Background: There is strong interest in the development of novel agents and strategies to further improve the therapeutic ratio of neoadjuvant chemoradiotherapy for rectal cancer. One innovative approach is to incorporate nanoparticle (NP) therapeutics, which are designed to preferentially accumulate in tumors. CRLX101 is an investigational nanoparticle-drug conjugate with a camptothecin payload. Preclinically, CRLX101 has been shown to be a potent radiosensitizer in colorectal cancer. The purpose of this Phase IB/II study is to assess tolerability and to evaluate whether the addition of CRLX101 to capecitabine and radiotherapy can improve pathologic complete response (pCR) and clinical outcomes for rectal cancer. **Methods:** This ongoing open label, single-arm multicenter Phase Ib/II study is designed to evaluate the addition of CRLX101 to a standard 5FU-based chemoradiotherapy regimen in patients with locally advanced rectal carcinoma (stage cT3-4N0 or cT1-4N+). Phase Ib employed a 3+3 dose escalation design with starting dose of 12 mg/m^2. Dose level +1 was 15 mg/m^2, the MTD for single agent CRLX101. 8 patients have completed treatment without DLT (3 in cohort 1 and 5 in cohort 2) and 1 patient is undergoing treatment at the 15mg/m^2 dose level. We have identified 15mg/m2 as the MTD /RP2D. The Phase II portion of the study is ongoing and will evaluate the efficacy of this MTD/RP2D and further characterize the safety of CRLX101 combined with CRT. Patients in the Phase Ib portion with resectable disease and who were treated at the RP2D will be included in the Phase II study population for efficacy analysis. Target accrual is 53 evaluable patients in the Phase II trial and a primary endpoint of pCR rate will be evaluated using a Simon two-stage design. Secondary objectives include evaluation of pathological response, disease free survival (DFS) and overall survival (OS). We hypothesize that our proposed regimen will improve the rate of pCR compared to 15-20% historical benchmarks. If results are consistent with a pCR rate of at least 35%, the treatment regimen will be considered worthy of further investigation. Clinical trial information: NCT02010567. Clinical trial information: NCT02010567.

TPS3630 Poster Session (Board #118a), Mon, 8:00 AM-11:30 AM

The CAIRO4 study: The role of surgery of the primary tumour with few or absent symptoms in patients with synchronous unresectable metastases of colorectal cancer—A randomized phase III study of the Dutch Colorectal Cancer Group (DCCG). *First Author: Jorine 't Lam - Boer, Radboud University Medical Center, Nijmegen, Netherlands*

Background: There is no consensus regarding resection of the primary tumour with few or absent symptoms in patients with synchronous unresectable metastatic colorectal cancer. A potential benefit of resection of the primary tumour is to prevent complications of the primary tumour in later stages of the disease. Retrospective studies also show a potential survival benefit for patients undergoing resection. However, surgery can cause severe morbidity and mortality in this patient group. We hereby propose a randomized trial in order to demonstrate that resection of the primary tumour improves overall survival. **Methods:** The CAIRO4 study is a multicentre, randomized, phase III study of the Dutch Colorectal Cancer Group (DCCG). Patients with synchronous unresectable metastases of colorectal cancer and few or absent symptoms of the primary tumour are randomized 1:1 between systemic therapy only, and resection of the primary tumour followed by systemic therapy. Patients will be stratified according to location of the primary tumour (colon versus rectum), WHO performance status (0-1 versus 2), hospital of inclusion, serum LDH (normal versus abnormal) and number of metastatic sites (single versus multiple). To demonstrate a survival benefit of 6 months in the experimental arm, a total of 218 events are needed (80% power, significance lever 0.05). Accounting for accrual time and follow-up, we need a total of 360 patients (180 patients per arm). Systemic therapy will consist of fluoropyrimidine-based chemotherapy in combination with bevacizumab. The primary objective of this study is to determine the clinical benefit in terms of overall survival of initial resection of the primary tumour. Secondary endpoints include progression free survival, surgical morbidity, quality of life and the number of patients requiring resection of the primary tumour in the control arm. Accrual has started in September 2012. As of January 2015, 64 centres in the Netherlands and Denmark are participating in the CAIRO4 study. Clinical trial information: NCT01606098.

TPS3631 Poster Session (Board #118b), Mon, 8:00 AM-11:30 AM

The ORCHESTRA trial: A phase III trial of adding tumor debulking to systemic therapy versus systemic therapy alone in (mCRC) multi-organ metastatic colorectal cancer. *First Author: Elske C. Gootjes, Department of Medical Oncology, VU University Medical Center, Amsterdam, Netherlands*

Background: In the current multidisciplinary approach of mCRC, local treatment of oligometastases is common practice. Results of large case series of selected patients treated with complete surgical resection of metastatic lesions suggest that this approach substantially improves survival rates to around 30-60%. Other techniques such as radiofrequency or microwave ablation (RFA, MWA), transarterial chemoembolization (TACE) or stereotactic ablative radiotherapy (SABR) can also be applied in local treatment. Curative treatment options are generally not available for patients with extensive hepatic and/or extrahepatic mCRC. These patients primarily receive palliative systemic treatment consisting of combination chemotherapy as well as targeted agents. So far, reports on the benefit of local treatment for metastases in multi-organ mCRC have major limitations, including being small, non-randomized, single-center and retrospective. The benefit from local treatment of metastases for these patients should be established to allow for interruption of the standard systemic therapy and exposure to possible adverse events from local treatment. **Methods:** The 'ORCHESTRA' trial is a randomized multicenter clinical trial for patients with multi-organ mCRC, comparing the combination of chemotherapy and maximal tumor debulking versuschemotherapy alone (NCT01792934). We will examine the interplay of both efficacy and toxicity for the combination of systemic chemotherapy and locoregional therapy. Our study design incorporates systemic as well as local therapy in the experimental arm and combines local treatment modalities to pursue maximal tumor debulking. We aim to improve overall survival of patients with multi-organ mCRC by maximal tumor debulking after induction chemotherapy with at least six months. A total of 478 patients will be included to meet the primary endpoint (power 80%, type I error rate 5%). We define local treatments feasible when they can be performed within a 3-month time period to prevent extensive delay of systemic therapy. Currently, 34 patients are included in 19 participating Dutch hospitals. Clinical trial information: NCT01792934.

TPS3632 Poster Session (Board #119a), Mon, 8:00 AM-11:30 AM

MErCuRIC1: A Phase I study of MEK1/2 inhibitor PD-0325901 with cMET inhibitor crizotinib in *RAS*MT and *RAS*WT (with aberrant c-MET) metastatic colorectal cancer (mCRC) patients. *First Author: Sandra Van Schaeybroeck, Queen's University Belfast Centre for Cancer Research and Cell Biology, Belfast, United Kingdom*

Background: *RAS* is mutated (*RAS*MT) in ~55% of mCRC, and phase III studies have shown that patients harbouring *RAS* mutations do not benefit from anti-EGFR MoAbs. In addition, ~50% of *RAS* Wild Type (*RAS*WT) will not benefit from the addition of an EGFR MoAb to standard chemotherapy. Hence, novel treatment strategies are urgently needed for *RAS*MT and > 50% of *RAS*WT mCRC patients. c-MET is overexpressed in ~50-60%, amplified in ~2-3% and mutated in ~3-5% of mCRC. Recent preclinical studies have shown that c-MET is an important mediator of resistance to MEK inhibitors (i) in *RAS*MT mCRC, and that combined MEKi/METi resulted in synergistic reduction in tumour growth in *RAS*MT xenograft models (1). A number of recent studies have highlighted the role of c-MET in mediating primary/secondary resistance to anti-EGFR MoAbs in mCRC, suggesting that patient with *RAS*WT tumours with aberrant c-MET (*RAS*WT/c-MET+) may benefit from anti-c-MET targeted therapies (2). These preclinical data supported the further clinical evaluation of combined MEKi/METi treatment in *RAS*MT and *RAS*WT CRC patients with aberrant c-MET signalling (overexpression, amplification or mutation; *RAS*WT/c-MET+). **Methods:** MErCuRIC1 is a phase I combination study of METi crizotinib with MEKi PD-0325901. The dose escalation phase, utilizing a rolling six design, recruits 12-24 patients with advanced solid tumours and aims to assess safety/toxicity of combination, recommended phase II (RPII) dose, pharmacokinetics (PK) and pharmacodynamics (PD) (pERK1/2 in PBMC and tumour; soluble c-MET). In the dose expansion phase an additional 30-42 *RAS*MT and *RAS*WT/c-MET mCRC patients with biopsiable disease will be treated at the RPII dose to further evaluate safety, PK, PD and treatment response. In the dose expansion phase additional biopsy and blood samples will be obtained to define mechanisms of response/resistance to crizotinib/PD-0325901 therapy. Enrolment into the dose escalation phase began in December 2014 with cohort 1 still ongoing. EudraCT registry number: 2014-000463-40. (1) Van Schaeybroeck S et al. Cell Reports 2014;7(6):1940-55; (2) Bardelli A et al. Cancer Discov 2013;3(6):658-73. Clinical trial information: 2014-000463-40.

