15-20%. CET improves response rates in KRAS wild-type (KRAS-WT) metastatic colorectal cancer. S0713 was designed to select patients (PTS) by KRAS-WT status to assess improvement in pCR with CET added to ICT and NACR for LARC. **Methods:** Eligibility: Stage II-III biopsy proven LARC, KRAS-WT, without bowel obstruction or prior therapy, adequate hematologic, hepatic and renal function, and performance status of 0-2. Peripheral neuropathy $>$ grade 2 was exclusionary. Enrollment target was 80 eligible PTS with planned interim analysis after 40 PTS received all therapy; if $<$ 7 pCR were observed at interim, the study was to close. Treatment consisted of ICT then NACR and surgery. Treatment regimen: Cycle 1: OX 50 mg/m2 day (d) 1,8,15,22,29, CET 400mg/m2 d1 then 250 mg/m2 d 8, 15, 22, 29 and CAP 825 mg/m2 p.o. BID Monday through Friday (M-F) d1-35; Rest d 36-49; Cycle 2: OX 50 mg/m2 d 50, 57, 71, 78, CET 250 mg/m2 d 50, 57, **64**, 71, 78 and CAP 825 mg/m2 p.o. BID M- F d 50-85 with radiation 180 cGy/d M-F x 5 weeks (4500 cGy) followed by 540 cGy boost x 3 (stage II; 5040cGy) or 5 (stage 3; 5400cGy). Surgery occurred 3-8 weeks after NACR. 80 eligible PTS would give a power of 90% if true pCR $>$ 35% at a significance of 0.04. The regimen would lack future interest if pCR $<$ 20%. **Results:** From February 2009 to April 2013, 83 PTS registered; 5 were ineligible; 4 not treated. 74 were available for toxicity evaluation (TOX); 72 had available data; 62 PTS (86%) had surgery. 1 grade 5 TOX and 2 grade 4 TOX occurred. 7 PTS withdrew for TOX, 2 for other reasons. 18 of 62 PTS had pCR (25%, 95% CI 16-37%). 19 PTS (26%) had microscopic cancer; 35 PTS (49%) had minor/no response (10 no surgery). **Conclusions:** ICT and NACR with CET improved pCR over historical and recent rates of ~20%. Toxicity was generally acceptable. This approach can serve as a base for adding additional agents in KRAS-WT LARC. Additional analysis for resistance genes is ongoing. Clinical trial information: NCT00686166.

Safety and tolerability of veliparib combined with capecitabine plus radiotherapy in patients with locally advanced rectal cancer (LARC): Final results of a phase Ib study. *First Author: Michael Michael, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Background: Standard treatment for patients (pts) with LARC consists of chemoradiation followed by surgery. To achieve higher response rates and reduce risk of recurrence, further optimization is needed. Veliparib (ABT-888), a potent orally bioavailable PARP1/2 inhibitor, has been shown to enhance antitumor activity of chemotherapy and radiotherapy (RT) in preclinical models. Herein, we present the final results from a phase Ib dose-escalation study (NCT01589419) of veliparib plus capecitabine (C) and RT (C/RT) in pts with LARC. **Methods:** Stage II/III rectal cancer pts ($\geq$ 18 years) received C (p.o. 825 mg/m^2 BID) and RT (1.8 Gy QD) for approx. 5.5 weeks (5 days/week). Veliparib (p.o. 20–400 mg BID) was administered from day 2 until 2 days after RT (7 days/week). Pts underwent surgery 5–10 weeks after RT. Primary objectives were to determine the maximum tolerated dose (MTD) and recommended phase II dose (RP2D) of veliparib plus C/RT, using an exposure-adjusted continual reassessment method. Safety, pharmacokinetics (PK), and antitumor activity were also assessed. **Results:** As of 23 Nov 2014, 32 pts (81% male, median age 57 years) received study treatment (veliparib $<$ 400 mg, n = 16; 400 mg, n = 16). Most common adverse events possibly or probably related to treatment were fatigue (41%), nausea (41%), diarrhea (25%), and vomiting (22%); grade 3/4 events were diarrhea (n = 2), anemia, lymphopenia, and pulmonary embolism (n = 1 each). Dose-limiting toxicities (grade 2) occurred in 2 pts: radiation skin injury, and nausea and vomiting, at 70 and 400 mg veliparib, respectively. The MTD was not reached. The RP2D for veliparib was 400 mg BID. Veliparib (20–70 mg BID) PK was dose proportional, with no clear impact on the PK of C. Postsurgery tumor downstaging was observed in 72% of 32 evaluable pts; 28% achieved a pathologic complete response. Sphincter-sparing surgery was performed in 70% of 30 evaluable pts. **Conclusions:** Veliparib plus C/RT had an acceptable safety profile in LARC pts and the RP2D is 400 mg BID. Veliparib showed a dose-proportional PK profile and no effect on the PK of C. The combination treatment showed promising preliminary antitumor activity. Clinical trial information: NCT01589419.

Compliance to chemoradiation (CRT) using mitomycin (MMC) or cisplatin (CisP), with or without maintenance 5FU/CisP chemotherapy (CT) in squamous cell carcinoma of the anus (SCCA) according to radiotherapy (RT) dose, overall treatment time (OTT) and chemotherapy (CT) and their impact on long-term outcome: Results of ACT II. *First Author: Robert Glynne-Jones, Mount Vernon Centre for Cancer Treatment, London, United Kingdom*

Background: Concurrent CRT is standard treatment for patients with SCCA. We explored CRT compliance in ACT II, which compared 5FU/CisP with 5FU/MMC (wks 1 & 5) of a uniform RT dose (50.4Gy, 28 daily fractions (F) of 1.8Gy). **Methods:** We investigated the association between poor compliance and baseline factors (age, sex, site, T & N stage), type of CT (MMC/CisP) with progression free survival (PFS). Compliance was categorized as follows: RT, 5 groups: A = per protocol (50.4Gy in 28F in 38-42 days), B = $\leq$ 40Gy, C = 40-48.6Gy in 23-27F, D = 50.4Gy in $>$ 42 days, E $>$ 52.2Gy. CT, 2 groups: 1 = wks1 & 5 & 2 = wk1 only. **Results:** 933 and 862 of 940 pts were evaluable for RT & CT compliance respectively. Median follow-up was 5.1 yrs. Baseline characteristics of evaluable patients were similar to all 940 ACT II patients. Canal tumors, CisP, GFR$<$60 & WBC $<$ 11 were borderline significant predictors of poor wk5 CT compliance (p 0.09, 0.07, 0.06 & 0.08 respectively). Poor CT compliance at wk5 impacted significantly on PFS (treatment adjusted HR: 1.63 (95% CI: 1.23-2.17), p = 0.001). No baseline factors analyzed, or chemotherapy type, were significant independent predictors of poor RT compliance. **Conclusions:** In ACT II poor CT & RT compliance (lower dose/prolonged OTT) adversely impacted on PFS. Treatment interruptions should be minimized and prolonged OTT compensated by hyperfractionation or possibly additional dose. Intensity Modulated RT may improve compliance. Patients with poor compliance to RT/CT may need closer monitoring following treatment. Clinical trial information: 26715889.

Impact of RT compliance on PFS (N=933).

Group	Total events/ No of pts	3 y PFS rate %	Treatment-adjusted HR (95% CI)	P-value
A	221/786	76	1.00	0.0001
B	11/18	44	3.71 (2.01-6.82)	
C	11/21	56	2.26 (1.23-4.14)	
D	39/93	62	1.62 (1.15-2.28)	
E	6/15	59	1.60 (0.71-3.61)

Comprehensive multiplatform biomarker analysis of 212 anal squamous cell carcinomas. *First Author: Patrick McKay Boland, Roswell Park Cancer Institute, Buffalo, NY*

Background: Squamous cell anal carcinoma is a rare, HPV-associated malignancy accounting for 2% of digestive system cancers. Usually these malignancies are detected early and successfully managed with chemoradiation. Uncommonly, these cancers recur or present with metastases. In this setting, cisplatin and 5-fluorouracil represent the only endorsed regimens. Beyond standard therapy, few therapeutic options exist. The purpose of this study is to identify other novel, potential targets and therapeutic options for this disease, utilizing a multiplatform approach. **Methods:** 212 squamous cell anal carcinoma specimenswere tested via a multiplatform profiling service (Caris Life Sciences, Phoenix, AZ) consisting of gene sequencing (Sanger or next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]) and gene amplification (CISH or FISH). Tissue from a metastatic site was submitted in 80.2% of the cases. Documentation of positive HPV or HIV status was provided in six cases. **Results:** IHC overexpression was noted in MRP1 (97.6%, 81/83), EGFR (89.7%, 35/39), TOPO1 (68.3%, 123/180), MGMT (67.2%, 125/186), and PTEN (46.9%, 90/192). EGFR and HER2 were amplified (ISH) in 7.4% (5/68) and 1.8% (2/111) of cases. High mutation rates were seen in biomarkers associated with the PIK3CA/Akt pathway: PIK3CA (26.8%, 26/97), FBXW7 (11.8%, 8/68), PTEN (3.1%, 2/64), and Akt1 (1.5%, 1/68). PIK3CA exon 9 mutations were detected in 75% of all PIK3CA mutations. KRAS mutations were rare (1.8%, 2/111). Point mutations in other genes were also identified, including a few co-occurring mutations. **Conclusions:** Multiplatform tumor profiling identified several potential targets. Protein expression aberrations identified potential treatment options not routinely considered. Mutations in PIK3CA, Akt1, and FBXW7 and PTEN loss indicate potential for targeting the PI3 kinase pathway. Targeting the ErbB-family receptors, namely with anti-EGFR agents or newer generation pan-HER inhibitors, may represent another option, given EGFR and HER2 amplification as well as EGFR overexpression. Differences in anal carcinomas whose etiology is of viral origin may present different treatment options based on the driver mutations.

Checkpoint kinase (CHK) 1/2 inhibitor LY2606368 in a phase I, dose-expansion study in patients (pts) with metastatic squamous cell carcinoma (mSCC) of the anus. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute, Nashville, TN*

Background: LY2606368 is a CHK 1/2 inhibitor. CHK1 is a multifunctional kinase essential for checkpoint control, DNA repair, cell cycle replication, and proliferation. Potent inhibition of CHK1 is predicted to generate DNA damage and mitotic catastrophe. LY2606368 was evaluated as a single agent in an expansion cohort of pts with mSCC of the anus. **Methods:** This was a phase I study in pts with advanced cancer (NCT01115790). Preliminary signs of activity in the dose-escalation phase warranted a dose-expansion cohort of pts with mSCC of the anus given LY2606368 at the maximum tolerated dose (MTD) of 105 mg/m^2 IV on day 1 of a 14-day schedule. Radiographic assessment every 6 weeks and pretreatment biopsies were obtained. Safety, tolerability, preliminary efficacy, and pharmacogenetic results are reported. **Results:** Of 26 pts enrolled, 62% had $\geq$ 2 prior regimens (median = 2 regimens; range: 1 - 13) and 92% of pts had prior radiotherapy. The most frequently reported adverse event (AE) was neutropenia, which occurred in 92% of pts (grade 4: 77%), but was of relatively brief duration; 1 pt experienced febrile neutropenia. Other drug-related AEs occurring in $>$ 20% of pts were thrombocytopenia (58%), anemia (38%), and fatigue (31%). Nonhematologic AEs included nausea (19%), diarrhea (15%), anorexia and headache (12% each), which were mostly grade 1 or 2. One pt (4%) had a CR, 3 pts (12%) had a PR, and 11 pts (42%) had SD, for an overall response rate of 15% (90% CI: 5, 32) and a disease control rate of 58% (90% CI: 40, 74). Of the 4 pts with response, 3 pts (including the pt with a CR) remain on treatment, and 1 had a prolonged duration of response (10.1 mos) before discontinuing therapy. Tissue samples were available from 14 pts with evaluable response data. Alterations of genes in the PI3K pathway occurred in 5/8 (63%) pts with clinical benefit vs 1/6 (17%) pts without (p = 0.12). **Conclusions:** The CHK 1/2 inhibitor LY2606368 demonstrated an acceptable safety profile despite a relatively high rate of transient grade 4 neutropenia. Single-agent activity was observed in pretreated mSCC of the anus, a disease with a high unmet medical need. The MTD of 105 mg/m^2 is confirmed as the recommended phase II dose. Clinical trial information: NCT01115790.

Role of race and socioeconomic status in overall and cancer-specific survival of anal cancer patients. *First Author: Jessica Belmonte, UC Irvine Medical Center, Orange, CA*

Background: Treatment of anal cancer (AC) relies on a multidisciplinary approach and highly-coordinated care. As such, health disparities may arise in vulnerable populations. Our aim was to analyze the overall and cancer-specific survival (OS, CSS) of AC patients stratified by race/ethnicity while accounting for treatment and socioeconomic (SES) differences, as this has not been studied before. **Methods:** Incident cases of squamous cell AC were identified in the California Cancer Registry during 2004-2009. In-situ through stage IV AC were included. Univariate OS and CSS estimates were generated using Kaplan-Meier methods. Multivariate analysis (MVA) of OS and CSS were performed using Cox proportional-hazard regression models, adjusting for age, gender, SES, stage, grade, surgery, chemotherapy, and radiation therapy. **Results:** We identified 4303 incident cases of AC, including 3023 Caucasians (C), 342 African-Americans (AA), 555 Hispanics (H), 115 Asians (As) and 268 Others (O, Native American and unidentified race/ethnicity). Five-year OS for AAs was statistically shorter than for C and H counterparts (see table below). Higher SES was independently associated with a longer OS (p-trend $<$ 0.0001) and CSS (p-trend 0.0101), compared to lower SES in MVA. After adjustment for SES and other covariates, and compared to C as a referent group, AAs were observed to have an independent increased risk of mortality (for OS, HR = 1.9, 95%CI 1.5-2.3 and for CSS, HR = 1.8, CI 1.3-2.4). This risk difference (AA vs. C) was observed in each stage and significant for all except stage II. **Conclusions:** In squamous cell AC, health disparities exist between racial/ethnic groups as exemplified by worse outcomes in the AA cohort vs. other racial/ethnic groups. The differences in survival cannot be accounted for by SES alone or treatment. SES is independently associated with outcome in AC. Additional determinants of health must be identified to facilitate improvement in outcomes.

Univariate overall survival estimates (by Kaplan Meier Method).

	12 months	36 months	60 months
Caucasian	92%	80%	72%
Black	85%	71%	65%
Hispanic	92%	78%	68%
Asian	91%	79%	70%
Native American/Other	97%	94%	90%

Log-Rank P-value for the above K-M survival curves $<$ 0.0001

Comprehensive genomic profiling of anal squamous cell carcinoma to reveal frequency of clinically relevant genomic alterations in the PI3K/mTOR pathway. *First Author: Eric M. Sanford, Foundation Medicine, Inc., Cambridge, MA*

Background: Anal squamous cell carcinoma (ASCC) is an HPV-associated rare tumor that has nearly doubled in incidence since 1973, with cisplatin-based chemotherapy as the only treatment shown to be effective for patients with metastatic disease. We performed comprehensive genomic profiling (CGP) on 70 patients with ASCC to identify the spectrum of clinically relevant genomic alterations (CRGA). **Methods:** DNA was extracted from 40 microns of FFPE sections. CGP was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 692X for the entire coding regions of 236 cancer-related genes plus 47 introns from 19 genes frequently rearranged in cancer. CRGA were defined as GA linked to FDA-approved agents or investigational agents in clinical trials. **Results:** There were 48 female and 22 male patients with a median age of 59.5 years (range 31-88). Three tumors (4%) were grade 1, 33 (47%) were grade 2, and 34 (49%) were grade 3. At the time of sequencing, 5 (7%) cases were stage II, 13 (19%) were stage III, and 47 (67%) were stage IV, with staging information unavailable for 5 (7%) patients. HPV-16 or HPV-18 was detected in 61 (87%) tumors: 59 were positive for HPV-16 and 2 were positive for HPV-18. CGP revealed 238 GA (3.4 per tumor), 111 of which were CRGA (1.6 per tumor). At least one CRGA was detected in 53 (76%) cases. The most common CRGA were in *PIK3CA* (27 cases; 39%), *PTEN* (10 cases; 14%), and *FBXW7* (8 cases; 11%). For the 9 (13%) tumors where HPV DNA was not detected, a significant enrichment of LOF mutations was observed in *TP53* (6 of 8 altered cases; p $<$ 0.0001) and *CDKN2A*(5 of 5 altered cases; p $<$ 0.0001). Clinical outcomes for PI3K/mTOR pathway-altered patients are being investigated. **Conclusions:** ASCC features a high rate of potentially targetable PI3K/mTOR pathway alterations, with 37 (53%) tumors harboring alterations in *PIK3CA*, *PTEN*, or *FBXW7*—a mutational profile similar to HPV positive head and neck and cervical SCC. The enrichment of *TP53* and *CDKN2A* alterations in tumors where HPV DNA was not detected was similarly found in HPV negative head and neck squamous cell carcinoma, suggesting a distinct route to carcinogenesis for HPV negative ASCC.

3523 Poster Session (Board #15), Mon, 8:00 AM-11:30 AM

Programmed cell death-Ligand 1 (PD-L1) expression and outcome in patients with squamous cell cancer of anal canal (SCCAC). *First Author: Swetha Gujja, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: PD-L1 expression has been associated with worse prognosis in a variety of cancers. In anal carcinoma, the prevalence of PD-L1 positivity in tumor tissue is unknown. To evaluate the influence of PD-L1 expression on prognosis of subjects with SCCAC, a retrospective analysis was conducted. **Methods:** Subjects with SCCAC were identified from tumor registry at the University of Arkansas for Medical Sciences and Kansas University between 1992 and 2011. The charts were reviewed to confirm the diagnosis, stage, treatment and outcome of the subjects. Paraffin tissue blocks of the subjects were stained for PD-L1 expression using rabbit polyclonal antibody (ab153991, ABCAM). PDL1 positivity was defined as any membranous or cytoplasmic immunoreactivity within the tumor cells. Nuclear or general blush staining only was considered negative.Kaplan-Meier curves and the Wilcoxon test were used to compare subjects positive vs. negative for PD-L1 expression for differences in Overall (OS) and Recurrence-Free (RFS) survival. **Results:** Samples from 41 subjects were evaluated for PD-L1 expression. Median age was 52 years (range 30-94). Males were 51%. There were 80% Caucasians, 15% African-Americans, 5% others. 22% were early stage (0, I, II), 48% late stage (III, IV) and 29% unknown. 93% were p16-positive by immunohistochemistry. 71% had chemo-radiation, 2.4% had chemotherapy, 17% had surgery and 10% had unknown treatment. PD-L1 positivity was seen in 62% of late/ unknown stage and 33% of early stage disease. PD-L1-positive vs. negative patients respectively had RFS medians of 1.5 vs. 4.9 years (p = 0.068) and OS medians of 2.2 vs. 7.6 years (p = 0.64). **Conclusions:** PD-L1positivity was associated with poorer RFS, with a trend towards statistical significance. OS was not significantly different between the PD-L1 positive and negative groups. However, larger sample size may show statistically significant difference in RFS and OS.

3524 Poster Session (Board #16), Mon, 8:00 AM-11:30 AM

Sequential liver and lung resection for colorectal cancer metastases: In which patients should surgery be proposed? *First Author: Muthukumarassamy Rajakannu, Centre HepatoBiliaire, Hopital Paul Brousse, Villejuif, France*

Background: Resection of colorectal cancer (CRC) liver or lung metastases is an established therapeutic strategy. However, controversies exist when metastases are found concomitantly in both the organs or when the patients, who have undergone either liver or lung resection, have a recurrence in the other organ. **Methods:** All consecutive patients operated for CRC liver and lung metastasis (LLM) at our institution from January 1990 to December 2012 were reviewed. Our policy was to propose sequential surgery of both sites with perioperative chemotherapy, provided that the strategy was potentially curative. We aimed to evaluate Overall Survival (OS) of these patients, to develop a clinical usable prognostic score and to find out if cure is possible. **Results:** A total of 150 patients (89 men - 61 women; median age - 56 years) were included in the study. Median number of LLM resected was 3 and 1 respectively. Median follow-up was 5 years (Range 0.6 - 22.8 years). Median OS, 5-year OS and 10-year OS from first metastasis resection were 6 years, 59% and 35% respectively. Multivariate analysis identified metastatic CRC at initial diagnosis [P = 0.027], Pre-Lung resection CEA level > 100 ng/ml [P = 0.007], Pre-Lung resection CA19-9 level > normal [P = 0.029], Interval between 1st liver and 1st lung resection < 24 months [P = 0.004], > 2 lung metastases resected [P = 0.049] and Non-curative lung resection [P = 0.012] were independent predictors of OS. Simultaneous presentation of LLM and perioperative chemotherapy was not associated with OS. Prognostic model was developed using 5 preoperative factors. LLM score > 3 was associated with good 5-year survival [AUROC 0.7, Sensitivity 90%, Specificity 67%]. Fifteen patients were considered as cured with > 5 years disease-free survival from the last surgery (median LLM score 7). **Conclusions:** Good long-term survival can be achieved in patients who undergo sequential resection of the liver and lung metastases from CRC with 10% being cured. LLM score is an effective way to select patients for sequential resection. Higher the score better is the survival after sequential surgery and better is the chance of cure. Conversely, the role of surgery should be questioned in patients with LLM score < 3.

3525 Poster Session (Board #17), Mon, 8:00 AM-11:30 AM

Impact of *UGT1A1* genotype on prognosis in Japanese advanced colorectal cancer patients treated by irinotecan-based regimens. *First Author: Wataru Ichikawa, Division of Medical Oncology, Showa University, School of Medicine, Tokyo, Japan*

Background: The influence of *UGT1A1*6* and *UGT1A1*28* on prognosis of irinotecan (IRI)-based regimens has been controversial, although *UGT1A1* genotypes are risk factors for IRI-related toxicities in Asians. We conducted a prospective analysis to examine the correlation between *UGT1A1* genotypes and safety/efficacy of IRI-based regimens in Japanese patients (pts) with advanced colorectal cancer (aCRC) (NCT 01039506). The validated nomogram for predicting the probability of severe neutropenia induced by IRI-based regimens was proposed based on safety analysis (ASCO 2014, Abst No. 3543). We analyzed the efficacy in terms of *UGT1A1*genotypes. **Methods:** 1,376 pts who had histologically confirmed aCRC and received IRI-based regimens were enrolled. *UGT1A1* genotypes were categorized into three groups: wild (**1/*1*), hetero (**1/*6*, **1/*28*), and homo (**6/*6*, **6/*28*, **28/*28*). The primary objective was to investigate the non-inferiority of hetero or homo to wild in progression-free survival (PFS) under the non-inferiority margin of hazard ratio (HR) of 1.25, using propensity score weighting to adjust for baseline characteristics. Progression was evaluated by investigators according to the RECIST 1.1 criteria. The association of prognosis with IRI exposure was also examined. **Results:** The efficacy analysis was performed using 1,339 pts. The prevalence of *UGT1A1* genotypes were 47% wild, 42% hetero, and 11% homo. The median PFSs according to *UGT1A1*genotypes were 6.0 (95% CI, 5.6–6.7) months (mo) in wild, 6.0 mo (5.4–6.6) in hetero, 5.6 mo (4.4–6.1) in homo. The HR of hetero to wild was 0.988 (0.864–1.130; non-inferiority p = 0.0006) and that of homo to wild was 1.202 (0.988–1.463, non-inferiority p = 0.6977). The HRs in the homo group with a starting dose not less than 80% to wild and with a dose less than 80% of the standard IRI dose were 1.037 (0.779–1.379, p = 0.8052) and 1.393 (1.106–1.754, p = 0.0049), respectively. **Conclusions:** This analysis revealed that PFS in the *UGT1A1* hetero group were non-inferior to the wild group. However, the homo group had worse PFS as compared with the wild group. The excessive dose reduction of the starting IRI dose might account for the unfavorable results in the homo group.

3526 Poster Session (Board #18), Mon, 8:00 AM-11:30 AM

Masitinib plus FOLFIRI for second line treatment of metastatic colorectal cancer: An open label phase Ib/II trial. *First Author: Julien Taieb, Paris Descartes University, Georges Pompidou European Hospital, Paris, France*

Background: Masitinib (MAS) is a selective inhibitor of c-Kit and mast cell function. Increased mast cell activity in the tumor microenvironment is linked to poor prognosis and a protumoral immune response in colorectal cancer (CRC). In vitro, MAS acts as a chemosensitizer of 5-fluorouracil and irinotecan in CRC cell lines. This trial evaluated MAS in combination with chemotherapies. We report here findings from the cohort receiving MAS + FOLFIRI. **Methods:** Patients (pts) with nonresectable, metastatic CRC after progression to first line treatment received MAS + FOLFIRI until progression, refusal or unacceptable toxicity. Patients previously treated with irinotecan were excluded. Phase 1 evaluated safety of the combination with Dose Limiting Toxicity (DLT) determining subsequent dose and recruitment. DLT was defined as grade 3 non hematological adverse event (AE) or any grade 4 AE related to MAS. Phase 2 evaluated efficacy. **Results:** Eighteen pts (50% with mutated KRAS) from 6 centers in France were treated. MAS dose was reduced from 9 to 6 mg/kg/day for the final 3 pts based on new mechanistic understanding and to minimize risk of toxicity. No DLT was reported for the phase 1 stage (3 pts) at 9 mg/kg/day. After a median follow-up of 22.8 months, median OS was 17.6 months (95%CI [8.9; 20]) and median PFS was 6.2 months (95%CI [3.1; 9.2]). Overall response rate was 28%, including 1 pt with a confirmed complete response. Efficacy was still evident in the 3 pts treated at 6 mg/kg/day with PFS of 9.2, 6.2 and 5.6 months without any grade 3-4 AE in this cohort. Overall, 6/18 pts (33%) reported grade 3-4 AE and 4/18 pts (22%) experienced serious AE. No treatment related deaths were reported. **Conclusions:** The safety profile of MAS + FOLFIRI was acceptable. Efficacy findings seem to compare favorably against historic benchmarks (see table). MAS may therefore offer patients a new active compound for mCRC. A confirmatory phase 3 trial evaluating FOLFIRI+/- MAS at 6 mg/kg/day as second line for mCRC is ongoing.

	MAS + FOLFIRI	*FOLFIRI wildtype KRAS	*FOLFIRI mutant KRAS
OS (months)	17.6	12.5	11.1
PFS (months)	6.2	3.9	4.9
Objective Response Rate	28%	10%	14%
Complete	6%	0%	0%
Partial	22%	10%	14%

3527 Poster Session (Board #19), Mon, 8:00 AM-11:30 AM

A phase II study of NK012, a polymeric micelle formulation of SN-38, in colorectal cancer patients who had received prior oxaliplatin-based regimen. *First Author: Akihito Tsuji, Department of Medical Oncology, Kochi Health Sciences Center, Kochi, Japan*

Background: NK012 is a micelle-forming macromolecular prodrug of SN-38, an active metabolite of irinotecan. In the completed phase I study, the recommended dose was decided to be 28 mg/m^2, with a DLT of myelosuppression. This phase II study was conducted to evaluate an efficacy and safety of NK012 in patients with recurrent or metastatic colorectal cancer. **Methods:** This was a multicenter, open-label, single-arm phase 2 study. Patients with a history of oxaliplatin-based treatment against metastatic colorectal cancer, or recurrence within 6 months after the last dose of adjuvant oxaliplatin had been enrolled. NK012 (28 mg/m^2) was administered intravenously every 3 weeks. Administrations continued until disease progression. Objective clinical response was evaluated according to RECIST 1.1. The primary endpoint was overall response rate (ORR). **Results:** In the 58 patients registered, 53 patients received NK012. Median number of previous oxaliplatin-based therapy was 11.0 courses. 4.2% of patients had a history of previous irinotecan. Median treatment period was 3 courses. ORR was 3.8 %, and DCR (CR+PR+SD) was 56.0%. Median PFS and OS were 99.0 and 451 days, respectively. Major adverse drug reactions were absolute neutrophil count (ANC) decreased, of which grade 4 or more manifested in 81% of patients. Ratio of Grade 4 ANC decreased was higher in patients who had received previous oxaliplatin for more than 6 months. Grade 3 diarrhea manifested in 5.7%, but no diarrhea of Grade 4 manifested. **Conclusions:** Efficacy of NK012 against recurrent or metastatic colorectal cancer was comparable with that of irinotecan monotherapy previously reported, and disease control by NK012 was suggested. Unlike irinotecan, the major ADR was myelosuppression, with mild gastrointestinal toxicity. These safety profiles implicate a possibility of combination with less-myelotoxic anticancer agent(s) like 5-FU/LV and of being preferable to FOLFIRI. Further optimization of dosage and schedule of NK012 administration and its combination strategy would be worthwhile.

3528 Poster Session (Board #20), Mon, 8:00 AM-11:30 AM

Can we use radiofrequency ablation for liver metastases from colorectal cancer over 25 mm initially but downsized by systemic chemotherapy? *First Author: Leonor Benhaim, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Radiofrequency ablation (RFA) can be a valid treatment for liver metastases from colorectal cancer (CRLM) and is mostly dedicated to metastases unsuitable for surgical resection. Tumor size at the time of the RFA procedure is the main predictive factor for in situ recurrence (ISR) at the ablated zone. However, regardless to tumor size during procedure, the diameter of liver metastases at presentation, before chemotherapy infusion, may be predictive for ISR, although it has never been assessed. The aim of this study was to determine the risk for ISR after RFA for liver metastasis larger than 25mm initially but that have been downsized by preoperative chemotherapy. **Methods:** We retrospectively reviewed all RFA performed in patients treated for CRLM who had previously received at least one cycle of systemic chemotherapy from January 2004 to December 2012. Each tumor site treated by RFA was studied independently. Metastases were divided into 2 groups according to its size. Group1: $\leq$ 25mm before and after chemotherapy. Group 2: $>$ 25 mm before chemotherapy; 2A: $\leq$ 25mm after chemotherapy 2B: $>$ 25 mm after chemotherapy. **Results:** 133 CRLM were ablated in 83 patients after systemic chemotherapy (median follow-up 21 months). Among those patients, 57 underwent RFA combined with hepatectomy. The rate of 1-year ISR was significantly higher in group 2A than in group 1 (31.8% vs. 15.5% respectively, $p = 0.0006$). The highest rate of 1-year IRS was 63.6% in group 2B which was significantly higher than in group 1 ($p < 0.001$) and 2A ($p = 0.04$). Time to in situ recurrence (TTISR) was significantly shorter in group 2A than in group 1 (HR: 2.89; 95%CI [1.04-8.01], $p = 0.004$). The shortest TTISR was observed in group 2B. In multivariate analysis, RFA group was the only significant indicator for ISR after RFA ($p < 0.001$). **Conclusions:** Initially oversized CRLM do remain beyond the optimal indications for RFA despite downsizing and should be consider as contraindication to RFA procedure. The rate of ISR remains in this situation doubled to that of upfront small liver metastasis reaching 32%.

3529 Poster Session (Board #21), Mon, 8:00 AM-11:30 AM

Long-term follow-up of bone marrow micrometastases in colon cancer patients. *First Author: Carsten T. Viehl, Department of Surgery, Spitalzentrum Biel, Biel/Bienne, Switzerland*

Background: There is suggestive evidence from investigations with short follow-up that bone marrow (BM) micrometastases are a poor prognostic factor in colorectal cancer patients. The objective of the present prospective study was to evaluate the long-term prognosis of bone marrow micrometastases (BMM) in a large cohort of colon cancer patients. **Methods:** Overall, 144 stage I-III colon cancer patients underwent BM aspirations from both iliac crests prior to open oncologic colon resections. The BM aspirates were stained with the pancytokeratin antibody A45-B/B3, and analyzed for the presence of epithelial tumor cells by an automated cellular imaging system and by visual verification by a pathologist. Overall (OS) and disease-free survival (DFS) were analyzed by Cox proportional hazard regression analyses. **Results:** Median age was 74 years, 47% of patients were female. BMM were found in 55 patients (38%). Median follow-up was 74 months (87 months for patients who survived) with no loss to follow-up. Overall, 30 patients (21%) had a recurrence and 56 patients (39%) died. In univariate analyses, BMM-positive patients had a significantly worse OS (hazard ratio [HR] 0.61; 95% confidence interval [95%CI] 0.50,0.74; $p < 0.001$) and DFS (HR 0.61; 95%CI 0.57,0.65; $p < 0.001$) compared to BMM-negative patients. In multivariable analyses, the presence of BMM remained an independent prognostic factor for OS and DFS (table). **Conclusions:** The presence of BMM is a frequent phenomenon occurring in over one third of stage I-III colon cancer patients. The present prospective cohort study provides compelling evidence that BMM represent a significant, independent prognostic factor for DFS and OS in colon cancer patients even with long-term follow-up. The use of adjuvant chemotherapy in node negative patients with BMM may be justified. Clinical trial information: NCT00826579.

Multivariable analysis.