TPS3633 Poster Session (Board #119b), Mon, 8:00 AM-11:30 AM

Development of a phase Ib/IIa proof-of-concept study of imalumab (BAX69), a first-in-class anti-macrophage migration inhibitory factor (MIF) antibody, as the 3rd or 4th line treatment in metastatic colorectal cancer (mCRC). *First Author: Xiaochun Liu, Baxter Healthcare Corporation, Deerfield, IL*

Background: Patients with mCRC who fail 2 or 3 lines of treatment have few effective treatment options. MIF is dramatically upregulated in CRC tissue and its serum concentration positively correlates with increased tumor aggressiveness and risk of hepatic metastasis in CRC pts. MIF appears to contribute to cancer progression in tumor-associated anti-apoptosis, angiogenic growth factor expression, neovascularization and hypoxic adaptation. Imalumab is a novel recombinant, fully-human, monoclonal antibody specific for the pathogenic form of MIF (oxMIF). Imalumab showed preliminary antitumor activity with acceptable tolerability in a phase I study (NCT01765790) in patients with cancers, including mCRC. Imalumab has synergistic effects with chemotherapeutic agents in mCRC preclinical models independent of KRAS or p53 mutational status, leading us to evaluate imalumab-based combination regimens. **Methods:** We adopted a two-step approach for this trial. A safety run-in dose escalation phase will be conducted first with imalumab at 7.5mg/kg weekly in combination with 5-FU/LV or panitumumab in mCRC patients with or without KRAS/NRAS mutation, respectively. In the absence of dose limiting toxicities (DLTs), imalumab will be escalated to 10mg/kg weekly to evaluate DLT (primary endpoint) and determine the recommended phase II dose of imalumab combined with 5-FU/LV or panitumumab. Then, a randomized (2:1) phase II portion will investigate whether imalumab plus 5-FU/LV (KRAS/NRAS mut) or panitumumab (KRAS/NRAS wild type) is superior to standard of care at the 3rd or 4th line treatment setting in prolonging progression-free survival (primary endpoint) in mCRC patients. Secondary endpoints include safety and tolerability, overall survival and response rate, the pharmacokinetic (PK) profile of imalumab in combination with 5 FU/LV or panitumumab, quality of life, and biomarker association with treatment response. An accrual of 12-24 pts for the safety run-in phase and 66 pts for the randomized phase is planned. Eligibility includes diagnosis of mCRC and failure of 2-3 lines of therapies. Clinical trial information: pending.

TPS3634 Poster Session (Board #120a), Mon, 8:00 AM-11:30 AM

Phase III study of regorafenib versus placebo as maintenance therapy in RAS wild type metastatic colorectal cancer (RAVELLO trial). *First Author: Erika Martinelli, Medical Oncology, Second University of Naples, Naples, Italy*

Background: Treatment of metastatic colorectal cancer (mCRC) has improved due to the introduction of more active chemotherapies (CT) and novel targeted agents that have significantly increased response rate (RR), progression free survival (PFS) and overall survival (OS). Recently, CORRECT and CONCUR trials have demonstrated both activity and efficacy of regorafenib, a small multi-kinase inhibitor, as monotherapy in pretreated mCRC. The wide range of action of regorafenib makes it an ideal candidate for monotherapy in earlier disease treatment lines in which different pathways could be involved in the acquisition of resistance. To improve long term efficacy of first line therapy several therapeutic approaches of maintenance treatment have been explored in mCRC. **Methods:** RAVELLO is an academic randomized, double-blind, placebo-controlled, multi-center, phase III study designed to evaluate efficacy and safety of regorafenib as maintenance treatment after first line therapy. Eligible patients: pathologically confirmed mCRC RAS wild type (KRAS and NRAS genes) treated with a first line fluoropyrimidine-based CT in combination with an anti-EGFR (epidermal growth factor receptor) monoclonal antibody for a minimum of 4 to a maximum of 8 months, with a stratification by response to the first line treatment (complete response/partial response or stable disease). 480 patients will be enrolled and randomly assigned in a 1:1 ratio to receive 160 mg regorafenib or placebo per os, every day for 3 weeks of every 4 weeks cycle, until disease progression or unacceptable toxicity. Primary endpoint is PFS. With a two-tailed alpha error of 0.05, the study will have 90% power to detect a 3-month prolongation of median PFS from randomization (corresponding to a hazard ratio of progression of 0.67 with 6-month median PFS expected in the control arm). Secondary endopoint are OS, safety, and biomarker correlative studies. Currently, one patient has been enrolled and is on treatment. EudraCT number: 2013-005428-41. Clinical trial information: 2013-005428-41.

TPS3635 Poster Session (Board #120b), Mon, 8:00 AM-11:30 AM

A phase 3 open-label, randomized, multicenter study of imprime PGG in combination with cetuximab in patients with KRAS wild type metastatic colorectal cancer. *First Author: Richard Dale Huhn, Biothera, Eagan, MN*

Background: Imprime PGG (Imprime) is a beta-1,3/1,6 glucan complex carbohydrate biologic, which harnesses innate immune effector cells to enhance killing of antibody-targeted, complement-opsonized tumor cells. In a phase 2 single-arm clinical trial in metastatic colorectal cancer (mCRC), the combination of Imprime with cetuximab resulted in 24% objective response rate (ORR), 62% disease control rate (DCR), and median time to progression (TTP) of 12 wks (Tamayo ME, Ann Onc 2010), representing approximate 100% increases vs historical control (Cunningham, NEJM 2004). ORR was 45%, DCR, 82% and TTP of 24 wks in patients (pts) with KRAS wild-type (WT) tumors (post hoc analysis). Single-agent cetuximab has been shown to improve ORR, progression-free survival (PFS) and overall survival (OS) in pts with epidermal growth factor receptor (EGFR) expressing, KRAS WT mCRC who failed oxaliplatin- and irinotecan-based therapy or are intolerant to irinotecan. The mechanism of action of cetuximab is thought to rely on competitive blockade of endogenous ligand binding and downstream signaling, internalization and down regulation of EGFR, as well as antibody-dependent cellular cytotoxicity (ADCC) (Erbitux USPI). The current trial, sponsored by Biothera and registered with ClinicalTrials.gov (NCT01309126) is to confirm these findings in phase 3. **Methods:** Eligible pts have received prior oxaliplatin- and irinotecan-based therapy or are intolerant to irinotecan, have measurable disease and ECOG performance status of 0 or 1. Approximately 795 pts will be randomized 2:1, stratified by geographic region, prior chemotherapy and site, to receive weekly open-label Imprime plus cetuximab or cetuximab alone. The primary endpoint of the study is OS and the primary analysis will occur when ~709 deaths have occurred. Secondary endpoints include PFS, ORR (based on RECIST 1.1), quality of life, safety and pharmacokinetics. Exploratory endpoints include biomarker analyses. Pt screening and enrollment is underway in the United States and Europe. Clinical trial information: NCT01309126.

4000 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase III, randomized, double-blind, multicenter, placebo (P)-controlled trial of rilotumumab (R) plus epirubicin, cisplatin and capecitabine (ECX) as first-line therapy in patients (pts) with advanced MET-positive (pos) gastric or gastroesophageal junction (G/GEJ) cancer: RILOMET-1 study. *First Author: David Cunningham, Royal Marsden Hospital, Sutton, Surrey, United Kingdom*

Background: R is a fully human monoclonal antibody to hepatocyte growth factor. A phase 2 study showed improved overall survival (OS) and progression-free survival (PFS) with R + ECX vs P + ECX in MET-pos G/GEJ cancer (*Lancet Oncol* 2014;15:1007). This phase 3 trial evaluated the efficacy and safety of R + ECX in MET-pos G/GEJ cancer. **Methods:** Key eligibility criteria: ≥ 18 yr; previously untreated, pathologically confirmed unresectable advanced G/GEJ adenocarcinoma; ECOG score 0–1; tumor MET-pos by IHC; HER2-negative. Pts were randomized 1:1 to receive ECX (IV epirubicin 50 mg/m^2 D1, IV cisplatin 60 mg/m^2 D1, oral capecitabine 625 mg/m^{2}BID D1−21) + R 15 mg/kg or P IV Q3W and stratified by disease extent (locally advanced vs metastatic) and ECOG score (0 vs 1). Primary endpoint: OS. A log-rank test stratified by randomization factors compared OS between arms. The study was powered to detect a HR of 0.69. Key secondary endpoints: PFS, 12-mo survival rate, objective response rate (ORR), safety and pharmacokinetics (PK). **Results:** 609 pts were randomized from Nov 2012 to Nov 2014. The study was stopped early based on an imbalance in deaths (R vs P: 128 vs 107 deaths, data cutoff: 27 Nov 2014). R was not superior to P for OS (one-sided test, p = 0.99). OS, PFS and ORR were statistically worse in the R arm. No subgroups seemed to benefit with R, including those with higher percentages of cells with ≥ 1+ MET expression. Most common AEs that were higher with R: peripheral edema, hypoalbuminemia, deep vein thrombosis and hypocalcemia. **Conclusions:** RILOMET-1 did not meet its primary endpoint; OS was statistically significantly worse with R. PK and MET biomarker analyses are pending. Clinical trial information: NCT01697072.

	R (n = 304)	P (n = 305)	R vs P
Median OS,* mo	9.6 (7.9–11.4)	11.5 (9.7–13.1)	HR† = 1.37 (1.06–1.78) p = 0.016
Median PFS,* mo	5.7 (5.3–5.9)	5.7 (5.5–7.1)	HR† = 1.30 (1.05–1.62) p = 0.016
12-mo survival rate*	38.4% (30.2%–46.6%)	49.7% (41.5%–57.4%)	Diff = -11.4 (-22.9–0.2) p = 0.053
ORR*	30% (24.6%–36.0%)	39.2% (33.3%–45.4%)	Odds ratio = 0.67 (0.46–0.96) p = 0.027

*95% CI shown. †Stratified.

4001 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Relationship between PD-L1 expression and clinical outcomes in patients with advanced gastric cancer treated with the anti-PD-1 monoclonal antibody pembrolizumab (MK-3475) in KEYNOTE-012. *First Author: Yung-Jue Bang, Seoul National University College of Medicine, Seoul, South Korea*

Background: Tumors use the PD-1 pathway to evade immune surveillance. Pembrolizumab, an anti–PD-1 monoclonal antibody, has shown antitumor activity in advanced cancers. We assessed the safety and efficacy of pembrolizumab in patients with advanced gastric cancer in KEYNOTE-012 (Clinicaltrials.gov identifier, NCT01848834). **Methods:** Archival tumor samples from patients from Asia-Pacific (AP) and rest of the world (ROW) with recurrent or metastatic adenocarcinoma of the stomach or gastroesophageal junction were screened for PD-L1 expression using a prototype IHC assay with the 22C3 antibody. Only patients with distinctive stromal or ≥ 1% tumor nest cell PD-L1 staining were eligible. Patients received pembrolizumab 10 mg/kg every 2 weeks for up to 24 months or until complete response, progression, or unacceptable toxicity. Imaging was performed every 8 weeks. Primary efficacy end point is ORR assessed per RECIST v1.1 by independent central review. Secondary end points include duration of response, PFS, and OS. **Results:** Of the 162 patients screened, 65 (40%) were PD-L1^{+}. Of these 65 patients, 39 enrolled (19 from AP, 20 from ROW; median age, 63 years [range, 33-78]). The number of prior therapies for advanced disease ranged from 0 to 5; 67% received ≥ 2 prior therapies. Median follow-up duration was 8.8 months (range, 6.2-12.6); 13 patients (33%) remain on therapy. Four patients experienced 5 total grade 3-5 drug-related adverse events: peripheral sensory neuropathy, fatigue, decreased appetite, hypoxia, and pneumonitis (n = 1 each). There was 1 drug-related death (hypoxia). ORR was 22% (95% CI, 10-39) by central review and 33% (95% CI, 19-50) by investigator review. Median time to response was 8 weeks (range, 7-16), with a median response duration of 24 weeks (range, 8+ to 33+). PD-L1 expression level was associated with ORR (1-sided $P = 0.10$). The 6-month PFS rate was 24%. The 6-month OS rate was 69%. **Conclusions:** Pembrolizumab demonstrated manageable toxicity and promising antitumor activity in advanced gastric cancer. These results support the ongoing development of pembrolizumab for gastric cancer. Clinical trial information: NCT01848834.