	OS		DFS	
	HR (95%CI)	p-value	HR (95%CI)	p-value

3530 Poster Session (Board #22), Mon, 8:00 AM-11:30 AM

Phase I study of anti-VEGF receptor-3 (VEGFR-3) monoclonal antibody (mab) LY3022856/IMC-3C5 (3C5). *First Author: Wasif M. Saif, Tufts University School of Medicine Tufts Cancer Center - Medical Center, Boston, MA*

Background: Many cancers metastasize to regional lymph nodes (LN). LN involvement by tumor is an adverse prognostic factor. 3C5 is a human IgG1 mab to VEGFR-3, which is a principal mediator of lymphangiogenesis (LA). **Methods:** This was a first-in-human study (NCT01288989). Part A (A) was a dose escalation study, followed by Part B (B), a planned 15-patient (pt) colorectal (CRC) expansion cohort. The primary endpoint of A was to establish the safety profile and maximum tolerated dose of 3C5 in pts with advanced solid tumors refractory to standard therapy: for B was to establish safety, tolerability, and dose confirmation in pts with advanced refractory CRC. Secondary objectives were pharmacokinetics (PK; noncompartmental parameters), antitumor activity, and immunogenicity. Pharmacodynamics was an exploratory objective. **Results:** Between April 2011 and August 2014, 44 pts were treated (23 in A, 21 in B): median age 58 years (range 33 to 79), male 59%, white 82%, black 9%, Asian 9%; median weight 77 kg (range 52 to 132). Starting dose was 5 mg/kg weekly (qwk), escalated to 10 mg/kg qwk and 20 mg/kg qwk and reached the highest planned dose of 30 mg/kg qwk without dose limiting toxicity. Treatment-emergent adverse events (AE) of any grade occurring in more than 15% of patients were: nausea 41%, fatigue 32%, vomiting 30%, anorexia 27%, pyrexia 25%, edema 23%, urinary tract infection (UTI) 21%, constipation 18%, cough 18%, and hypoalbuminemia 16%, diarrhea 16%. The most common grade 3/4 AEs were UTI, small bowel obstruction 7% each, and nausea, dyspnea, anemia, hypomagnesemia, pneumonia, bile duct stenosis 5% each. No responses per RECIST were noted. 4 of 8 pts with CRC treated at 30 mg/kg on A had prolonged progression free survival (PFS) (10 to 39 weeks). In B, 3C5 at 30 mg/kg qwk resulted in a median PFS of 6.3 weeks (95% confidence interval = 5.1, 14.4). No significant changes in serum VEGF-C/D levels were detected from pt samples after 3C5 administration. **Conclusions:** 3C5 was well tolerated up to a dose of 30 mg/kg qwk. 3C5 does not appear to have significant anti-tumor activity as monotherapy in CRC. Future development will be considered in indications in which LA plays a prominent role. Clinical trial information: NCT01288989.

3531 Poster Session (Board #23), Mon, 8:00 AM-11:30 AM

Relationship between metformin use and recurrence and survival in patients (pts) with resected stage III colon cancer (CC) receiving adjuvant chemotherapy: Results from NCCTG N0147 (Alliance). *First Author: Preet Paul Singh, Washington University School of Medicine, St. Louis, MO*

Background: Although preclinical and epidemiological data suggest that metformin may have antineoplastic properties in CC, the impact of metformin use on pt survival in stage III CC undergoing curative resection is unknown. **Methods:** Before randomization to FOLFOX +/- cetuximab, 1958 stage III CC pts enrolled on N0147 study completed a questionnaire that included information on diabetes mellitus (DM) and metformin use. Cox models assessed the association between metformin use and outcomes of disease free survival (DFS), overall survival (OS) and time to recurrence (TTR), adjusting for clinical/pathological factors. **Results:** 1691 (86%), 115 (6%) and 152 (8%) of 1958 pts reported no history of DM, DM with metformin use, or DM with no metformin use, respectively. The two treatment arms were pooled since metformin use showed homogeneous effects on outcomes across arms. There was no difference in DFS, OS and TTR irrespective of metformin use when DM pts were compared to non-DM pts, after adjusting for tumor/pt factors (Table). Within the cohort of DM pts ($n = 267$), DFS (HR = 0.90; 95% CI: 0.59-1.35; $p = 0.595$), OS (HR = 0.99; 95% CI: 0.65-1.49; $p = 0.948$) and TTR (HR = 0.87; 95% CI: 0.56-1.35; $p = 0.534$) were similar in metformin users compared to non-users. Survival outcomes were comparable regardless of duration of metformin use (< 1, 1-5, 6-10, 11+ years) before randomization ($p = 0.361$ for DFS; $p = 0.068$ for OS). There were no interaction effects observed between metformin use and clinical/pathological factors (*KRAS*, *BRAF* mutation status, tumor site, T/N stage, gender, and age). **Conclusions:** Stage III CC patients treated with adjuvant chemotherapy who used metformin experienced similar DFS, OS, or TTR compared to non-DM pts or DM pts without metformin use.

	DFS		OS		TTR	
Group	HR (95% CI)	p value	HR (95% CI)	p value	HR (95% CI)	p value
Non-DM	Ref		Ref		Ref	
DM, metformin use	0.95 (0.67-1.36)	0.796	1.17 (0.82-1.67)	0.383	0.91 (0.62-1.33)	0.616
DM, no metformin use	1.15 (0.86-1.54)	0.361	1.26 (0.93-1.72)	0.138	1.14 (0.84-1.57)	0.401

3532 Poster Session (Board #24), Mon, 8:00 AM-11:30 AM

***DPYD c.1905+1G>A and c.2846A>T* and *UGT1A1*28* allelic variants as predictors of toxicity: Pharmacogenetic translational analysis from the phase III TRIBE study in metastatic colorectal cancer.** *First Author: Marzia Del Re, University of Pisa Department of Clinical and Experimental Medicine, Ghezzano, Italy*

Background: Adverse drug reactions (ADRs) caused by fluoropyrimidines depend, at least in part, from DPD deficiency resulting from the loss-of-function mutations c.1905+1G > A and c.2846A > T. Moreover, irinotecan ADRs appear frequently in patients bearing the *UGT1A1*28* variant, associated with reduced UGT1A1 expression. In this study, we analyse the association between *DPYD* and *UGT* variants with ADRs by 5-fluorouracil and irinotecan in subjects enrolled within the phase III TRIBE study, whose final results have been recently reported. **Methods:** Out of 508 randomized patients, blood samples for pharmacogenetic analyses were available for 440 patients. DNA was extracted from 200 μl of blood and analyses of *DPYD* c.1905+1G > A, c.2846T > C and *UGT1A1*28* was performed by a Pyrosequencing platform (Qiagen, USA). The study was approved by the local Ethics Committee. **Results:** Each of the *DPYD* c.1905+1GA and c.2846AT genotypes were found in 5 out of 440 subjects, with a combined frequency of 2.2%. c.1905+1GA and c.2846AT had the same impact on ADRs and, taken together, patients bearing these variants (N = 10) had an increased risk of G3/4 neutropenia (OR: 4.14, p = 0.043) and stomatitis (OR: 10.36, p = 0.003) as compared to wild-type patients. Five out of 10 DPYD mutant patients experienced a G4 ADR after the first cycle of therapy. *UGT1A1*28*/**28* was found in 39/436 patients (8.9%); these patients had an increased risk of G3/4 neutropenia as compared to both *1/*1 (OR: 3.81, p < 0.001) and *1/*28 (OR: 2.28, p = 0.022) genotypes. Patients bearing *DPYD* c.1905+1GA, c.2846AT and *UGT1A1*28*/**28* (N = 49) had an increased risk of G3/4 neutropenia (OR: 2.98, p < 0.001), febrile neutropenia (OR: 2.78, p = 0.023) and G3/4 stomatitis (OR: 6.83, p < 0.001). No significant correlation with G3/4 diarrhea was found. **Conclusions:** *DPYD* c.1905+1GA, c.2846AT and *UGT1A1*28*/**28* are associated with a higher risk of G3/4 ADRs also in the TRIBE trial, underscoring the predictive role of *DPYD* and *UGT1A1* variants across various fluoropyrimidine and irinotecan-containing schedules, and therefore their potential usefulness in treatment tailoring.

3533 Poster Session (Board #25), Mon, 8:00 AM-11:30 AM

Dual targeting of vascular endothelial growth factor-A (VEGF-A) and angiopoietins (Ang) without chemotherapy in metastatic colorectal cancer (mCRC): Results of the VENGEANCE study. *First Author: Jennifer Mooi, Austin Health, Melbourne, Australia*

Background: VEGF-A and Ang play complementary roles in regulation of blood vessel growth, maturation and function. Hence we postulate that combined blockade of VEGF-A and Ang would have clinical activity in mCRC. Trebananib/AMG386 (Treb) is a peptibody that inhibits binding of Ang 1/2 to the Tie2 receptor. Previous studies have established the safety of Treb with various VEGF inhibitors including bevacizumab (Bev). **Methods:** VENGEANCE is an open label Phase II study evaluating the combination of Bev and Treb without chemotherapy as 1st line treatment of mCRC. Key eligibility criteria: patients (pts) with unresectable mCRC, no prior therapy, PS 0-2, adequate organ function, and in whom investigator considers not requiring immediate cytotoxic chemotherapy. Treatment: Bev 7.5mg/kg q3w and Treb 15 mg/kg qw. Primary endpoint: disease control rate (pts without disease progression, i.e. RECIST CR+PR+SD) at 6 mths (DC6m). 2 stage Simon design required stage I: DC6m >5/17 pts, stage II: DC6m >13 pts, for a positive study. Secondary endpoints: response rate (RR), toxicity, progression-free survival (PFS) and overall survival (OS). **Results:** 45 pts were enrolled from 4 Australian sites from Sep 2010 to Aug 2013. Med follow up is 33.7 mths. At time of analysis, 7 pts remain on study treatment (3 PR, 4 SD; duration on study 19 – 32 mths). Key AEs of interest were GI hemorrhage, TIA, cardiac ischemia, PE, GI perforation and CNS hemorrhage (2% each) and g3 hypertension (4%). **Conclusions:** Treb plus Bev showed promising activity that merits evaluation in further randomized studies, including combinations with chemotherapy. RR of the combination is greater than previously reported for Bev monotherapy (3%).The toxicity profile is manageable and the combination does not appear to increase toxicities in excess of those expected with Bev +/- chemotherapy. Clinical trial information: NCT01249521.

Endpoint outcomes.

	DC6m	ORR	Med PFS (mths)*	Med OS (mths)*
Treb + Bev (N=45)	60 % (n=27 non-PD, n=18 PD)	15.5% (n=7 PR, no CR)	9.0 (6.5 – 12.8)	33.4 (27.1 – 39.5)

3535 Poster Session (Board #27), Mon, 8:00 AM-11:30 AM

Tumor response outcomes in first-line treatment of wild-type (WT) *RAS* metastatic colorectal carcinoma (mCRC) following modified FOLFOX6 (mFOLFOX6) + either panitumumab (pmab) or bevacizumab (bev). *First Author: Fernando Rivera, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Background: In the PEAK study, pmab + mFOLFOX6 was associated with longer overall survival (OS) than bev + mFOLFOX6 in first-line *RAS* WT mCRC. RECIST overall response rates (ORR) were similar between treatment arms. Here, we report exploratory analyses of tumor assessments beyond RECIST. **Methods:** PEAK was a randomized phase 2 study of first-line pmab + mFOLFOX6 vs bev + mFOLFOX6 in previously untreated mCRC. ORRs (investigator assessed), median duration of response (DoR; from first confirmed response to disease progression or death [secondary endpoint]) and depth of response (DpR; defined as the percentage of tumor shrinkage at nadir or progression) in *RAS* WT patients (pts) were calculated by treatment. Early tumor shrinkage (ETS) was defined as the proportion of pts with ≥ 30% tumor shrinkage at week 8 (exploratory analysis). **Results:** Overall, 169 pts with *RAS* WT mCRC were included in the ORR analysis and 154 had tumor-shrinkage data available at baseline and week 8. Significantly more pts in the pmab + mFOLFOX6 arm had ETS at week 8 vs the bev + mFOLFOX6 arm (Table). ORRs were similar in the two arms, while DoR was significantly longer and DpR significantly greater with pmab + mFOLFOX6 (Table). ≥ 30% vs < 30% tumor shrinkage at week 8 was associated with longer median PFS (HR: 0.52 [95% CI: 0.29–0.92] and HR: 0.65 [95% CI: 0.38–1.13]) and OS (HR: 0.44 [95% CI: 0.15–1.32] and HR: 0.23 [95% CI: 0.08–0.66]) for pmab + mFOLFOX6 and bev + mFOLFOX6, respectively. **Conclusions:** Although ORR appeared to be similar or only numerically improved in the pmab arm of PEAK, the responses observed appeared to occur earlier, last longer and be deeper in our exploratory analyses. This is consistent with the observed OS and PFS benefit, and with data reported earlier from the FIRE3 study. Clinical trial information: NCT00819780.

3536 Poster Session (Board #28), Mon, 8:00 AM-11:30 AM

Expression of amphiregulin (AREG) and response to first-line panitumumab (pmab) + FOLFIRI in metastatic colorectal cancer (mCRC). *First Author: Claus-Henning Kohne, Onkologie Klinikum Oldenburg, Oldenburg, Germany*

Background: Biomarker analyses have shown that patients (pts) with *RAS*wild-type (WT) mCRC can achieve overall survival (OS) benefits with first-line pmab plus chemotherapy. Other biomarkers may exist that could optimize pt selection. Epidermal growth factor receptor (EGFR) ligand (eg AREG) levels have been correlated with OS during anti-EGFR therapy. Here we investigate the relationship between AREG expression and treatment outcome in a single-arm first-line mCRC study of pmab + FOLFIRI. **Methods:** Qualified reverse transcription quantitative polymerase chain reaction (RT-qPCR) assays were used to measure AREG RNA expression in archival formalin-fixed, paraffin embedded tumor samples from mCRC pts in two pmab trials (STEPP and 314). The STEPP analysis was used to establish a cut-off point in AREG expression that identified the best responders. This cut-off was applied prospectively to samples previously analyzed for *RAS* in the 314 trial. Using the *RAS* MT subgroup as a non-responding comparator, Cox proportional hazards (PH) models were used to evaluate AREG expression levels as a continuous covariate. Decision curves were used to estimate the progression-free survival (PFS) hazard ratio (HR) with increasing levels of baseline AREG expression. **Results:** In the 314 trial 100 pts had evaluable AREG levels. Among 50 *RAS* WT pts, high AREG expression was associated with objective response (OR) (Table). The high AREG group had better PFS HRs (*RAS* WT/*RAS*MT: 0.30 [95% confidence intervals {CI} 0.12–0.75] compared with the low AREG group (PFS HR 0.49 [95% CI 0.21–1.1]). There was a significant biomarker-by-AREG expression interaction in the Cox PH model (p = 0.03). **Conclusions:** Treatment decision curves based on the PH model suggest that most *RAS* WT patients express AREG at levels where treatment benefit is predicted. Future analysis of samples from a *RAS* WT population may provide further insights. Clinical trial information: NCT00508404.

3537 Poster Session (Board #29), Mon, 8:00 AM-11:30 AM

A phase II, randomized, double-blinded, placebo-controlled study of simtuzumab or placebo in combination with FOLFIRI for the second line treatment of metastatic KRAS mutant colorectal adenocarcinoma. *First Author: J. Randolph Hecht, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Simtuzumab (SIM) is a humanized antibody that inhibits lysyl oxidase-like molecule 2 (LOXL2), a matrix enzyme that catalyzes the cross-linking of collagen and is widely expressed across desmoplastic tumors. Inhibiting LOXL2 is expected to block formation of desmoplasia, which is thought to play an important role in tumor progression and metastasis. In Phase I, SIM was safe in patients (pts) with advanced solid tumors and showed early evidence of efficacy. Based on these results, a randomized, double-blind, placebo-controlled phase II study of SIM+5-fluorouracil, leucovorin and irinotecan (FOLFIRI) vs. placebo (pbo)+FOLFIRI as second line therapy in pts with metastatic KRAS mutant colorectal adenocarcinoma (CRC) was conducted. **Methods:** Enrolled pts had advanced KRAS mutated CRC that had progressed on first-line oxaliplatin-based chemotherapy. Pts were ECOG performance status (PS) $\leq$ 2. Subjects were randomized in a 1:1:1 ratio to receive SIM 200 mg, SIM 700 mg, or pbo in combination with FOLFIRI every 2 weeks, and the randomization was stratified according to ECOG PS (0 or $>$ 0). The primary endpoint was progression free survival (PFS) and the secondary endpoints were overall survival (OS) and objective response rate (ORR). **Results:** Between April, 2012 and December, 2014, 249 pts were randomized and treated; 85 pts (200 mg SIM/FOLFIRI), 84 pts (700 mg SIM/FOLFIRI), and 80 pts (pbo/FOLFIRI). Median PFS was 5.4 months (HR 1.45; 95% CI 1.01 to 2.06; p = 0.04 vs pbo), 5.5 months (HR 1.32; 95% CI 0.92 to 1.89; p = 0.10 vs pbo), and 5.8 months for the 200 mg SIM/FOLFIRI, 700 mg SIM/FOLFIRI, and pbo/FOLFIRI arms, respectively. Median OS was 10.5 (HR 1.50; 95% CI 0.98 to 2.30; p = 0.06 vs pbo), 11.4 (HR 1.23; 95% CI 0.80 to 1.91; p = 0.25 vs pbo), and 16.3 months, respectively. ORR was 5.9%, 11.9%, and 10%, respectively. There were no differences in the safety profile of the SIM/FOLFIRI groups versus pbo/FOLFIRI group. **Conclusions:** The addition of SIM to FOLFIRI does not improve PFS or OS in advanced KRAS mutant CRC pts. Exploratory analyses to investigate the potential prognostic factors influencing PFS or OS are being conducted. Clinical trial information: NCT01479465.

3538 Poster Session (Board #30), Mon, 8:00 AM-11:30 AM

Population-based assessment of surrogate endpoints (SE) in stage I-III colon (CCa) and rectal cancers (RCa). *First Author: Richard M. Lee-Ying, BC Cancer Agency, Vancouver, BC, Canada*

Background: In adjuvant CCa trials, 3 year disease free survival (3Y DFS) is a validated SE of 5 year overall survival (5Y OS), but this SE is less established in RCa. Effective systemic therapies introduced since 2004 may diminish the association between 3Y DFS and 5Y OS. The objective of this study was to measure SE in CCa and RCa in a population based setting, stratifying by tumor stage and era of diagnosis. **Methods:** Patients diagnosed with stage I-III CCa and RCa referred to any 1 of 5 regional cancer centers in British Columbia between 1990 and 2009 were followed by the GI Outcomes Unit. Clinical, pathological, and treatment characteristics were prospectively collected. R2 resections and early relapses were excluded. Relapses were classified as loco regional (LR) or distant. DFS and OS were measured from the date of definitive surgery until relapse or death. Correlation between DFS and OS endpoints was determined using Pearson's r coefficients. Hazard ratios (HR) were generated using multivariate Cox regression and compared between DFS and OS. 5Y OS HR was compared to calculated 5Y OS using 3Y DFS rates and the validated SE model. **Results:** Of 9147 referred patients with early stage CCa or RCa, 9031 were eligible, with 5357 CCa and 3674 RCa. The median age was 67, 55% were male, 17/34/49% had stage I/II/III disease, respectively, 51% received adjuvant chemotherapy and 87% of RCa received radiation. There were 2494 (28%) relapses of which 90% were distant. The correlation between HR for DFS and OS, 3Y DFS and 5Y OS, and 3Y LR DFS and 5Y OS were all very strong in the total population, for CCa and RCa, across stages and eras (Table 1). Predicted 5Y OS HR were similar to the observed HR where all estimates fell within the observed confidence intervals. **Conclusions:** A strong association between 3Y DFS and 5Y OS was observed in this population-based cohort, which did not differ between CCa and RCa. Correlations remained significant when stratified by tumor stage and treatment era. 3Y LR DFS was a strong surrogate of 5Y OS in RCa.

Risk factors for interval advanced colorectal neoplasia after screening colonoscopy. *First Author: Laura W. Musselwhite, Herbert Yeargan Center for Global Health, Duke University Medical Center, Durham, NC*

Background: Knowledge of risk factors for interval colorectal neoplasia could inform screening strategies in asymptomatic individuals. Few studies have evaluated risk factors for advanced neoplasia at 5 years in individuals who have had screening colonoscopy. **Methods:** We studied 1193 participants aged 50-75 to identify factors associated with interval advanced neoplasia during a 5-year follow-up period. Participants underwent screening and 5-year colonoscopy from 1994-1997 at 13 Veterans Affairs Medical Centers. Advanced neoplasia included an adenoma $\geq$ 1cm, villous histology, high-grade dysplasia, or carcinoma. Risk factors were self-reported at baseline. We performed a multivariable logistic regression analysis of risk for interval advanced neoplasia, adjusting for age, smoking, alcohol use, BMI, colon cancer in first degree relatives, diabetes, cardiovascular disease, and prior outcome. **Results:** Participants were mostly male (97%) and white (83%). At 5 years, 392 participants (33%) had small adenomas $<$ 1cm, and 92 participants (7.7%) had advanced neoplasia. In multivariable analyses, risk for interval advanced neoplasia was associated with age in 10-year increments (OR, 2.09; 95% CI, 1.39-3.13), diabetes (OR, 1.95; 95% CI, 1.12-3.41), prior small adenomas (OR, 4.02; 95% CI, 1.65-9.80), and prior advanced neoplasia (OR, 12.41; 95% CI, 5.08-30.30). **Conclusions:** In this prospective screening study, we identified diabetes as an independent risk factor for interval advanced neoplasia. Future guidelines should consider enhanced follow up of diabetic patients.

3540 Poster Session (Board #32), Mon, 8:00 AM-11:30 AM

A phase Ib study of AUY922 and cetuximab in patients with KRAS wild-type (WT) metastatic colorectal cancer (mCRC). *First Author: Somasundaram Subramaniam, Swedish Cancer Inst, Seattle, WA*

Background: Heat shock protein-90 (HSP90) is a molecular chaperone which has an important role in EGFR stability. AUY922 inhibits ATPase activity of HSP90. Combined HSP90/EGFR inhibition is effective in pre-clinical models. In this phase IB study, we examined safety, tolerability and maximum tolerated dose of AUY922 in combination with cetuximab in patients with KRAS WT mCRC. **Methods:** This was a single-center open-label dose escalation study. Patients who had disease progression on $\geq$ 2 prior chemotherapy regimens were eligible. Treatment with prior cetuximab was allowed. Inclusion criteria: ECOG 0-1, $\geq$ 1 measurable lesion and adequate organ function. All patients received weekly treatment with cetuximab and AUY922, with dosing per table below. **Results:** Median age 54.5 (range 25 – 77), M/F: 5/11. Patients had a median of 3 prior regimens (range 2-6) and 15 patients (94%) had progressed on prior cetuximab. Median time to progression was 7.9 weeks (range 5.9 – 29.9) and median overall survival was 37.2 weeks (range 4.9 – 115.1). One patient (6%) had a partial response (PR) and 4 patients (25%) had stable disease (SD), for a disease control rate of 31.3%. For patients with disease control, median survival was 45.7 weeks (range 37.6 – 115.1). Treatment was well-tolerated without dose-limiting toxicities. Grade 3 toxicities were seen in 62.5% of patients treated including anemia(2 patients), nausea/vomiting(2), dehydration(2), fever(1), fatigue(1), anorexia(1), abdominal pain(1), headache (1), diarrhea(1) and prolonged QTc interval(1). There were no grade 4 toxicities. Pharmacokinetic studies showed AUY922 half-life of approximately 50 hours, and no interaction with co-administration of cetuximab. **Conclusions:** AUY922 can be safely administered with cetuximab in patients with mCRC. Median survival of 37.2 weeks is suggestive of clinical activity in this heavily pre-treated patient population. Further studies of this combination are warranted. Recommended Phase II dose is weekly cetuximab 250mg/m2 and AUY922 70mg/m2.

Cohort	AUY922 Dose (mg/m2)	Cetuximab Dose (mg/m2)	Number of patients	Patients with Disease Control (PR/SD)
1	40	250	3	2 (1PR, 1SD)
2	55	250	5	1 (SD)
3	70	250	4	1 (SD)
Expansion	70	250	4	1 (SD)

3541 Poster Session (Board #33), Mon, 8:00 AM-11:30 AM

PRODIGE 20: Bevacizumab + chemotherapy (BEV-CT) versus chemotherapy alone (CT) in elderly patients (pts) with untreated metastatic colorectal cancer (mCRC)—A randomized phase II trial. *First Author: Thomas Aparicio, Hôpital Avicenne, Assistance Publique Hôpitaux de Paris, Bobigny, France*

Background: AVEX study has demonstrated increased progression-free survival (PFS) with capecitabine + bevacizumab compared to capecitabine alone in pts aged over 70 with mCRC. The treatment with bevacizumab has so far not been evaluated in combination with other standard chemotherapy regimens for elderly pts. **Methods:** Pts aged 75 and over were randomly assigned in a 1:1 ratio to BEV-CT versus CT. Following regimens were authorized: LV5FU2, FOLFOX and FOLFIRI, chosen by the investigators. The primary endpoint, assessed 4 months after randomization was composite, based on efficacy: tumor control (stable disease or objective tumor response) and absence of decrease of the Spitzer QoL index and safety: absence of severe cardiovascular toxicities and unexpected hospitalization. The decision rules for the experimental arm were: if >15 pts met the efficacy criterion and if >25 pts met the safety criterion, the BEV-CT treatment is considered efficient and well tolerated. **Results:** 102 pts were randomized (51 BEV-CT and 51 CT arm), median age was 80 (range 75-91), men (55%), ECOG 0: 27%, 1: 53% and 2: 20%. CT was LV5FU2 in 53 pts (27 BEV-CT and 26 CT) and a doublet regimen in 49 pts (24 BEV-CT and 25 CT) including 23 FOLFOX and 26 FOLFIRI. Primary tumor was resected in 31 pts in BEV-CT and 30 pts in CT. Of the 46 pts evaluable in the BEV-CT arm, 23 pts (50% [90% CI: 37.1-62.9]) responded to the efficacy criterion and 28 pts (61% [90% CI: 47.7-73.0]) to the safety criterion. Multivariate analysis show that primary tumor resected and normal independent activity of daily living are predictive for the composite criterion. **Conclusions:** BEV-CT arm responded to the efficacy and safety criterion. Addition of bevacizumab to 1st line chemotherapy in pts aged over 75 years with a mCRC is efficient and well tolerated. Clinical trial information: NCT01417494.

Preliminary follow-up results.

	CT	BEV + CT
Grade 3-5 toxicities	65%	80%
Median time to autonomy failure in months (m)	5.5 [95% CI: 3.8-NA]	5.9 [95% CI: 3.8-14.8]
Median time to QoL deterioration (m)	13.6 [95% CI: 11.6-NA]	Not achieved
Median PFS (m)	7.8 [95% CI: 6.6-10.6]	10.7 [95% CI: 8.2-13.8]
Median overall survival (m)	19.7 [95% CI: 13.4-21.9]	21.7 [95% CI: 14.6-NA]

3542 Poster Session (Board #34), Mon, 8:00 AM-11:30 AM

A prospective, multi-center study of individualized, pharmacokinetically (PK)-guided dosing of 5-fluorouracil (5-FU) in metastatic colorectal cancer (mCRC) patients treated with weekly or biweekly 5-FU/oxaliplatin containing regimens. *First Author: Volker Kunzmann, Universitätsklinikum Wurzburg, Würzburg, Germany*

Background: Numerousstudies have demonstrated that body surface area (BSA)-based dosing leads to under- and overexposure in a large number of patients. PK-guided dosing of 5-FU can optimize 5-FU exposure resulting in higher overall dose intensity with reduced toxicities and improved outcomes. This study was initiated to validate use of PK-guided 5-FU dosing for mCRC patients in clinical practice. **Methods:** 75 mCRC patients from 8 academic and/or community-based medical centers located throughout Germany received up to 6 cycles of infusional 5-FU according to either the AIO (n = 16), FOLFOX6 (n = 26) or FUFOX (n = 33) regimen. Initial dosing of infusional 5-FU for all patients was based on BSA and subsequent doses were adjusted according to the previous cycle 5-FU area under the concentration-time curve (AUC) to target an AUC of 20 to 30 mg•h/L. Primary objective was to confirm that PK-guided dosing of 5-FU leads to an increased proportion of patients in the target AUC range at cycle 4 versus cycle 1. Secondary objective was to determine whether PK-guided 5-FU dose adjustment reduced treatment-related toxicities compared to historical patient groups. **Results:** Average 5-FU AUC at cycle 1 was 20 ± 15 mg•h/L, with 62%, 32% and 6% of the patients below, within or above target AUC range, respectively. By cycle 4, average 5-FU AUC was 25 ± 7 mg•h/L (p = 0.007), and a significantly higher proportion of patients were within the target 5-FU AUC range (55%, p = 0.005). Fewer 5-FU-related grade 3-4 toxicities of diarrhea (5%), nausea (3%), fatigue (0%) and mucositis (0%) were observed compared to historical data (12%, 9%, 12%, 15%, respectively). **Conclusion:** PK-guided adjustment of 5-FU dosing in routine clinical practice resulted in significantly higher 5-FU exposure, more patients achieving target exposure, and less 5-FU-related toxicities. Clinical trial information: 2011-003553-26.

3543 Poster Session (Board #35), Mon, 8:00 AM-11:30 AM

The PRIME trial: Quality-adjusted survival in patients with *RAS* wild-type (WT) metastatic colorectal cancer (mCRC) receiving first-line therapy with panitumumab plus FOLFOX versus FOLFOX alone. *First Author: Jianmin Wang, RTI Health Solutions, Durham, NC*

Background: The pivotal phase III PRIME trial demonstrated that, compared with FOLFOX alone, panitumumab plus FOLFOX prolongs overall survival (OS) and progression-free survival (PFS) in patients with *RAS* WT mCRC without having a detrimental effect on overall quality of life. The objective of this analysis was to use the quality-adjusted time without symptoms of disease or toxicity of treatment (Q-TWiST) method to compare quality-adjusted survival between the treatment arms of PRIME. **Methods:** Patients with *RAS* WT mCRC from each treatment arm of PRIME were included in this analysis, and the area under the survival curve (AUSC) was estimated using the nonparametric Kaplan-Meier method (48 months follow-up). The AUSC was partitioned into three health states: toxicity (TOX), time without symptoms of disease progression or toxicity (TWiST, i.e., PFS minus TOX), and relapse (REL, ie, OS minus PFS). The durations of the health states were then adjusted using utility weights derived from patient-reported EuroQoL 5 measures. The null hypothesis of no difference between treatment arms was tested based on the normal approximation, with standard errors (SE) calculated by the bootstrap method. In the primary analysis, TOX consisted of grade 3 and 4 adverse events. A sensitivity analysis, with grade 2, 3, and 4 adverse events classified as TOX, was performed. **Results:** Of 1,183 patients with mCRC who were randomized, 512 patients had *RAS* WT tumors (panitumumab plus FOLFOX, n = 259; FOLFOX alone, n = 253) and were included in this analysis. Patients receiving panitumumab plus FOLFOX had a significantly longer Q-TWiST (20.5 months) than patients receiving FOLFOX alone (18.2 months) resulting in 2.3 ± 1.0 (SE) additional quality-adjusted months ($P < 0.03$). The sensitivity analysis yielded similar results, indicating that the analysis was robust. **Conclusions:** This Q-TWiST analysis showed that in a previously untreated *RAS* WT mCRC population, patients treated with panitumumab plus FOLFOX had a significantly improved duration of quality-adjusted survival compared with patients treated with FOLFOX alone. Clinical trial information: NCT00364013.

3544 Poster Session (Board #36), Mon, 8:00 AM-11:30 AM

An investigator initiated multicenter phase I/II study of TAS-102 with bevacizumab for metastatic colorectal cancer refractory to standard therapies (C-TASK FORCE). *First Author: Yasutoshi Kuboki, Department of GI oncology, National Cancer Center Hospital East, Japan, Kashiwa, Japan*

Background: In global phase III RECOURSE trial, TAS-102 significantly improved overall survival (OS), progression-free survival (PFS) and disease control rate (DCR) over placebo for metastatic colorectal cancer (mCRC) patients (pts) refractory to standard therapies. In preclinical models, TAS-102 with bevacizumab (BEV) demonstrated enhanced activity against CRC cells compared with either drug alone. This phase I/II study was conducted to determine the recommended phase II dose (RP2D) and evaluate the efficacy, safety and pharmacokinetics of this combination in pts with mCRC refractory to standard therapies. **Methods:** Eligibility criteria were: mCRC pts who were refractory or intolerant to fluoropyrimidines, irinotecan, oxaliplatin, anti-angiogenesis therapy and anti-EGFR antibody (if *KRAS* wild-type) and had no prior regorafenib treatment. Phase I was designed to determine RP2D in the dose de-escalation design of TAS-102 (35 mg/m^2 BID on days 1–5 and 8–12 q4w for level 1 and 30 mg/m^{2}BID for level −1) with a fixed BEV dose (5 mg/kg q2w). Primary endpoint was centrally assessed PFS at 16 weeks in pts treated with RP2D. Using a single stage binomial design, this study required 21 pts, with a centrally assessed PFS rate at 16 weeks of 50% deemed promising and 25% unacceptable (alpha = 0.1; beta = 0.2). **Results:** From February to July 2014, 25 pts were enrolled. In phase I, dose-limiting toxicity was not observed in 6 pts at level 1, which was determined as the RP2D. Centrally assessed PFS rate at 16 weeks (n = 21) was 42.9% (80% C.I.: 27.8–59.0%). Median PFS and DCR by central assessment were 3.7 months and 64.0%, and by investigator assessment were 5.4 months and 72.0%, respectively (n = 25). Median OS was not reached. The most common grade 3 or worse adverse events were neutropenia (68%), febrile neutropenia (8%), thrombocytopenia (4%) and anorexia (4%) without unexpected safety signals. Drug–drug interaction was not indicated by PK analysis. **Conclusions:** The combination ofTAS-102 with BEV showed promising antitumor activity with acceptable toxicity for mCRC pts; biomarker analysis will be presented. Clinical trial information: UMIN000012883. Clinical trial information: 000012883.

3545 Poster Session (Board #37), Mon, 8:00 AM-11:30 AM

Association between c-Met expression, miR-31-3p expression and progression free survival in the New EPOC study. *First Author: Sian Alexandra Pugh, University Surgery, University of Southampton, Southampton, United Kingdom*

Background: Cetuximab in combination with chemotherapy resulted in a shorter progression free survival (PFS) when given before and after resection for colorectal liver metastases (CRLM) in the New EPOC study. MiR-31-3p expression in the primary tumor of these patients was shown to be predictive of the effect of cetuximab and other studies implicate c-Met in resistance to anti-EGFR therapy. We evaluated if c-Met expression in CRLM, in parallel with miR-31-3p, was associated with the earlier progression seen with cetuximab. **Methods:** MiR-31-3p expression was determined by qPCR and c-Met protein expression by immunohistochemistry in paired primary tumor and CRLM tissue for 94 New EPOC patients (Chemo (CT) n = 48, ChemoCetux (CTC) n = 46). c-Met expression was scored dependent on staining intensity; 0, negative; 1, weak; 2, moderate; 3, strong. Consequences of elevation or lowering of c-MET and miR-31-3p expression in paired primary tumor and CRLM on PFS were studied. **Results:** Expression of miR-31-3p and c-Met in primary tumor and matching CRLM were correlated in CT (miR-31-3p: r = 0.6 p = 0.00001, c-Met: r = 0.3 p = 0.03) but not CTC patients (miR-31-3p: r = 0.1 p = 0.47, c-Met r = 0.1 p = 0.36). In CTC, median PFS was 27.9 months for patients in whom c-Met expression was lower in the CRLM vs 14.5 months for those in whom c-Met was unchanged/elevated (HR 3.54 95%CI 1.36, 7.37 p = 0.007). This difference was not observed in CT (HR 1.01 95%CI 0.41, 2.49 p = 0.991). Patients treated with CTC (but not CT) in whom c-Met was lower and miR-31-3p was elevated in CLRM (compared to primary) had a particularly favourable PFS (median not reached) compared to the other 3 groups (log rank p = 0.002). **Conclusions:** In a trial that showed substantial detriment with EGFR inhibition a subgroup has been identified who derived significant benefit from cetuximab. The loss of correlation between primary tumors and CRLM suggests that cetuximab may modulate miR-31-3p and c-Met expression and that these may be implicated in the mechanism by which earlier progression occurred in these patients. Clinical trial information: 22944367.

3546 Poster Session (Board #38), Mon, 8:00 AM-11:30 AM

Therapy of gastrointestinal malignancies with an anti-Trop-2-SN-38 antibody drug conjugate (ADC) (sacituzumab govitecan): Phase I/II clinical experience. *First Author: Alexander Starodub, Indiana University Health, Goshen Center for Cancer Care, Goshen, IN*

Background: Sacituzumab govitecan (IMMU-132) is a conjugate of a humanized anti-Trop-2 (trophoblast cell-surface antigen) coupled site-specifically to SN-38 (7.6 moles SN-38/IgG), an active metabolite of irinotecan, using a proprietary linker. Trop-2 is widely expressed in most epithelial cancers, including gastrointestinal (GI) tumors, and therefore the safety and efficacy of this new ADC is being examined in esophageal (EAC), gastric (GC), pancreatic (PC), and colorectal cancers (CRC). **Methods:** A Phase I/II clinical trial (ClinicalTrials.gov, NCT01631552) was initiated in patients with diverse epithelial cancers, administering IMMU-132 i.v. on days 1 and 8 of 21-day treatment cycles. Treatment was continued based on tolerance or until progression. **Results:** In Phase I, 23 assessable pts were given 8, 10, 12, or 18 mg/kg. Dose-limiting neutropenia occurred at 18 mg/kg. For Phase II, enrollment was expanded to multiple cycles of 8 and 10 mg/kg. Safety data from 123 patients given 8-10 mg/kg showed neutropenia (G3, 18%; G4, 6%), febrile neutropenia (G3, 2%; G4, 2%), but only 3% G3 diarrhea (no G4). Other G3 toxicities included anemia (6%), fatigue (5%), leucopenia (2%), vomiting (2%), and asthenia (1%). No pt developed antibodies to the ADC. Among assessable patients by RECIST 1.1, of 15 EAC pts (median 3 prior therapies), 2 had PR (1 confirmed, duration 6 mo, 1 continuing; 13% ORR), and 7 (46%) SD (median time to progression (TTP) = 5.0 mo). All 3 GC pts had SD (one continuing for 11 mo). Of 14 PC pts (median 2 prior therapies), 7 (50%) had SD with a median TTP of 3.4 mo. In 26 CRC pts (median 4 prior therapies), there was 1 PR (confirmed, duration 10 mo), 14 SD (54%), and a median TTP of 5.1 mo. **Conclusions:** Repeated cycles of IMMU-132 monotherapy are well tolerated with seemingly more favorable neutropenia and diarrhea rates compared to irinotecan. Objective responses in esophageal cancer and extended stabilization in colorectal cancers are encouraging for this monotherapy. The manageable toxicity and promising disease control in these pts warrant further study in combination with other appropriate agents for GI malignancies. Clinical trial information: NCT01631552.

3547 Poster Session (Board #39), Mon, 8:00 AM-11:30 AM

Evaluation of miR 31 3p as a biomarker of prognosis and panitumumab benefit in *RAS*-wt advanced colorectal cancer (aCRC): Analysis of patients (pts) from the PICCOLO trial. *First Author: Pierre Laurent-Puig, UMR-S1147, INSERM, Paris Descartes University, Paris, France*

Background: miR 31 3p expression has previously shown correlation with outcomes in *KRAS* wild-type (wt) aCRC patients receiving EGFR-targeted therapy. We have therefore evaluated miR 31 3p in a large randomized trial of panitumumab. The *a priori* hypothesis was that pts with the lowest miR 31 3p expression would have better outcomes and increased benefit from panitumumab. **Methods:** miR 31 3p was measured in tumor from 213 pts randomized to irinotecan (Ir, n = 111) or irinotecan/panitumumab (IrPan, n = 102) in a trial of second line therapy for aCRC (PICCOLO). The analysis population comprised *RAS* wt (*KRAS* and *NRAS* wt) pts (n = 188: Ir = 101, IrPan-87). End-points were progression-free survival (PFS), overall survival (OS), complete/partial response rate (RR) and disease control rate (DCR). The predefined model divided pts into 3 tertiles with high, intermediate (int) and low miR 31 3p expression, and compared outcomes and treatment effects across these groups. Multivariate analysis was performed, adjusting for Köhne score. **Results:** In the prognostic analysis, compared with low expression pts and after adjustment for treatment arm, int and high pts had worse OS (HR 1.58, 2.03 respectively; p = 0.0012) and worse PFS (HR 1.60, 1.60 respectively; p = 0.018). In multivariate analysis, miR 31 3p and Köhne score were independently associated with OS (p = 0.0006 and p = 0.002 respectively). miR 31 3p was also significantly independently associated with RR (p = 0.015) and DCR (p = 0.074). In the predictive analysis, panitumumab produced marked PFS benefit in pts with low and int miR 31 3p expression (HR = 0.50 [p = 0.019] and HR = 0.57 [p = 0.031] respectively), but not in pts with high expression (HR 0.72, p = 0.23); however, a statistically significant treatment/expression interaction was not seen. **Conclusions:** Pts with lower miR 31 3p have significantly better OS, PFS, RR and DCR, independent of treatment. Pts with low/int miR 31 3p had significant PFS benefit from panitumumab whilst pts with high miR 31 3p did not; however this study was not powered to demonstrate a statistically significant treatment/expression interaction. miR-31-3p is a highly promising biomarker in aCRC.

3548 Poster Session (Board #40), Mon, 8:00 AM-11:30 AM

C-reactive protein and interleukin-6 as markers of systemic inflammatory response and as prognostic factors for metastatic colorectal cancer. Data from the randomized phase III NORDIC-VII study. *First Author: Maria Thomsen, Oslo University Hospital, Oslo, Norway*

Background: A systemic inflammatory response (SIR) affects prognosis and treatment outcome in metastatic colorectal cancer (mCRC). The aim of the study was to explore the prognostic significance of several SIR-derived markers and the correlation between the best marker of SIR and plasma interleukin-6 (IL- 6). **Methods:** The study was based on data from the randomized phase III NORDIC–VII study (Nordic FLOX +/- cetuximab as first line treatment of mCRC). The effect of different markers of SIR, including modified Glasgow Prognostic Score (mGPS), derived Neutrophil Lymphocyte Ratio (dNLR), levels of platelets and levels of C-reactive protein (CRP) on survival were analyzed by Kaplan-Meier plots, log-rank test, and Cox Proportional Hazards model. Further, the relationship between CRP, IL-6 and *RAS* and *BRAF* mutation status was examined. **Results:** 374 patients were eligible for the comparison of markers of SIR and 393 were eligible for the final analysis related to CRP, IL-6 and *RAF* and *BRAF* mutation status.The prognostic significance of CRP was at least as good as the other markers of SIR. CRP together with IL-6 were selected for further investigation. Log-transformed CRP and IL 6 were highly correlated (r = 0.661, p < 0.001) and an increasing level of pretreatment CRP was associated with impaired survival. Stratified by CRP level ≤ 10, 11-30, 31-60, and > 60 mg/L, the different groups showed a median overall survival (OS) of 24.3, 20.6,17.1 and 12.3 months, respectively (HR = 1.34, 95% CI 1.22-1.48, p < 0.001), and had a median progression-free survival (PFS) of 8.9, 7.6, 8.2, and 6.6 months, respectively (HR = 1.21, 95% CI 1.10-1.33, p < 0.001). Furthermore, CRP levels had a similar influence on prognosis in subgroups of patients based on *RAS* and *BRAF* mutation status. **Conclusions:** This is the largest study analyzing markers of SIR in a population of homogenously treated mCRC patients. Increasing CRP values were associated with impaired prognosis and the prognostic significance of CRP is at least equal to that of other markers of SIR. CRP values were highly correlated with IL-6 levels and may be used as a marker for plasma levels of IL-6. Clinical trial information: NCT00145314.

3549 Poster Session (Board #41), Mon, 8:00 AM-11:30 AM

Epidermal growth factor receptor mutations may confer resistance or cross-resistance to cetuximab and panitumumab and can be detected in circulating tumor DNA. *First Author: Mascha Binder, University Medical Center Hamburg, Hamburg, Germany*

Background: Acquired resistance to epidermal growth factor receptor (EGFR) targeted antibodies represents a clinical challenge in the treatment of gastrointestinal tumors such as metastatic colorectal cancer, but its molecular mechanisms are incompletely understood. **Methods:** We scanned *KRAS* exon 2/3/4, *NRAS* exon 2/3/4 and the overlapping epitopes of the EGFR antibodies cetuximab and panitumumab for mutations in pre- and post-treatment tumor tissue of 21 patients with gastrointestinal cancer treated with chemotherapy +/- EGFR antibodies by targeted next-generation sequencing ("tumor tissue" cohort). Binding, signaling and drug sensitivity studies were performed in Ba/F3 cells stably transduced with wt and mutant *EGFR*. Results were validated in circulating tumor DNA (ctDNA) of an independent "liquid biopsy" cohort of 27 patients. **Results:** We describe a novel *EGFR* exon 12 mutation acquired in tumors of 1 out of 3 patients treated with panitumumab in the "tumor tissue" cohort. This mutation introduces a positive charge within the overlap of the panitumumab and cetuximab epitopes. It abrogates antibody binding and mediates cross-resistance to both antibodies in *EGFR*-mutant transfected Ba/F3 cells. In ctDNA from the "liquid biopsy" cohort, we found this novel mutation in 1 out of 6 panitumumab-treated patients while about one third of patients show acquired *RAS* mutations. **Conclusions:** We show that acquired resistance by epitope-changing mutations also emerges during panitumumab treatment and may follow similar biochemical principles as in cetuximab resistance. Such mutations can be easily detected by next-generation sequencing of ctDNA and may perspectively help in tailoring EGFR-targeted therapies.

3550 Poster Session (Board #42), Mon, 8:00 AM-11:30 AM

***PIK3CA* mutations in colorectal and endometrial cancer with double somatic mismatch repair mutations compared to Lynch syndrome.** *First Author: Stacey Shiovitz, University of Washington, Seattle, WA*

Background: Double somatic mutations in mismatch repair (MMR) genes have recently been described in a high proportion of colorectal and endometrial cancers with microsatellite instability (MSI) not attributable to *MLH1* hypermethylation or germline mutation. We sought to define the molecular phenotype of this new tumor subtype. **Methods:** We identified patients with double somatic colorectal and endometrial tumors from two Ohio-based prospective Lynch syndrome screening studies who had abnormal tumor testing (MSI and/or by immunohistochemistry (IHC) without coexistent *MLH1* methylation), but normal germline MMR testing. We determined the frequency of *PIK3CA*, *BRAF*, *KRAS*, *NRAS*, and *PTEN* mutations in double somatic tumors by targeted next-generation sequencing and compared the mutation frequencies to tumors of other MSI sub-groups: Lynch syndrome, *MLH1* hypermethylation, and microsatellite stable (MSS) tumors. The frequencies were compared among groups with a logistic regression model. **Results:** We found that 28/35 (80%) of double somatic tumors had *PIK3CA* mutations compared to 6/21 (29%) in Lynch syndrome tumors, 4/13 (31%) in *MLH1* hypermethylated tumors, and 17/90 (19%) in MSS tumors, $p < 0.0001$. Among double somatic cases, a *PIK3CA* mutation was observed in 100% (13/13) of endometrial tumors and 68% (15/22) of colorectal tumors. These frequencies were significantly higher than all other case groups when analyzing by tumor type (colorectal $p < 0.0001$, endometrial $p = 0.02$). As expected, *BRAF* V600 mutations were frequent in *MLH1* hypermethylated tumors (8/13) and not detected in any double somatic or Lynch tumors ($p < 0.0001$). No substantive differences were observed for *KRAS*, *NRAS*, or *PTEN*. **Conclusions:** *PIK3CA* mutations are present in the majority of double somatic colorectal and endometrial cancers at frequencies significantly higher than those observed in other MSI sub-groups. *PIK3CA* mutation status may improve identification of Lynch syndrome by tumor-based screening and better define an emerging molecular entity in colorectal and endometrial cancers.

3551 Poster Session (Board #43), Mon, 8:00 AM-11:30 AM

A simplified nomogram to predict long-term survival after conversion chemotherapy followed by hepatectomy for initially unresectable colorectal liver metastases. *First Author: Katsunori Imai, Centre Hépato-Biliaire, AP-HP, Hôpital Paul Brousse, Villejuif, France*

Background: Although the recent advances in surgury and chemotherapy have enabled hepatectomy in patient with initially unresectable colorectal liver metastases (CRLM), limited number of patients could actually benefit from this strategy. The aim of this study was to develop a simplified nomogram to predict long-term survival for initially unresectable CRLM treated with conversion chemotherapy followed by hepatectomy. **Methods:** From a cohort of 1275 patients who underwent hepatectomy between 1990 and 2012, 439 patients (34.4%) with initially unresectable CRLM were enrolled in this study. A nomogram to predict overall survival was developed based on the result of multivariate cox model. The predictive performance of the model was assessed by C-index, Kaplan-Meier curve, and calibration plots. **Results:** The median number of liver metastases was 5 both at diagnosis and at hepatectomy, and median tumor size was 50 mm at diagnosis and 35 mm at hepatectomy, respectively. Median number of preoperative chemotherapy courses was 10 with 136 patients (31.0%) receiving more than 1 line. Concomitant extrahepatic disease was observed in 148 patients (33.7%). Liver curative and globally curative surgery were achieved in 380 (86.6%) and 335 patients (76.3%), respectively. The 5-year overall and disease-free survival was 39.9% and 10.0%, respectively. Based on the multivariate cox model, 5 independent prognostic factors were selected into the nomogram and assigned score for each factor as follows; primary N positive: 5, tumor number at hepatectomy > 6: 7, carbohydrate antigen 19-9 at hepatectomy > 37 ng/mL: 10, disease progression during first-line chemotherapy: 9, and presence of concomitant extrahepatic disease: 3. The model achieved good discrimination and calibration, with a C-index of 0.66. The overall survival for patients with total score > 15 was significantly worse than those with £ 15 (5-year survival rate: 4.1% vs 46.3%, $P < 0.0001$). **Conclusions:** The proposed nomogram could easily stratify individual patients with initially unresectable CRLM into prognostic groups. Patients with nomogram-predicted score > 15 should be contraindicated to surgery.

3552 Poster Session (Board #44), Mon, 8:00 AM-11:30 AM

Variations in genes regulating tumor-associated macrophages (TAMs) to predict outcome of bevacizumab (bev)-based treatment in patients with metastatic colorectal cancer (mCRC): Results from TRIBE and FIRE3 trials. *First Author: Yu Sunakawa, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: TAMs with the M2-like phenotype are regulated by NF-kB pathway including TBK1, which can influence tumor progression by secretion of proangiogenic factors and tumor promoting cytokines, such as VEGF-A and CCL18. These factors drive tumor angiogenesis, migration and immunosuppression. The CCL2/CCR2 axis, histidine-rich glycoprotein (HRG), PIGF and VEGF play a critical role in the polarization of M1 and M2 phenotypes and the recruitment of TAMs to tumor microenvironment. We hypothesized that genes involved in regulating TAMs may predict outcome of bev-based therapy in patients (pts) with mCRC. **Methods:** We analyzed genomic DNA extracted from blood or tumor samples of pts receiving bev plus FOLFIRI in 2 prospective trials, using PCR-based direct sequencing. Eleven functional polymorphisms in 7 genes (*CCL2*, *CCR2*, *HRG*, *PIGF*, *NFKB1*, *TBK1* and *CCL18*) were tested for associations with clinical outcome in a discovery cohort of 228 pts (male 61%, median age 60, follow-up time 27 months [m]) enrolled in TRIBE (T) trial (NCT00719797), then validated in 244 *KRAS* exon 2 (*KRAS*) wild-type (wt) pts (male 69%, median age 64, follow-up time 39 m) enrolled in FIRE3 (F) trial (NCT00433927). 246 pts receiving cetuximab plus FOLFIRI in F served as negative control. **Results:** *TBK1* rs7486100 (A > T) was associated with response rate (RR) and overall survival (OS) in *KRAS* wt pts of T cohort (n= 95, any T vs A/A: 58 % vs 82 %, p= 0.046; 25.1 m vs 49.1 m, adjusted HR 2.39, p= 0.046, respectively). In F cohort, the association was observed for progression-free survival (any T vs A/A: 10.1 m vs 12.3 m, adjusted HR 1.42, p= 0.047) although there was no statistically association with RR and OS (23.7 m vs 28.6 m, p= 0.15). No polymorphism was established between *KRAS* mutant of T cohort and F cohort. No association was seen in control. **Conclusions:** *TBK1* rs7486100 is associated with outcome of bev-based chemotherapy in mCRC pts, suggesting that NF-kB signaling may play a critical role in tumor angiogenesis as an independent pathway. Our results also suggest that *TBK1* may be a potential biomarker to identify pts benefitting from bev-based treatment.

3553 Poster Session (Board #45), Mon, 8:00 AM-11:30 AM

Comprehensive genomic profiling of clinically advanced colorectal carcinoma to reveal frequent opportunities for targeted therapies. *First Author: Jeffrey S. Ross, Albany Medical College, Albany, NY*

Background: For patients presenting with advanced and metastatic colorectal carcinoma (CRC), standard cytotoxic therapy can provide significant benefit but patients eventually develop progressive disease. We queried whether comprehensive genomic profiling (CGP) could uncover clinically relevant genomic alterations (CRGA) that could lead to targeted therapy selection. **Methods:** DNA was extracted from 40 microns of FFPE sections from 3,117 clinically advanced CRC. CGP was performed using a hybrid-capture, adaptor ligation based next generation sequencing assay to a mean coverage depth of > 600X. The results were evaluated from each sample for all classes of genomic alterations. **Results:** There were 1746 male (56%) and 1371 female (44%) patients with all (100%) of cases either stage III or IV at the time of sequencing. The median frequency of GA per case was 5.7. The CRGA frequency was 2.1 CRGA per case. The most frequent GA were in *APC* (76%), *TP53* (75%) and *KRAS* (53%), all were higher than in TCGA (61%, 44% and 34% respectively). There was 100% concordance with the *KRAS* status determined by the CGP assay and standard hot-spot sequencing assays performed on the same tumor. The combined *KRAS* and *NRAS* mutation frequency was 56% and *BRAF* was mutated in 7%. Only 1.4% of the cases with *KRAS*, *NRAS*, or *BRAF* mutations harbored combination of any 2 out of the 3 genes. Potential CRGA that could lead to targeted therapy-based clinical trials included: *PIK3CA* (18%), *PTEN* (8%), *ERBB2* (5%), *SRC* (4%), *SMAD2* (3%), *NF1* (3%), *EGFR* (3%), *ERBB3* (2%), *MET* (1%) and *KIT* (1%). Either WNT signaling, cell cycle/apoptosis, and/or RTK/RAS signaling pathways were the altered in 83% cases. Clinical outcome case examples demonstrating efficacy of therapies targeting *BRAF*, *ERBB2*, *FGFR2*, and *MET* in CRC patients will be presented. **Conclusions:** When CRC is evaluated by CGP, a significant number of the patients harbored CRGA which have the potential to influence and personalize therapy selection. Given the limited treatment options and poor prognosis of patients with advanced chemo-refractory CRC deep genomic profiling has the potential to identify new treatment paradigms and meet an unmet clinical need for this disease.

3554 Poster Session (Board #46), Mon, 8:00 AM-11:30 AM

Genetic variant of TWEAK to predict clinical outcome in mCRC patients (pts) treated with first line FOLFIRI and Bevacizumab (FOLFIRI/BEV) in FIRE-3 and TRIBE cohorts. *First Author: Anish Parekh, Norris Comprehensive Cancer Center of USC, Los Angeles, CA*

Background: Tumor necrosis factor-like weak inducer of apoptosis (TWEAK), acting via the Fn14 cell surface receptor, is a multifunctional pro-inflammatory/pro-angiogenic cytokine that participates in wound repair and tissue regeneration in different tissues. Studies have shown that TWEAK induces embryonic fibroblast proliferation through Ras/ERK signaling pathway. TWEAK produced in the tumor microenvironment acts on vascular endothelial cells and contributes to inflammatory angiogenesis in mCRC pts. In this study, we tested whether SNPs in TWEAK (rs3803800, rs1128963) and Fn14 (rs8052002, rs13209) predict clinical outcome in mCRC pts treated with first line FOLFIRI/BEV in two independent cohorts. **Methods:** Genomic DNA was isolated from blood or tissue samples of 525 pts treated with first-line FOLFIRI/BEV in FIRE-3 arm B (n = 295) and TRIBE arm A (n = 230) trials. FIRE-3 arm B served as the training set (Median follow up: 39.6 mos; Median PFS: 11.3 mos. and OS: 25 mos). TRIBE arm A served as the validation set (Median follow up: 45.1 mos; Median PFS and OS: 10.4 and 27.3 mos. PCR-based DNA sequencing was used to determine SNPs, which were selected based on frequency and function. FIRE-3 FOLFIRI/Cet (n = 297) was control arm. **Results:** In the overall population analysis, the TWEAK rs3803800 was significantly associated with shorter PFS (9.2 mos) compared to carrying the G/G genotype (11.3 mos) in the FIRE-3 trial in both univariate (HR: 1.39 [1.03-1.86]; P = 0.026) and multivariate analyses (HR: 1.50 [1.11-2.03], P = 0.008). For KRAS mutant pts in the TRIBE trial, any A allele of TWEAK rs3803800 was associated with a similar trend toward worse PFS compared to G/G in multivariate analyses (HR: 1.64 [0.94-2.86], p = 0.079), which is confirmed in the FIRE-3 trial (8 v. 12.3 mos, logrank test P = 0.019)(HR: 2.11 [0.97-4.49], Wald test P = 0.058). No significant difference in control arm. **Conclusions:** This study provides the first evidence that TWEAKrs3803800 could be a predictive marker for PFS in mCRC pts treated with first line FOLFIRI/BEV. It also retained a significant correlation with outcomes related to KRAS mutation, which was confirmed in a validated cohort.

3555 Poster Session (Board #47), Mon, 8:00 AM-11:30 AM

Calculators for overall survival (OS) and progression-free survival (PFS) in metastatic colorectal cancer (mCRC): Construction from 19,678 ARCAD patients. *First Author: Katrin Marie Sjoquist, NHMRC Clinical Trials Centre, University of Sydney and Cancer Care Centre, St. George Hospital, Sydney, Australia*

Background: Predicting survival in mCRC is difficult; even experienced oncologists can be inaccurate. Estimation of prognosis based on readily available clinicopathologic factors has the potential to inform clinical practice and aid in risk stratification for clinical trials. We constructed prognostic calculators for OS and PFS in mCRC using the multi-trial ARCAD database. **Methods:** 19,678 mCRC pts accrued to 24 randomized phase III clinical trials since 1997 used to construct and validate Cox models for PFS and OS, stratified on treatment arm within study. Candidate variables included age, sex, BMI, performance status, colon vs. rectal cancer, prior chemotherapy, number of metastatic sites, sites of metastases (liver, lung, lymph nodes), and baseline bilirubin, albumin, white blood cell count, hemoglobin, platelets, and absolute neutrophil count. Missing data (< 11%) were imputed, continuous variables modeled with splines, and clinically relevant pairwise interactions considered if $p < 0.001$.Final models were internally validated (bootstrapping to obtain optimism-corrected calibration, discrimination C-indices) and externally validated using a 10% holdout sample from each trial. **Results:** Sex, liver, and lung metastases were not prognostic for OS; prior chemo, colon vs. rectum, liver and lymph node metastases, and sex did not predict PFS. No clinically relevant pairwise interactions were identified. Models for OS and PFS using remaining variables and were well calibrated with C-indices of 0.66 and 0.60, respectively. In external validation, concordance of predicted (> vs. < 50% probability) and actual (yes/no) 1-year OS and 6-month PFS was 71% and 67%, respectively, and median 1-year OS and 6-month PFS predictions fell within the actual 95% Kaplan-Meier intervals. Work is ongoing to include molecular markers (BRAF, KRAS mutation); calculators will be updated to include these markers by the time of presentation. **Conclusions:** The proposed calculators are well calibrated and internally and externally valid. These tools have the potential to aid prognostication and patient/physician communication, and balance risk in randomized trials in mCRC.

3556 Poster Session (Board #48), Mon, 8:00 AM-11:30 AM

Predicting individualized post-operative survival for colorectal cancer using a new mobile application derived from the National Cancer Database. *First Author: Emmanuel M. Gabriel, Roswell Park Cancer Institute, Buffalo, NY*

Background: For patients treated with surgery for colorectal cancer, prediction calculators can estimate post-operative survival and assist in the decision making process for adjuvant treatment. **Methods:** We queried the National Cancer Database (NCDB) from 1998-2006 for patients with either colon or rectal cancer who had surgical resection. Within each subset, patients were randomized to a test cohort (n_t) comprising 90% of the dataset and a validation cohort (n_v) comprising the remaining 10%. Multivariate logistic regression of n_t identified independent predictors of the 5-year overall survival (OS), which were used to build prediction models. Model performance was validated and calibrated using n_v. Correlation of observed to predicted OS using n_v was expressed as area under receiver operating characteristic curve (AUC). Prediction models were translated into a mobile application. **Results:** A total of 402,844 patients and 106,037 patients were identified from the colon and rectum datasets, respectively. Independent predictors of OS included patient specific characteristics (age, gender, race, Charlson Deyo comorbidity index, pre-operative CEA level), pathologic factors (site of tumor, size, grade, pathologic TNM stage, margin status, number of nodes examined) and treatment options (type of surgery, neoadjuvant or adjuvant chemoradiation). Length of post-operative stay and unplanned readmission rates were also associated with OS. Our prediction models showed that the predicted OS rates were accurate compared to the actual OS rates (colon AUC = 0.714, rectum AUC = 0.735). These models were translated into mobile application software for a point-of-care, user-friendly medium. **Conclusions:** We developed accurate, individualized post-operative survival calculators for colon and rectal cancer integrated into a mobile-based application platform. Unique to existing calculators, our prediction models utilize nationwide "big data", culminating in highly comprehensive and statistically robust survival calculators.

3557 Poster Session (Board #49), Mon, 8:00 AM-11:30 AM

Impact of primary tumor stage on survival following resection of metachronous liver and/or lung metastases in colorectal cancer. *First Author: Hui-Li Wong, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Background: Resection of isolated liver and/or lung metastases in patients (pts) with metastatic colorectal cancer (mCRC) offers a chance at long-term survival. Multiple prognostic models have been developed to predict outcomes following resection, but the role of primary tumor stage remains controversial, contributing to a recent debate regarding the impact of stage on the value of routine pt follow-up. **Methods:** Consecutive pts with resected liver and/or lung metastases following prior therapy for an early stage CRC entered into a comprehensive, prospective database between 2000 and 2014 were identified. Cox regression analysis was performed to examine the impact of initial tumor stage on overall survival. **Results:** 867 pts with metachronous mCRC were identified; median follow-up was 40.1 months. 215 (25%) had undergone liver and/or lung resection, including 21 with initial stage I CRC, 53 with stage II colon cancer (CC), 70 with stage III CC and 71 with locally advanced rectal cancer (LARC). 5-year overall survival (OS) declined with increasing stage: 100% in stage I, 75% in stage II, 35% in stage III and 52% in LARC ($P < 0.001$). On multivariate analysis, initial stage was predictive of OS, where best outcomes were seen in pts with stage I or II disease (Table). **Conclusions:** Pts with a previous stage I primary cancer contribute only a small proportion of those undergoing resection of metachronous disease but have excellent outcomes, suggesting routine follow-up of stage I pts is worthwhile. With increasing primary tumor stage, survival outcomes deteriorate. However, the majority of 5-year survivors are pts with high-risk primaries, justifying follow-up in this pt group. Better markers of recurrence risk and of benefit from metastasectomy would be beneficial.

Molecular subtypes and outcomes in regorafenib-treated patients with metastatic colorectal cancer (mCRC) enrolled in the CORRECT trial. *First Author: Michael Teufel, Bayer Pharma AG, Berlin, Germany*

Background: In the CORRECT Ph3 trial (NCT01103323), regorafenib improved overall survival (OS) and progression-free survival (PFS) vs placebo in patients with mCRC who progressed on standard therapies (Grothey 2013). Initial biomarker analyses suggested that regorafenib provides a clinical benefit in various mutational subgroups (Jeffers 2013). Here we present additional exploratory analyses to evaluate clinical benefit in CRC subgroups defined by gene expression. **Methods:** Gene expression analysis (Affymetrix ST1.0 array) was conducted on archival tumor tissue from 281 of the 760 patients (37%) enrolled in CORRECT. Next-generation sequencing (NGS) was done on 239 specimens (FoundationONE). Gene expression data were subjected to hierarchical molecular tumor classification (Marisa 2013). Cox proportional hazards models were used to identify potential prognostic or predictive biomarkers. **Results:** The distribution of the 6 different CRC subtypes characterized by gene expression clusters originally defined by Marisa and the classification of the 281 patients from CORRECT are shown in the table. The six Marisa subtypes derived a similar OS benefit from regorafenib. Although the numbers of patients in the subgroups are small, a greater PFS benefit for regorafenib was seen in patients in the 'high-risk' subgroup (C4 +C6, n = 26; HR = 0.10; 95%CI 0.02 - 0.35; p = 0.0009) than the 'low-risk' subgroup (C1+C2+C3+C5, n = 255; HR = 0.58; 95%CI 0.44 - 0.77; p = 0.002). NGS analyses suggested that the chromosomal instability group (CIN) was the predominant subgroup in CORRECT. **Conclusions:** Molecular characterization by gene expression analysis may allow the identification of CRC subgroups that correlate with regorafenib clinical benefit. Data suggest this does not depend on the presence of mutations. Additional exploratory analyses, including the use of the recently defined Consensus molecular subtypes (Dienstmann ASCO 2014), to validate these results are ongoing. Clinical trial information: NCT01103323.