4002 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Neoadjuvant chemotherapy for resectable oesophageal and junctional adenocarcinoma: Results from the UK Medical Research Council randomised OEO5 trial (ISRCTN 01852072). *First Author: Derek Alderson, Queen Elizabeth Hospital, Birmingham, United Kingdom*

Background: Neoadjuvant chemotherapy (2 cycles cisplatin/5 fluorouracil) (CF) followed by surgery is a standard of care for locally advanced oesophageal cancer. We investigated whether more chemotherapy (4 cycles epirubicin/cisplatin /capecitabine (ECX)) would improve outcomes. **Methods:** A multi-centre, randomised, phase III trial comparing 2 cycles of CF with 4 cycles of ECX followed by oesophagectomy with 2-field lymphadenectomy for lower oesophageal and junctional (Types I and II) adenocarcinoma. Primary outcome was overall survival (OS); 842 patients (677 deaths) would detect an increase in 3-year survival from 30% to 38% (or 37%) with 82% (or 70%) power with $2\alpha = 5\%$. Deaths accrued more slowly than anticipated but the Independent Data Monitoring Committee considered the data sufficiently robust for release. Secondary outcomes include disease-free (DFS) and progression-free survival (PFS), pathological R0 resection rate, Mandard grade and quality of life. **Results:** From 2005-2011, 897 patients (451 CF, 446 ECX) from 72 UK centres were randomly allocated (1:1). Baseline characteristics were similar between the groups (overall, male 90%, median age 62 (IQR 56-67), staging included PET 60%, T3 N0 22%, T3 N1 65%). 96% CF received 2 cycles, 89% ECX > 3 cycles. Grade 3/4 toxicity was lower with CF (30% v 47% p < 0.001.) Of those patients having a resection R0 rates were CF 60%, ECX 66% with a Mandard grade ≤ 3 achieved in CF 15% v ECX 32% with 3 and 11% achieving complete response. Post-operative complications were similar (CF 57%, ECX 62%) as were deaths at 30 (CF 2%, ECX 2%) and 90 days post-surgery (CF 4%, ECX 5%). PFS and DFS favoured ECX, hazard ratio (HR, 95% CI) PFS 0.86 (0.74-1.01), DFS 0.88 (0.75-1.03). HR for OS was 0.92 (0.79-1.08, p = 0.3017) based on 315 CF and 298 ECX deaths, with similar 3 year survival rates CF 39% (35-44%) vs ECX 42% (37-46%). **Conclusions:** There is some evidence of a benefit from the prolonged ECX regimen, in terms of PFS, DFS and tumour regression at resection, but this does not translate into a survival benefit. Overall chemotherapy toxicity was higher with 4 cycles of ECX compared to 2 cycles of CF but surgical morbidity was not increased. Clinical trial information: 01852072.

4003 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

INTEGRATE: A randomized, phase II, double-blind, placebo-controlled study of regorafenib in refractory advanced oesophagogastric cancer (AOGC): A study by the Australasian Gastrointestinal Trials Group (AGITG)—Final overall and subgroup results. *First Author: Nick Pavlakis, Department of Medical Oncology, Royal North Shore Hospital, The University of Sydney, Sydney, Australia*

Background: REG is an oral multi-kinase inhibitor warranting evaluation in AOGC following failure of 1st or 2nd line chemotherapy (CT) where few options exist. **Methods:** International (Australia & New Zealand (ANZ), Korea, Canada (NCIC CTG)) phase II RCT with 2:1 randomization to 160 mg REG or matched Placebo (PBO) on days (D) 1-21 each 28 D cycle until disease progression (PD) or prohibitive adverse events. Primary endpoint: progression free survival (PFS). Final analysis used data to December 31, 2014. **Results:** 152 patients (pts) enrolled (November 2012 to February 2014) yielding 147 pts evaluable for analysis (97 REG and 50 PBO). M:F (118:29); primary site: OGJ (56), stomach (85); lines of prior CT: 1 (62), 2 (85); ECOG PS 0 (62): 1 (85). Median (med.) treatment wks: 8 (REG) v 4 (PBO). Med. REG dose intensity: 150 mg (130 mg Korea and 160mg ANZ/Can). 27 PBO pts received REG following PD. REG Med. PFS 11.1 wks (95% CI: 7.7 – 13.3) v PBO 3.9 wks (3.7 - 4.0), HR 0.40, p < 0.0001. Med. REG OS 25 wks (95% CI: 18.9-29.6) v PBO 19.4 wks (95% CI: 14.9 – 22.7), HR 0.74, p = 0.11. Pre-specified analyses found REG effect greater in Korea than ANZ/Can (HR 0.12 v 0.61, p = 0.0009) but consistent across age, NLR, primary site, lines of CT, peritoneal metastases (mets) presence, number of met. sites, and VEGF-A (Table). Results comparable for ITT population (n = 152). REG was well tolerated, with expected spectrum of toxicities. **Conclusions:** REG was highly effective in prolonging PFS across a broad range of pts, with a non-significant positive OS trend. Regional differences were found in the magnitude of effect but REG was effective in all regions and subgroups. A phase III trial is merited. Clinical trial information: 12612000239864.

4004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

SWOG S0518: Phase III prospective randomized comparison of depot octreotide plus interferon alpha-2b versus depot octreotide plus bevacizumab (NSC #704865) in advanced, poor prognosis carcinoid patients (NCT00569127). *First Author: James C. Yao, Department of GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment options for advanced carcinoid tumors (NETs) are limited. Somatostatin analogues (SSA) prolong progression-free survival (PFS) among patients (pts) who are treatment naïve or have stable disease. Interferon (INF) added to SSA has also demonstrated antitumor activity. Bevacizumab (BEV), added to SSA, octreotide (OCT), was associated with tumor regression and encouraging antitumor activity in a phase II study. The current study compares BEV + OCT to INF α-2b + OCT. Method: Pts with metastatic or unresectable, well-differentiated, G1/2 NETs with progressive disease or other poor prognostic features were randomly assigned (1:1) to receive OCT LAR 20 mg q 21 days with either BEV 15 mg/kg every 21 days or INF α-2b 5 million units three times per week. PFS by central review was the primary endpoint. Results: 427 pts were enrolled, of whom 402 were eligible, between December 2007 and September 2012. Median PFS by central review was 16.6 (95% CI: 12.9 – 19.6) months in BEV arm and 15.4 (95% CI: 9.6 – 18.6) months in the INF arm (HR 0.93; 95% CI 0.73-1.18; P = 0.55). By investigator review, median PFS was 15.4 (95% CI: 12.6 – 17.2) months in BEV arm and 10.6 (95% CI: 8.5 – 14.4) months in the INF arm (HR 0.90; 95% CI: 0.72 - 1.12; P = 0.33). TTF was significantly longer with BEV compared to INF (HR 0.72; 95% CI 0.58 - 0.89; P = 0.003). Median TTF was 9.9 (95% CI: 7.3 – 11.1) months in the BEV arm and 5.6 (95% CI 4.3 – 6.4) months in the INF arm. Confirmed radiologic response rates were 12% (95% CI: 8% - 18%) in the BEV arm and 4% (95% CI: 2% - 8%) in the INF arm. Common AEs with BEV + OCT included HTN (32%), proteinuria (9%), and fatigue (7%); and with INF + OCT included fatigue (27%), neutropenia (12%), and nausea (6%). Conclusion: BEV + OCT was associated with longer TTF compared to IFN + OCT; radiologic responses also appeared to be more frequent among pts treated with BEV + OCT. However, no significant differences in PFS were observed, suggesting that BEV and IFN have similar antitumor activity in pts with advanced carcinoid. Support: NIH/NCI grants CA180888, CA180819, CA180799, CA180820, CA180821 and CA025224, and in part by Genentech. Clinical trial information: NCT00569127.