Two-stage hepatectomy for extensive colorectal liver metastases: How to predict the failure to complete both sequential procedures? *First Author: Katsunori Imai, Centre Hépato-Biliaire, AP-HP, Hôpital Paul Brousse, Villejuif, France*

Background: Two-stage hepatectomy (TSH) has been adopted as a treatment strategy for extensive bilateral colorectal liver metastases (CRLM) unable to be resected by a single hepatectomy. However, one of the most critical problems is the risk of failure to achieve both two sequential procedures. The aims of this study were to identify the predictive factors and develop a predictive model for failure of TSH for the optimal selection of patients who could benefit from this strategy. **Methods:** Among a total of 845 patients who underwent hepatectomy for CRLM Between 2000 and 2012, 125 patients (14.8%) with extensive bilateral CRLM were scheduled to perform TSH and were enrolled in this study. Based on the result of multivariate logistic analysis, a predictive model for failure of TSH was developed. **Results:** The median number and size of liver metastases was 9 and 37 mm, respectively. Concomitant extrahepatic disease was present in 34 patients (27.2%). On an intention-to-treat basis, the 5-year overall survival (OS) rate was 33.2%. Among the 125 patients who were planned for TSH, 44 patients (35.2%) could not proceed to the second-stage mainly because of tumor progression, and their OS were significantly worse than those who completed (5-year OS: 0% and 44.2%, $P < 0.0001$). Multivariate logistic analysis revealed that carcinoembryonic antigen > 30 ng/dL (relative risk (RR) 2.73, $P = 0.034$), tumor size > 40 mm (RR: 2.89, $P = 0.036$), chemotherapy cycles > 12 (RR: 3.46, $P = 0.0098$), and tumor progression during first-line chemotherapy (RR: 6.56, $P = 0.01$) were the independent predictive factors for failure of TSH. For patients without any factors, the probability of failure was 10.5% with 5-year OS of 41.9%. The addition of subsequent factors increased the probability to 43.5% for one (5-year OS 38.8%), 72.7% for two (29.2%), 88.5% for three (0%), and 95.5% for four factors (not reached). The OS for patients with predictive score of 3-4 was significantly worth than that of 0-2 (5-year OS; 0% and 36.8%, $P < 0.0001$). **Conclusions:** TSH in patients with more than 3 risk factors should be contraindicated. Avoidance of these risk factors significantly reduces the risk of failure and is crucial for the long-term survival.

3560 Poster Session (Board #52), Mon, 8:00 AM-11:30 AM

Effects of regorafenib (REG) therapy on health-related quality of life (HRQoL) in patients with metastatic colorectal cancer (mCRC) in the phase III CONCUR trial. *First Author: Jane Chang, Bayer HealthCare Pharmaceuticals, Whippany, NJ*

Background: In the phase III CORRECT and CONCUR trials, REG significantly improved overall survival (OS) *vs* placebo (PBO) in patients with mCRC whose disease progressed on standard treatments. In CORRECT, overall HRQoL was similar between REG and PBO. This analysis reports the HRQoL effects of REG in CONCUR. **Methods:** CONCUR (NCT01584830) was an international, multicenter trial which enrolled patients in Asia (N = 204). Patients were randomized 2:1 to receive REG 160 mg (n = 136) or PBO (n = 68) once daily for weeks 1–3 of each 4-week cycle. Planned HRQoL analyses were conducted using the European Organisation for Research and Treatment of Cancer Quality of Life (EORTC QLQ-C30) and the EuroQol-five dimension (EQ-5D) questionnaires. EORTC QLQ-C30 global health status (GHS) and the EQ-5D index and visual analogue scale (VAS) scores were expressed as least squares mean (LSM) time-adjusted area under the curve (AUC) to allow comparison of change in HRQoL across the treatment period. An exploratory *post-hoc* analysis assessed time to deterioration (TTD) of HRQoL, defined as the earliest ≥ 10-point score decline in GHS or physical functioning (PF) domain score, progression or death. **Results:** Overall changes from baseline in HRQoL scores appeared similar in the REG and PBO groups. LSM time-adjusted AUC of the EORTC QLQ-C30 GHS domain, EQ-5D index and VAS scores did not differ significantly between groups (table). TTD of HRQoL was significantly longer with REG *vs* PBO in *post-hoc* analyses (table). **Conclusions:** REG provided additional clinical benefit while maintaining HRQoL *vs* PBO in Asian patients. Clinical trial information: NCT01584830.

LSM time-adjusted AUC (95% CI)	REG (n = 131)	PBO (n = 63)
EORTC QLQ-C30 GHS	60.76 (58.81 to 62.71)	61.16 (58.48 to 63.83)
Difference from PBO	−0.40 (−3.53 to 2.72)	
EQ-5D index	0.70 (0.67 to 0.73)	0.74 (0.70 to 0.78)
Difference from PBO	−0.03 (−0.08 to 0.01)	
EQ-5D VAS	69.28 (67.48 to 71.08)	70.46 (68.01 to 72.91)
Difference from PBO	−1.18 (−4.01 to 1.66)	
Median TTD (95% CI)	REG (n = 136)	PBO (n = 68)
EORTC QLQ-C30 GHS	8.0 (7.6 to 8.0)	7.0 (5.9 to 7.4)
HR	0.54 (0.40 to 0.74; p < 0.01)	
EORTC QLQ-C30 PF	7.9 (7.3 to 8.0)	7.0 (5.0 to 7.6)
HR	0.59 (0.44 to 0.80; p < 0.01)	

3561 Poster Session (Board #53), Mon, 8:00 AM-11:30 AM

Moving foward and beyond the standard through a non-operative management in rectal cancer? Our watch and wait approach experience in Co-Recto. *First Author: Ilma Soledad Iseas, Clinical Oncology Unit, Hospital Bonorino Udaondo, Buenos Aires, Argentina*

Background: Controversies exist about the proper management of pts with clinical complete tumor regression after preoperative therapy. A non-operative management (NOM) of selected patients has achieved promising long-term outcomes in some Watch and Wait (W&W) series. Regardless of encouraging results, and in spite of being a readily accepted strategy by patients, reluctance to recommend this strategy as an affordable option still exists in rectal cancer guidelines. Our aim is to evaluate the NOM for pts with clinical complete response discussed in Co-Recto(interdisciplinary and cooperative team for the Management of rectal cancer) Argentina **Methods:** Pts with resectable rectal cancer (stage I-III) selected for neoadjuvant therapy in Co-Recto between 2008-2014 were retrospectively reviewed to determine pts with clinical complete response(cCR) selected for Non operative management. cCR was defined between digital exam, endoscopic criteria, MRI and CEA. F-up for W&W policy was performed during the first two years with MRI and EUS three-monthly and CT six-monthly. **Results:** 32pts with cCR were included. Initial staging was performed by MR (30/32, 94%) and EUS(6/32, 19%). 40.5% (12/32) were T2-T3ab N0; 59.5% (19/32 were T3c/d-T4, N+ and 49% (16/32) had CRM+. Median distance from anal verge was 30mm . Involvement into/beyond the elevator muscle: 34%(11/32) . CRT consisted of long-course RT (50.4 Gy) with capecitabine (825 mg/m2 bod for 7 d/w). Induction chemotherapy (CAPOX) was administered in 37.5% followed by CRT. Response assessment was done at 7 w (5-12w). Adjuvant therapy was administered in 18%. LR was observed in 3/32 pts (9%) within the rectal wall. 2/3 a mesorrectal nodal recurrence without endoluminal recurrence, 1/3 had endoluminal component. All feasible of salvage resection. PFS was 36 m(25-49m) Distant metastases and extrarectal pelvic recurrence weren´t observed in any case. After fup of 40 m (8-66m), no deaths occurred. **Conclusions:** a NOM with a close fup was a feasible approach, had optimal outcome avoiding surgical functional sequelae. To mitigate the remaining skepticism about W&W, collaborative randomized trials should be implemented.

3562 Poster Session (Board #54), Mon, 8:00 AM-11:30 AM

Effect of genetic variation on overall survival in a clinical trial of metastatic colorectal cancer (mCRC). *First Author: Heinz-Josef Lenz, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: TRIBE, a phase III randomized trial comparing FOLFIRI + BEV (Arm A) vs FOLFOXIRI + BEV (Arm B) as first-line treatment for mCRC, were recently published in the NEJM. No known predictive biomarkers for BEV-based chemotherapy exist. Here we assess the impact of genetic variation with overall survival (OS). **Methods:** The Illumina HumanExome array (248,538 SNPs) was genotyped on 418 genomic DNA samples from TRIBE. The analysis included 385 pts and 37,043 coding SNPs (MAF $>$ 1%) following quality control. An additive genetic model in a Cox proportional hazard framework was utilized to identify associations with OS adjusting for relevant confounders. A subgroup analysis by study arm, sex, and primary location was performed. A Bonferroni correction was applied to minimize false positives. **Results:** Arm A (N = 163) had a mean age of 59.9 years, median OS of 26.2 mos while Arm B (N = 222) had a mean age of 59.9 years, median OS of 31.0 mos. We identified 12 statistically significant associations ($P< 1.35x10^{-6}$) with OS; yielding six statistically significant subgroup interactions ($P< 4.4x10^{-4}$). In all patients group, *VEGFR2* rs10008360 is significantly associated with OS (HR = 5.76; 95%CI: 2.66-12.46; $P= 8.8x10^{-6}$); significant in Arm B (HR = 9.81; 95%CI: 3.59-26.81; $P= 8.52x10^{-6}$) and left-sided CRCs(HR = 10.48; 95%CI: 3.73-29.49; $P= 8.4x10^{-6}$), The strongest association was detected in Arm B with the missense variant rs3750025 in *DSPP* (HR = 22.7; 95%CI: 7.4-69.5; $P= 4.2x10^{-8}$), including a significant statistical interaction by study arm ($P= 2.0x10^{-5}$). The median OS in Arm B for rs3750025 AA and AG/GG genotypes were 31.0 (95%CI: 28.4-36.1) and 3.9 (1.6-7.2) mos. Among right-sided CRCs, *ZNF749* rs2240038 yielded a statistically significant association (HR = 40.3, $P= 2.27x10^{-7}$) with a median OS of 24.8 (20.5-30.9) and 4.4 (4.0-5.9) mos for the GG and GA/AA genotypes. **Conclusions:** This is the first study to identify novel biomarkers for OS among clinically relevant subgroups defined by study arm, tumor location and sex. These results demonstrate the clinical potential for novel biomarker discovery using genetic variation. Further validation of our findings in FIRE3 trial is ongoing.

3563 Poster Session (Board #55), Mon, 8:00 AM-11:30 AM

Improvement in long-term survival in patients with metastatic colorectal cancer (CRC) after liver resection with modern chemotherapy and hepatic arterial infusion (HAI). *First Author: Nancy E. Kemeny, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Hepatic resection of liver metastases from CRC is associated with 5-year (y) and 10-y overall survival (OS) of 30-50% and 20%. The aim of this study was to update OS of 5 consecutive adjuvant (adj) studies using HAI + systemic (sys) after liver resection and to determine effects of clinical factors on long-term OS. **Methods:** Patients (pts) treated on protocols with HAI FUDR/dexamethasone + sys from 1991 to 2015 with the following inclusion criteria: completely resected hepatic metastases, no extrahepatic disease, bilirubin $<$ 1.5mg/dl, platelet count $>$ 100,000/μL, and no concurrent infection. Pts on studies before 2003 were treated with HAI + sys FU/LV or irinotecan (CPT) and pts on studies after 2003 were treated with HAI + sys oxal/FU/LV or CPT/FU/LV ± molecular targeted therapies. OS was calculated from the time of liver resection until death and was estimated using the Kaplan-Meier method. Using Greenwood's formula, 95% CI at fixed time points for outcomes were calculated and compared between treatment years (before 2003 vs after 2003). **Results:** 329 pts were included with a median follow-up of 9.6 y. 5-y OS for those treated before and after 2003 was 56% [95% CI: 49%-63%] and 80% [95% CI: 71%-85%], respectively ($p < 0.01$). 10-y OS for pts treated before 2003 was 40%, while 10-y OS is not yet obtainable for pts treated after 2003. Various clinical factors and significant p-values (*p) known to influence survival are shown in the table below. **Conclusions:** Survival for pts undergoing hepatic resection and adj HAI is improving. Pts treated before 2003 with liver resection and adj HAI + sys have a 5-y OS of 56%, while pts treated after 2003 with HAI + modern sys chemotherapy have a 5-y OS of 80%.

3564 Poster Session (Board #56), Mon, 8:00 AM-11:30 AM

Phase 3 RECOURSE trial of TAS-102 versus placebo with best supportive care in patients with metastatic colorectal cancer: Geographic subgroups. *First Author: Atsushi Ohtsu, National Cancer Center Hospital East, Kashiwa, Japan*

Background: TAS-102 is comprised of an antineoplastic thymidine-based nucleoside analog, trifluridine, and the thymidine phosphorylase inhibitor, tipiracil hydrochloride, at a molar ratio of 1:0.5 (weight ratio, 1:0.471). The efficacy and safety of TAS-102 in patients (pts) with metastatic colorectal cancer refractory/intolerant to standard therapies were evaluated in the RECOURSE trial; enrollment criteria included ≥ 2 prior lines of standard chemotherapy. Primary results of RECOURSE demonstrated a significant improvement in overall survival (OS) and progression-free survival (PFS) with TAS-102 vs placebo (PBO) (hazard ratio [HR] = 0.68 and 0.48 for OS and PFS, respectively; both $P< 0.0001$). **Methods:** RECOURSE data were evaluated for efficacy and safety, including rate of hospitalizations, of TAS-102 vs PBO by each geographic subgroup of US, EU, and Japan (JP). **Results:** Of 768 pts, 99 US (mean age, 60 y), 403 EU (mean age, 62 y), and 266 JP (mean age, 62 y) pts were randomized to receive TAS-102 or PBO. Median OS with TAS-102 vs PBO was 6.5 mo vs 4.3 mo in US pts, 6.8 mo vs 4.9 mo in EU pts, and 7.8 mo vs 6.7 mo in JP pts. HRs for OS and PFS for US, EU, and JP pts all favored TAS-102 (Table). There were no marked differences among the US, EU, and JP subgroups with respect to overall incidence of adverse events (AEs), ≥ Grade 3 AEs, serious AEs (SAEs), or hospitalizations. **Conclusions:** Similar to the overall RECOURSE population, OS and PFS benefits were observed in each geographic subgroup randomized to TAS-102 vs PBO, with an acceptable safety profile. Clinical trial information: NCT01607957.

3565 Poster Session (Board #57), Mon, 8:00 AM-11:30 AM

Using mutational load in next generation sequencing (NGS) to identify mismatch repair (MMR) deficiency in colorectal cancer (CRC). *First Author: Francesca Battaglin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NCCN guidelines recommend screening all CRC patients diagnosed at age ≤ 70 years and those > 70 who meet Bethesda Criteria with either immunohistochemistry (IHC) for MMR protein expression or PCR for microsatellite instability (MSI), and also recommend tumor sequencing for RAS/BRAF mutations in all CRC patients with metastatic disease. MMR status is also needed for management of all stage II colon cancer patients, and BRAF mutational status is useful in work up of MMR-deficient (dMMR) tumors. We hypothesized that the higher mutational burden of dMMR tumors would permit their identification on the basis of the mutation count in an NGS panel, thus allowing a single multi-gene NGS assay to reliably detect not only RAS/RAF mutations but also MMR deficiency. **Methods:** Under an IRB waiver, an institutional electronic database was queried to identify all CRC analyzed with MSK-IMPACT, our custom 341-gene NGS assay. Tumor mutational load, defined as the raw number of somatic mutations identified, was determined for each case and compared between MMR-proficient and MMR-deficient cases. **Results:** We identified 149 unique CRC patients tested with MSK-IMPACT. Of these, 93 had MMR status available, including 8 dMMR cases. 83 of 85 (98%) of MMR-proficient cases had 16 or fewer mutations, while two outliers with 158 and 250 mutations each were found to be POLE-mutant. MMR-deficient tumors had a higher mutational load with a significantly higher median number of somatic mutations (49, range 23-67) than MMR-proficient tumors (6, range 0-16), p = 0.0024. **Conclusions:** This preliminary analysis suggests that using a cut-off for mutational load, such as 20 mutations for MSK-IMPACT, may provide a highly sensitive and specific means of screening for MMR deficiency with the same assay used for tumor genotyping. If validated, the use of a single multi-gene sequencing assay to screen for both dMMR and RAS/BRAF mutations could be cost effective, particularly in metastatic CRC, but also in early stage disease, while providing additional genetic information that may be useful for research purposes. Larger numbers of known dMMR tumors are currently being analyzed with MSK-IMPACT to validate this hypothesis.

3566 Poster Session (Board #58), Mon, 8:00 AM-11:30 AM

Genomic analysis of colitis-associated cancers. *First Author: Rona D. Yaeger, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with inflammatory bowel disease (IBD) [Crohn's disease (CD) and ulcerative colitis (UC)], are at increased risk for small bowel or colorectal cancers (Colitis Associated Cancers, CAC). The genomic alterations (GA) associated with CAC have not been well-described. We hypothesized that GA associated with CAC are different than those seen with sporadic colorectal cancer (CRC). Identification of these alterations may lead to improved early detection and therapeutic options. **Methods:** We determined GA in 15 CAC cases confirmed as being associated with IBD at MSKCC including 11 UC and 4 CD, 14 primary and 1 metastasis (median age 55, range 29-77; 73% male). Primary tumor sites were ileum (2), right colon (5), and left colon (8). Histologic subtypes were moderately differentiated adenocarcinoma (4), mucinous (7), and signet ring/diffuse (4). Hybridization capture of the entire coding sequence of 405 cancer-related genes, including those associated with early onset IBD, was applied to DNA extracted from FFPE tumor specimens and sequenced to high, uniform coverage (> 500x). All classes of GA including substitution, indel, copy number alteration and rearrangement were determined. **Results:** Potentially clinically relevant GA were identified in 8/15 CAC, including *ERBB2* amplification (amp), *ERBB2* S310F, *EML4-ALK*, *FGFR2* amp, *FGFR2* amp + *FGFR2-TACC2* (same patient), *PDGFRA* T134M, and *BRAF* V600E + *TSC2* truncation (same patient). *IDH1* R132H/C were found in 2/4 CD cases (one concurrent with *FGFR2* amp/fusion). Overall, 5.7 GA per tumor were detected (range 1-12). GA in *TP53,* the most commonly altered gene, occurred in 14/15 cases (93%; 10 known hot spot mutations), compared to 52% in CRC TCGA. *KRAS* and *APC* mutations occurred in 33% and 20%, respectively, compared to 43% and 76% in CRC TCGA. Other recurrently altered genes included *SMAD4* (20%) and *RNF43* (13%). Key GA associated with early onset IBD were not identified. **Conclusions:** Comprehensive genomic profiling identified a high frequency of potentially clinically relevant GA in CAC. GA seen in CAC suggest substantial differences from those of sporadic CRC; *APC* activation is infrequent and *TP53* mutations are nearly universal including frequent possibly gain of function. Study of additional cases is ongoing.

3567 Poster Session (Board #59), Mon, 8:00 AM-11:30 AM

FOLFOX-aflibercept followed by maintenance therapy with fluoropyrimidine-aflibercept as first-line therapy in patients with metastatic colorectal cancer: A GERCOR single-arm phase II study (VELVET). *First Author: Benoist Chibaudel, Institut Hospitalier Franco-Britannique, Levallois-Perret, France*

Background: VEGF inhibition with (ziv-)aflibercept, a recombinant human fusion protein, in combination with FU/irinotecan improves patient outcomes (overall survival (OS), progression-free survival (PFS), overall response rate (ORR)) in second-line therapy of patients with metastatic colorectal cancer (MCRC) (Van Cutsem, JCO 2012). The VELVET study evaluated the efficacy and safety of the OPTIMOX-aflibercept first-line treatment strategy (EudraCT 2012-003521-25). **Methods:** Main eligibility criteria were: previously untreated, unresectable, evaluable or measurable MCRC, age ≥ 18 years, ECOG PS 0-2. Patients received mFOLFOX7-aflibercept (aflibercept 4mg/kg, folinic acid 400mg/m², oxaliplatin 100mg/m², 5FU infusion 3000mg/m²/46h) fortnightly regimen as induction therapy (6 cycles) followed by maintenance therapy with fluoropyrimidine (5FU or capecitabine) and aflibercept until disease progression or limiting toxicity. CT-scan tumor assessments using RECIST1.1 were done every 8 weeks. A Minimax Simon's two-stage design was used with a targeted improvement of 6m-PFS rate (primary endpoint) from 70% to 85%. **Results:** From May 2013 to May 2014, 49 patients were included. One patient did not receive study treatment. Thirty-seven (84.1%, se 5.5) patients were alive at 6 months without documented RECIST progression. The Kaplan-Meier 6m-PFS was 81.9% (66.8-90.6) and median PFS was 9.3 months (95%CI: 8.7-12.6). The ORR was 59.2% (N = 29/49) and 65.9% (N = 29/44) in the ITT and evaluable populations, respectively. Most common (≥ 10%) grade 3-4 adverse events reported were hypertension (23%), fatigue (12%), neuropathy (10%), neutropenia (10%). Two on treatment deaths were reported: 1 due to stroke and 1 due to neutropenic sepsis attributable to the study treatment. Circulating angiogenic biomarkers results will be presented at the meeting. **Conclusions:** OPTIMOX-aflibercept could be an active first-line treatment strategy in patients with metastatic colorectal cancer. This study warrants further investigation to confirm efficacy and safety of the combination in a randomized controlled trial. Clinical trial information: EudraCT 2012-003521-25.

3568 Poster Session (Board #60), Mon, 8:00 AM-11:30 AM

Cetuximab biweekly plus mFOLFOX6 as first-line therapy in patients (pts) with KRAS wild-type (wt) (exon 2) metastatic colorectal cancer (mCRC): Primary endpoint and subgroup analysis of the CEBIFOX trial. *First Author: Stefan Kasper, Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany*

Background: The multicenter, single-arm, phase II CEBIFOX trial (Simon's two stage minimax design) evaluated the efficacy of mFOLFOX6 + biweekly cetuximab (500 mg/m²) as 1st line therapy in *KRAS* wt (exon 2) mCRC. Final efficacy data as well as extended molecular and clinical subgroup analyses are presented. **Methods:** Primary endpoint was objective response rate (ORR) per RECIST 1.0, secondary endpoints were safety, metastasectomy rate, quality of life, progression-free (PFS) and overall survival (OS). Extended molecular profiling was performed using NGS-based panel sequencing including *NRAS* (exon 2-4), *KRAS* (exon 2-4), *BRAF* (exon 15) and *PI3KCA* (exon 10 and 21). Clinical parameters included: tumor localisation (right sided vs. left sided-LCRC), liver-limited disease (LLD), early tumor-shrinkage (ETS), depth of response (DPR), metastasectomy and inflammation markers (neutrophil/lymphocyte ratio-NLR). Differences in ORR, PFS and OS were calculated for subgroups using chi-square and logrank tests. Hazard ratios were calculated by Cox regression analysis. **Results:** Among 57 pts of the ITT, 50 pts were evaluable for response with an ORR of 72%, and a disease control rate of 90%. Median PFS and OS (ITT) were 9.5 (7.4-11.6) and 29.4 (16.7-42.0) months. Metastasectomy was achieved in 33.3%; grade 3/4 adverse events occurred in 52% of the ITT population, including leukocytopenia, rash and GI-toxicity. New *RAS* and *BRAF* mutations were detected in 17.4% and 13.3%, respectively with a negative impact on treatment efficacy. Pts with LCRC (75%), ETS (59.2%), secondary metastasectomy and LLD (49.1%) had significantly prolonged OS, whereas pts with high NLR (> 5; 28.6%) had inferior OS (all p-values < 0.05). Median DPR was -46.4%, and correlated significantly with PFS and OS (p < 0.01). **Conclusions:** This study supports the efficacy and safety of biweekly cetuximab given in combination with mFOLFOX6 in pts with mCRC. Extended mutational analyses of key oncogenes and routinely assessed clinical parameters can help to identify patients with maximum likelihood of benefit from anti-EGFR antibody-based immunochemotherapy. Clinical trial information: NCT01051167.

3569 Poster Session (Board #61), Mon, 8:00 AM-11:30 AM

Phase I study of preoperative chemoradiation with temozolomide and capecitabine in patients with locally advanced rectal cancer. *First Author: Yong Sang Hong, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Preoperative chemoradiation (CRT) with capecitabine is one of the standard treatment strategies in patients with locally advanced rectal cancer (LARC). Temozolomide improved survival of patients with glioblastoma when administered with radiotherapy (RT), especially in those with hypermethylated *MGMT* (O^6-methylguanine DNA methyltransferase). *MGMT* hypermethylation has been suggested as one of the colorectal carcinogenesis pathways. **Methods:** RT was delivered with 45 Gy/25 daily fractions with coned-down boost of 5.4 Gy/3 fractions. Concurrent chemotherapy consisted of fixed dose of capecitabine (825 mg/m^2 twice daily) and escalated dose of temozolomide (45 [level 1], 60 [level 2], and 75 mg/m^2/day [level 3]). *MGMT* hypermethylation was examined by methyl-specific PCR in the pre-treatment tumor samples. **Results:** Between May 2013 and Apr 2014, a total of 22 patients with LARC of cT3-4N0 or $cT_{any}N1$-2 were accrued. Dose-limiting toxicity did not occur among 10 patients up to dose level 3, and the dose level 3 was chosen as the recommended dose (RD). Additional 12 patients were accrued in the RD. There was no grade 4 adverse event (AE), and grade 3 AEs included leucopenia (9.1%), nausea (4.5%), and vomiting (4.5%). Pathologic complete responses (pCR) were observed in 7 patients (7/22, 31.8%). *MGMT* hypermethylation was found in 16 patients (16/22, 72.7%). The pCR rate was 37.5% (6/16) in the hypermethylated *MGMT* group and 16.7% (1/6) in the unmethylated MGMT group (p= 0.62). **Conclusions:** The RD of temozolomide was determined to 75 mg/m^2/day when added in the preoperative CRT with capecitabine. Preoperative CRT with temozolomide plus capecitabine was tolerable. There was a tendency of higher pCR rates in those with hypermethylated *MGMT*, therefore, further randomized study will be warranted. Clinical trial information: NCT01781403.

3570 Poster Session (Board #62), Mon, 8:00 AM-11:30 AM

S-1 as adjuvant chemotherapy for stage III colon cancer: Updated outcomes of ACTS-CC trial. *First Author: Yusuke Kinugasa, Division of Colon and Rectal Surgery, Shizuoka Cancer Center Hospital, Shizuoka, Japan*

Background: The ACTS-CC trial, a randomized phase III trial, demonstrated that adjuvant therapy with S-1 for stage III colon cancer was non-inferior in 3-year disease-free survival (DFS) to that of tegafur-uracil plus leucovorin (UFT/LV). We updated DFS and overall survival (OS), and performed some clinically relevant subgroup analyses. **Methods**: A total of 1,535 patients with stage III colon cancer were randomly assigned to receive S-1 (80-120 mg/day on days 1-28 every 42 days, 4 courses) or UFT/LV (UFT: 300- 600 mg/day and LV: 75 mg/day on days 1-28 every 35 days, 5 courses). Primary endpoint was DFS. Secondary endpoints were OS and safety. **Results:** A total of 1518 patients (758 in the S-1 group and 760 in the UFT/LV group) were included in the efficacy analysis. Median follow-up was 63.5 months, the mean age at enrollment was 64.5 years, wide lymph node dissection (D3) was done in 79.8%, the median number of dissected lymph nodes was 17, and stage IIIA/IIIB/IIIC were 15%/71%/14%. The hazard ratio (HR) for DFS was 0.88 (95%CI, 0.74-1.06; p = 0.177). The 5-year DFS rate was 70.2% in the S-1 group and 66.9% in the UFT/LV group. In the subgroup analysis, no significant interactions were identified between the major baseline characteristics and the DFS in S-1 and UFT/LV, except for histological type; favors S-1 in patients with poorly-differentiated adenocarcinoma. Approximately 5% of patients in the both groups experienced second cancers. Among the patients with recurrences in each group, 46.3% and 44.7% underwent surgical resection as an initial treatment for recurrence. The HR for OS was 0.92 (95%CI, 0.72-1.17; p = 0.488). The 5-year OS rates were 86.0% and 84.4% in the S-1 and UFT/LV group, respectively. **Conclusions:** Adjuvant therapy of S-1 for stage III colon cancer was confirmed to be non-inferior both in DFS and OS to those of UFT/LV after long follow-up. Favorable OS might be brought by the high resection rate of recurrent lesions. Clinical trial information: NCT00660894.

3571 Poster Session (Board #63), Mon, 8:00 AM-11:30 AM

Immunohistochemistry to initiate a complex screening cascade in the detection of Lynch syndrome. *First Author: Grainne O'Kane, St. James's Hospital, Dublin, Ireland*

Background: Lynch Syndrome (LS) accounts for 2-4% of all colorectal cancers (CRC) and is caused by germline mutations in DNA mismatch repair (MMR) genes. Increasing literature supports routine screening for LS using immunohistochemistry (IHC) to detect loss of MMR protein expression on tumour samples. We reviewed practices at 3 Irish cancer centres. The number of MMR deficient (dMMR) tumours detected was evaluated, and the subsequent number of genetic referrals and LS diagnoses determined. **Methods:** Colorectal databases at 3 Irish academic centres were reviewed from January 2005 - 2013. Centre 1 performs IHC upon physician request, centre 2 implemented reflex IHC (rIHC) in November 2008, and centre 3 has been performing rIHC since 2005. All new diagnoses of colorectal adenocarcinoma with available histology were included. Pathology reports were reviewed and genetic referrals analysed. **Results:** A total of 4,021 new CRC were diagnosed in 3,929 patients across 3 centres. The results are presented in the table below. The implementation of universal screening using rIHC in cancer centre 3 detected an increased number of dMMR tumours (11%, p<0.01), however this did not result in a similar increase in cancer genetics referrals or lynch syndrome diagnoses. A high proportion of patients underwent germline testing once referred. **Conclusions:** Increased IHC testing for MMR proteins results in more Lynch syndrome diagnoses. Adherence to protocols for cascade testing and appropriate clinical referral is required to realise the benefit of universal screening.

		Centre 1 (IHC when requested)	Centre 2 (rIHC since Nov 2008)	Centre 3 (rIHC since 2005)

3572 Poster Session (Board #64), Mon, 8:00 AM-11:30 AM

Cost-effectiveness for extended RAS/RAF testing in metastatic colorectal cancer. *First Author: Marwan R. Al-hajeili, Karmanos Cancer Ctr, Grosse Pointe Farms, MI*

Background: Epithelial growth factor receptors (EGFR) inhibitors (Cetuximab and panitumumab) are monoclonal antibodies directed against EGFR and promote apoptosis. Douillard et al demonstrated the benefit of using EGFR inhibitors agents in wild type (WT) KRAS metastatic colorectal cancer (mCRC) and lack of benefit in mutated KRAS mCRC patients. Only WT KRAS mCRC are candidate for EGFR inhibitors, they constitute 57.6% of all mCRC patients, 27.3% of them carry other RAS/RAF mutations that preclude them from EGFR inhibitors benefits. Insurance companies are willing to pay the cost of KRAS testing and EGFR inhibitors treatment for all WT KRAS mCRC. We conducted this analysis to assess the cost-effectiveness of the extended testing for other RAS/RAF mutations for WT KRAS mCRC patients. **Methods:** A decision analysis model using (Treeage pro Software, Williamstown, MA) was developed to assess and compare treatment costs and disease outcomes associated with presence or absence of additional mutations (RAS/RAF) in a WT KRAS mCRC. . For utility estimate, Quality of life (QoL) assessment based on Skindex-16 for EGFR inhibitors side effects. The difference in median survival time was used to calculate incremental effectiveness of using EGFR inhibitors based on the extended testing or not. Costs were determined through Medicare records and direct hospital charges for extended testing, and treatment with EGFR inhibitors. For sensitivity analysis, we modify mutations probability and the extended testing cost, in both 1-way and combined 2-way sensitivity analyses. **Results:** The total expected cost was $56,306.06 vs. $42,683.75 favoring additional testing. The median overall survival was 15.8 vs.14.5 months favoring additional testing. In order to conclude extended testing is not worth it, mutation probability has to be less than 1.8%, or extended testing cost of more than 14000 $ in one way sensitivity testing. However, for two-way analysis, the mutation probability needs to be less than 17% and test cost needs to be more than $8,200. **Conclusions:** Our analysis shows that extended testing for other RAS/RAF mutations is cost-effective in WT KRAS mCRC patients before treating with EGFR inhibitors.