4005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Randomized phase II study of everolimus (E) versus everolimus plus bevacizumab (E+B) in patients (Pts) with locally advanced or metastatic pancreatic neuroendocrine tumors (pNET), CALGB 80701 (Alliance). *First Author: Matthew H. Kulke, Dana-Farber Cancer Institute, Boston, MA*

Background: Both VEGF pathway and mTOR inhibitors are active in pNET. Treatment with the mTOR inhibitor E improves progression free survival (PFS), but it is not known if the addition of a VEGF pathway inhibitor to an mTOR inhibitor enhances antitumor activity in pNET. This randomized phase II study evaluated E or E+B in pts with advanced pNET. **Methods:** Pts were randomized 1:1 to receive either E (10 mg po qd) or E (10 mg po qd) co-administered with B (10 mg/kg IV q 2 wks). Pts in both arms received concurrent standard dose octreotide. The primary endpoint was PFS. The potential superiority of E+B vs. E was assessed using a stratified log-rank test with 90% power (1-sided $\alpha = 0.15$) to detect a HR of 0.64. Secondary endpoints included overall survival (OS), response rate (RR), and safety. **Results:** 150 pts were randomized; 75 per arm. Pt characteristics were similar between treatment arms and included: median age 59 years (range 21-86), 56% male, ECOG PS 0 (57%) and 1 (43%), prior cytotoxic chemotherapy 24%. The median number of 28-day treatment cycles was 13 (E+B) and 12 (E), with a range of 1-44 cycles. Median follow up was 25.9 months. Pts on E+B experienced a higher frequency of grade 3 AEs, including diarrhea (14% vs. 3%; p = 0.01), hyponatremia (12% vs. 3%; p = 0.02), hypophosphatemia (11% vs. 3%; p = 0.04), proteinuria (16% vs. 1%; p = 0.001), and hypertension (41% vs. 12%; p < 0.0001). The frequency of grade 4 AEs was 11% in both arms; a single grade 5 event occurred on E. The median PFS was 16.7 mos (E+B) vs. 14 mos (E); HR = 0.80 (95% CI: 0.55, 1.17; 116 PFS events), 1-sided p = 0.12. The median OS was 36.7 mos (E+B) vs. 35.0 mos (E), HR = 0.75 (95% CI: 0.42-1.33; 49 OS events), 1-sided p = 0.16. Treatment with E+B was associated with a significantly higher RR (31%) compared to E alone (12%), p = 0.005) **Conclusions:** Treatment with E+B led to superior PFS compared to E but with more adverse events in this randomized phase II study. The RR was significantly higher in pts treated with E+B. The combination of E+B warrants further investigation in pts with advanced pNET. Clinical trial information: NCT01229943.

4006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

High response rate and PFS with PEGPH20 added to nab-paclitaxel/gemcitabine in stage IV previously untreated pancreatic cancer patients with high-HA tumors: Interim results of a randomized phase II study. *First Author: Sunil R. Hingorani, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Poor outcomes in pancreatic cancer (PDA) are associated in part with tumor stroma limiting chemotherapy perfusion. PDAs express high levels of hyaluronan (HA), which contributes to elevated interstitial pressures. PEGylated recombinant human hyaluronidase, PEGPH20, depletes HA in tumors. In a Phase Ib study of PEGPH20 with Gemcitabine (Gem), patients (pts) whose tumors were HA^{high} had improved ORR, PFS and OS compared to those with tumors that were HA^{Low}. **Methods:** This is an ongoing phase II, open-label, randomized study of PEGPH20 +Nab-Paclitaxel (Nab) + Gem (PAG) vs. Nab + Gem (AG) in previously untreated pts with Stage IV PDA. Pts receive 3 μg/kg twice weekly (Cycle 1) and then weekly (Cycle 2+) PEGPH20 in combination with standard dosing of AG. HA status was tested retrospectively. Primary endpoint is PFS, secondary endpoints include: ORR, OS and Safety. Due to a temporary clinical hold, ORR is from data through April 2014; and PFS is data through December 2014. **Results:** 146 pts were enrolled and 135 pts received at least one dose of study drug. The mean age was 65.1 yrs. (Range 29-83 yrs), 93% had a KPS of $\geq$ 80. The most common AEs related to study drugs (PAG vs. AG) were: fatigue (68% vs. 69%), nausea (55% vs. 44%), anemia (42% vs. 53%) peripheral edema (58% vs. 31%) and muscle spasms (55% vs. 2%). There was an imbalance of thromboembolic (TE) events with 42% vs. 25% of subjects having at least one TE event. Overall RR and PFS are shown in the table below. **Conclusions:** PEGPH20 + Nab/Gem is generally well tolerated in advanced PDA. Patients with HA^{high} tumors receiving PAG had greater ORR and longer PFS than HA^{high} patients receiving AG. Overall survival will be presented at the time of the meeting. ClinicalTrials.gov Identifier NCT01839487. Clinical trial information: NCT01839487.

Endpoint/Population	PAG	AG	P-value
ORR			
N = 135	25/74 (34%)	14/61 (23%)	0.17
HA^{High} N = 34	12/17 (71%)	5/17 (29%)	0.02
HA^{Low} N = 28	9/18 (50%)	5/10 (50%)	0.94
PFS			
N = 135	42/74; 5.7 months	39/61; 5.2 months	0.10
HA^{High} N = 48	12/25; 9.2 months	15/23; 4.3 months	0.03
HA^{Low} N = 58	22/36; 4.8 months	15/22; 5.6 months	0.81

4007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

CONKO-005: Adjuvant therapy in R0 resected pancreatic cancer patients with gemcitabine plus erlotinib versus gemcitabine for 24 weeks—A prospective randomized phase III study. *First Author: Marianne Sinn, Charité - Universitätsmedizin Berlin, Medical Oncology, Berlin, Germany*

Background: Adjuvant chemotherapy with gemcitabine (Gem) for 6 months significantly improves survival of pancreatic cancer patients. CONKO-005 was designed to evaluate an additional effect of the EGFR-tyrosinkinase-inhibitor erlotinib (Erlo 100 mg p.o. daily) in combination with Gem (1000 mg/m² i.v. day 1,8,15, q29) for 24 weeks in pts after R0 resection. **Methods:** In an open-label multicenter design, pts were randomised within 8 weeks after operation to receive GemErlo or Gem; stratified by lymph node involvement, operation techniques, study centre. The primary endpoint was disease-free survival (DFS). The study was planned with a power of 80% at a significance level of 0.05 to detect an improvement of DFS from 14 to 18 months. Secondary objectives were median overall survival (OS) and treatment safety. Kaplan-Meier analyses were performed; survival data for the treatment arms compared using log-rank test. **RESULTS:** Between April 2008 and July 2013, 219 pts were randomized to GemErlo and 217 to Gem. Pts characteristics are well balanced (GemErlo/Gem): age (median 63/65 years), tumor status (T3/T4 88/86%), nodal status (N pos 64/66%), grading (G3 33/34%). After a median follow up of 41 months (March 2015), 350 events (80%) occurred. Median treatment duration was 22 weeks in both groups. Grade 3/4 toxicities were (GemErlo%/Gem%): rash 7/0.4, diarrhea 5/1, nausea 2/2, fatigue 5/2, hypertension 3/1,GGT 9/9, neutropenia 27/28, thrombopenia 5/2. There was no difference in DFS (median: GemErlo 11.6 months, Gem 11.6 months; HR 0.89, 95%CI 0.72-1.10) or OS (median: GemErlo 24.6 months, Gem 26.5 months; HR 0.90, 95%CI 0.71-1.15). There was no correlation between the grade of rash and an improved DFS in the GemErlo group (median: rash grade 0-1 vs > = grade 2 12.2 vs 11.0 months; HR 0.91, 95%CI 0.66-1.25). OS curves show a late divergence in favour of GemErlo (estimated survival after 2/3/4/5-years: 54/36/31/28% vs 53/33/22/19%). **Conclusion:** The combination therapy of GemErlo for 24 weeks did not improve DFS or OS. There is a trend in favour of long-term survival in pts treated with GemErlo. Clinical trial information: DRKS00000247.

4008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Preoperative modified FOLFIRINOX (mFOLFIRINOX) followed by chemoradiation (CRT) for borderline resectable (BLR) pancreatic cancer (PDAC): Initial results from Alliance Trial A021101. *First Author: Matthew H. G. Katz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Infusional 5-FU, oxaliplatin, leucovorin and irinotecan (FOLFIRINOX) is effective for metastatic PDAC. The tolerability and efficacy of neoadjuvant FOLFIRINOX and CRT for BLR PDAC is unknown. **Methods:** Patients (pts) with ECOG PS 0/1 and PDAC meeting any of the following centrally-reviewed radiographic criteria: 1) tumor-vessel interface (TVI) with superior mesenteric/portal vein (SMV) ≥ 180°, 2) TVI with superior mesenteric artery (SMA) < 180°, 3) TVI with hepatic artery of any degree, received mFOLFIRINOX (oxaliplatin 85 mg/m^2, irinotecan 180 mg/m^2, leucovorin 400 mg/m^2 on day 1 followed by 5-FU 2400 mg/m^2 x 48 hours for 4 cycles) and CRT (50.4 Gy in 28 fractions) with capecitabine (825mg/m^2 BID) prior to pancreatectomy and postoperative gemcitabine (1000 mg/m^2 d1, 8,15 x 2 cycles). **Results:** 22 of 23 enrolled pts started therapy (median age 64 years, 64% ECOG PS 0). All pts completed mFOLFIRINOX and 21 (95%) completed CRT. The best RECIST responses during pre-op treatment were 2 CR, 4 PR, 15 SD and 1 PD. 7 patients did not undergo planned resection due either to progression (6) or refusal (1). Among the 15 (68%) patients who did undergo pancreatectomy, 14 (93%) operations were R0; 80% and 27% of operations required vein or hepatic artery resection, respectively; 7 (47%) specimens had < 5% residual tumor cells following therapy. Among all pts, 68% [95% CI (45.1 – 86.4)] underwent R0/R1 resections and 2 (9%) achieved pathologic CR. Related grade III and IV adverse events were observed in 46% (10 of 22) and 5% (1 of 22) of pts during chemotherapy, 38% (8 of 21) and 0% during CRT, and 15% (2 of 13) and 31% (5 of 13) following pancreatectomy; 1 pt died within 90 days of surgery. 18 pts are alive with an immature median follow-up of 10 months. **Conclusions:** In this multi-institutional study of pts with PDAC tumors that had a substantial radiographic interface with the SMV, SMA or hepatic artery, mFOLFIRINOX and CRT was associated with manageable toxicity that did not preclude subsequent resection. Although a RECIST response was uncommon, the efficacy of this preoperative regimen is suggested by high rates of R0 resection and pathologic response. Clinical trial information: NCT01821612.