3573 Poster Session (Board #65), Mon, 8:00 AM-11:30 AM

Molecular classification of the invasive front in colorectal cancer. *First Author: Darragh McArt, CCRCB, Queen's University, Belfast, United Kingdom*

Background: Despite the use of 5-FU-based adjuvant therapies, a large proportion of stage III (locally advanced) colorectal cancer (CRC) patients will relapse and die of metastatic disease. Recent data from phase III trials using the anti-VEGF or the anti-EGFR mAbs have shown that, in contrast to the metastatic setting, these agents do not prolong survival in stage III CRC. Therefore, novel drugs are needed that result in further increases in overall survival in stage III CRC patients. The aim of this study was to investigate the invasive front of stage III CRC at the molecular level and correlate with clinical and pathological variables. **Methods:** mRNA was extracted from macrodissected FFPE CRC, central tumour and invasive front from 25 patients. Transcriptional analysis was performed using the CRC DSA microarray. Samples were analysed using limma for lists of differential expressed genes and using a supervised learning approach, pamr, to extract succinct gene lists between contrasts and visualised with bootstrap clustering and heatmaps. Expression of E-cadherin was measured using IHC. **Results:** IHC staining showed loss of E-cadherin expression in tumour cells at the invasive front, in keeping with an epithelial-to mesenchymal transition (EMT). Limma and pamr analysis depicted strong overlap of probes to differentiate central tumour from the invasive front. Prominent classifiers evidenced included genes with a role in inflammation and immune signalling (eg. CXCL5, C7, IL8), EMT (eg. SFRP2, WNT5A) and growth factor receptor signalling (eg. IGF1). Comparison of this expression list with the recent published gene lists, characterizing the poorest prognostic EMT/stem-cell like subgroup, showed that there is a high degree of overlap between these two signatures. **Conclusions:** Taken together, our study is the first to indicate that, in order to disseminate and metastasize, tumour cells at the invasive front develop an EMT phenotype with a molecular signature, similar to the poor prognostic stem-like molecular CRC subgroup. This data could aid in the identification of novel treatment strategies to prevent tumour recurrence/metastasis in stage III CRC.

3574 Poster Session (Board #66), Mon, 8:00 AM-11:30 AM

Zonal differences in PD-1 expression in centre of tumour versus periphery in microsatellite stable and unstable colorectal cancer. *First Author: Grainne O'Kane, The Mater Misericordiae University Hospital, Dublin, Ireland*

Background: Colorectal cancers that show evidence of microsatellite instability (MSI-H) are marked by a high tumour infiltrating lymphocyte population (TiL) which is thought to be prognostic. Programmed Death-1(PD-1) is a negative regulator of the immune system and targeting the interaction with its ligand PD-L1 offers a potential therapeutic target in many malignancies. We aimed to characterize CD8 and PD-1 expression in both the tumour centre and tumour periphery of microsatellite stable (MSS) and unstable colorectal cancers. **Methods:** Paraffin-embedded tumour blocks were cut at 5um, prepared and stained using specific antibodies for CD8 and PD-1. The tumour periphery was defined as the area within a 400x high power field (HPF) from the outline of the tumor. The tumour centre was defined as the area at least one 400x HPF apart from the tumour outline toward the centre of the tumour. Images were taken at 40x, 100x, 200x and 400x. Positive cells were averaged across 3 high power fields and classified as high or low positivity. **Results:** Forty-two specimens have been analysed to date including 28 MSI-H and 13 MSS tumours. Sixty-eight percent of MSI-H specimens were stage II and 69% of MSS were stage III. In the MSI-H group, a high CD8 count in the tumour centre and tumour periphery correlated with earlier tumour size and stage. PD-1 positivity was seen in 61% of MSI-H tumour centres compared to no positivity in the tumour centres of MSS specimens. The periphery of both MSS and MSI-H specimens showed significant PD1 expression with 71% and 85% of samples showing positivity respectively. There was no association between high or low densities of staining and stage. **Conclusions:** Zonal differences exist in the expression of CD8 and PD-1 in microsatellite stable and unstable tumours. A high proportion of MSI-H tumours show PD-1 activity in the centre of the tumour despite an improved prognosis. Further profiling of other T cell populations may help to further understand this expression which may act as a biomarker or provide a therapeutic target.

3575 Poster Session (Board #67), Mon, 8:00 AM-11:30 AM

A phase III, randomized, double-blind, placebo-controlled trial to evaluate the efficacy and safety of pregabalin in the prevention and reduction of oxaliplatin-induced painful neuropathy (PreOx). *First Author: Daniel Ciampi de Andrade, Instituto do Câncer de São Paulo Octavio Frias de Oliveira, São Paulo, Brazil*

Background: Patients with colorrectal cancer receiving Oxaliplatin usually develop acute and chronic painful chemotherapy-induced peripheral neuropathy (CIPN). Despite having different mechanisms, both conditions lead to central sensitization (CS). Recent data suggest that the degree of CS after acute use of Oxaliplatin increases the risk of painful CIPN. We hypothesized that preemptive use of anti-hyperalgesic drug (pregabaline) during Oxaliplatin infusions would decrease the incidence of chronic painful CIPN. **Methods:** Pain-free, chemotherapy-naïve patients (stage III/IV) receiving at least one complete cycle of modified FLOX (5-FU+leucovorin for 6 consecutive weeks+oxaliplatin 85 mg/m2 at weeks 1, 3 and 5, every 8 weeks) were randomised (1:1). Eligible patients received either pregabaline or placebo (150-600mg/d) for three days before and three days after each oxaliplatin infusion. Patients were followed for 3-6 months after the end of chemotherapy. Clinical assessments were performed at baseline, at the end of chemotherapy treatment and after the followup period. The main outcome was average pain at the last visit assessed by the visual numerical scale (0-10) item of the Brief Pain Inventory in pts with neuropathic pain according to the Douleur Neuropathique-4 score (DN4). Secondary endpoints were pain interference (BPI), pain dimensions (McGill Pain Questionnaire), score of the Neuropathic Pain Symptom Inventory (NPSI). **Results:** 206 patients (56.6±11yo, 111 female) were enrolled. Both groups presented similar baseline demographic characteristics ($p > 0.20$). The cumulative dose of oxaliplatin was similar between groups throughout the study. Data from 82 patients in the pregabaline and 84 in the placebo group were retained for analises. At the last visit, pain intensity in the pregabaline group was 0.85±2.35 and 0.88±2.40 in the placebo group ($p = 0.673$). Scores from other pain scales did not differ between groups. **Conclusions:** The preemptive use of the antihyperalgesic drug pregabaline during oxaliplatin infusions was safe, but did not decrease the incidence of chronic pain related to CIPN. Clinical trial information: NCT0145016.

3576 Poster Session (Board #68), Mon, 8:00 AM-11:30 AM

Placebo-controlled, double-blinded multi-center phase III trial of XELIRI/FOLFIRI plus simvastatin in metastatic colorectal cancer. *First Author: Sung Hee Lim, Samsung Medical Center, Seoul, Korea South*

Background: The purpose of this randomized phase III trial was to evaluate the addition of synthetic 3-hydroxy-3methyglutaryl coenzyme A (HMG-CoA) reductase inhibitor, simvastatin to XELIRI/FOLFIRI in patients with previously treated metastatic colorectal cancer. **Methods:** We undertook a double-blind, placebo-controlled phase III trial of 269 patients with previously treated metastatic colorectal cancer, enrolled to 5 centers in South Korea. Patients were randomly assigned (1:1) to receive irinotecan 180 mg/m^2 as a 90-min infusion followed by leucovorin 200mg/m^2 in a 2-h infusion, and then 5-FU 400mg/m^2 bolus injection followed by 2400mg/m^2 as a 46-h continuous infusion (FOLFIRI) or irinotecan 250mg/m2 as a 90-min infusion with capecitabine 1000mg/m^2 twice daily for 14days (XELIRI) plus simvastatin (134 patients) or XELIRI/FOLFIRI plus placebo (135 patients). The primary end point was progression-free survival (PFS) and secondary end points included response rate, duration of response, overall survival (OS), time to progression (TTP) and toxicity. **Results:** Between April 2010 and July 2013, 269 patients were enrolled and assigned to treatment groups (134 simvastatin, 135 placebo). The median progression-free survival (PFS) was 5.9 months (95% CI, 4.5-7.3) in XELIRI/FOLFIRI plus simvastatin group and 7.0 months (95% CI, 5.4-8.6) for XELIRI/FOLFIRI plus placebo group ($P = 0.937$). There was no significant difference in overall survival (median, 15.9 months (simvastatin) vs. 19.9 months (placebo), $P = 0.826$). Grade 3 or higher grade nausea and anorexia were noted slightly more in patients with simvastatin arm compared to placebo arm (4.5 vs 0.7%, 3.0 vs 0% respectively). **Conclusions:** These results show that the addition of 40mg simvastatin to XELIRI/FOLFIRI did not improve PFS in previously treated metastatic colorectal cancer although it does not increase toxicity. Clinical trial information: NCT01238094.

3577 Poster Session (Board #69), Mon, 8:00 AM-11:30 AM

A randomized controlled trial to evaluate laparoscopic versus open with Japanese D3 dissection for stage II,III colorectal cancer (CRC): First efficacy results from Japan Clinical Oncology Group Study JCOG0404. *First Author: Tomonori Akagi, Oita University Faculty of Medicine, Department of Gastroenterological and Pediatric Surgery, Oita, Japan*

Background: The benefits of laparoscopic surgery (LAP) compared with open surgery (OP) have been suggested; however, the long-term survival of LAP for advanced CRC requiring Japanese D3 dissection is still unclear. We conducted a trial to confirm the non-inferiority of LAP to OP in terms of overall survival (OS). Favorable short-term complications and clinical benefits of LAP have already been demonstrated. Overall survival, the primary endpoint, and late post-operative complications are presented here. **Methods:** Only accredited surgeons from 30 Japanese institutions participated. Eligibility criteria included histologically proven CRC; tumor located in the cecum, ascending, sigmoid or rectosigmoid colon; T3 or deeper lesion without involvement of other organs; N0-2 and M0; tumor size = < 8 cm; age 20-75 years. Patients with pathological stage III received adjuvant chemotherapy with fluorouracil plus leucovorin. The planned sample size was 1050 patients with a power of 80%, a one-sided alpha of 5% and the non-inferiority margin of the hazard ratio (HR) as 1.366. **Results:** A total of 1057 patients were randomized (OP 528, LAP 529) between October 2004 and March 2009. Conversion to OP was needed for 29 patients in LAP arm. 5-year OS was 90.4% (95%CI: 87.5-92.6%) in OP, and 91.8% (89.1-93.8%) in LAP. The non-inferiority of laparoscopic D3 in OS was not demonstrated (HR: 1.06 [90%CI: 0.79-1.41(> 1.366)], p = 0.073). 5-year RFS was 79.7% (76.0-82.9) in OP and 79.3% (75.6-82.6) in LAP (HR: 1.07 [95%CI: 0.82-1.38]). Proportion of grade (G) 2-4 late complications was 22.6% (OP 12.5%, LAP 10.1%). Late complications (G2-G4) included constipations (OP 6.0%, LAP 4.4%), diarrhea (OP 2.9%, LAP 2.7%), paralytic ileus (OP 1.2%, LAP 1.7%), and bowel obstruction of small intestine (OP 3.1%, LAP 2.1%). **Conclusions:** The non-inferiority of laparoscopic D3 in OS was not demonstrated for stage II,III CRC. However, since OS of both arms are almost identical and better than expected, laparoscopic D3 is acceptable as a treatment option for stage II,III CRC. Clinical trial information: NCT00147134.

3578 Poster Session (Board #70), Mon, 8:00 AM-11:30 AM

Effect of Sym004 on acquired resistance to cetuximab in colorectal cancer (CRC) in a novel mouse avatar model. *First Author: Deepak B. Vangala, Department of Medicine, Knappschaftskrankenhaus, Ruhr-University Bochum, Bochum, Germany*

Background: Monoclonal antibodies against EGFR have shown improved survival for mCRC-patients in clinical trials. Unfortunately, virtually all patients acquire resistance to these agents during the course of treatment. Preclinical models of acquired resistance with close resemblance to the patient tumor are lacking. Sym004, a novel monoclonal anti EGFR antibody mixture has shown to overcome cetuximab (c-mab) resistance in HNSCC cell lines. **Methods:** Samples of 100 CRC patients undergoing surgery were implanted subcutaneously in nude mice. Treatment cohorts of 10 wildtype (WT for KRAS, BRAF, NRAS, PI3K) tumors and 3 tumors with either KRAS, BRAF or PI3K mutation respectively were generated for i.p. treatment with Sym004, c-mab (25mg/kg biw) or control. Primary observational period was 29 days. In case of response, treatment was continued until acquired resistance – defined as tumor doubling after primary observational period – arose. **Results:** Tumors with KRAS, BRAF or PI3K mutations were resistant to c-mab. All but two tumors with WT-status responded to c-mab and Sym004 during primary observational period (stable disease or tumor regression). Sym004 showed a significantly deeper response in 4 cases at day 29. Acquired resistance for c-mab developed in 4 tumors at days 33, 48, 60 and 71, respectively. In two of these cases tumor volume was stable with Sym004 and in the other two cases acquired resistance developed with substantial delay (d60 vs d33, d105 vs d60). Complete remission with c-mab and Sym004 occurred in two cases, one of which faster with Sym004 and lasting 100 days beyond end of treatment (c-mab: 10 days). **Conclusions:** Here, we present the first preclinical patient derived xenograft model of acquired resistance to anti-EGFR targeted therapy in CRC. We show that Sym004 is able to generate a deeper and prolonged response in 5 of 10 tested WT CRC patient derived tumors. This superior response rate of Sym004 suggests that clinical trials of Sym004 in CRC are warranted. Lastly, our successful proof of principle experiments for *in vivo* modeling of secondary resistance in CRC indicate that this strategy can serve as a testing platform for treatment optimization of targeted therapy addressing secondary resistance.

3579 Poster Session (Board #72), Mon, 8:00 AM-11:30 AM

Long-term outcome after R1 resection for colorectal liver metastases: Is a cure possible? *First Author: Isamu Hosokawa, Centre Hépato-Biliaire, AP-HP, Hôpital Paul Brousse, Villejuif, France*

Background: Increasingly efficient chemotherapy regimens have improved the outcomes after R1 resection (tumor-free margin < 1 mm) for colorectal liver metastases (CLM). However the long-term survival benefit and the potential of cure after R1 resection are not clearly demonstrated. The aim of this study was to evaluate long-term outcomes after R1 resection using an aggressive strategy consisting of modern perioperative chemotherapy and repeated surgeries, and to define factors predictive of cure after R1 resection. **Methods**: All resected CLM patients at our institution from 2000 to 2009 were prospectively evaluated. Exclusion criteria were: presence of extrahepatic disease, use of ablative treatment modalities, and incomplete macroscopic (R2) resection. Cure was defined as a disease-free interval ≥ 5 years from last hepatic or extrahepatic resection to last follow-up. **Results**: Of 639 patients consecutively resected for CLM, 384 (60%) were eligible for the study, 193 (30%) of whom underwent R0 resection (tumor-free margin ≥ 1 mm), and 191 (30%) underwent R1 resection. The 5-year overall survival rates (OS) for patients with R0 resection and R1 resection were 65% and 56%, respectively (P = 0.15). Of the 191 patients who underwent R1 resection, 121 patients had a more than 5 years follow-up. Of these, 23 patients (19%) were considered "cured" and 88 patients (73%) were considered "non-cured". For the included 111 patients, after a mean follow-up of 57 months, 5- and 10-year OS were 47% and 32%, respectively, and disease-free survival rates were 15% and 14% at 5 and 10 years, respectively. Although there were no significant differences in the number or maximum size of metastases at diagnosis between the two groups, cured patients more often responded to first-line chemotherapy (P = 0.02) with fewer cycles (P = 0.002). Independent predictive factors of cure included: ≤ 10 total cycles of preoperative chemotherapy and objective response following preoperative chemotherapy. **Conclusions:** In the era of modern chemotherapy, cure can be achieved overall in 19% of patients after R1 resection for CLM. The best conditions to achieve cure after R1 resection rely on a good response to an efficient and relatively short first-line chemotherapy.

3580 Poster Session (Board #73), Mon, 8:00 AM-11:30 AM

Continuing single-agent capecitabin as maintenance therapy after induction of XELOX (or FOLFOX) in first-line treatment of metastatic colorectal cancer. *First Author: Rui-hua Xu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Colorectal cancer (CRC) is one of the most common malignant tumors. All advanced CRC will progress after first-line treatment. Therefore, it is emergent to seek an efficient and low toxic maintaining regimen to prolong progression free survival (PFS). Some clinical researches demonstrated that maintaining treatment followed first-line treating could extend PFS. Our previous non-randomized small sample study indicated that patients receiving first-line treatment of XELOX followed by capecitabine as maintaining therapy had significantly prolonged median time to progression (TTP). Therefore, we plan to initiate the first randomized study to evaluate the efficacy and safety of maintenance therapy with capecitabine following induction of (XELOX) or (FOLFOX) versus observation until progression in first-line therapy in metastatic CRC. **Methods:** This is a multi-center, randomized phase III study. Patients who received 18-22 weeks chemotherapy with XELOX or FOLFOX and achieved objective response or stable disease were randomized 1:1 to received maintenance therapy of capecitabine (1,000 mg/m^2 twice a day from days 1–14, every 3 weeks) or only observation until disease progression. The primary endpoint was PFS, which was defined as the interval between initial treatment and the first documentation of disease progression or death. **Results:** The intent-to-treat population comprised 275 patients (capecitabine maintenance, n= 136; observation, n=139); there were no significant differences in baseline characteristics. The median follow-up was 29.0 months (range, 0–62.5 months). Median PFS in capecitabine maintenance group was significantly longer than the observation group (11.0 months [95% confidence interval (CI) 9.45 to 12.5m] versus. 8.0months, [95%CI 7.2m to 8.8m]; p < 0.001). The most common grade 3 or 4 toxicities in capecitabine maintenance versus observation were neutropenia, hand–foot syndrome, and mucositis. **Conclusions:** Maintenance therapy with capecitabine single agent following induction of XELOX or FOLFOX improved the outcome in patients with mCRC, as compared with the observation group. Clinical trial information: NCT02027363.

3581 Poster Session (Board #74), Mon, 8:00 AM-11:30 AM

Baseline carcinoembryonic antigen (CEA) serum levels to predict bevacizumab-based treatment response in patients with KRAS exon wild-type metastatic colorectal cancer (mCRC) receiving 1st-line therapy with FOLFIRI plus cetuximab or bevacizumab (AIO KRK0306, FIRE3 trial). *First Author: Marlies Michl, Department of Hematology and Medical Oncology and Comprehensive Cancer Center, University Hospital Grosshadern, LMU Munich, Munich, Germany*

Background: Recently, Prager et al. proposed the hypothesis that carcinoembryonic antigen (CEA) is involved in tumor angiogenesis and therefore might predict bevacizumab-based treatment response in metastatic colorectal cancer (mCRC) (Cancer Research, 2013; Cancer Science, 2014). The present study aimed to evaluate this hypothesis in the FIRE-3 trial where patients (pts) with KRAS exon 2 wild-type mCRC were randomized to receive first-line chemotherapy with either FOLFIRI + cetuximab (cet) or FOLFIRI + bevacizumab (bev). **Methods:** Baseline CEA levels were analyzed either as continuous variable (ln) or categorized in two groups ($\leq$ / $>$ 25% quartile; $\leq$ / $>$ 6.2ng/ml) with regard to their predictive impact on PFS and OS in the two different treatment arms. Correlations relied on Cox regression analysis. Survival was estimated by Kaplan-Meier. **Results:** For analysis of CEA, 522/592 pts (cet: 257 pts; bev: 265 pts) were eligible. When CEA baseline level was evaluated as a continuous variable, CEA (ln) was inversely correlated with PFS (p= 0.02) and OS (p= 0.001) in the bev arm, but not in the cet arm. Using the 25% quartile of CEA as a cut-off, only in the bev arm an effect on OS (24.2 mo vs. 33.3 mo; HR 0.60; CI95%:0.41-0.88; p= 0.009) and PFS (10.4 mo vs. 11.7 mo; HR 0.67; CI95%:0.48-0.94; p= 0.02) was observed, but not in the cet arm. Pts with high CEA baseline levels ($>$ 6.2ng/ml) showed a shorter OS in the bev arm compared to the cet arm (bev: 24.2 mo vs. cet: 30.0 mo; HR 1.52; CI95%:1.16-2.00; p= 0.002). In pts with low CEA baseline level ($\leq$ 6.2ng/ml) no significant survival difference was observed between arms (HR 0.92; CI95%:0.58-1.44; p= 0.70). Univariate analysis identified CEA as an independent predictor of OS in the bev arm, but not in the cet arm. **Conclusions:** The present analysis supports the hypothesis that CEA acts as a predictor of bev activity, while outcome parameters in the cet arm are not affected by baseline CEA. Patients with elevated CEA baseline levels appeared to benefit from anti-EGFR directed therapy, while anti-VEGF based treatment was inferior.

3582 Poster Session (Board #75), Mon, 8:00 AM-11:30 AM

A phase III multicenter trial comparing two different sequences of second/third line therapy (irinotecan/cetuximab followed by FOLFOX-4 vs. FOLFOX-4 followed by irinotecan/cetuximab in K-RAS wt metastatic colorectal cancer (mCC) patients refractory to FOLFIRI/Bevacizumab. *First Author: Stefano Cascinu, Clinica di Oncologia Medica, Università Politecnica delle Marche, AO Ospedali Riuniti, Ancona, Italy*

Background: Improvements in survival have been reported in mCC with the addition of bevacizumab or cetuximab to chemotherapy. However, their efficacy in different therapy lines and the optimal sequence are still controversial. While bevacizumab seems to lose its efficacy along the course of treatment lines, cetuximab is active even in 2° and 3° line therapy. We designed a randomised, phase III study to compare efficacy and safety of two different sequences of Cetuximab or FOLFOX to optimize the treatment of mCC pts refractory to FOLFIRI/bevacizumab. **Methods:** Pts were randomised in a 1:1 ratio to receive as 2° or 3° line cetuximab/irinotecan followed by FOLFOX-4 (Arm A) or FOLFOX-4 followed by cetuximab/irinotecan (Arm B). Primary end point was progression free survival (PFS); secondary end points were overall survival and toxicity. **Results:** 109 mCC pts were enrolled and 108 were evaluable for analysis. 63 patients were males and 45 females, with a median age of 61 years. Efficacy results are reported in the table. Treatments were well tolerated with a low number of serious adverse reactions in both arms (8 and 4, respectively), even if grade 3-4 toxicity was overall higher in cetuximab treatment. **Conclusions**: While the primary end point was not met (PFS was not statistically different), FOLFOX seems to be more effective than cetuximab (overall survival: 18.6 months vs 12.4 months) as 2° line treatment in patients receiving bevacizumab/FOLFIRI. This seems to confirm preclinical and clinical (FIRE-3) data suggesting that a prior anti-VEGF therapy may determine a lower sensitivity to a subsequent anti-EGFR treatment. Clinical trial information: NCT01030042.

3583 Poster Session (Board #76), Mon, 8:00 AM-11:30 AM

HER3 as a biomarker of prognosis and panitumumab (Pan) benefit in *RAS*-wt advanced colorectal cancer (aCRC). *First Author: Jenny F. Seligmann, University of Leeds, Leeds, United Kingdom*

Background: EGFR pathway activation is important in aCRC, but EGFR expression is not predictive for anti-EGFR drug efficacy. Signalling occurs across ErbB receptors and EGFR may mediate oncogenesis by dimerization with other receptors, including HER3. Therefore, we here explore HER3 mRNA expression as a biomarker of prognosis and predictor of Pan benefit in a randomized trial in aCRC. **Methods:** HER3 expression, *KRAS*, *NRAS* and *BRAF* mutations were assessed in tumor from 308 patients (pts) randomized to 2nd-line irinotecan (Ir) or IrPan (PICCOLO, *Lancet Onc* 14:749-59). Prognostic analysis was in all Ir alone pts. Predictive analysis, in the 208 *RAS*-wt pts, compared baseline values with outcomes using Cox proportional hazards models. HER3 was treated first as a continuous variable; an exploratory binary model of high *vs* low expression was also tested. **Results:** Higher HER3 was significantly prognostic for OS (HR [per 2-fold change] = 0.91 [0.83-0.99], p = 0.04), but not PFS (HR = 0.93 [0.83-1.05], p = 0.25). Higher HER3 was associated with PFS benefit in IrPan-treated pts (HR = 0.71 [0.61-0.82], p $<$ 0.001), but not Ir-treated pts (HR = 0.96 [0.82-1.13], p = 0.65). There was a strong biomarker/treatment interaction (p = 0.001), which remained after adjustment for *BRAF* status and primary tumor location; this was also seen for OS (interaction p = 0.004). HER3 status (above/below 66th centile) was not prognostic for OS (p = 0.35) or PFS (p = 0.86). However, it was predictive of Pan benefit: in *RAS*-wt pts with high HER3, median PFS was 8.2 mo (IrPan) vs 4.4 mo (Ir) (HR = 0.33 [0.19-0.58], p $<$ 0.001); but pts with low HER3 had no benefit: 3.3 mo (IrPan) vs 4.3 mo (Ir) (HR = 0.96 [0.67-1.38], p = 0.84); interaction p = 0.002. A predictive effect was also seen for OS (interaction p = 0.01). **Conclusions:** Among *RAS*-wt pts, HER3 hold promise as a predictive biomarker for Pan benefit. High HER3 identified 1/3rd who gained markedly from Pan, *vs* 2/3^{rds} who did not benefit, with statistically significant biomarker/treatment interactions for PFS and OS. This finding is of potential clinical utility, and deserves further study to confirm.

3584 Poster Session (Board #77), Mon, 8:00 AM-11:30 AM

DYPD genotyping to predict toxicity in patients with stage III colon cancer treated with 5-fluorouracil-based adjuvant chemotherapy in the PETACC-8 phase III trial. *First Author: Valérie Boige, Service de Gastro-Enterologie, Institut Gustave Roussy, Villejuif, France*

Background: Previous pharmacogenetic studies have shown the prognostic impact of several rare dihydropyrimidine dehydrogenase gene (DPYD) variants on 5-FU-related toxicity. However, conflicting results highlight the need for prospective validation in large homogeneous patient populations uniformly treated with current standard combination therapies used in colon cancer (CC). **Methods:** We genotyped 1545 patients with resected stage III CC treated in the PETACC-8 randomized phase III trial with adjuvant FOLFOX-4 alone or combined with cetuximab, and tested the individual associations between 25 DPYD variants and 5FU-related adverse events (5FUAEs). Logistic regressions were used to assess univariate and multivariable associations. **Results:** The incidence of grade $\geq$ 3 5FUAEs in D949V and V732I (DPYD*6) carriers were 18/21 (85.7%) and 121/199 (60.8%), respectively. After adjusting for multiple variables, statistically significant associations were identified between grade $\geq$ 3 5FU-AEs and both D949V (OR = 6.3; 95% CI = 0.037-0.49; p = 0.0007) and V732I variants (OR = 6.3; 95% CI = 0.037-0.49; p = 0.0004). Both SNPs were significantly associated with grade $\geq$ 3 overall hematologic toxicity (p = 0.0006 and 0.00002, respectively), and V732I with grade $\geq$ 3 neutropenia (0.0002). The association for D949V and V732I with the occurrence of grade $\geq$ 3 hematologic toxicity was validated in an independent cohort of 339 patients with metastatic colorectal cancer receiving FOLFOX in the FFCD2000-05 phase III trial (p = 0.02 and p = 0.001, respectively). **Conclusions:** In this large phase III study, statistically significant associations were found between DPYD variants (D949V and V732I) and increased incidence of grade 3 or greater 5FU-AEs in patients treated with adjuvant 5-FU-based combination chemotherapy.

3585 Poster Session (Board #78), Mon, 8:00 AM-11:30 AM

Outcomes for FOLFIRI plus bevacizumab (BEV) or cetuximab (CET) in patients previously treated with oxaliplatin-based adjuvant therapy: A combined analysis of data from FIRE-3 and CALGB 80405. *First Author: Volker Heinemann, Department of Internal Medicine III and Comprehensive Cancer Center, Klinikum Grosshadern, Ludwig-Maximilians University of Munich, Munich, Germany*

Background: mCRC previously treated with adjuvant therapy may differ biologically from untreated mCRC. This study examines outcomes for BEV vs. CET in the patients on FIRE-3 and C80405 who previously received adjuvant oxaliplatin (OX). **Methods:** In both studies, pts with KRAS wt (codons 12 and 13) mCRC and performance status 0-1 were treated with standard chemotherapy and randomized to either CET 400 mg/m2 X 1, then 250 mg/m2 qw or BEV 5 mg/kg q2w. Rx continued until progression, death, unacceptable toxicity, or surgery with curative intent. Patients previously treated with adjuvant oxaliplatin ($<$ 12 months prior to enrollment in 80405, $<$ 6 months prior for FIRE-3) were identified for this analysis. **Results:** 125 patients received adjuvant OX (67 from 80405 and 58 from FIRE-3); 56 were randomized to BEV and 69 to CET. Baseline demographics were similar for both treatment groups and similar between patients enrolled in FIRE-3 vs. 80405. All received FOLFIRI as the chemotherapy regimen. In the combined analysis, CR + PR in the CET arm vs. BEV was 58% vs 42%, respectively (chi square p = 0.08). PFS was 11.3 mos for BEV and 10.2 mos for CET (HR 1.2, p = 0.24) with 117 PFS events. Median OS for BEV was 41.0 mo vs. 28.5 mo for CET (HR 1.4, p = 0.18) with 79 OS events. **Conclusions:** No significant difference in OS by biologic was found in this unplanned subset analysis. Patients with prior OX exposure had very good overall outcomes with both biologics.

3586 Poster Session (Board #79), Mon, 8:00 AM-11:30 AM

Final results from ASPECCT: Randomized phase 3 non-inferiority study of panitumumab (pmab) vs cetuximab (cmab) in chemorefractory wild-type (WT) *KRAS* exon 2 metastatic colorectal cancer (mCRC). *First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Adelaide, Australia*

Background: The primary analysis of ASPECCT demonstrated that pmab was non-inferior to cmab for overall survival (OS) in chemorefractory WT *KRAS*mCRC. Here, we report the final analysis of ASPECCT. **Methods:** In ASPECCT, patients (pts) had WT *KRAS*mCRC, ECOG performance status (PS) $\leq$2, prior irinotecan, oxaliplatin, and fluorouracil treatment, and no prior anti-EGFR therapy. Pts were stratified by geographic region (North America/Western Europe/Australia vs rest of world) and ECOG PS (0-1 vs 2) and randomized 1:1 to receive pmab 6 mg/kg q2w or cmab 400 mg/m2 followed by 250 mg/m2 qw. The primary endpoint was OS assessed for non-inferiority (retention of $\geq$50% of the cmab effect vs best supportive care [BSC]; HR=0.55 [95% CI: 0.41 - 0.74] based on NCIC CTG C0.17). Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), and safety. All pts were followed for survival for up to 2 years after the last pt was randomized and a final analysis of efficacy and safety was conducted. No formal hypothesis testing was performed. **Results:** 999 pts were randomized and treated: 499 pmab and 500 cmab. 90% of pts had died at the time of this analysis (78% in the previously reported primary analysis). Baseline demographics and disease characteristics were similar between arms. Non-inferiority results for OS are shown (Table). Overall, any grade and grade 3-4 adverse events (AEs) were similar between arms. AEs of interest were (pmab vs cmab): grade 3-4 skin toxicity 13% vs 10%, grade 3-4 infusion reactions 0.5% vs 2%, and grade 3-4 hypomagnesemia 7% vs 3%. **Conclusions:** Consistent with the primary analysis, the final analysis of ASPECCT showed that pmab was non-inferior to cmab for OS in chemorefractory WT *KRAS*mCRC. Safety profiles were as expected for pmab and cmab. Clinical trial information: NCT01001377.

	Pmab N = 499	Cmab N = 500
Median OS, mos (95% CI)	10.2 (9.4-11.4)	9.9 (9.0-10.8)
HR (95% CI)	0.94 (0.82-1.07)	
***P* value**	0.0002	
OS retention rate*	1.11 (0.88-1.33)	
Median PFS, mos (95% CI)	4.2 (3.2-4.8)	4.4 (3.2-4.8)
HR (95% CI)	0.98 (0.87-1.12)	
ORR,% (95% CI)	21.6 (18.1-25.5)	19.2 (15.8-22.9)

3587 Poster Session (Board #80), Mon, 8:00 AM-11:30 AM

Randomized phase 3 study of panitumumab (pmab) vs cetuximab (cmab) in chemorefractory wild-type (WT) *KRAS* exon 2 metastatic colorectal cancer (mCRC): outcomes by hypomagnesemia (hypomag) in ASPECCT. *First Author: Marc Peeters, Antwerp University Hospital and University of Antwerp, Edegem, Belgium*

Background: ASPECCT met its primary endpoint of non-inferiority of overall survival (OS) of pmab vs cmab. We evaluate outcomes by hypomag, an on-treatment, anti-EGFR related adverse event that develops due to the inhibition of EGFR function. Conflicting reports have suggested hypomag is associated with survival. **Methods:** Patients (pts) with previously treated WT *KRAS* exon 2 mCRC were randomized 1:1 to receive pmab or cmab. The primary endpoint was non-inferiority of OS. Progression-free survival (PFS) and objective response rate (ORR) were secondary endpoints. Pts were categorized $\pm$ any grade hypomag during the study and data from the primary analysis was evaluated by treatment arm. Analysis of Mg supplementation during hypomag was not conducted. **Results:** 999 pts were randomized and treated: 499 pmab, 500 cmab. Any grade hypomag was 28.8% and grade $\geq$3 was 7.3% in the pmab arm vs 18.9% and 2.6% in the cmab arm, respectively. Median time to first hypomag onset was 82 days in the pmab arm and 57 days in the cmab arm. In the pmab arm, 1.0% of pts discontinued treatment and 5% of pts had dose modifications due to hypomag vs $<$0.5% and 3% in the cmab arm, respectively. Results are shown (Table). **Conclusions:** In ASPECCT, rates of hypomag were higher in the pmab vs the cmab arm. Pts who developed any grade hypomag with pmab or cmab had higher ORR, PFS, and OS compared with those pts who did not. Clinical trial information: NCT01001377.