4009 Clinical Science Symposium, Sun, 4:30 PM-6:00 PM

Comprehensive genomic profiling of biliary tract cancers to reveal tumor-specific differences and frequency of clinically relevant genomic alterations. *First Author: Jeffrey S. Ross, Albany Medical College, Albany, NY*

Background: Intrahepatic cholangiocarcinoma (IHCCA), extrahepatic cholangiocarcinoma (EHCCA) and gallbladder carcinomas (GBCA) typically present at an advanced stage and chemotherapy provides only modest benefit in most cases. We queried whether comprehensive genomic profiling (GCP) of IHCCA, EHCCA and GBCA would reveal distinctive patterns of genomic alterations (GA) and identify clinically relevant GA (CRGA) that could lead to targeted therapies. **Methods:** DNA was extracted from 412 IHCCA, 57 EHCCA and 85 GBCA. CGP was performed on hybridization-captured libraries to a mean coverage depth of > 600X for 236 cancer-related genes. The CGP assay included base substitutions, INDELs, copy number alterations and fusions/rearrangements. CRGA were defined as GA linked to drugs on the market or under evaluation in mechanism driven clinical trials. **Results:** Patient characteristics were similar for all three tumor types. IHCCA and GBCa were more common in females and EHCCA were more common males. Findings in the table below. Multiple antitumor responses to targeted therapies in each of the 3 tumor types will be presented. **Conclusions:** IHCCA, EHCCA and GBCA share frequent GA in cell cycle regulation (*CDKN2B*) and chromatin remodeling (*ARID1A*). IHCCA is further characterized by *FGFR* fusions, *IDH1/2* substitutions, *BRAF* substitutions and *MET* amplification with a low *KRAS* mutation frequency. EHCCA and GBCA have frequent *ERBB2* amplifications (GBCA > EHCCA) and PIK3CA/MTOR pathway alterations. *KRAS* mutation frequency is high in EHCCA and low in GBCA. The diverse landscape of CRGA in biliary tract cancers can serve as targets for therapies, either approved or in clinical trials for the majority of patients with CCA, BDCA and GBCA and have the potential to improve outcomes for patients with these aggressive forms of malignancy.

CGP Findings	IHCCA	EHCCA	GBCA
Total GA/patient	3.6	4.4	4.0
CRGA/patient	2.0	2.1	2.0
***ERBB2* Amplification**	4%	11%	16%
***BRAF* Substitutions**	5%	3%	1%
***KRAS* Substitutions**	22%	42%	11%
***PI3KCA*Substitution**	5%	7%	14%
***FGFR1-3* Fusions and Amplifications**	11%	0	3%
***CDKN2A/B* Loss**	27%	17%	19%
***IDH1/2* Substitutions**	20%	0	0
***ARID1A* Alterations**	18%	12%	13%
***MET* amplification**	2%	0	1%

4010 Clinical Science Symposium, Sun, 4:30 PM-6:00 PM

Pembrolizumab (MK-3475) for patients (pts) with advanced esophageal carcinoma: Preliminary results from KEYNOTE-028. *First Author: Toshihiko Doi, National Cancer Center Hospital East, Chiba, Japan*

Background: Expression of the PD-1 ligands PD-L1 and PD-L2 has been associated with poor prognosis in esophageal cancer. Pembrolizumab is a highly selective humanized monoclonal antibody against PD-1 designed to block the interaction between PD-1 and PD-L1 and PD-L2. We assessed pembrolizumab safety and efficacy in pts with PD-L1+ esophageal carcinoma. **Methods:** KEYNOTE-028 (NCT02054806) is a nonrandomized, multicohort, phase Ib trial of pembrolizumab for PD-L1+ advanced solid tumors. Key eligibility criteria for this cohort included squamous cell carcinoma (SCC) or adenocarcinoma of the esophagus or gastroesophageal junction, measurable disease, PD-L1 expression in ≥ 1% of cells in tumor nests or PD-L1+ stromal bands determined centrally by IHC, failure of standard therapy, ECOG PS 0-1, and no autoimmune disease. Pembrolizumab 10 mg/kg is being given every 2 weeks for up to 2 years or until confirmed progression, unacceptable toxicity, or investigator decision. Response is assessed every 8 weeks for the first 6 months and every 12 weeks thereafter. Primary end points are safety, tolerability, and ORR per RECIST v1.1 by investigator review. **Results:** Of the 90 pts with esophageal cancer who were screened, 37 (41%) had PD-L1+ tumors. Of the 23 pts treated between March and December 2014, 83% were men and median age was 65. Histology was squamous in 77% of pts, adenocarcinoma in 18%, and mucoepidermoid in 5%. Eighty-seven percent of pts received ≥ 2 prior therapies for metastatic disease; all pts received ≥ 1 platinum-based therapy. Six pts (26%) experienced drug-related adverse events (DRAEs), including 2 (9%) who experienced grade 3 DRAEs. There were no grade 4 DRAEs, and no pts died or discontinued due to a DRAE. ORR (confirmed and unconfirmed) was 23% (n = 5); best response was stable disease in 18% (n = 4) and progressive disease in 59% (n = 13). One pt did not have response assessed at the time of analysis. Six pts, including all responders, remain on treatment. **Conclusions:** Pembrolizumab has an acceptable safety profile and provides promising antitumor activity in pts with heavily pretreated, PD-L1+ advanced esophageal carcinoma. These data support further study of pembrolizumab for pts with esophageal carcinoma. Clinical trial information: NCT02054806.

4011 Clinical Science Symposium, Sun, 4:30 PM-6:00 PM

Hepatitis B- and C-associated hepatocellular carcinoma in a large U.S. cancer center: Do clinicopathologic features or patient outcomes differ by the potentially causative viruses? *First Author: Marc Isamu Uemura, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hep B virus (HBV) and hep C virus (HCV) are the main viral causes of hepatocellular carcinoma (HCC) development and are responsible for ~50% of USA cases. Because HBV is a DNA virus (*Hepadna family*) and HCV is an RNA virus (*flavivirus family*), it is unclear whether such virologic differences influence clinico-pathologic features of HCC or patient outcomes. We evaluated such differences in a large-scale, single-center study. **Methods:** Between 1992 to 2011, 815 HCC patients (HCV = 472, HBV = 343) were referred for treatment at the Univ. of Texas MD Anderson Cancer Center. Under IRB approval, detailed patient characteristics at time of diagnosis were documented. Chi-square tests were used to assess the significance of differences in the distributions of categorical variables between HBV and HCV groups. Median survival (mos.) was calculated using Kaplan Meier product-limit method and survival rates were compared using the log rank test. **Results:** 63% of patients were Texas residents with male to female ratio = 3:1. Patients with HBV were more likely to develop HCC at younger age than HCV patients, with poorly differentiated tumor (PDT), portal thrombosis (PT), larger tumor size (> 5 cm), extensive liver involvement (> 50%), high alpha-fetoprotein, and advanced CLIP stage (3-6). On the other hand, patients with HCV were more likely to exhibit underlying cirrhosis, have a history of greater alcohol and cigarette use, and had higher co-occurrence of diabetes mellitus (DM). One-year survival rates were similar between both groups (43.3%) and median survivals were 10.9 and 9.3 mos. for HCV and HBV, respectively (P = 0.9). **Conclusions:** Significant clinico-pathologic variations exist in HCC patients associated with HCV vs HBV, which may impact patients' eligibility for treatment, but not prognosis.

Mean +/- SD (age) and proportion (%) of HCC characteristics in HCV and HBV.

METGastric: A phase III study of onartuzumab plus mFOLFOX6 in patients with metastatic HER2-negative (HER2-) and MET-positive (MET+) adenocarcinoma of the stomach or gastroesophageal junction (GEC). *First Author: Manish A. Shah, Weill Cornell Medical College, New York, NY*

Background: Dysregulation of the MET/HGF pathway is associated with poor prognosis in GEC. Onartuzumab (O), a monovalent anti-MET antibody, inhibits the MET/HGF pathway. We investigated first-line mFOLFOX6 + O in metastatic, HER2-, MET+ GEC. **Methods:** This double-blind, placebo-controlled phase 3 study randomized patients (pts) 1:1 to mFOLFOX6 + placebo (P) or O (10 mg/kg; q2w). Eligibility criteria: no prior treatment for metastatic disease, age ≥ 18 yrs, ECOG PS 0–1, retained organ function, HER2-, MET+ (IHC 1+, 2+ or 3+) GEC. Co-primary endpoints: overall survival (OS) in ITT and MET 2+/3+ pts. Secondary endpoints: progression-free survival (PFS), overall response rate (ORR) and safety. The study was designed to enroll ~800 pts and powered to demonstrate improvement of median OS from 9 to 12.3 mo (ITT pts; HR 0.73) and 9 to 18 mo (MET 2+/3+ pts; HR 0.49). Enrollment stopped early due to negative final results from a phase 2 trial assessing mFOLFOX6 + O. **Results:** The ITT population comprised 562 pts (enrolled 19 Nov 2012–7 Mar 2014). The treatment arms were well balanced: median age (59 yrs O, 58 yrs P), male (67% O, 65% P), and MET 2+/3+ (38% O, 39% P). Serious adverse events (AEs) were slightly more frequent with O v P (35.8% v 32.5%). Grade ≥3 AEs more commonly seen with O included neutropenia (35.1% v 29.3%), thrombocytopenia (4.3% v 1.1%), peripheral edema (4.7% v 0.4%), and pulmonary embolism (6.1% v 3.6%). At data cutoff (25 Apr 2014), 26% of ITT pts in each arm had OS events. In the MET2+/3+ subgroup, 38% of P and 33% of O pts had OS events. See Table for efficacy data. Exploratory subgroup analyses showed improved OS for the O arm in non-Asian pts and pts with no prior gastrectomy regardless of MET status. **Conclusions:** The addition of onartuzumab to mFOLFOX6 was ineffective in ITT or MET 2+/3+ pts. Subgroup analysis suggests non-Asian pts and pts without prior gastrectomy may benefit. Further analyses may delineate the role of the MET pathway in GEC. NCT01662869. Clinical trial information: NCT01662869.

FOLFOX alone or combined to rilotumumab or panitumumab as first-line treatment in patients (pts) with advanced gastroesophageal adenocarcinoma (AGEA): An open-label, randomized phase II trial (PRODIGE 17 ACCORD 20 MEGA). *First Author: David Malka, Gustave Roussy, Villejuif, France*

Background: EGFR and HGF/c-Met pathways are often deregulated in AGEA. We assessed whether EGFR or HGF inhibition with panitumumab or rilotumumab is beneficial in the first-line treatment of pts with AGEA. **Methods:** Pts ≥18 yrs with non-HER2+, measurable AGEA and ECOG performance status (PS) 0-1 were randomized (minimization procedure; stratification factors: Lauren classification, disease stage, center) to mFOLFOX6 (oxaliplatin 85 mg/m², folinic acid 400 mg/m², fluorouracil: 400 mg/m² bolus then 2400 mg/m² over 46 h) alone (arm A) or combined to panitumumab (6 mg/kg; arm B) or rilotumumab (10 mg/kg; arm C), every 2 weeks until limiting toxicity or disease progression. The primary endpoint was 4-month progression-free survival rate (4-PFS) (Fleming's one-step design, one-sided A=5%, B=10%, H0: 40%; H1: 60%; 153 evaluable pts needed). **Results:** 162 pts (median age, 64 [range, 23-87]; ECOG PS 0/1, 33/67%) were enrolled from 2011/01/14 to 2013/08/19 in 29 French centers. Most had metastatic (97%), intestinal (69%) adenocarcinoma of the stomach (50%) or GE junction (30%). Main results were (median follow-up, 23.6 months; 95%CI, 19.7-27.3): **Conclusions:** All combination regimens reached the primary study endpoint. Adding panitumumab or rilotumumab seemed more toxic and not more effective than mFOLFOX6 alone. Subgroup analyses according to tumor biomarker status (e.g., RAS/BRAF and MET) will be presented later. Clinical trial information: 2009-012797-12.

Objective response rate (%) [95%CI] [3]	54 [40-67]	44 [30-59]	50 [36-64]
4-PFS (%) [3]	71 [57-82]	63 [48-77]	63 [49-75]
Median PFS (months) [95%CI] [3]	5.8 [5.2-7.3]	5.2 [3.7-7.6]	7.6 [4.0-9.0]
Median overall survival (months) [95%CI]	13.1 [8.7-16.9]	8.3 [6.2-16.9]	11.5 [7.9-17.1]

[1] n = 159 pts evaluable for safety. [2] G5, 1/4/3 pts, respectively. [3] n = 158 evaluable pts (intent-to-treat population).

4014 Poster Discussion Session; Displayed in Poster Session (Board #123), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

A randomized, open-label phase II study of AZD4547 (AZD) versus Paclitaxel (P) in previously treated patients with advanced gastric cancer (AGC) with Fibroblast Growth Factor Receptor 2 (FGFR2) polysomy or gene amplification (amp): SHINE study. *First Author: Yung-Jue Bang, Seoul National University College of Medicine, Seoul, South Korea*

Background: The prognosis for AGC patients failing 1st line treatment is poor. FGFR2 amplification occurs in ~5-10% and polysomy in > 20% of gastric cancers (GCs). AZD is a selective FGFR1-3 inhibitor with activity in *FGFR2* amplified models. SHINE assessed the efficacy and safety of AZD in AGC patients with *FGFR2*amplification or polysomy. **Methods:** Patients with disease progression after 1 prior line of therapy were assigned to *FGFR2* amplified or polysomy arms and randomised to oral AZD (80mg bd, 2weeks on/1week off) or P. The primary endpoint was progression-free survival (PFS). Secondary endpoints included safety. FGFR2 status confirmed by FISH testing. Exploratory biomarker analysis assessed FGFR2 gene expression by nanostring and intra-tumoral heterogeneity of *FGFR2*amplification by image analysis of FISH stained sections. **Results:** Of 960 pts enrolled, 71 patients were randomised (41 AZD arm, 30 P arm). AGC *FGFR2* amp prevalence was 9%. The overall median PFS on the AZD arm was 1.8 mths vs 3.5 mths for P and for the *FGFR2* amplified arm was 1.5 mths for AZD vs 2.3 months for P. Pts on AZD mostly experienced G1/G2 AEs. Most common AEs causally related to AZD were stomatitis (8 pts/20%), dry mouth (7 pts/17.5%) and RPED (6/15% pts) and fully resolved off treatment. Elevations in plasma phosphate were observed on the AZD arm during the 2 week dosing period and resolved during the 1 week off. Only 21% of *FGFR2*amplified tumors had elevated FGFR2 expression and Image analysis showed four out of seven tumor samples, highly amplified by FISH, were amplified in < 20% of the tumor section. **Conclusions:** AZD was well-tolerated. The analysis of PFS did not show any statistically significant difference in favour of the AZD arm, compared with the P arm in *FGFR2* amplified or polysomy patients selected by FISH. Exploratory biomarker analysis revealed marked intra-tumor heterogeneity of *FGFR2* amplification and low concordance with elevated FGFR2 expression. The observed increase in plasma phosphate provides evidence that AZD at this dose and schedule causes pharmacologic target inhibition. Clinical trial information: NCT01457846.

Untreated metastatic diffuse gastric adenocarcinoma (DGAC): Randomized phase III study of S-1 and cisplatin vs. 5-FU and cisplatin (the DIGEST trial). *First Author: Jaffer A. Ajani, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The prognosis for metastatic DGAC is poor but the first line therapy for patients (pts) with DGAC is the same as that of without DGAC. Analyses of the FLAGS study suggested that S-1/Cisplatin might be better than 5-FU/cisplatin in DGAC. Therefore, a prospective international study was executed. **Methods:** Pts with metastatic DGAC (histology confirmed by central pathology review) with PS 0-1, adequate organ function, measurable/evaluable disease were consented and randomized to S-1 (25 mg/m² po BID on days 1-21 q 4 weeks)/cisplatin (75 mg/m² q 4 wks; CS) or 5-FU (800 mg/m² continuous infusion for 5 days q 3 wks)/cisplatin (80 mg/m2 q 3 wks; CF). Randomization was 2:1 in favor of CS, stratified by histologic subtype, extent of metastasis, ECOG PS and geographical region. The primary endpoint was overall survival (OS). The study was stopped early after 361 pts were randomized versus a target 500 pts, and 264 events (deaths) were observed versus an analysis target of 427 events. **Results:** 690 pts were screened and 361 were randomized (239 to CS and 122 to CF). Both arms were well balanced with respective pts characteristics. For ITT pts, the median OS was 7.5 months (95%CI; 6.7-9.3) for CS and 6.6 months (5.7-8.1) for CF (HR 0.99, 95%CI; 0.76-1.28, *p*= 0.9312). There was no statistical difference in progression-free survival. Overall response rate was 34.7% for CS compared to 19.8% for CF (*p*= 0.012). The median number of cycles was 4 in both arms. The dose intensity was > 90% in both arms. The rate at least one Gr. ≥ 3 AE related to study medication was 45.2% in CS and 55.9% in CF. The most frequent (≥ 5%) Gr. ≥ 3 AEs for CS were neutropenia (27.3%), anemia (16.1%), fatigue (10.4%), hyponatremia (7.7%), abdominal pain (5.7%), and asthenia (5.7%) and for CF were neutropenia (28.3%), anemia (8%), asthenia (10.2%), hyponatremia (10%), hypophosphatemia (7.9%), hypokalemia (7%), anorexia (5.9%), and hyperkalemia (5%). One drug related death occurred in both CS (0.4%) and CF (0.8%). **Conclusions:** In the DIGEST trial, CS did not prolong OS of pts with metastatic DGAC compared to CF. However, efficacy and safety were similar for CS and CF. (Supported by Taiho Oncology Inc, NJ, USA). Clinical trial information: NCT01285557.

4016 Poster Discussion Session; Displayed in Poster Session (Board #125), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Pathological response to neoadjuvant 5-FU, oxaliplatin, and docetaxel (FLOT) versus epirubicin, cisplatin, and 5-FU (ECF) in patients with locally advanced, resectable gastric/esophagogastric junction (EGJ) cancer: Data from the phase II part of the FLOT4 phase III study of the AIO. *First Author: Claudia Pauligk, Krankenhaus Nordwest, University Cancer Center, Frankfurt, Germany*

Background: Pathological response can be a potent surrogate factor for efficacy of neoadjuvant chemotherapy. Data from our phase II/III study comparing perioperative FLOT with ECF(X) in resectable stages were analyzed for pathological response upon request of the German Cancer Aid in order to further sponsor the trial. **Methods:** In the FLOT4, 714 patients (pts) are stratified and randomized to either 3+3 perioperative cycles of ECF/ECX (epirubicin 50 mg/m^2, d1; cisplatin 60 mg/m^2, d1; 5-FU 200 mg/m^2 (or capecitabine 1250 mg/m^2 p.o) d1-d21, qd21) or 4+4 cycles of perioperative FLOT (docetaxel 50mg/m^2, d1; 5-FU 2600 mg/m^2, d1; leucovorin 200 mg/m^2, d1; oxaliplatin 85 mg/m^2, d1, qd14). Central pathology (by AT) is performed according to Becker classification. **Results:** Samples of 157 pts of the phase-II part of the study were analyzed. Median age was 63 yrs; 79.6% of pts were male. The primaries were gastric in 43.3%, EGJ in 56.1% and not evaluable in 0.6% of pts. In the most relevant categories complete (CR) and subtotal (SR) histopathological response, FLOT was superior to ECF with CR 12.8% vs. 5.1% and SR 16.7% vs. 10.1%, respectively, with statistical significance for CR+SR (FLOT, 29.5% vs. ECF, 15.2%, p = .036). Also, significantly more pts in the ECF-arm had no pathological regression or even did not reach surgery (ECF, 41.8% vs. FLOT, 24.4%; p = .027). See also Table. **Conclusions:** Perioperative FLOT shows more pathological remissions (CR + SR) than ECF/ECX in patients with resectable gastric cancer. Clinical trial information: NCT01216644.