Pmab Arm	Hypomag – Yes (n = 143)	Hypomag – No (n = 353)	HR (95% CI)
Median OS - mos (95% CI)	13.8 (11.6 – 15.5)	8.7 (8.1 – 9.8)	0.61 (0.48 – 0.77)

3588 Poster Session (Board #81), Mon, 8:00 AM-11:30 AM

A single arm phase II study of neoadjuvant transarterial regional therapy (TACE) using preloaded Irinotecan Beads in patients with resectable colorectal liver metastases (CRLM). *First Author: Robert Peter Jones, University of Liverpool, Liverpool, United Kingdom*

Background: Perioperative chemotherapy confers 3-year progression free survival advantage following CRLM resection. Good pathologic response is associated with improved overall survival. Chemoembolisation using DEBIRI gives sustained delivery of drug directly to tumor, thereby maximising response and reducing systemic exposure. This study examined the safety and feasibility of neoadjuvant DEBIRI before CRLM resection and subsequent early disease free survival (DFS). **Methods:** Patients with resectable CRLM received segmental DEBIRI (median dose 100 mg Irinotecan, range 25-200) 1 month before surgery, with radiological endpoint of near stasis during the procedure. Primary study end-point: tumor resectability. Secondary end-points: safety; radiologic response (RECIST); pathologic tumor response; disease-free survival. **Results:** 40 patients received DEBIRI-TACE. All proceeded to surgery, 38 underwent hepatectomy (2 peritoneal disease, resectability rate 95%). 30-day post-operative mortality 5% (n = 2), neither death TACE related (1 intraoperative pneumomediastinum, 1 aspiration pneumonia). 66 lesions (median 2 per patient) resected. RECIST at 1 month demonstrated 60% stable disease/partial response (24/40). Histologic major or complete pathologic response in 77.3% of targeted lesions (51/66). Correlation between radiologic and histologic response was poor. At 12-month follow-up, 18/40 (45.0%) of patients had disease recurrence (56% intrahepatic, 44% extrahepatic) (55% 1 year DFS). 2 patients died of recurrent disease (95% 1 year overall survival). **Conclusions:** Resection after neoadjuvant DEBIRI-TACE for CRLM is feasible and safe. Single treatment with DEBIRI-TACE resulted in tumor pathologic response and 1 year DFS similar to that seen after neoadjuvant systemic chemotherapy. RECIST at 1 month did not correlate with pathologic response or 1 year DFS. Clinical trial information: NCT00844233.

3589 Poster Session (Board #82), Mon, 8:00 AM-11:30 AM

Treatment until progression: Data of the "on-treatment" population of the FIRE-3 (AIO KRK-0306) study. *First Author: Sebastian Stintzing, Department of Hematology and Oncology, Klinikum Grosshadern and Comprehensive Cancer Center, University Hospital Grosshadern, LMU Munich, Munich, Germany*

Background: The FIRE-3 study (AIO KRK-0306) was designed as a randomized multicenter trial to compare the efficacy of FOLFIRI plus cetuximab (cet) to FOLFIRI plus bevacizumab (bev) as first-line treatment in KRAS WT mCRC patients. FOLFIRI plus cet as first-line treatment of KRAS WT mCRC patients resulted in comparable overall response rates (ORR) and progression free survival (PFS) when compared to FOLFIRI plus bev. Overall survival (OS) was significantly longer in the FOLFIRI plus cet arm. **Methods:** In this exploratory analysis outcome parameters were calculated in dependence of progression during antibody treatment. As reported before by Saltz et al. (ASCO GI 2007) an "on study treatment" population was defined using all RAS wild-type pts that were treated until progression or death occurred. To exclude early progressing patients the analysis was also performed in patients with a PFS >6 months. **Results:** See Table. **Conclusions:** In general, patients progressing during 1st-line treatment had a shorter PFS and OS than patients that had progressed after stop of treatment for any cause. Patients that discontinued treatment for other reasons than progression had a significantly longer median OS when treated with FOLFIRI plus cetuximab in first-line when compared to FOLFIRI plus bevacizumab. This effect was also seen after exclusion of early progressors (PFS <6 mo).

All patients		Median PFS (95% CI)	p	Median OS (95% CI)	p
PFS event during treatment	FOLFIRI + Cet (n= 72)	7.6 (6.1-9.7)	0.94	22.6 (17.3-27.9)	0.50
	FOLFIRI + Bev (n= 74)	7.4 (6.0-9.0)		20.8 (15.5-23.7)	
PFS event after treatment	FOLFIRI + Cet (n= 106)	10.8 (10.0-13.3)	0.59	38.3 (27.1-45.0)	0.01
	FOLFIRI + Bev (n= 111)	11.7 (10.3-13.1)		28.2 (24.8-33.3)	
Patients PFS >6months		**Median PFS (95% CI)**	**p**	**Median OS (95% CI)**	**p**
PFS event during treatment	FOLFIRI + Cet (n= 46)	11.0 (8.8-12.2)	0.85	27.9 (23.6-33.8)	0.85
	FOLFIRI + Bev (n= 46)	9.9 (9.0-11.7)		26.1 (23.1-31.5)	
PFS event after treatment	FOLFIRI + Cet (n= 91)	12.4 (10.5-14.1)	0.35	38.7 (36.4-49.8)	0.002
	FOLFIRI + Bev (n= 100)	12.4 (11.1-13.4)		28.8 (25.6-35.0)	

3590 Poster Session (Board #83), Mon, 8:00 AM-11:30 AM

Influence of molecular alterations on site-specific (ss) time to recurrence (TTR) following adjuvant therapy in resected colon cancer (CC) (Alliance Trial N0147). *First Author: Ryan Eldredge Wilcox, Mayo Clinic, Rochester, MN*

Background: Influence of tumor molecular alterations on ssTTR after resection of stage 3 CC has not been well studied. Phase 3 trial N0147 (adjuvant FOLFOX +/- cetuximab) provided an opportunity to assess possible correlations. **Methods:** 3098 stage 3 CC pts were enrolled and sites of all recurrences were reviewed centrally: liver, lung, peritoneal, local (< 5 cm of anastomosis), regional, and other metastatic. Genetic markers include MMR, mutations (mut) in *KRAS* exon 2 (codons 12, 13), *BRAF* V600E exon 15. Cumulative incidence rate (CIR) was estimated for ss recurrences. Associations between biomarkers and TTR across sites (interaction) were assessed by a frailty Cox model. Association between biomarker and ssTTR were evaluated by multivariable Cox model when the site-biomarker interaction effect presents, adjusting for age, T/N stage, type of surgery, tumor sidedness, and treatment. **Results:** Most common recur sites were liver, regional, peritoneal, and lung, with 3 yr CIR of 8.4%, 8.3%, 5.5% and 5.4%, respectively, with no difference between treatment arms (p = 0.9). Interactions between sites of recurrence and *BRAF* (p = .006) or MMR (p = .018) status were significant and marginal for combined *KRAS/BRAF (p = .10)*. Compared to wild type (wt) pts, *BRAF* mut pts had shorter TTR for peritoneal HR2.14; 95% CI, 1.36-3.37; p_{adj}= .001] and metastatic sites [HR, 1.19; 95 CI, 1.07-3.42; p_{adj}= .033], but not for liver or lung. *KRAS* mut/*BRAF* wt pts had shorter TTR for liver (HR, 1.55; 95% CI, 1.19-2.03) and lung (HR, 1.81, 95% CI, 1.32-2.50), and *KRAS* wt/*BRAF* mut pts had shorter TTR for peritoneal (HR, 2.14; 95% CI, 1.36-3.37) compared to double wt pts. dMMR pts had longer TTR for liver (HR, 0.44; 95% CI, 0.25-0.78; p_{adj}= .002) and peritoneal (HR, 0.46; 95% CI, 0.25-0.82; p_{adj}= .004) compared to pMMR pts. **Conclusions:** Status of MMR and *BRAF*, but not *KRAS* (alone), influences site of recurrence and TTR. Accordingly, these biomarkers may assist in treatment and follow-up approaches. Clinical trial information: NCT00079274.

3591 Poster Session (Board #84), Mon, 8:00 AM-11:30 AM

Patients' and physicians' risk-benefit trade-off preferences for metastatic colorectacl cancer treatments. *First Author: Juan Marcos Gonzalez, RTI Health Solutions, Durham, NC*

Background: Preferences for treatment-related benefits and risks associated with metastatic colorectal cancer (mCRC) therapies may vary between patients and physicians. **Methods:** A literature review and clinician interviews were carried out to develop risk-benefit profiles. PFS and probabilistic adverse outcomes were described in an online discrete-choice experiment completed by patients and physicians. Participants assessed a series of 10 choices between pairs of hypothetical medication profiles . Each profile included attributes within a pre-determined range: PFS (12 months, 8 months, 6 months), severe papulopustular rash (PR) (0%, 5%, 10%, 25%), serious hemorrhage (0%, 2%, 10%, 35%), cardiopulmonary arrest (0%, 2%, 10%, 20%), and gastrointestinal perforations (0%, 2%, 10%, 20%). Choice questions were based on an experimental design with known statistical properties. Random-parameter choice models produced preference weights indicating the strength of trade-off. These weights were used to calculate the maximum acceptable risk of different adverse events associated with various mCRC therapies. **Results:** A total of 127 patients and 150 physicians completed the discrete-choice survey. The mean maximum level of treatment-related risk patients were willing to accept for a 4-month increase in PFS from 8 to 12 months was 16.7% (0.0%-82.9%) for PR, 13.8% (4.6%-23.2%) for gastrointestinal perforation, 10.3% (3.3%-17.1%) for serious hemorrhage and 5.1% (1.7%-8.7%) for cardiopulmonary arrest. For the same PFS improvement, physicians were willing to accept a risk of severe PR that exceeded 25% and more than 20% risk for gastrointestinal perforation, which were the maximum levels shown in the survey for each of these treatment-related adverse events. Physicians were also willing to accept 18.9% (12.3%-24.5%) risk for serious hemorrhage and 7.0% (3.0%-10.8%) for cardiopulmonary arrest for the same 4-month PFS improvement. **Conclusions:** The benefit-risk tradeoff data obtained in this study show potential risk-tolerance differences between patients and oncologists, highlighting the importance of understanding preferences from the patient's perspective when making treatment decisions.

3592 Poster Session (Board #85), Mon, 8:00 AM-11:30 AM

Phase II trial of preoperative radiation with concurrent capecitabine, oxaliplatin, and bevacizumab followed by surgery and postoperative 5-fluorouracil, leucovorin, oxaliplatin (FOLFOX), and bevacizumab in patients with locally advanced rectal cancer: 5-year clinical outcomes of a trial of the ECOG-ACRIN Cancer Research Group (E3204). *First Author: Jerome Carl Landry, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: As previously reported, the regimen of preoperative capecitabine, oxaliplatin, and bevacizumab with radiation therapy (RT) followed by surgery and postoperative 5-FU, leucovorin, oxaliplatin (FOLFOX) andbevacizumabfor locally advanced rectal cancer did not improve pathologic complete response (path CR) rates. However, the effect of an intensified adjuvant regimen is not reflected in path CR. The purpose of this report is to describe the 5-year oncologic outcomes of this regimen. **Methods:** Fifty-seven patients (pts) with resectable T3/T4 rectal adenocarcinoma were enrolled. Preoperative treatment: capecitabine (825 mg/m² bid M-F), oxaliplatin (50 mg/m² weekly), bevacizumab (5 mg/kg D1,15,29), and RT (50.4 Gy). Surgery was performed by 8 weeks after neoadjuvant therapy. Beginning 8 – 12 weeks after surgery, patients received FOLFOX plus bevacizumab (5 mg/kg) Q2 weeks for 12 cycles. **Results:** Fifty-three of 57 enrolled pts were eligible and included in the analysis. Most patients were clinical (c)T3 (92%) and cN positive (64%). Of the 48 patients who underwent curative surgery, 26 (54%) began adjuvant chemotherapy. After a median follow-up period of 41 months, the 5-year overall survival (OS) rate for all patients was 80% (90% confidence interval (CI) [67%, 92%]). Only 2 patients experienced cancer recurrence, 1 distant and 1 locoregional, respectively. The 5-year recurrence free survival rate (RFS) was 81% (90% CI [68%, 94%]). **Conclusions:** Despite the path CR primary endpoint of this trial not being reached, the 5-year OS and RFS rates were excellent. However, as previously reported, the neoadjuvant and surgical toxicity of this regimen was significant and was the primary reason for the low compliance with adjuvant systemic therapy. Due to the lack of an improvement in the path CR rate, the substantial associated toxicity, and negative phase III trials of adjuvant bevacizumab in colon cancer, this regimen cannot be recommended for further study. Clinical trial information: NCT00321685.

3593 Poster Session (Board #86), Mon, 8:00 AM-11:30 AM

Time-dependent patterns of recurrence and death in resected colon cancer (CC): Pooled analysis of 12,223 patients from modern trials in the ACCENT database containing oxaliplatin. *First Author: Lindsay A. Renfro, Mayo Clinic, Rochester, MN*

Background: A 2009 analysis of 20,898 CC patients from 18 randomized studies of adjuvant therapy (AT) in the ACCENT database showed that treatment with AT (versus surgery alone) lowers the risk of recurrence and death at all time points, especially in stage III (versus stage II) disease. However, this analysis evaluated only FU/LV therapies and excluded modern oxaliplatin-based (OX) therapies. **Methods:** With mature follow-up now available (median 6 years), 12,233 patients from ACCENT enrolled to C-07, C-08, N0147, MOSAIC, and XELOXA (18% stage II, 82% stage III) were pooled to examine the impact of OX and tumor specific factors (tumor stage, nodal stage, tumor location, and tumor grade) on the time course of recurrence and death from all causes. For each endpoint, continuous-time risk was modeled over 8 years post-treatment in (1) OX-treated patients from all trials and (2) patients concurrently randomized to OX versus 5FU/LV, where the latter set of analyses supported time-dependent treatment comparisons. **Results:** Addition of OX reduced the risk of recurrence and death at all time points and in all disease subgroups, with no differences in the timing of outcomes between treatment groups (i.e., OX did not simply postpone recurrence or death compared to 5FU/LV alone; see Table). OX significantly reduced recurrence risk during the first 4 years, and significantly reduced risk of death from 2 to 6 years post-treatment. Recurrence risk peaked near 14 months for both treatment groups, with 83% of patients treated with OX (80% of patients treated with 5FU/LV) who recurred within 8 years doing so by 3 years post-treatment. Risk of recurrence and death increased with increased tumor and nodal burden. **Conclusions:** These analyses support the addition of oxaliplatin to fluoropyrimidines as a curative therapy in the adjuvant setting and strongly underscore the need for adequate surveillance of CC patients, especially during the first 3 years after adjuvant therapy.

		Year 1	Year 2	Year 3	Year 4	Year 5
Recur	5FU	11.0%	10.5%	5.2%	3.4%	2.0%
	OX	8.6%	8.8%	4.7%	2.2%	1.9%
Death	5FU	2.9%	5.4%	5.4%	4.9%	3.8%
	OX	2.8%	5.3%	4.3%	4.5%	3.2%

3594 Poster Session (Board #87), Mon, 8:00 AM-11:30 AM

Monitoring minimal residual disease (MRD) by *KRAS* mutation burden in urinary or plasma circulating tumor (ct) DNA in colorectal cancer (CRC) patients with resectable liver metastases. *First Author: Cecile Rose T. Vibat, Trovagene, San Diego, CA*

Background: Over half of patients with CRC will develop liver metastases. Surgical resection greatly improves outcomes in these patients. Non-invasive markers are needed to better monitor treatment responses and guide complex treatment decisions. This study evaluated the utility of quantifying *KRAS* mutation burden in urine and plasma ctDNA for monitoring MRD in surgical CRC patients with liver metastases. **Methods:** A blinded retrospective ctDNA analysis was conducted in 20 Stage I-IV CRC patients with *KRAS* positive primary tumor, 16 of whom had undergone curative or palliative intent surgical resection of primary tumor or liver metastases in combination with various systemic therapies. Urine and plasma specimens were collected prior, during, immediately after surgery, and at additional time points post-surgery. 193 matched urine and plasma specimens (archived 3-5 years) were tested using a novel, NGS-based method for quantitative detection of *KRAS* mutations in ctDNA. **Results:** In a blinded analysis, a *KRAS* mutation that correlated with *KRAS* mutation in tissue was identified in 95% of evaluable baseline plasmas (19 of 20) and 92% of evaluable baseline urines (11 of 12). 12 of 12 (100%) matched urine and plasma pairs at baseline were concordant (11 KRAS positive and 1 KRAS negative). Analysis of 193 archival longitudinal urine and plasma samples demonstrated a clear correlation and highly comparable fold change between plasma and urinary ctDNA *KRAS* levels on treatment. Significantly, in 5 of 5 patients with curative intent surgery, urine or plasma ctDNA *KRAS* levels were undetectable at 7 days post-surgery. In contrast, ctDNA *KRAS* remained detectable or increased after surgery in 10 of 11 patients with incomplete, palliative surgery. **Conclusions:** We demonstrate for the first time a clear correlation between the dynamics of urine and plasma *KRAS* ctDNA changes, and clinical applicability of ctDNA for assessing post-surgery MRD in CRC patients. A prognostic significance of post-surgical *KRAS* levels and the overall survival in Stage IV CRC patients with liver metastases is being evaluated in a larger cohort. Supported by IGA MZ Grant 13660.

3595 Poster Session (Board #88), Mon, 8:00 AM-11:30 AM

TAS-102 vs placebo (PBO) in patients (pts) ≥65 years (y) with metastatic colorectal cancer (mCRC): An age-based analysis of the RECOURSE trial. *First Author: Eric Van Cutsem, University Hospitals Leuven, Leuven, Belgium*

Background: TAS-102 is comprised of an antineoplastic thymidine-based nucleoside analog, trifluridine, and the thymidine phosphorylase inhibitor, tipiracil hydrochloride, at a molar ratio of 1:0.5 (weight ratio, 1:0.471). Efficacy and safety of TAS-102 in pts with mCRC refractory to standard therapies were evaluated in the RECOURSE trial; enrollment criteria included ≥ 2 prior lines of standard chemotherapy. Primary results of RECOURSE demonstrated a significant improvement in overall survival (OS) (TAS-102 7.1 mo vs PBO 5.3 mo; HR=0.68; $P<0.0001$) and progression-free survival (PFS) (HR=0.48; $P<0.0001$). **Methods:** This prespecified analysis compared the efficacy and safety of TAS-102 vs PBO in pts ≥ 65 y and < 65 y with mCRC. A retrospective analysis of pts ≥ 75 y was also performed. **Results:** Of 800 randomized pts, 352 (44.0%) were ≥ 65 y and 60 (7.5%) were ≥ 75 y. Median OS in pts ≥ 65 y was 7.0 mo with TAS-102 vs 4.6 mo with PBO (HR=0.62, 95% CI: 0.48-0.80, $P=0.0002$). PFS HR was 0.41 (95% CI: 0.32-0.52, $P<0.0001$) for pts ≥ 65 y, also favoring TAS-102. In pts ≥ 65 y, disease control rate (complete or partial response or stable disease) was 48.7% with TAS-102 vs 15.5% with PBO. An age-related difference in overall incidence of adverse events (AEs) was not observed in either treatment arm. Treatment-related AEs, ≥ Grade 3 AEs, and severe AEs were generally more common in pts ≥ 65 y than in pts < 65 y (Table). Mean drug exposure was similar among pts ≥ 65 y and ≥ 75 y, as was overall safety profile. **Conclusions:** Significant improvements in OS and PFS were observed in pts ≥ 65 y who received TAS-102 vs PBO, with a mild increase in toxicity. Pts ≥ 65 y and < 65 y showed a generally favorable safety profile. A significant increase in toxicity in pts ≥ 75 y was not apparent vs the overall ≥ 65 y population. Clinical trial information: NCT01607957.

Phase I study of ganetespib (G), capecitabine (C), and radiation (RT) in rectal cancer. *First Author: Bassel F. El-Rayes, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Ganetespib (G) is a heat shock protein 90 inhibitor . Preclinical data show that G is a potent radiosensitizer for rectal cancer. The aim of this study is to determine the recommended phase II dose of G when combined with capecitabine (C) and radiation (RT) in resectable rectal cancer. **Methods:** Patients (pts) with stage II or III rectal adenocarcinoma with distal border within 12 cm of anal verge, no prior therapy, and adequate organ functions, were eligible. A 3+3 dose escalation design was used. Pts received 2 weeks of G at 150 mg/m^2 I.V. on days -14, -11, -7, and -4. Pre and post-treatment tumor biopsies were obtained. C (825 mg/m^2) and RT (50.4Gy) were administered 5 days per week for 5.5 to 6 weeks starting day 1. G was administered on days 1, 8, 15, 29 and 36. G dose levels were 60, 80, 100, and 120 mg/m^2. Pharmacokinetic sampling for C and G were performed on days 1, 2, 15, and 16. Dose limiting toxicities (DLT) were defined as the occurrence of any treatment related: grade (gr) 4 hematologic or gr 3 or higher non-hematologic toxicities, gr 3 nausea, vomiting or diarrhea lasting > 4 days, any interruption of RT > 10 days, more than 2 interruptions in RT, delay in completion of RT for > 14 days, or inability to deliver more than 85% of planned RT dose. **Results:** 16 pts were enrolled in the study; 1 pt received only day-14 and was not .evaluable for toxicity. Evaluable pts had a median age of 61 yrs, 7 females, and endoscopic stage: T3N0 (6 pts), T3N1 (6), T3N2 (2), T4N1 (1); 3 pts were treated on each dose level, 2 pts on dose level 4 required dose reduction, so we enrolled 3 additional pts on level 3 (100 mg/m^2). One DLT was observed (gr 3 diarrhea for more than 4 days). Other toxicities on the study were: diarrhea gr 3 (3 pts), gr 2 (6), gr 1 (2), radiation dermatitis gr 2 (9), gr 1 (3), fatigue gr 2 (5), gr 1 (4), hand foot syndrome gr 2 (1), mucositis gr 1 (2), and nausea/vomiting gr 2 (2), gr 1 (8). 12 pts have completed surgical resection (2 APR and 10 LAR). Pathologic complete response (pCR) rate was 25% (3/12) and 2 pts had residual tumors less than 1 cm (pT1N0). Six of 9 (67%) pts had clearing of lymph nodes disease on pathologic specimen. **Conclusions:** G can be safely combined with standard C and RT in the neoadjuvant setting in rectal cancer. Preliminary data on activity appear promising. Clinical trial information: 01554969.

3597 Poster Session (Board #90), Mon, 8:00 AM-11:30 AM

Therapeutic biomarker differences between MSI-H and MSS colorectal cancers. *First Author: Zoran Gatalica, Caris Life Sciences, Phoenix, AZ*

Background: Approximately 15% of colorectal cancers (CRC) display high level of microsatellite instability (MSI-H) due to either hereditary predisposition (Lynch syndrome, LS) or somatic hypermethylation of MLH1. They carry a significantly different prognosis and responses to treatments compared with microsatellite stable (MSS) or low microsatellite instability (MSI-L) CRC. We investigated therapeutically important biomarkers, which may underlie different treatment options for CRC. **Methods:** Sixty-four MSI-H (including 20 confirmed LS cases), 9 MSI-L and 558 MSS cases were profiled at Caris Life Sciences (Phoenix, AZ) using immunohistochemistry and sequencing (NextGen and Sanger). **Results:** Compared with non-MSI-H, MSI-H tumors had significantly higher expression of Thymidylate Synthase (TS) (85% vs. 31%), PTEN (71% vs. 48%) expressions and significantly higher mutation rates of *BRAF* (35% vs. 5%), *CTNNB1* (10% vs. 0.7%), *HNF1A* (32% vs. 0.2%), *BRCA1* (19% vs. 5%) and *BRCA2* (50% vs. 14%). MSI-H cancers were also significantly more often infiltrated with PD-1+ lymphocytes (71% vs. 43%). Features found specific to sporadic MSI-H tumors (defined as MSI-H and *BRAF V600E*) in comparison with non-MSI-H tumors included higher mutation rates on select genes within the PI3K/AKT/mTOR pathway, including *FBXW7* (31% vs. 7%), *PTEN* (19% vs. 3%) and *STK11* (18% vs. 1%). 20 confirmed LS cases also exhibited significantly higher TS (100%) expression, *CTNNB1* (10%) and *HNF1A* (40%) mutations than non-MSI-H and lower *FBXW7* (10% vs. 31%), *PTEN* (10% vs. 19%) and *STK11* (0% vs. 18%) mutation rates than sporadic MSI-H tumors (all $p < 0.02$). **Conclusions:** Significantly higher TS expression is a characteristic of both sporadic MSI-H and Lynch tumors, potentially explaining the observed reduced clinical benefit from 5-FU. Higher PD-1+ TIL, *BRCA1/2* and *CTNNB1* mutations suggest MSI-H as a more promising group for targeted immunotherapy, PARP and Wnt pathway inhibitors. Different molecular features of sporadic MSI-H and Lynch subgroups including PI3K/AKT/mTOR offer insight into targeted therapies for these subgroups of CRC.

3598 Poster Session (Board #91), Mon, 8:00 AM-11:30 AM

Measuring the impact of Next Generation Sequencing (NGS) technique implementation in metastatic colorectal cancer (mCRC) drug development program. *First Author: Carolina Ortiz, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Molecular screening and biomarker enrichment strategies in mCRC trials may impact patient (pt)´s outcome. The introduction of NGS technologies in clinical investigation may enhance pt inclusion through the discovery of a wider set of mutations (mt) in oncogenes and tumor suppressor genes. **Methods:** From March/2012 to December/2014 411 pts with chemorefractory mCRC underwent genetic tumor profiling as part of the molecular enhancement strategy in our early drug development program. Base extension chemistry followed by mass detection (MassARRAY, Sequenom) (SQ) was used including 268 frequent hotspots in 25 oncogenes with a sensitivity of 10% of mutant alleles. Since June/2014, Amplicon sequencing (NGS) was implemented assessing mt in 59 oncogenes and tumor suppressors with a sensitivity of 3% mutant alleles. **Results:** From March/2012 to Jun/2014 324 pts were screened using SQ, 261 mt were detected: 0.80 mt per patient. A total of 117 pts (36%) resulted wild-type (wt) after the test. Frequency of mt were: 48.77% *KRAS*, 16.67% *PI3KCA,* 7.41% *NRAS*, 7.41% *BRAF*, along with minor events: 2 mt in *AKT1* and 1 mt in *PDGFRA*, *GNAS* and *ERBB2* allowing a total of 89 inclusions on matched targeted therapies (27.47% inclusion rate per total samples). From Jun/2014 to Dec/2014 78 pts were screened with NGS, 5 pts (6%) were wt. A total of 160 mt were detected (1.83 mt per patient): 44.83% *KRAS*, 4.6% *NRAS*, 51.72% *TP53*, 43.68% *APC*, 5.75% *BRAF*, 5% *PI3KCA*, 4.6% *SMAD4*, 3.45% *PTEN* and 1mt in *GNAS*, *AKT2*, *MET*, *STK11*, *FBXW7, JAK3, FGFR1, NOTCH1, MSH6, RNF43, RET* and *NF2* providing 21 inclusions to treatment with targeted therapy (26.4% inclusions per total samples). **Conclusions:** Our results show that NGS techniques allow the identification of a wider spectrum of mts per patient compared to prior generation genomic tests, although this has failed to be translated yet into higher inclusion rates in clinical trials with targeted agents. An enhanced discovery of mutations in tumor suppressor genes, thus far out of therapeutic reach and other factors like recent implementation of NGS and the increasing search for more specific molecular populations can contribute to this fact.

3599 Poster Session (Board #92), Mon, 8:00 AM-11:30 AM

A genome-wide association study (GWAS) of overall survival (OS) in 609 metastatic colorectal cancer (mCRC) patients treated with chemotherapy and biologics in CALGB 80405. *First Author: Federico Innocenti, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Support: U10CA180821, U10CA180882, CA31946, Bristol-Myers Squibb, Genentech, Pfizer **Background:** Irinotecan/5-FU (FOLFIRI) or oxaliplatin/5-FU (FOLFOX), combined with bevacizumab or cetuximab, are first-line treatments for mCRC. We aimed to identify germline variants associated with survival in mCRC patients treated with these regimens. **Methods:** In CALGB 80405, patients with wild-type *KRAS* (codons 12 and 13) mCRC received either FOLFOX (> 80% of patients) or FOLFIRI and were randomized to either cetuximab or bevacizumab. The primary endpoint of the study was OS.DNA was extracted from peripheral blood and genotyped for ~700,000 single-nucleotide polymorphisms (SNPs). The association between SNPs and OS in 609 patients (both arms combined) of European genetic ancestry was tested by a Cox proportional hazards model. **Results:** Median OS in genotyped patients was 29.6 months, and was comparable to that of the parent study (Venook et al., ASCO 2014). The three most significant SNPs associated with OS were in the genes *RDH14* (hazard ratio, HR 1.63, $p < 1.12 \times 10^{-6}$), *TMEM16J* (HR 1.52, $p < 2.03 \times 10^{-6}$), and *AXIN1* (HR 1.40, $p < 4.26 \times 10^{-6}$). Among these genes, the most compelling evidence for a link to the biology of CRC is for *AXIN1*. The AXIN1 protein functions as a negative regulator of WNT signaling by interacting with APC in CRC (Li et al., Cell 2012). In the present GWAS, rs11644916 (G to A) in *AXIN1* is a common germline intronic variant (30% allele frequency). Median OS for patients with the AA, AG or GG genotypes of rs11644916 was 18.4 (95% CI 14.2-27.6), 25.6 (23.6-30.4) or 36.6 (32.9-41.1) months, respectively. Testing of arm and extended RAS analysis as covariates did not alter the association with the rs11644916 in *AXIN1*. **Conclusions:** This is the first, large GWAS ever conducted in mCRC patients treated with standard of care in a randomized phase III trial. A common SNP in the *AXIN1* gene confers worse OS. This study selects *AXIN1* as a new putative determinant of CRC progression. Further replication in additional patient cohorts and functional studies in CRC experimental models are required. Clinical trial information: NCT00265850.

3600 Poster Session (Board #93), Mon, 8:00 AM-11:30 AM

Modified FOLFIRI (Irinotecan 150 mg/m2) compared to FOLFIRI (Irinotecan 180 mg/m2) in Korean patients with gastrointestinal cancer. *First Author: Kyu-Pyo Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: The aim of this study was to investigate the association between initial irinotecan dose and UGT1A1 genotype, dose intensity, response rate, neutropenia and survival in advanced colorectal and gastric patients. **Methods:** This is an update of a prospective pragmatic trial performed UGT1A1 *6 and *28 genotyping in colorectal and gastric cancer patients who received FOLFIRI as 1st or 2nd line palliative chemotherapy. Patients were grouped as "defective" if the patient had a mut/mut genotype for either UGT1A1*6 or *28; and the others (wt/wt, wt/mut) were grouped as "control". Initially safety including Gr ¾ neutropenia, febrile neutropenia and diarrhea was evaluated for the first cycle of FOLFIRI treatment. Patients were comprised of colorectal cancer (1st line, 602; 2nd line, 332) and gastric cancer (1st line, 216; 2nd line, 395). We updated the efficacy analysis which included response rate, progression free survival and overall survival. **Results:** A total of 1,575 patients were enrolled. The initial dose of irinotecan was 180 mg/m^2 and 150 mg/m^2 in 63.9% and 32.5% of the patients. Grade ¾ neutropenia, febrile neutropenia and diarrhea were observed in 28.3%, 2.2% and 1.4% at the 1st cycle and 55.6%, 3.6% and 3.8% during all cycles of FOLFIRI. Although multivariate analysis revealed defective genotype and female gender to be significant associated with Gr ¾ neutropenia ($P < 0.0001$, $P = 0.0125$, $P = 0.0011$), these factors did not have an effect on the PFS (HR 0.988 [0.831-1.174], 1.013 [0.905-1.134]) and OS (HR 0.925 [0.742-1.155], 1.031 [0.899-1.184]). However, when initial dose was compared, HR favored 180 mg/m^2 over 150 mg/m^2 after adjusting for UGT1A1 genotypes, sex and dose intensity of irinotecan for PFS (HR 0.640 [0.559-0.733]) and OS (HR 0.619 [0.522-0.734]). In a subset analysis, colorectal cancer patients who received 1st line FOLFIRI showed a significant benefit for initial usage of 180 mg/m^2 over 150 mg/m^2 in PFS ($P < 0.001$)and OS($P < 0.001$). **Conclusions:** Our findings indicate that lowering the starting dose of irinotecan may be associated with inferior efficacy of FOLFIRI. Clinical trial information: NCT01271582.