A phase III study of laparoscopy-assisted versus open distal gastrectomy with nodal dissection for clinical stage IA/IB gastric cancer (JCOG0912): Analysis of the safety and short-term clinical outcomes. *First Author: Masakazu Takagi, Shizuoka General Hospital, Shizuoka, Japan*

Background: Although the number of patients undergoing laparoscopy-assisted distal gastrectomy (LADG) has been increasing, there is no confirmatory randomized controlled trial (RCT) to evaluate the efficacy of LADG compared with open distal gastrectomy (ODG). Safety and short term outcome are presented. **Methods:** We conducted a RCT to confirm the non-inferiority of overall survival (OS) of LADG to ODG in patients with clinical IA (T1N0) or IB (T1N1 or T2 [MP] N0) gastric cancer. D1 or more dissection is applied for clinical stage IA and D2 dissection for clinical stage IB. Only the credentialed surgeons can be responsible for both procedures. The primary endpoint is (OS). The planned sample size was 920. **Results:** Between March 2010 and November 2013, 921 patients (LADG 462, ODG 459) were enrolled from 33 institutions. Operating time was longer in LADG than ODG (median 278 vs 194 min, $p < 0.001$). Blood loss was smaller in LADG than ODG (median 38 vs 115 ml, $p < 0.001$). There were no grade 3 or 4 intraoperative adverse events in either arm. There was no difference in the overall proportion of in-hospital, non-hematological grade 3 or 4 adverse events excluding biochemical data (3.3%: LADG, 3.7%: ODG). The proportion of grade 3 or 4 serum AST/ALT increased was higher in LADG than ODG (16.4% vs 5.3%, $p < 0.001$). The proportion of the patients who required an analgesic on postoperative days 5–10 was smaller in LADG than ODG (50.3% vs 59.3%, p = 0.006). The median time from surgery until the first episode of flatus was shorter in LADG than ODG (2 days vs 3 days, $p < 0.001$). There was no difference in both the highest body temperatures during the first 3 days after the surgery and the highest body temperatures during hospitalization. **Conclusions:** Although the elevation of serum AST/ALT should be taken care, this trial confirmed that LADG performed by the credentialed surgeons was safe as ODG in terms of adverse event and short-term clinical outcomes. LADG will be an alternative procedure in clinical IA/IB gastric cancer if the non-inferiority of LADG in OS is confirmed by the primary analysis planned in 2018. Clinical trial information: UMIN000003319.

A randomized, double-blind, placebo-controlled phase III study of S-1 in patients with sorafenib-refractory advanced hepatocellular carcinoma (S-CUBE). *First Author: Masatoshi Kudo, Department of Gastroenterology and Hepatology, Kinki University School of Medicine, Osaka, Japan*

Background: An unmet medical need persists for patients (pts) with sorafenib-refractory advanced hepatocellular carcinoma (HCC). This study was conducted to evaluate the efficacy and safety of S-1 in pts with sorafenib-refractory advanced HCC. **Methods:** Japanese men and women (aged ≥ 20 years) with Child-Pugh (C-P) A or B liver function and disease progression with or intolerance to sorafenib were randomized in a 2:1 ratio. S-1 (80, 100, or 120 mg/day) or a placebo was administered orally, according to the body surface area on days 1–28 of a 42-day cycle until disease progression or unacceptable toxicities were observed. The primary endpoint was overall survival (OS). Secondary endpoints included progression-free survival (PFS), overall response rate (ORR), and safety. For a statistical consideration of the heterogeneous population with advanced HCC, we conducted the subgroup analysis. **Results:** A total of 334 pts were enrolled (S-1 = 223, placebo = 111). Patient characteristics were well balanced; median age, 70.0 years; C-P A liver function, 81.0%; vascular invasion, 17.7%; and extrahepatic metastasis, 53.8%. The median OS was 337.5 days with S-1 and 340.0 days with the placebo (hazard ratio [HR], 0.86; 95% confidence interval [CI], 0.67–1.10; P = 0.220). The median PFS were 80 and 42 days, respectively (HR, 0.60; 95% CI, 0.46–0.77; P < 0.001). ORRs were 5.4% and 0.9%, respectively (P = 0.068). In the subgroup analysis showed the efficacy of S-1 on OS was different depending on patient characteristics; C-P liver function, HR was 0.79 (C-P A) and 1.19 (C-P B); Tumor stage, HR was 2.08 (Stage I/II) and 0.79 (Stage III/IV). The main adverse events (AEs) with S-1 were anorexia, fatigue, elevated total bilirubin, and diarrhea. Most AEs were mild to moderate, and the study discontinuation rate due to AEs was 19.2% in S-1 pts. **Conclusions:** Although S-1 did not statistically extend OS compared to the placebo in pts with sorafenib-refractory advanced HCC, the subgroup analysis showed S-1 has potential to improve OS in the clinically-important population. The observed benefit in the outcomes of PFS and subgroup analysis warrant further investigation. Clinical trial information: JapicCTI-090920.

The protective effect of hormonal intake on risk of hepatocellular carcinoma in the United States. *First Author: Gehan Botrus, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the United States, the incidence of hepatocellular carcinoma (HCC) has been tripled over the last two decades. Despite the overwhelming effect of several environmental risk factors of this cancer, the association between oral contraceptive (OC) and hormone replacement therapy with HCC has been poorly investigated. The current study aimed at addressing such association among American women. **Methods:** Under the IRB approval from the University of Texas MD Anderson Cancer Center, we conducted hospital-based case-control study where cases are pathological or radiological diagnosed patients with HCC. Controls are spouses of patients at MD Anderson who had cancers other than GI cancers. Between 2005 and 2014 total of 235 female cases and 257 female controls were enrolled. Cases and controls were interviewed for lifetime intake of OC, hormonal replacement, type of hormone, method of hormonal use, and duration of exposure. We performed multivariate logistic regression analyses by using all variables that were significant at $P < .05$ in the univariate analyses to estimate odds ratio (OR) and 95% confidence interval (CI). The estimated ORs were adjusted for age, race, diabetes, hepatitis C virus, hepatitis B virus, cigarette smoking, alcohol drinking, and family history of cancer. **Results:** Ever use of OC was reported by 75.1% of the controls and 61.3% of the cases ($P = .001$) leading to 43% reduction in HCC risk where the estimated OR (95% CI) was 0.57 (.35-.91). Ever intake of estrogen hormone during lifetime was recalled by 49.8% controls and 30.6% cases ($P = .001$) yielding 62% reduction in HCC risk, OR (95% CI) = .38 (.24-.59). Combined hormonal use from OC and estrogen hormonal replacement was reported by 89% of the controls and 75% of cases. The estimated OR (95% CI) was .47 (.27-.84), $P = .01$. A dose response relationship was observed with duration of exposure where the estimated OR (95% CI) were .53 (.28-1), .37 (.16-.83), and .35 (.19-.64) for lifetime years of exposure of < 5, 5-10, and > 10 years respectively. **Conclusions:** This is the largest study in USA showing protective effect of hormonal use on HCC. Experimental investigations are necessary for thorough assessment of the relationship between hormonal exposure and risk of HCC in females.

Multi-institutional phase II study of high dose, hypofractionated proton beam therapy (HF-PBT) for unresectable primary liver cancers: Long term outcomes in patients (pts) with intrahepatic cholangiocarcinoma (ICC). *First Author: Theodore S. Hong, Massachusetts General Hospital, Boston, MA*

Background: Modern radiotherapy (RT) techniques such as protons permit delivery of ablative doses of RT to the liver. Prior reports of PBT in hepatocellular carcinoma (HCC) demonstrate local control (LC) rates exceeding 85% but outcomes with high dose RT in pts with ICC remain lacking. We report on clinical outcomes of high dose, HF-PBT in pts with unresectable ICC. **Methods:** Pts enrolled on an NCI sponsored, multi-institutional, phase II study (NCT00976898). Key eligibility were HCC or ICC, unresectable by multidisciplinary review, Child's A/B, ECOG PS 0-2, no extrahepatic disease, no prior RT. Maximum tumor size was 12 cm if solitary, 10 cm if 2 tumors, and 6 cm if 3. PBT was given in 15 fractions to a maximum total dose of 67.5 GyE. Sample size was calculated to demonstrate $>$ 80% LC at 2 yrs for HCC pts with acceptable precision for estimating outcomes for ICC. **Results:** From 2009-2014, 93 pts were enrolled, of whom 90 were evaluable. 41 pts had ICC, 2 pts had mixed HCC/ICC, and 47 pts had HCC (reported separately). In this ICC specific-analysis (n = 43), median age was 67 (range 29-87), 16 (37%) were male. 36 (84%) and 5 (12%) pts had Child-Pugh A and B cirrhosis, respectively. 2 (4%) pts had no cirrhosis. 25 (58%) pts had prior systemic therapy. 25 (58%) pts had prior systemic therapy. 39 pts(90.6%) had 1 tumor, 2 pts (4.7%) had 2 , 2 pts (4.7%) had 3 . Median tumor size was 6.0 cm (range 2.2-10.9). Median RT dose received was 58 GyE (range 15.1-67.5). 6 (14%) pts developed Gr 3 RT-related toxicity, including thrombocytopenia (2), hyperbilirubinemia (2), gastric ulcer (1), pain (1), elevated LFTs (1), and liver failure/ascites (1). With a median follow up of 13 months (range 5d–51 mo) among 22 pts still alive, the 2 year LC was 96%. mOS was 21 months (95% CI 13-29) and mPFS was 9 months (95% CI 6-24). When excluding Child's B (N = 38), mOS was 23 months (95% CI 15-49) and mPFS was 10 months (95% CI 5-24); 2 yr OS rate was 48% and 2 yr PFS rate was 38%. **Conclusions:** High dose PBT for ICC results in high rates of LC and OS. This data forms the basis for the ongoing NRG GI-001 study, a randomized trial of gem/cis +/- hypofractionated RT. Support: NCI # P01CA2123 Clinical trial information: NCT00976898.