3601 Poster Session (Board #94), Mon, 8:00 AM-11:30 AM

Clinical utility of a circulating cell-free DNA assay for clinical trial enrollment in refractory metastatic colorectal cancer patients. *First Author: Van Karlyle Morris, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Circulating cell-free DNA (cfDNA) isolated from the plasma of cancer patients has been shown to accurately reflect the genomic mutation profile of the tumor, and assays are now available for clinical use. However, physician and patient assessment of clinical utility of these assays in patients has not been previously evaluated. **Methods:** Patients (pts) were prospectively consented as part of the Assessment of Targeted Therapies Against Colorectal Cancer (ATTACC) protocol, with collection of 20mL of blood for cfDNA extraction and sequencing on a 54-gene panel in a CLIA-certified lab (Guardant360, Guardant Health). FFPE tissue from prior resections or biopsies underwent 50-gene sequencing (Ion Torrent, Life Technology). Results from both assays were returned to the treating physicians for patient care and clinical trial selection. Follow up surveys and chart reviews assessed clinical utility. **Results:** 120 mCRC pts were enrolled between 6/1/2014 and 1/7/2015, with a median of 3 prior lines of therapy. With cfDNA sequencing, 83% (99/120) of samples had a detectable genomic alteration (including 26% with detectable amplifications in EGFR, MET, or ERBB2), with an average of 4.2 mutations/pt. Sequencing of tissue provided detectable mutations in 88% of cases (106/120), with an average of 2.9 mutations /pt. cfDNA testing provided results within a median of 11 days, 14-days faster than tissue testing. 54% of cfDNA cases had potentially actionable alterations, and 66% of cases could be genomically matched to at least one clinical trial in the institution. 52% of these pts were able to be enrolled in the identified trial, with the remainder limited by eligibility criteria (9%), lack of patient interest (22%), or no current trial openings (17%). Physicians felt that the cfDNA testing improved the quality of care they were able to provide in 75% of the cases, and improved patient satisfaction with the efforts to personalize experimental options in 92% of cases. **Conclusions:** cfDNA sequencing can provide timely information on potentially actionable mutations and amplifications, thereby facilitating clinical trial enrollment and improving the perceived quality of care.

3602 Poster Session (Board #95), Mon, 8:00 AM-11:30 AM

Outcome evolution of matched molecular targeted agents (MTAs) in metastatic colorectal cancer (CRC) patients (pts): VHIO experience. *First Author: Guillem Argilés, Vall d'Hebron Institute of Oncology, VHIO, Barcelona, Spain*

Background: Biomarker-driven selection of new MTAs has not been widely successful in CRC as we reported in 2012. New screening platforms and drugs have reached early drug development. We aimed to evaluate outcome evolution between 2012 and 2014 **Methods:** MTAs given to CRC pts based on molecular tumor profiling (MTP) from Jan/2012 to Dec/2014 were compared to the reported in 2012. MTP included mutations (mt) detected by Sequenom (Sq), VHIO-Card Amplicon panel, cMET amplifications (amp), PTEN and PDL1 expression. Benefit was calculated comparing treatment failure of prior line (TTF1) to the MTAs' one (TTF2). TTF2/TTF1≥1.3 supposed MTAs benefit. Relevant MTAs-biomarker pairs were analyzed. **Results:** A total of 174 MTAs were given. Pairs biomarker-MTAs were: *KRAS*mt: MEK inhibitors (i)+PI3Ki or MEKi + anti-receptor tyrosine kinase (RTK) mAbs; *PIK3CA*mt or PTEN loss: PI3Ki, MTORi, dual PI3K-MTORi, MTORi + anti-RTK mAbs; cMET path activation: METi [mAbs or RTKi]; *BRAF V600*mt: BRAFi, BRAFi + MEKi +/- CDK4i, BRAFi + anti-EGFR mAbs +/- PI3Ki; *RAS* wild-type (wt): 2nd generation anti-EGFR mAbs. Median (m)TTF1 was 21.9 weeks (w) (18.9-24.8), mTTF2 8.3w (7.7-8.9), with 17.2% of pts benefiting from MTA (i.e. TTF2/TTF1≥1.3). Derived benefit was not higher to the reported in 2012 mTTF1 16.3w (14-18.5), mTTF2 7.9w (7.2-8.5) with 14.3% pts benefiting from MTAs (p=0.47). *BRAF V600E* mt pts receiving BRAFi combos was the group with more benefit from MTAs (30%) **Conclusions:** Recent evolution with MTAs in CRC does not widely correlate with better outcome in overall population. However, significant benefit is observed when there is a mechanistic rationale for MTA (*BRAF V600E*). Further CRC molecular subtyping is needed to improve outcomes.

MatchedMTAs	pts	mTTF1 w	mTTF2 w	% clinical benefit
*BRAF V600E*mt(BRAFi combos)	23	21.8 (12-31.7)	10.9 (7.3-14.4)	30.4%
*RAS*mt(MEKi + PI3Ki)	51	18.1 (11.4-24.9)	7.9 (7.1-8.6)	11.8%
*RAS*mt (MEKi + anti-RTKsmAbs)	22	25.4 (21.5-29.4)	6 (4.2-7.8)	18.2%
*RAS*wt (2nd generation anti-EGFR mAbs)	38	21.6 (14.8-28.3)	12.6 (7-18.2)	21.1%
*PIK3CA*mt/PTEN loss (s/a PI3K-path i)	40	15 (10.8-19.3)	8.4 (7.5-9.3)	20%
*PIK3CA*mt/PTEN loss (combos PI3K-path i)	24	24.4 (9.8-39.9)	8 (7.9-8.1)	17.2%

3603 Poster Session (Board #96), Mon, 8:00 AM-11:30 AM

Retrospective study of patients (pts) who were managed with Watch and Wait strategy (W&W) after neoadjuvant chemoradiation (NCRT) for Locally Advanced Rectal Cancer (LARC). *First Author: Sina Vatandoust, Flinders Medical Centre and Flinders Centre for Innovation in Cancer, Flinders University, Adelaide, Australia*

Background: The management of LARC involves NCRT followed by resection +/- adjuvant chemotherapy. Rectal resection has associated short and long-term morbidity and functional compromise. Complete Response (CR) is observed in ~ 20% of cases after NCRT and resection may be avoidable in these pts. We retrospectively report a cohort of pts who received NCRT and have been followed up with 'W&W'. **Methods:** All patients with LARC who had CR to NCRT, and did not proceed to surgery but instead were managed by a surveillance strategy, were identified from clinical records. All pts had received long course NCRT as suggested by multidisciplinary team meeting. CR was defined as the absence of any residual viable cancer, proven through examination, colonoscopy (+ biopsy if indicated) and imaging (including MRI). Pts with metastatic rectal cancer were excluded. Data on demographics, management and outcomes were extracted from records. Follow up included regular 3 monthly physical examination, sigmoidoscopy/colonoscopy (+ biopsy if indicated) and MRI scans. Follow up times were calculated from date of diagnosis of rectal cancer. **Results:** 22 pts achieved a CR and were managed by 'W&W', without surgery. Median follow up 19 (9-49) months (mo), 50% (n = 11) male, median age 62 (34-78), Stage at diagnosis: T2N0 4.5% (n = 1), T2N1 27.3% (n = 6), T3N0 13.6% (n = 3), T3N1 22.7% (n = 5) and T3N2 31.8% (n = 7). 2 pts had other concurrent cancers (1 with metastatic small cell carcinoma and 1 with breast cancer). 2 pts (9.1 %) developed salvageable local recurrences: 1 had local recurrence 11 mo after primary diagnosis and underwent ultra-low anterior resection; the other had recurrence 8 mo after the primary diagnosis and underwent low anterior resection, both with clear margins. Both were detected on follow-up reviews (evident at sigmoidoscopy). Another pt developed metastatic disease 10 mo after the original diagnosis. All 22 pts are alive at the time of this report. **Conclusions:** In this cohort of pts with LARC who had achieved CR to NCRT, W&W did not lead to unsalvageable local recurrence. Prospective study design and longer follow up is needed to confirm the utility of this approach.

3604 Poster Session (Board #97), Mon, 8:00 AM-11:30 AM

Predictors of clonal evolution in metastatic colorectal cancer patients. *First Author: M. Pia Morelli, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Concordance of somatic mutations between primary and metastatic colorectal tumors is high in colorectal cancer (CRC), circulating cell-free DNA (cfDNA) accurately reflects the mutation status of metastatic disease. Intervening treatment and metastatic dissemination may result in clonal evolution from pre-existing intratumoral heterogeneity, with the resulting discordance in minor clones.**Methods:** Patients (pts) were prospectively consented for collection of cfDNA from plasma samples for sequencing on a 54-gene platform optimized for very low allele frequencies (Guardant360), with concurrent sequencing of clinically available and macrodissected historic FFPE tissue (50-gene Ion-Torrent panel), both performed in CLIA-compliant labs. Eligible cases had plasma and tissue sequencing where the modal mutation was present with ≥ 1% and ≥ 5% allele frequencies, respectively. Minor clones were defined as those with an allele frequency < 10% of the highest detected allele frequency in the sample.**Results:** 61 pts were enrolled after a median of two prior lines of therapy for metastatic disease, with plasma collected a median of 12.6 months after FFPE tissue (18 metastatic/44 primary tumor tissue). 213 mutations were detected on both tissue DNA and cfDNA, with at least one mutation detected in all cases; 54% of the mutations were present in both samples, with 32% of the mutations uniquely present in the plasma. Microsatellite instability (P = 0.025), intervening treatment with oxaliplatin (P = 0.04) or cetuximab/panitumumab (P < 0.001), but not irinotecan or bevacizumab, were associated with the detection of new minor clones. There was no association with reference tissue source, time from tissue collection, location nor number of metastatic sites.Minor clones represented 30% of the detected mutations and were concordant for only 11%, in contrast to 84% concordance for major clones (P < 0.0001). .**Conclusions:** Intervening chemotherapy and microsatellite instability results in the appearance of new minor clones in potentially clinically relevant genes in more than half of metastatic CRC pts. Based on this small data set, development of minor clones may be dependent on exposure to specific cytotoxic or molecular drugs.

3605 Poster Session (Board #98), Mon, 8:00 AM-11:30 AM

Prognostic and predictive value of tumour budding in stage II colorectal carcinoma. *First Author: Bojana Mitrovic, Mount Sinai Hospital, Department of Pathology and Laboratory Medicine, Toronto, ON, Canada*

Background: High-grade tumor budding (HGTB) is reported to be an independent adverse prognostic factor in colorectal cancer (CRC). Its presence is not routinely assessed by pathologists due to uncertainties about its clinical value, risk group thresholds, and the reproducibility of its assessment. Moreover, the benefit of chemotherapy in stage II CRC with HGTB remains to be demonstrated. This study aimed to (1) confirm the prognostic significance of HGTB in stage II CRC (2) determine the optimum threshold for HGTB reporting and (3) determine the responsiveness of stage II CRC with HGTB to chemotherapy. **Methods:** Whole slide images from CRC resections of 979 QUASAR trial patients (majority stage II) were evaluated for tumor budding as per the method of Ueno (2002). A tumor bud was defined as a single cell or a cluster of < 5 cells on a hematoxylin and eosin stained section. The highest tumor bud count per 1.23 mm^2field was recorded. The optimal cutoff for HGTB was determined by maximal likelihood methods. Influence of risk group on recurrence and all-cause mortality was investigated in stratified logrank analyses in 'training' ($n = 501$) and then 'test' ($n = 478$) data sets. **Results:** The optimal cut-off for HGTB was determined to be 10+ buds/1.23 mm^2field. Defined as such, HGTB was associated with significantly worse outcome: 10-year recurrence 35% vs 22% (risk ratio [RR] = 1.93 [95%CI 1.48–2.51], $2p < 0.00001$) and mortality 51% vs 36% (RR = 1.73 [1.38–2.16], $2p < 0.00001$), which was largely independent of other factors, including N and T-stage, grade, MMR, KRAS and BRAF status. There was a non-significant trend towards increasing chemotherapy efficacy with increasing bud counts ($p = 0.12$). **Conclusions:** HGTB is a strong independent predictor of disease recurrence and survival in stage II CRC. The proportional reductions in recurrence with chemotherapy in patients with higher bud counts appear at least equivalent to those with low counts, hence the absolute reductions in recurrence with chemotherapy should be about twice as large in patients with 10+ than < 10 tumor bud counts.

3606 Poster Session (Board #99), Mon, 8:00 AM-11:30 AM

Risk of colorectal cancer after diagnosis of prostate cancer: A population-based study. *First Author: Danielle Nicole Desautels, University of Manitoba, Winnipeg, MB, Canada*

Background: Prior studies on risk of colorectal cancer (CRC) among survivors of prostate cancer (PC) have not controlled for important confounding factors such as competing risk of death and other cancers, and comorbidities. We assessed the risk of CRC (overall, sub-site- and treatment-specific) among PC survivors. **Methods**: A historical cohort study was performed by linking the Manitoba Cancer Registry and the Manitoba Health administrative databases. Each subject diagnosed with PC as his first cancer between 1987 and 2009 was age-matched with up to five men with no history of invasive cancer on the index date (date of PC diagnosis). All subjects were followed up to the date of diagnosis of CRC or another cancer, death, migration from the province, or study end-point (December 31, 2009). Competing-risk proportional hazard models were used to compare the CRC incidence rates with adjustment for age, history of lower gastrointestinal endoscopy, intensity of health care visits, diabetes and socio-economic status. There were three mutually exclusive (and competing) outcomes: CRC, another primary cancer, and death. Time dependent analysis was performed to assess effect of radiation treatment. **Results**: 14,164 men with PC and 69,051 controls were followed for a total of 559,081 person-years. Men diagnosed with PC had an increased risk of subsequently being diagnosed with CRC (all CRC: hazard ratio (HR) 1.14; 95% confidence interval (CI): 1.02-1.27; rectal cancer: HR 1.36; 95%CI: 1.09-1.71). Among men with PC, treatment with radiation was associated with increased risk for rectal/rectosigmoid cancer (HR 2.06; 95%CI: 1.42-2.99) compared to men with PC not treated with radiation, with the majority of excess cases being diagnosed within 5 years from PC diagnosis. **Conclusions**: Following a diagnosis of PC, the probability of diagnosing a CRC is increased, in particular rectal cancer among those treated with radiation. CRC screening soon after PC diagnosis should be considered.

3607 Poster Session (Board #100), Mon, 8:00 AM-11:30 AM

A phase II study of 5-fluorouracil (5-FU), ziv-aflibercept, and radiation for the preoperative and adjuvant treatment of patients (pts) with stage II/III rectal cancer. *First Author: Peter Acs, Florida Cancer Specialists/SCRI, Ft. Myers, FL*

Background: Radiation exposure upregulates VEGF expression which protects endothelial cells from the effects of radiation therapy. Combining an angiogenesis inhibitor with radiation therapy may help to suppress VEGF expression and enhance antitumor activity. Aflibercept is an antiangiogenic agent that binds to VEGF-A, VEGF-B and placental growth factor. This phase II, non-randomized study combined ziv-aflibercept (aflibercept outside the US) with chemoradiation as preoperative treatment for pts with stage II/III rectal cancer, followed by 4 months of mFOLFOX6 plus ziv-aflibercept. **Methods:** Pts with stage II/III adenocarcinoma of the rectum received preoperative 5-FU (225 mg/m^2 IVCI, days 1-42), radiation (50.4 Gy, Mon.-Fri., weeks 1-6), and ziv-aflibercept (4 mg/kg IV, days 1-15) each 28 day cycle for 6 weeks. Six weeks from last dose of ziv-aflibercept, pts underwent surgical resection. Treatment with mFOLFOX6 plus ziv-aflibercept began 8 weeks after surgery for 4 cycles. The primary objective was to evaluate the pathologic complete response (pCR) rate. Secondary objectives included overall survival (OS), disease-free survival (DFS), sphincter preservation (SP) rate, and safety. **Results:** Thirty-nine pts were treated: median age 60 yrs (range, 36-89), 64% male, 82% ECOG 0, 69% stage III. Ninety-five percent of pts received preoperative treatment, 82% underwent resection, and 54% received postoperative treatment. The most common treatment-related toxicities (% G1/2; % G3/4) included diarrhea (51%; 21%), fatigue (59%; 5%), mucositis (38%; 15%), nausea (46%; 0), and hypertension (13%; 21%). Three postoperative complications of G3 pelvic abscess (2) and G3 GI fistula (1) were seen. Of the 32 pts resected, 8 pts (25%) achieved pCR, and pathologic partial response was seen in 24 pts (75%: 9 macroscopic, 15 microscopic). The SP rate was 72%; 31 pts (97%) had R0 resection. Median OS/DFS have not yet been reached. **Conclusions:** The 5-FU-based chemoradiation therapy combined with ziv-aflibercept in localized rectal cancer pts was well tolerated and showed a pCR rate in range with historical data. Median DFS is pending. Clinical trial information: NCT01749956.

3608 Poster Session (Board #101), Mon, 8:00 AM-11:30 AM

Prospective evaluation of a 409-gene next generation sequencing platform to facilitate genotype-matched clinical trial enrollment. *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We initiated a prospective, institution-wide study to determine whether genomic testing with a 409-gene panel in solid tumors can identify new actionable genomic information (beyond that identified by smaller hot-spot panels) and lead to enrollment in genotype matched trials using agents relevant to the alteration(s) identified. **Methods:** Eligible patients (pts) had no remaining standard of care therapy anticipated to extend life by more than 3 months, ECOG performance status of ≤ 1, and a willingness to consider clinical trial enrollment. The pts' tumors were initially sequenced using a hotspot panel (predominantly a 50-gene panel, Ion Torrent, Life Technology), and if no actionable alterations were found, then tumor and paired germline were sequenced with a 409-full-length gene panel (Ion Proton). Actionable genes were defined as those for which a matched genotype selected trial exists in the institution. **Results:** 200 pts across more than 30 tumor types were consented and underwent 409-gene testing. Novel alterations in an actionable gene not found on a previous hot-spot panel were found in 39.5% of pts. Of these 79 pts, the specific somatic gene variant was of known activity based on existing literature in only 23%; for 77% the somatic variant was of unknown significance. Of the 79 pts, 20 pts (25%) were enrolled in a genotype matched trial, with 8 (10%) anticipated to enroll in the next line of therapy. Reasons for non-enrollment were the treating physician's opinion that there was insufficient evidence for the functional significance of the variant (23, 29%), exclusion criteria or lack of available slots (16, 20%), or other reasons including pt choice (12, 15%). **Conclusions:** A significant population of pts with variants in potentially actionable cancer genes not evaluated in a traditional hot-spot cancer gene panel can be identified using a 409-gene targeted gene panel. The high number of somatic variants of unknown significance represents a knowledge gap of clinical importance. While many factors contribute to bottlenecks in utilizing the expanded sequencing results, expanded genomic testing combined with robust decision support can facilitate trial enrollment.

3609 Poster Session (Board #102), Mon, 8:00 AM-11:30 AM

A phase II single arm feasibility trial of neoadjuvant chemotherapy (NAC) with oxaliplatin/fluorouracil (OxMdG) then short-course preoperative radiotherapy (SCPRT) then immediate surgery in operable rectal cancer (ORC): COPERNICUS (NCT01263171). *First Author: Simon Gollins, North Wales Cancer Treatment Centre, Bodelwyddan, United Kingdom*

Background: Feasibility was assessed of giving NAC prior to SCPRT then immediate surgery in ORC at high risk of metastatic relapse. **Methods:** Patients (pts) had non-metastatic rectal adenocarcinoma. Pre-treatment pelvic MRI showed resection margin was not at risk (disease > 1mm from mesorectal fascia) but adverse risk factors were present (disease > T3b or node positive or extramural vascular invasion). Pts received 4x2-weekly cycles of oxaliplatin 85mg/m^2 + levofolinic acid 175 mg, fluorouracil (FU) 400 mg/m^2 (bolus), then FU 2400 mg/m^2 (continuous IV in 46 hr). Within 14 days pts had pelvic SCPRT to 25 Gy in 5 daily fractions. Definitive surgery then occurred within a week. Post surgery pts received 16 weeks of OxMdG or oxaliplatin/capecitabine. The primary endpoint was the proportion of pts completing protocol treatment including surgery. **Results:** 60 UK pts were recruited May 2012-June 2014. At baseline: male 44 (73%), median age 63 (IQR: 56.5-70), WHO PS 0/1 55/5. On pre-treatment MRI tumour was T2/3x/3a/3b/3c/3d/4 in 2/2/16/24/12/1/3 and N0/1/2 in 7/40/13 pts. All pts commenced OxMdG with 57(95%) receiving all 4 cycles. 20 pts (33%) needed a dose reduction and 22 (37%) a dose delay. 58 pts commenced SCPRT (all received full dose) and 57 underwent surgery: anterior resection in 43 (75%), abdominoperineal resection in 11 (19%), Hartmanns in 3 (5%). Three pts withdrew prior to surgery: one lost to follow up after SCPRT, one pt choice and one due to cardiospasm during NAC. Median gap between OxMdG and starting SCPRT was 10 days (IQR: 5-15) and between completing SCPRT and surgery 10 days (IQR: 5-13). Postoperative histology was T0/1/2/3a/3b/3c/4a in 7/3/19/8/9/10/1 pts, N0/1/2 in 39/13/5 pts and ypT0ypN0 in 7/57 pts (12%). All 57 resected pts had a clear (R0) resection margin with no 30 day postoperative mortality. **Conclusions:** This is the first trial to report on giving NAC prior to SCPRT then surgery within a short time interval in ORC, which proved feasible with good compliance and promising efficacy. The UK NCRI intend to include a similar regimen in a future phase III trial. Clinical trial information: NCT01263171.

3610 Poster Session (Board #103), Mon, 8:00 AM-11:30 AM

Characterization of the immune microenvironment of synchronous primary tumor and liver colorectal metastases. *First Author: Marc Van Den Eynde, Institut Roi Albert II, Cliniques universitaires St-Luc, UCL, Brussels, Belgium*

Background: The adaptive Th1 immune response (CD3, CD8, CD45RO T cells) observed in resected primary colorectal tumor (PCT) and liver colorectal metastases (LCM) is an important prognostic factor. Preoperative treatment modifies the LCM immune microenvironment with a significant association between pathological response and increase of T (CD3, CD8) and B cells (CD20) and downregulated T regulatory cells (FoxP3). We investigated the impact of different preoperative treatments on the quality and density of the immune infiltrates in synchronous resected PCT and LCM. **Methods:** Metastatic colorectal patients (n = 107) undergoing curative liver surgery for all resected LCM (n = 338) were investigated. 28 patients have been operated concomitantly for synchronous LCM (n = 102) and PCT (n = 23 available) after surgery alone (S), chemotherapy (Cht) alone, Cht + anti-VEGF and Cht + anti-EGFR. The density of CD3 (T cells), CD8 (cytotoxic), CD45RO (memory), CD20 (B cells) and FoxP3 (regulatory) in the core (CT) and invasive margin (IM) of all synchronous LCM and PCT was quantified on immunostained slides. The mean density value (CT, IM) was calculated for each marker with a dedicated image analysis software on whole-slide imaging. Comparisons were made using the Wilcoxon-Mann-Whitney test. **Results:** Global analysis of immune cell density in LCM and corresponding PCT showed no significant correlation even when further subcategorizing by treatment (preoperative or S), metastasic burden or subdividing by the least, the mean or the highest infiltrated LCM for patients with multiple LCM.Compared to PCT, LCM were more frequently associated with a high immune infiltrate for CD3 and CD45RO in the IM ($p < 0.001$) and CD8 in CT and IM ($p < 0.001$). Conversely, high CD20 and FoxP3 density were higher in the CT of PCT ($p < 0.005$). When comparing preoperative treatment to S, only Cht+anti-EGFR significantly increases CD3 and CD8 in CT of LCM but not PCT ($p < 0.001$). **Conclusions:** Cytotoxic/memory T cells and B/regulatory T cell densities were significantly higher in LCM and PCT, respectively. Only anti-EGFR treatment increases T cells densities in the CT of the LCM but not in the PCT, suggesting a specific treatment effect in this tumor region.

3611 Poster Session (Board #104), Mon, 8:00 AM-11:30 AM

Reduced PD-1/PD-L1 expression in KRAS-mutant versus wild-type microsatellite instable (MSI-H) colorectal cancer (CRC) and association of wnt pathway corepressor TLE-3. *First Author: Namrata Vijayvergia, Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA*

Background: MSI-H CRC comprises ~15% of CRC & has higher PD-1 & PD-L1 (P(+)) expression in CD4+ lymphocytes & tumor cells, respectively, compared to non-MSI-H CRC. Immune-checkpoint inhibitor therapy is being tested in clinical trials for MSI-H CRC (NCT02060188, NCT01876511). Human homologue of Groucho, Transducin-like-Enhancer of Split orthologue (TLE-3), inhibits Wnt signaling by competition with b-catenin for LEF/TCF binding. We investigated different biomarkers that may characterize P(+) MSI-H CRC. **Methods:** 55 MSI-H (including 13 Lynch Syndrome cases) CRCs were profiled at Caris Life Sciences (Phoenix, AZ). Immunohistochemistry (IHC) & mutation analysis was performed to compare P(+) & P(-) MSI-H CRC. PD-1 expression was measured on Tumor Infiltrating Lymphocytes (TIL) with the cutoff of 1+, 1% (1/HPF); PD-L1 expression was measured on tumor cells with the cutoff of 2+, 5%. IHC assays underwent a stringent validation process meeting CLIA/CAP criteria. Fisher's exact test was used to compare categorical variables. **Results**: Analysis of 55 MSI-H tumors revealed 39 (71%) were P(+) (39 PD-1(+); 1 also PD-L1(+)) & 16 (29%) were P(-). The P(+) group expressed TOPO-1/2 (43%/93%), EGF-R (88%), TS (90%), RRM1 (77%), PTEN (77%), c-MET (50%), and MGMT (53%) by IHC, and the expression was not significantly different compared to the P(-) group. TLE-3 protein expression, however, was 43% in P(+) and only 8% in P(-) MSI-H tumors ($P = 0.04$). Only 9 (27%) of P(+) tumors harbored a KRAS mutation, while 10 (62%) had KRAS mutation in P(-) tumors ($P = 0.04$). **Conclusions:** PD-1/PD-L1 protein expression is inversely associated with KRAS mutation status in MSI-H CRC. This is relevant to clinical trials testing immune checkpoint inhibitors in MSI-H CRC. The signaling between KRAS mutation & low or absent PD-1/PD-L1 should be further investigated. TLE-3 expression may dampen b-catenin signaling in P(+) tumors.

3612 Poster Session (Board #105), Mon, 8:00 AM-11:30 AM

Proteomic signatures of colorectal cancer to identify distinct and reproducible subgroups and to reflect prognosis. *First Author: Michael Sangmin Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While colorectal cancer (CRC) has classically been categorized by gene expression, proteomic analysis directly elucidates the functional state of protein signaling, which may better reflect cellular behavior. We performed an antibody-based proteomic analysis (reverse-phase protein array; RPPA) of a large cohort of MD Anderson (MDACC) and The Cancer Genome Atlas (TCGA) samples to determine patterns of protein expression in CRC. **Methods:** Protein was extracted from 725 archived CRC tumor samples (263 MDACC discovery set, and 462 TCGA validation set), and RPPA was performed to determine the expression levels of 127 cellular proteins. Upon unsupervised hierarchical clustering, samples dichotomized with distinct patterns of protein expression. The proteins with highest discriminatory utility were identified by LIMMA in the discovery set and confirmed in the validation set. Clinical variables and DNA sequencing results were available for correlation. **Results:** Among the top 40 discriminant proteins for the dichotomized groups in each dataset, 24 were common to both and correlated with each other. One group was notable for high EMT/reactive stroma (high fibronectin, low E-cadherin), while the other group was notable for high TSC/MTOR (high MTOR, phospho-MTOR, Tuberin), and high RTK pathway components (high BRAF, HER2, HER3). This latter group also was notable for elevated beta-catenin and elevated phospho-AMPK. In the MDACC and TCGA cohorts, the high RTK group was more likely to have lymphovascular invasion ($p = 0.023$ in MDACC, $p = 0.017$ in TCGA) and less likely to have BRAF mutation ($p = 0.011$ in MDACC, $p = 0.002$ in TCGA). On multivariate Cox regression analysis of relapse-free survival of 171/233 Stage II-III MD Anderson patients with complete data, stage (HR 3.121, 95% CI 1.373-7.093, $p = 0.007$) and proteomic grouping (HR 2.105, 95% CI 1.037-4.274, $p = 0.039$) were significantly associated with inferior relapse-free survival, while age, BRAF mutation status, and lymphatic invasion status were not significant. **Conclusions:** CRCs appear to have distinct subsets defined by proteomic features. These findings reflect distinct differences in cellular function that have prognostic implications.

3613 Poster Session (Board #106), Mon, 8:00 AM-11:30 AM

Genetic variants of kinases suppressors of Ras (KSR) to predict tumor response to first-line cetuximab in patients with mCRC: Prospective analysis in the FIRE 3 trial. *First Author: Leonor Benhaim, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Activation of EGFR pathway in RAS-BRAF wild-type models can be modulated by scaffold proteins kinase suppressor of ras (KSRs) that binds RAS promoting ERK activation. We previously showed in patients with KRAS-BRAF wild-type tumor treated with FOLFIRI-cetuximab that KSR2 rs11068551 TT was associated to significantly longer PFS. On the other hand, among female patients treated with FOLFIRI-bevacizumab the KSR1 rs2241906 CC genotype was associated to significantly shorter PFS. We aimed at validate our finding by investigating the correlation between KSR variants and clinical outcomes in patients enrolled in the FIRE 3 trial. **Methods:** Genomic DNA was isolated from tissue samples of 592 patients with KRAS exon 2 wild-type enrolled in the randomized phase III, FIRE 3 trial that was designed to compared the efficacy of two targeted agents when associated to FOLFIRI regimen. Patients were randomly assigned to first-line FOLFIRI associated with either bevacizumab (n = 295) or cetuximab (n = 297) (NCT00433927). In both arms, DNA was amplified by PCR and KSR variants were detected by direct sequencing. **Results:** We confirmed prospectively that KSR2 rs11068551 could predict outcomes in patients receiving cetuximab. 1/Patients with the TT genotype (n = 40) demonstrated a significant lower response rate than patients carrying C (n = 133) in the cetuximab arm (55% vs. 77%, p= 0.008). 2/ Patients with left-sided tumors and TT genotype (n = 32) showed a significant longer PFS (12.9 vs. 10.2 months, log rank p = 0.049) than patients harboring any of the C allele (n = 128) in the cetuximab arm. 3/ No association between KSR2 rs11068551 and outcomes was seen in the bevacizumab arm. We did not confirm the relation between KSR1 rs2241906 and outcomes (response rate, PFS or OS) even when adjusted with gender and location. **Conclusions:** We prospectively validated the predictive value of KSR2 rs11068551 mCRC pts treated with first-line cetuximab-containing therapy. This predictive value may dependent on tumor location. We could not confirm the predictive value of KSR1 rs2241906 in patients receiving bevacizumab-containing treatment.

3614 Poster Session (Board #107), Mon, 8:00 AM-11:30 AM

Phase II trial of autophagy inhibition using hydroxychloroquine (HCQ) with FOLFOX/bevacizumab in the first-line treatment of advanced colorectal cancer. *First Author: Arturo Loaiza-Bonilla, University of Pennsylvania, Philadelphia, PA*

Background: We have shown that autophagy, the regulated dissolution of cellular elements to maintain survival in adverse environmental conditions, is a determinant of resistance to chemotherapy in colorectal cancer models, and is reversed by chloroquine (Selvakumaran M, et al. Clin Cancer Res, 2013). A Phase I run-in demonstrated that full doses of mFOLFOX6/ bevacizumab were tolerated with HCQ 600mg PO twice daily. **Methods:** We report a Phase II trial in previously-untreated patients with metastatic colorectal cancer. Patients were treated every two weeks with 5-FU (400mg/m2 bolus, then 2400 mg/m2 over 46h) together with leucovorin 200mg/m2, oxaliplatin 85mg/m2, bevacizumab 5mg/kg, all IV, repeated every two weeks, with HCQ as above. After 12 cycles, oxaliplatin was omitted and patients were continued on 5-FU, bevacizumab, and HCQ. Imaging was performed every 8 weeks. **Results:** Twenty-four patients (pts) have been accrued, of whom 23 are eligible: 10 female/13 Male; 19 Caucasian/3 Black/1 East-Asian. Toxicity has been generally tolerable. Grade 3 effects included neutropenia 9/23), diarrhea (1/23), and anorexia (1/23). There were two episodes of myocardial infarction, one fatal, one of atrial arrhythmia, and two of pulmonary embolism in the course of the trial. 20/23 patients were able to maintain full dose of HCQ. Patients evaluable for response include 19 (4 pts too early). There were 1 complete response (5%), 9 partial responses (47%), and 7 stable disease (37%). Four patients went off study for resection of metastatic disease after 3-25 months. Median progression-free and overall survival have not been reached. Autophagy biomarkers in peripheral mononuclear cells show autophagy inhibition in the majority of patients. Six of thirteen patients with genomic testing available had a TP53 mutation. Four of these six patients had a major response (1CR, 3 PR). **Conclusions:** The combination of FOLFOX/ bevacizumab with HCQ is an active regimen in unselected patients with colorectal cancer. A randomized Phase II trial of the combination is in development. Clinical trial information: NCT01206530.

3615 Poster Session (Board #108), Mon, 8:00 AM-11:30 AM

Phase 1 extension study of BBI503, a first-in-class cancer stemness kinase inhibitor, in patients with advanced colorectal cancer. *First Author: Derek J. Jonker, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: Targeting cancer stem cells (CSC) has shown pre-clinical efficacy and holds therapeutic promise. BBI503 is a first-in-class cancer stemness kinase inhibitor with potent in vitro and in vivo activity against CSC. BBI503 works through inhibition of stemness pathways, including Nanog. High Nanog expression in patients with colorectal cancer (CRC) predicts poor prognosis. Patients with advanced CRC who had failed all standard treatments were enrolled in a phase I and disease-specific cohort expansion study. **Methods:** BBI503 was given orally and continuously in 28-day cycles until disease progression, unacceptable toxicity, or other discontinuation criteria were met. Eligible patients with CRC received BBI503 monotherapy at 20 mg to 500 mg total daily. Archival tissue was evaluated by IHC for Nanog expression. **Results:** 47 patients with heavily pre-treated CRC were enrolled (median 4 prior lines standard therapy). Bevacizumab was used in 80%, anti-EGFR AB in 60%, and regorafenib in 23%. Most (N = 35, 75%) received BBI503 at RP2D, 300 mg once daily. Median treatment duration was 8 weeks (range < 1 to 46+). Common adverse events (AE) considered related to therapy were grade 1 to 2 diarrhea, abdominal pain, fatigue, and nausea/vomiting/anorexia. At RP2D, Grade 3 AE were diarrhea (N = 3), fatigue (N = 3), nausea (N = 2), and weight loss (N = 1). Archival tissue was available from 39 patients (83%). DCR (CR+PR+SD) in evaluated patients with high Nanog expression (biomarker positive) was 56%, while DCR in biomarker negative patients was 13% (p = 0.040). Median overall survival (mOS) in biomarker positive patients (ITT) was 38 weeks, while mOS in biomarker negative patients (ITT) was 16 weeks (p = 0.089 Log-Rank). **Conclusions:** BBI503, a first-in-class cancer stemness kinase inhibitor, demonstrated tolerability at the RP2D administered to patients with pre-treated mCRC. Disease control and prolonged overall survival were observed in CRC patients with positive Nanog expression in tumor tissues. Further clinical evaluation of BBI503 alone or in combination with standard chemotherapeutic agents in CRC is warranted. Clinical trial information: NCT01781455.

3616 Poster Session (Board #109), Mon, 8:00 AM-11:30 AM

A phase Ib study of BBI608 in combination with FOLFIRI with and without bevacizumab in patients (pts) with advanced colorectal cancer (CRC). *First Author: Joleen Marie Hubbard, Mayo Clinic, Rochester, MN*

Background: BBI608 is an oral first-in-class cancer stemness inhibitor of Stat3. Potent anti-tumor activity was observed *in vitro* and *in vivo*,in mono- and combination therapy. In a phase I study, BBI608 monotherapy was generally well tolerated at 500 mg BID with encouraging signs of anti-tumor activity. **Methods:** A phase Ib open label, multi-center study in pts with advanced CRC was performed to determine RP2D, safety, tolerability, and preliminary anti-cancer activity of BBI608 in combination with FOLFIRI with or without bevacizumab. BBI608 was administered at 240 mg BID in combination with FOLFIRI (5-FU 400 mg/m^2 bolus with 2400 mg/m^2, irinotecan 180 mg/m^2, and leucovorin 400 mg/m^{2}infusion) with or without bevacizumab 5 mg/kg, administered bi-weekly until progression of disease, unacceptable toxicity, or other discontinuation criterion was met. **Results:** 9 pts were enrolled with 4 pts receiving FOLFIRI and 5 pts receiving FOLFIRI with bevacizumab in combination with BBI608. All pts were pretreated with ≥ 1 line and 67% (6/9) of pts with ≥ 4 prior lines of therapy. Combination treatment was well tolerated with no dose-limiting toxicity and safety profile similar to that of each regimen individually, with no difference in safety observed with addition of bevacizumab. Most common adverse events included grade 1 and 2 diarrhea, abdominal cramps, nausea, vomiting and anorexia. Grade 3 diarrhea was observed in 2 pts, and resolved with a brief BBI608 dose holiday or dose reduction to 160 mg BID and anti-diarrheal medications, respectively. Additionally, self-resolving grade 3 fatigue lasting 4-8 days was observed in 2 pts. No significant pharmacokinetic interactions were observed. Disease control (PR+SD) was observed in 9 of 9 evaluable pts (100%) with 1 PR (44% regression) and 8 SD with tumor size reduction (25%, 23%, 17%, 16%, 14%, 14%, 4% and 2%, respectively). The median progression free survival was 23.7 weeks with SD of ≥ 6 months in (33.3%) 3/9 pts. **Conclusions:** This phase Ib study demonstrated that BBI608 at 240 mg BID can be safely combined with FOLFIRI with and without bevacizumab. Encouraging anti-tumor activity was observed in pts with advanced and heavily pretreated CRC. Clinical trial information: NCT02024607.

3617 Poster Session (Board #110), Mon, 8:00 AM-11:30 AM

A phase Ib/II study of cancer stem cell inhibitor BBI608 administered with panitumumab in KRAS wild-type (wt) patients (pts) with metastatic colorectal cancer (mCRC) following progression on anti-EGFR therapy. *First Author: Kristen Keon Ciombor, Ohio State University Wexner Medical Center, Columbus, OH*

Background: BBI608 is an oral first-in-class cancer stemness inhibitor that works by targeting Stat3. Potent preclinical anti-tumor activity was observed *in vitro* and *in vivo*, in mono- and combination therapy. In a phase I study, BBI608 was well tolerated with encouraging signs of activity and a RP2D of 500 mg BID with additional ongoing studies showing that BBI608 can be safely combined with multiple chemotherapeutics. **Methods:** A phase Ib/II open-label, multi-center study in pts with advanced *K-Ras*wt mCRC was performed to determine safety and preliminary activity of BBI608 administered orally at 480-500 mg BID with panitumumab (6 mg/kg bi-weekly) until disease progression, unacceptable toxicity, or other discontinuation criterion was met. Following clearance of the DLT period in 6 pts, 18 more pts were enrolled. **Results:** All of the 24 pts enrolled were pre-treated with ≥2 lines of therapy and 12/24 with ≥3 lines of therapy. An MTD was not determined and BBI608 could be given in combination with full dose panitumumab. The safety profile was consistent with that of each agent as monotherapy and most common adverse events included grade 1-2 diarrhea, abdominal cramps, nausea and vomiting. Grade 3 hypokalemia and dehydration occurred in 2 pts. No significant pharmacokinetic interactions were observed. Disease control (SD+PR) was observed in 4 of 9 (44.4%) anti-EGFR naïve pts. Of those, 2 of 9 (22%) had PR (35.5% and 33.3% regressions), and 2 had SD. Disease control (only SD) was observed in 8/15 (53.3%) pts who had failed anti-EGFR (cetuximab) therapy, 2 of which had SD with regression (12.9% and 6.8%). The median progression free survival was 9 and 16.4 weeks in anti-EGFR naive and previously exposed pts, respectively. **Conclusions:** This phase Ib/II study demonstrated that BBI608 and bi-weekly panitumumab can be safely combined at full dose. The response rate in anti-EGFR naïve pts was notably greater than that of anti-EGFR monotherapy. Moreover, encouraging preliminary activity was observed in K-*Ras* wt mCRC regardless of prior anti-EGFR exposure, suggesting that BBI608 may sensitize pts to repeat anti-EGFR therapy. Clinical trial information: NCT01776307.

3618 Poster Session (Board #111), Mon, 8:00 AM-11:30 AM

Phase I/II study of everolimus (E) with irinotecan (Iri) and cetuximab (C) in 2nd line metastatic colorectal cancer (mCRC): Hoosier Cancer Research Network GI05-102. *First Author: E. Gabriela Chiorean, University of Washington, Seattle, WA*

Background: Preclinically, mTOR and EGFR inhibitors are synergistic. We hypothesized that the mTOR inhibitor E would enhance clinical efficacy when added to C. The Phase I portion determined the safety, and maximum tolerated dose (MTD), and the Phase II evaluated the response and survival rates with this combination. Preliminary results of the Phase I study (ASCO 2011, Shahda et al) determined the MTD as E 5 mg po daily (qd) combined with Iri and C. Here we report overall safety and efficacy results of the Phase I/II study. **Methods:** Patients (pts) were treated with Iri 125 mg/m^2 weekly (qw) x 2 every 3 wks, C 400 mg/m^2 loading, then 250 mg/m^2 qw, and escalating doses of E: 5 mg qod, 5 mg qd and 10 mg qd in 21-day cycles (Phase I), and 5 mg qd (Phase II). Eligibility allowed KRAS mutated (MUT) mCRC. During phase II, KRAS wild-type (WT) pts were randomized to Iri+C+E vs Iri+C, and all KRAS MUT pts received Iri+C+E. Archival tumors were analyzed for biomarkers of EGFR and mTOR pathways activation. The study was discontinued early due to funding termination by Novartis. **Results:** 43 pts were enrolled, median age 60 y (25-77), 24 male. 30 pts enrolled in phase I (KRAS WT n = 15, KRAS MUT n = 13, KRAS unknown n = 2), and 13 pts in phase II (KRAS WT: n = 5 Iri+C+E, n = 2 Iri+C; KRAS MUT n = 6 Iri+C+E). The most common gr 3/4 AEs were diarrhea (35%), neutropenia (23%), fatigue (21%), mucositis (21%), and rash (19%). Among KRAS WT pts (n = 22) there were 1 CR, 3 PR (RR 18%), 12 SD (54%), and among KRAS MUT pts (n = 19) there were 1 PR (5%) and 11SD (52%). Median progression-free survival (PFS) and overall survival (OS) rates were 6 and 16 mos, respectively for all KRAS WT pts treated with Iri+C+E (n = 20), and 8.3 and 21.6 mos, respectively for KRAS WT pts treated at MTD (n = 11). Median PFS and OS were 4.3 and 12.3 mos, respectively for KRAS MUT pts. Only 2 KRAS WT pts were randomized to Iri+C before study closure. PD markers will be presented. **Conclusions:** The combination of Iri+C+E has an expected toxicity profile, and was clinically active as second-line treatment for KRAS WT mCRC pts. Further studies should assess the CRC pts most likely to benefit from mTOR inhibitors in addition to EGFR blockade. (NCT00522665) Clinical trial information: NCT00522665.

3619 Poster Session (Board #112), Mon, 8:00 AM-11:30 AM

Programmed death-ligand 1 (PD-L1) expression in small bowel adenocarcinomas (SBA). *First Author: Katrina Pedersen, Mayo School of Graduate MedcI Education, Rochester, MN*

Background: SBAs are rare, resulting in a paucity of data on effective treatments. Highly active immune surveillance within all parts of the intestine may explain the rarity. In such an environment, tumor cells may express PD-L1 to inhibit immune-mediated cytotoxicity. We hypothesized that SBAs would have a high prevalence of PD-L1 IHC positive cells, which could be a marker for future immunotherapeutic efficacy. **Methods:** Forty-five archived SBA primary tumor samples were selected for IHC staining with the PD-L1 (anti-B7-H1 clone 5H1) antibody. Patient records were reviewed for clinical data outcomes including overall survival (OS), gender, primary site, and known microsatellite instability (MSI) status. **Results:** By site, we examined 25 (56%) duodenal, 14 (31%) jejunal, and five (11%) ileal tumors. 53% of tumors (24/45) demonstrated strong PD-L1 staining, with 4/45 (9%) in a cellular pattern and 21/45 (47%) in the intratumoral stroma, morphologically consisting of a mononuclear cell infiltration. Stratified by disease location, 11/25 (44%) of the duodenal tumors (9/11 stromal pattern, 1/11 cellular pattern, 1/11 positive for both), 9/14 (64%) of the jejunal tumors (8/9 stromal, 1/9 cellular), and 3/5 (60%) of the ileal tumors (2/3 stromal, 1/3 cellular) are PD-L1 positive by IHC. One site-unclassified tumor had positive stromal staining. An unadjusted survival analysis shows that PD-L1 staining within tumor cells is associated with poorer median OS (10 months vs. 5.5 years, p = 0.0009 by Log-Rank). Stromal PD-L1 staining does not exhibit a statistically significant difference in OS (median 66.9 months, vs 34.5 months p = 0.51). Of five tumors known to be MSI-H, 1/5 (20%, stromal pattern) has concomitant PD-L1 expression. **Conclusions:** To our knowledge, this is the first report of PD-L1 expression in SBA, with 53% staining positive. Given reported activity of anti-PD1 therapy in gastric cancer and MSI-H colon cancer, this indicates a potential role for immunotherapy in SBA. Those expressing PD-L1 intracellularly may have worse outcomes. Further studies to address prognostic and therapeutic implications PD-L1 expression are indicated.

TPS3620 Poster Session (Board #113a), Mon, 8:00 AM-11:30 AM

A phase III study of the impact of a physical activity program on disease-free survival in patients with high-risk stage II or stage III colon cancer: A randomized controlled trial (NCIC CTG CO.21). *First Author: Christopher M. Booth, Division of Cancer Care & Epidemiology, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

Background: Observational studies indicate that physical activity (PA) is associated with colon-cancer specific survival. The NCIC Clinical Trials Group CO.21 (CHALLENGE) trial is designed to determine the effects of a structured physical activity (PA) intervention on disease-free survival in high-risk stage II or III colon cancer survivors who have completed adjuvant chemotherapy within the previous 2-6 months. **Methods:** Phase III randomized controlled trial. Target sample size of 962 patients is powered to detect a Hazard Ratio of 0.75 for disease-free survival (DFS). Trial participants are stratified by centre, disease stage, body mass index, and performance prior to randomization to a structured PA intervention or general health education materials. The PA intervention consists of a behavioural support program and supervised PA sessions delivered over a three-year period, beginning with regular face-to-face sessions and tapering to less frequent face-to-face or telephone sessions. The goal of the PA program is to increase weekly PA by 10 MET-hours/week. The PA program is delivered by physical activity consultants trained in exercise physiology and behavior change. **Outcomes:** The primary endpoint is DFS. Main secondary endpoints include multiple patient-reported outcomes (including those that measure fatigue), objective physical functioning, biologic correlative markers (including assessment of the insulin pathway), and an economic analysis. Data are also being collected on motivational outcomes and behavior change that will inform program delivery. **Current Enrollment:** The study is open at 21 centers in Canada and 26 centers in Australia with recent expansion into the United States, Israel, and Korea. As of January 1, 2015 341 patients are randomized. The new international partnerships will accelerate accrual. **Summary:** Cancer survivors and cancer care professionals are interested in the potential role of PA to improve disease-free survival and quality of life. A randomized controlled trial is needed to provide compelling evidence to justify changes in health care policies and practice. Clinical trial information: NCT00819208.

TPS3621 Poster Session (Board #113b), Mon, 8:00 AM-11:30 AM

Genotype-directed phase II study of irinotecan dosing in metastatic colorectal cancer (mCRC) patients receiving FOLFIRI + bevacizumab: The GENIC study. *First Author: Grant Richard Williams, UNC Chapel Hill, Chapel Hill, NC*

Background: Infusional fluorouracil/leucovorin plus irinotecan with bevacizumab (FOLFIRI-bev) is a standard first-line option for mCRC. The active metabolite of irinotecan, SN-38, is inactivated via glucuronidation by UGT1A1. Common germline variants of UGT1A1 are well known to alter the rate of glucuronidation and exposure to SN-38. UGT1A1*28 decreases UGT1A1 expression such that *28/*28 homozygotes have greater SN-38 exposure and increased risk of neutropenia. Despite the well-described association of genotype and SN-38 exposure, irinotecan doses have been established independent of genotype. Dose-limiting toxicity in the ~10% of patients homozygous for *28/*28 may have led to under-dosing of patients with other genotypes. In phase I genotype-directed dose-finding studies of FOLFIRI +/- bev, *1/*1 and *1/*28 patients were able to tolerate significantly higher doses of irinotecan (Sharma GI ASCO 2014, Marcuello BJC 2011, Toffoli JCO 2010) with a promising efficacy signal. We hypothesize that genotype-guided irinotecan dosing—in which *1/*28 and *1/*1 genotypes receive higher doses of irinotecan—will increase the overall benefit of FOLFIRI-bev for patients with mCRC with tolerable toxicity. GENIC is a phase II multicenter, single arm trial designed to estimate the progression-free survival (PFS) of genotype-guided irinotecan dosing in patients receiving first-line FOLFIRI-bev for mCRC (NCT02138617). **Methods:** Patients with unresectable mCRC eligible for FOLFIRI-bev will be assigned irinotecan dose based on UGT1A1 genotype: *1/*1 = 310mg/m^2; *1/*28 = 260mg/m^2; or *28/*28 = 180mg/m^2. Fluorouracil, leucovorin, and bevacizumab are given at standard doses. The primary objective is to estimate PFS compared with recently reported PFS from FIRE-3 and 80405. 100 patients are planned to ensure 86 are evaluable, giving 80% power to detect a 3.5 month improvement in PFS. Secondary objectives will evaluate toxicity, response rate, and overall survival. Efficacy by genotype will be explored. The Patient Reported Outcomes (PRO) version of the CTCAE will evaluate patient reported tolerance and the concordance between patient and clinician assessment. Clinical trial information: NCT02138617.

TPS3622 Poster Session (Board #114a), Mon, 8:00 AM-11:30 AM

Treatment strategies in colorectal cancer patients with initially unresectable liver-only metastases: The randomized phase III CAIRO5 study of the Dutch Colorectal Cancer Group. *First Author: Joost Huiskens, Academic Medical Centre, Amsterdam, Netherlands*

Background: Colorectal cancer patients with unresectable liver-only metastases may be cured after downsizing of metastases by neoadjuvant systemic therapy. However, the optimal neoadjuvant induction regimen has not been defined, and the lack of consensus on criteria for (un)resectability complicates the interpretation of published results. **Methods:** CAIRO5 is a multicenter, randomized, phase III clinical study. Colorectal cancer patients with initially unresectable liver-only metastases are eligible, and will not be selected for potential resectability to avoid selection bias. The unresectability status is prospectively assessed by a central panel consisting of at least one radiologist and three liver surgeons, and defined as no radical resection possible in one session with resection only. Tumors of included patients will be tested for *RAS* and *BRAF* (for stratification purpose) mutation status. Patients with *RAS* wild type tumors are treated with doublet chemotherapy (FOLFOX/FOLFIRI, choice of investigator) and randomized between the addition of either bevacizumab or panitumumab, patients with *RAS* mutant tumors are randomized between doublet chemotherapy (FOLFOX/FOLFIRI) or triple chemotherapy (FOLFOXIRI), both with bevacizumab. Resectability status will be re-evaluated every two months. The primary study endpoint is median progression-free survival. Secondary endpoints include the R0/1 resection rate, and median overall survival. **Conclusion** CAIRO5 is a prospective multicenter trial that investigates the optimal systemic therapy for patients with initially unresectable, liver-only colorectal cancer metastases. **Discussion** The unique aspects of CAIRO5 concern the prospective phase III randomized comparison of neoadjuvant treatment regimens in this population with the use of uniform and transparent criteria for unresectability by an expert panel. This CAIRO5 panel may contribute to a consensus on criteria for unresectability and to awareness of secondary resections in these patients. Clinical trial information: NCT02162563.

TPS3623 Poster Session (Board #114b), Mon, 8:00 AM-11:30 AM

Phase II study of ruxolitinib with regorafenib for relapsed/refractory (r/r) metastatic colorectal cancer (mCRC). *First Author: David R. Fogelman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Therapeutic options are limited after patients (pts) with mCRC progress following treatment with current standards of care. As with pancreatic cancer (PC), CRC induces a systemic inflammatory response, possibly from inflammatory cytokine production by colorectal tumor cells themselves or by the local inflammatory milieu. Elevated levels of inflammatory cytokines are associated with more advanced disease and reduced survival. In the phase II RECAP study, treatment with the JAK1/JAK2 inhibitor ruxolitinib + capecitabine showed improved overall survival (OS) relative to placebo + capecitabine in pts with metastatic PC who had evidence of systemic inflammation as demonstrated by elevated C-reactive protein levels (Hurwitz et al. ASCO 2014. abs 4000). Given the evidence supporting a role for the JAK-STAT pathway in the systemic inflammatory response in CRC, ruxolitinib may be an effective therapeutic strategy in pts with r/r mCRC. **Methods:** Eligible pts are aged ≥ 18 years with histologically or cytologically confirmed adenocarcinoma of the colon or rectum that is metastatic; have an ECOG performance status of 0–2; have received fluoropyrimidine, oxaliplatin, and irinotecan-based chemotherapy, an anti-VEGF therapy (if no contraindication) and an anti-EGFR therapy (if *KRAS* wild-type and no contraindication). Exclusion criteria are prior regorafenib treatment; active GI disease interfering with absorption; known central nervous system metastases; hepatitis B virus (HBV) or hepatitis C virus viremia or at risk for HBV reactivation. The study consists of 2 parts. Part 1 is open label and dose finding and will assess the safety and tolerability of ruxolitinib in combination with regorafenib. In Part 2, pts are randomized 1:1 to receive 28-day cycles of ruxolitinib 15 mg twice daily + regorafenib 160 mg once daily (days 1–21) or placebo + regorafenib. The primary endpoint of part 2 is OS. Secondary endpoints include progression free survival, overall response rate, duration of response, and disease control. Treatment will continue as long as tolerated and discontinuation criteria are not met. Enrollment in this study was initiated in March 2014 and is ongoing. The planned enrollment is 373 pts. Clinical trial information: NCT02119676.

TPS3624 Poster Session (Board #115a), Mon, 8:00 AM-11:30 AM

FOLFOXIRI with or without bevacizumab as first-line treatment for unresectable liver-only metastatic colorectal cancer patients with RAS mutation-type. *First Author: Yanhong Deng, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: For liver limited metastatic colorectal cancers, complete resection of liver metastases is the only potentially curative treatment and can significantly improve overall survival. The current goal of medical treatment for colorectal cancer with initially unresectable liver metastases is to maximize the rate of secondary resection. This phase II study is to explore whether FOLFOXIRI plus bevacizumab compared with FOLFOXIRI alone as first-line treatment could improve radical resectability in patients with RAS mutaion-type, unresectable liver-only metastatic colorectal cancer. **Methods:** The primary endpoint is the conversion rate of liver metastases, which is defined as the proportion of patients who had a curative liver treatment following protocol treatment, i.e., liver metastases that can be radical resected with or without ablation with no postoperative evidence of residual malignant disease. Secondary endpoints include safety, objective response rate, overall survival, progression free survival, quality of life and an assessment of predictive molecular markers of response. 160 cases of patients meet inclusion criteria and are enrolled in the trial will be randomized to two therapy groups: experimental arm A (FOLFOXIRI plus bevacizumab) or control arm B (FOLFOXIRI alone) in a 1:1 allocation ratio, stratifying for centers, ECOG status, synchronous or metachronous metastases, and a risk score derived from Nordlinger. All patients will receive the study treatment regimen every 2 weeks, and a total of the maximum of 12 cycles. CT scan or MRI of the abdomen will be performed after 2 or 3 cycles of therapy to assess clinical response and resectability of liver metastases by multidisciplinary team including hepatic surgeon. If liver metastases are not deemed to be resectable at this assessment, but tumor assessment demonstrates stable disease or partial response, therapy will continue with re-assessment for clinical response and resectability after the next cycle. Clinical trial information: NCT02350530.

TPS3625 Poster Session (Board #115b), Mon, 8:00 AM-11:30 AM

LUME-Colon 1: A double-blind, randomized phase III study of nintedanib plus best supportive care (BSC) versus placebo plus BSC in patients with colorectal cancer (CRC) refractory to standard therapies. *First Author: Heinz-Josef Lenz, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Clinical studies with anti-VEGF agents, such as regorafenib (R), demonstrate that angiogenesis is critical to CRC tumor growth and metastasis. R has provided proof of principle in patients (pts) with refractory CRC, but is associated with a specific safety profile; there is a need for effective alternative treatments with different safety profiles. Nintedanib (N) is a triple angiokinase inhibitor of VEGF, PDGF and FGF signaling. N is approved in the European Union for the treatment of pts with advanced adenocarcinoma NSCLC after 1st-line chemotherapy and has shown clinical benefit in trials in several tumor types. In a phase I study of N in CRC, a clinically relevant anti-angiogenic effect was observed in 67% of pts. These findings and a manageable safety profile provide a rationale to examine N in refractory CRC. The objective of this study (NCT02149108; 1199.52) is to evaluate the efficacy and safety of N in pts with refractory CRC after failure with standard chemotherapy and biologic agents. **Methods:** 764 pts worldwide (including 10 US sites) – age ≥ 18 years, ECOG-PS 0–1, and histologically/cytologically confirmed CRC adenocarcinoma not amenable to surgery and/or radiotherapy – will be randomized 1:1 to receive either N (200 mg bid) + BSC or placebo (bid) + BSC in 21-day courses until disease progression or undue toxicity. The study is powered to distinguish a clinically meaningful effect in the co-primary endpoints PFS and OS. Secondary endpoints are objective tumor response and disease control. Pts will be stratified at randomization based on previous R treatment, time from onset of metastatic disease to randomization and region. PFS and OS will be evaluated by the log-rank test to determine the effect of N independently at the two-sided alpha level of 0.05. Other assessments include frequency and severity of adverse events and changes in laboratory parameters to measure safety; health-related quality of life; and biomarker analyses focusing on exploring predictive biomarkers and drug resistance mechanisms. As of Jan 7, 2015, 180 pts were randomized and recruitment is ongoing. Results are expected in 2016. Clinical trial information: NCT02149108.

TPS3626 Poster Session (Board #116a), Mon, 8:00 AM-11:30 AM

Induction mFOLFOX6 with or without aflibercept followed by chemoradiation (CRT) and surgery in high risk rectal cancer: Phase II randomized, multicenter, openlabel trial—The GEMCAD RIA study. *First Author: Carlos Fernandez-Martos, Instituto Valenciano de Oncologia, Valencia, Spain*

Background: Induction chemotherapy (CT) before CRT and surgery is now considered a new treatment alternative for patients with locally advanced rectal (LAR) cancer. Willet et al. (Nat Rev 2004) demonstrated that Induction treatment with anti VEGF therapy bevacizumab (BEV) before CRT, decreased tumor interstitial fluid pressure and blood flow, suggesting normalization of the tumor vasculature. The AVCROSS phase II trial (Nogue, The Oncologist 2011) showed that BEV combined with induction CT followed by BEV combined with CRT and surgery produced high pCR rates (36%) but with an unacceptable rate of surgical reoperations. Aflibercept (Afli) (ziv-aflibercept in the US) is a novel anti-angiogenic agent that acts as a soluble receptor that binds to human VEGF-A, VEGF-B, PlGF. We hypothesized that administering induction Afli/FOLFOX followed by CRT will improve pCR rate without compromise wound healing. **Methods:** We will conduct a multicenter phase II randomized trial, stratified by mrT stage and institution, with 2:1 allocation, comparing preoperative induction mFOLFOX6 with or without Afli prior to standard CRT (capecitabine with 50.4 Gy) and surgery. Primary endpoint: pathological complete response (pCR). 180 patients (p) will be recruited (120 p for mFOLFOX6 + Aflibercept group and 60 p for mFOLFOX6). Assumptions: 10% of dropouts, 0.10% one-sided type-I error, 80% power to detect a 15% difference in pCR. 2 interim analyses for safety, efficacy/futility (Lan de Mets, O'brien-Fleming). Major eligibility criteria: High-risk rectal cancer with 1 of the following criteria on high resolution MRI: Extramural vascular invasion or extramural extension > 5 mms into perirectal fat or mesorectal fascia threatened or involved in middle T3 tumors. mrT3 distal and mrT4 or N2 middle or distal tumors. Enrollment began in January 2015. ClinicalTrials.gov Identifier: NCT02340949 Clinical trial information: 02340949.

TPS3627 Poster Session (Board #116b), Mon, 8:00 AM-11:30 AM

SWOG S0820/PACES (Preventing Adenomas of the Colon with Eflornithine and Sulindac): A randomized, double-blind, placebo-controlled phase III clinical trial. *First Author: Jason A. Zell, UC Irvine Health, Chao Family Comprehensive Cancer Center, Orange, CA*

Background: After standard treatment for stage 0-III colorectal cancer (CRC), patients remain at increased risk for metachronous high-risk adenomas (HRAs) and 2ndprimary CRCs. Polyamines, in excess, are implicated in CRC carcinogenesis. In prior CRC chemoprevention clinical trials, low doses of polyamine-inhibitory agents eflornithine (E) and sulindac (S) demonstrated impressive efficacy. In the prior phase III clinical trial of colorectal adenoma (CRA) patients the combination E+S vs. placebo for 3-years resulted in > 92% reduction in risk of HRAs. Utility of these agents in colon cancer survivors, however, is unknown. **Methods: Eligibility:**Patients age > 18 with colon or rectosigmoid adenocarcinoma, stage 0, I, II, or III are eligible. Patients with major cardiovascular risk factors (MI, CVA) are excluded, as are patients with hearing loss > 30dB at 4K Hz and below. Daily low dose aspirin is allowed. **Study Design:** Patients are enrolled 9-15 months postoperatively for a 3-year duration in the randomized, double-blind, placebo-controlled Phase III trial. The intervention consists of eflornithine 250mg or matching placebo 2 tablets daily and sulindac 150mg or matching placebo one tablet daily. Baseline and end-of-study audiograms are required. Using a 2x2 factorial design, we will conduct 3 formal comparisons, each at the 2-sided, alpha = .0167 level with > 80% power. We tested the marginal effects of E &S, and the combined effect of E+S compared to placebo only. 1488 patients will be accrued over 5 years. Optional study components include pharmacogenetic, pharmacokinetic, & diet/lifestyle studies. The DSMC last met in October of 2014 and suggested that the trial continue as planned. **Endpoints:** The primary objective is to assess whether eflornithine 500 mg or sulindac 150mg are effective in reducing the 3-year event rate, defined as HRA or 2nd primary CRC, in Stage 0- III colon cancer patients. **Hypothesis:** In stage 0-III colon cancer patients during postoperative year 1-4, one or both of the single active agents will produce a 35% decrease in the rate of HRAs + 2nd primary CRCs; combination E+S will result in a 58% decrease compared to placebo alone. Clinical trial information: NCT01349881.

TPS3628 Poster Session (Board #117a), Mon, 8:00 AM-11:30 AM

Multi-center, randomized, controlled, open-label effectiveness study of primary tumor resection or not in asymptomatic colorectal cancer with unresectable metastatic disease. *First Author: Gong Chen, Sun Yat-Sen Univ Cancer Ctr, Guangzhou, China*

Background: It is still unclear whether asymptomatic colorectal cancer patients with unresectable metastatic disease can benefit from palliative resection of primary tumor. Retrospective studies showed a controversial result that some patients who received the resection of the primary tumor would prolong their overall survival time for 6 months. We plan to initiate the first randomized study to evaluate the efficacy of the resection of primary tumor in asymptomatic metastatic colorectal cancer patients who respond to initial chemotherapy. **Methods:** This is a multi-center, randomized, controlled, open label, phase III study. The primary endpoint of the study was overall survival (OS) based on independent assessment. Secondary end-points include progress free survival (PFS), health-related quality of life (HRQoL) and toxicity profiles. The study was designed to have 80% power to detect a 0.71 HR of OS in surgery arm (from 15 month to 21 month). Results from a one-sided log rank test at 0.025 significance level will be presented. Based on these assumptions, a total of 480 patients are needed to observe 320 events. All asymptomatic colorectal cancer patients with unresectable metastatic disease who agree to join this study will receive screening chemotherapy (any useful first line chemotherapy can be used here, except -becacizumab-which may affect the safety of surgery) for 6 months. Those who respond to chemotherapy or stable will be randomly assigned (1:1) to receive surgical resection of the primary tumor or continue chemotherapy. The patients in surgery group will receive chemotherapy after recover from surgery. Recruitment will begin in March 2015. The duration of the trial will be 72 months (36 months recruitment and 36 months follow-up). Clinical trial information: NCT02149784.

TPS3629 Poster Session (Board #117b), Mon, 8:00 AM-11:30 AM

Phase IB/II study of neoadjuvant chemoradiotherapy with CRLX101 and capecitabine for locally advanced rectal cancer. *First Author: Andrew Wang, UNC Chapel Hill, Chapel Hill, NC*