4021 Poster Discussion Session; Displayed in Poster Session (Board #130), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Quantification of tumor stroma as a biomarker in pancreatic adenocarcinoma. *First Author: Robert J. Torphy, UNC Chapel Hill, Chapel Hill, NC*

Background: Desmoplastic tumor stroma (TS) characterizes the primary tumor in pancreatic ductal adenocarcinoma, but its role in tumor progression and metastasis is less clear. The objective of this study was to evaluate the presence and prognostic significance of TS at primary and metastatic sites. **Methods:** Tissue sections of primary tumors from 57 patients who underwent curative resections and 46 primary and metastatic tumors from 15 patients with metastatic pancreatic cancer were digitally annotated for tumor epithelium and TS, reviewed by a pathologist, and quantified using Spectrum WebScope. Tumor stroma density (TSD) was quantified as TS per total tumor area. Resected patients received no adjuvant chemotherapy. Association of TSD with overall survival (OS) and recurrence-free survival (RFS) was performed using the multivariate Cox proportional hazards model from the "survival" R statistical package (3.1.1); where significance was determined with log-rank test p-value less than 0.05. **Results:** Median TSD in primary tumors was 0.57. TSD was no different in the primary tumors of patients who had localized compared to metastatic disease. TSD was decreased in solid organ (0.12) and lymph node metastases (0.22) (ANOVA, p = 0.0001). Furthermore in patients who underwent curative resections, high TSD was associated with longer OS (HR = 0.237; p = 0.009), with a median OS of 11 months in the low TSD ($<$ 0.57) group and 21.5 months in the high TSD ($\geq$ 0.57) group. TSD was also associated with RFS (HR = 0.286, p = 0.022), with a median RFS of 9 months in the low TSD group and 19 months in the high TSD group. The association of TSD with OS and RFS was adjusted for tumor grade, T, N and overall stage, ASA score, and smoking status. **Conclusions:** We demonstrate that stromal content is a measurable biomarker in this disease with meaningful clinical associations.Our results nominate that TSD should be used as an objective, quantitative assessment of TS in correlative and therapeutic trials of pancreatic cancer. TS appears to be associated with restraining tumor growth with decreasing TSD in patients with more aggressive disease. Also, the low TSD at metastatic sites should be considered in the context of stroma modulating therapies.

Prognostic value of plasma circulating tumor (ct) DNA *KRAS* mutations and serum CA19-9 in unresectable pancreatic cancer (PC) patients. *First Author: Julia S. Johansen, Department of Oncology, Herlev Hospital, Herlev, Denmark*

Background: Median overall survival (OS) time of patients with unresectable PC varies widely. Diagnostic tools are presently lacking to predict outcomes. The majority of pancreatic tumors have *KRAS* mutations. The study aim was to evaluate the utility of baseline and serial measurements of ctDNA *KRAS* mutation load, alone or in combination with serum CA 19-9, as an outcome prognostic biomarker in patients with unresectable PC undergoing palliative chemotherapy. **Methods:** In the Danish BIOPAC prospective biomarker study, plasma was collected from 182 unresectable PC patients (85 females, 97 males, median age 68, range 45-89 years; locally advanced disease n = 48; metastatic n = 134) undergoing treatment with gemcitabine (n = 151) or FOLFIRINOX (n = 31). ctDNA *KRAS* G12/13 mutation levels in archival ($\leq$ 6 years) plasma was assessed with enrichment PCR followed by next generation sequencing and standardized reporting of copies per 10^5 genome equivalents (GE). **Results:** In a prospective-retrospective study of 182 patients, interim analysis of ctDNA *KRAS* was conducted (after 168 deaths). 176 of 182 patients had evaluable baseline plasma samples. Of 176 patients, 143 (81%) had $>$ 1 copy mutant *KRAS* G12/13 ctDNA at baseline. To assess associations between *KRAS*, CA 19-9 and OS, *KRAS* and CA 19-9 values were dichotomized by finding thresholds maximizing similarity of OS in each group (thresholds: 41 *KRAS* copies/10^5 GE; 314 U/ml, CA 19-9). Both *KRAS* and CA 19-9 negatively predicted OS (Cox proportional hazards model). *KRAS* with CA 19-9 was a stronger predictor of death than either marker alone. The hazard rate (HR) of death for patients with *KRAS* $>$ 41 c/10^5GE and CA 19-9 $>$ 314 U/ml was 3.0 times as high (95% CI: 2.0 to 4.6) as those with *KRAS* $<$ 41 c/10^5GE and CA 19-9 $<$ 314 U/ml. This is compared to HR 2.1 (95% CI: 1.5 to 2.8) for patients with high *KRAS* vs low *KRAS*, and HR 1.8 (95% CI: 1.3 to 2.6) for patients with high CA 19-9 vs low CA 19-9. Shorter OS tend to associate with elevated *KRAS* and CA 19-9 during chemotherapy. **Conclusions:** Combination of pre-treatment plasma ctDNA *KRAS* mutation load and CA 19-9 is a strong prognostic factor in patients with unresectable PC receiving palliative treatment with gemcitabine or FOLFIRINOX.

Allelic ratio of *KRAS* mutations in pancreatic ductal adenocarcinoma. *First Author: Jochen K Lennerz, Massachusetts General Hospital, Boston, MA*

Background: Traditional sequencing studies of *KRAS* in pancreatic ductal adenocarcinoma (PDAC) delineated a mutation frequency of ~75% and that *KRAS* mutant tumors are associated with shorter overall survival. Recently highly-sensitive next-generation sequencing technologies have delineated that the *KRAS* mutation frequency in PDAC is ~93% indicative of a fraction of cases missed by traditional sequencing approaches. Here, we explored whether PDAC with *KRAS* mutations at low-allelic ratios carry prognostic differences. **Methods:** We employed the PDAC dataset (n = 142) from the International genome consortium (ICGC) initially reported by Biankin et al., 2012. We accounted for tumor purity by calculating the corrected allelic ratio (= allelic ratio/cellularity). Overall survival differences using a corrected allelic ratio cutoff of 10% were calculated employing Kaplan-Meier, log-rank, and Cox proportional hazard regression analysis (HR). **Results:** Accounting for tumor purity, we identified 115 cases (80.9%) with allelic ratios of mutant *KRAS* $\geq$ 10% while the remainder (n = 27 cases, 19.1%) harbored either mutant alleles below 10% (n = 17) or wild-type *KRAS* (n = 10). Allelic ratios span the full range from wild-type to $>$ 100% mutant *KRAS*. The lower as well as the upper end of this spectrum suggest heterogeneity within the cancer cell population (clonality) or variations in DNA content (ploidy), respectively. The subset with low-allelic ratios ($<$ 10%) of mutant *KRAS* had shorter overall survival (14.5 months) when compared to those with high-allelic ratios (20.3 months; HR 1.68 CI:0.9-3.13). While this difference did not reach statistical significance (P= 0.10), several prior studies employing thresholds around 10% (cutoff determined by sensitivity of the sequencing technology) have shown that the presence of a *KRAS* mutation is a marker of poor prognosis. **Conclusions:** *KRAS* is not simply mutated or wild-type in PDAC – it has actually never been. While over 90% of PDAC carry mutated *KRAS* alleles, the impact on PDAC biology may vary with the tumor-specific allelic ratio and dosage of mutated *KRAS*. Therefore, we propose that the tumor-specific allelic ratio of somatically mutated genes should become part of a comprehensive molecular diagnostic report.

4024 Poster Session (Board #133), Mon, 8:00 AM-11:30 AM

A phase II study of sequential capecitabine plus oxaliplatin (XELOX) followed by docetaxel plus capecitabine (TX) in patients with unresectable gastric adenocarcinoma: The TCOG T3211 trial. *First Author: Ming-Huang Chen, Division of Hematology and Oncology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*

Background: Fluorouracil and platinum can be considered a standard option for advanced gastric cancer (AGC). Docetaxel is also an effective agent with no cross-resistance with fluorouracil and platinum. Concomitant combination of docetxel with fluorouracil and platinum had been explored, but demonstrated intolerable toxicities. A different way to include all active agents in first-line treatment of gastric adenocarcinoma may be to use them sequentially. We aimed to evaluate the activity and the safety profile of sequential chemotherapy with capecitabine plus oxaliplatin followed by docetaxel plus capecitabine in the first-line treatment of AGC. **Methods:** We conducted a phase II study of first-line sequential chemotherapy in AGC. Treatment consisted of 6 cycles of capecitabine plus oxaliplatin (XELOX, Capecitabine 1000 mg/m^2 bid on day 1-10 and Oxaliplatin 85 mg/m^2 on day 1, Q2W) followed by 4 cycles of docetaxel plus capecitabine (TX, Docetaxel 30 mg/m^2 on D1 and D8, Capecitabine 825 mg/m^2 bid on day 1-14, Q3W). Primary end-point was the objective response rate. **Results:** Fifty-one patients were enrolled: median age 63 years; Male/Female: 37/14. Main grade 3-4 toxicities were ANC decreased (25.5%), diarrhea (11.8%), hand-foot syndrome (15.7%) and anemia (11.8%). The objective response rate was 56.9%. Median PFS and OS were 8.6 and 10.8 months, respectively. Five patients (9.8%) received surgery after chemotherapy and four were still on disease-free status. **Conclusions:** This sequential treatment demonstrated feasibility with a favorable safety profile and produced encouraging results in terms of activity and efficacy. Clinical trial information: NCT01558011.

4025 Poster Session (Board #134), Mon, 8:00 AM-11:30 AM

Risk of death due to heart disease after radiotherapy for esophageal cancer: A SEER study. *First Author: Jonathan Evans Frandsen, Department of Radiation Oncology, Huntsman Cancer Hospital; University of Utah School of Medicine, Salt Lake City, UT*

Background: Radiation therapy (RT) improves local control as well as overall survival when combined with chemotherapy for patients with esophageal cancer (EC). Significant doses of RT are delivered to the heart during treatment for EC, but little data exist regarding the long term heart morbidity after RT for EC. We hypothesized an increased risk of heart disease related death (HDRD) among patients in the Surveillance, Epidemiology, and End Results (SEER) database who received RT as part of their initial treatment for EC. **Methods:** Using the SEER Program, all individuals from 1973 to 2011 with EC were identified. Two cohorts were created: (1) patients who received RT as part of their initial therapy and (2) those who did not. The primary endpoint, heart disease specific survival (HDSS), was analyzed using Kaplan Meier methods. Cox proportional-hazards regression methods were used for univariate and multivariate analyses. **Results:** We identified 40,778 patients with EC. 26,377 patients received RT and 14,401 patients did not. HDSS analysis revealed increased risk of HDRD in those receiving RT ($P < 0.05$), with an absolute risk of HDRD of 2.8%, 5.3% and 9.4% at 5-, 10- and 20-years, respectively. Log rank test of HDSS revealed that the risk of HDRD became significant at 8 months with an absolute risk of HDRD of 0.4% ($p < 0.05$). The following were associated with HDRD: RT, age, race, stage at presentation, time period of diagnosis, and known comorbid condition keeping one from esophagectomy. On multivariate analysis, RT remained predictive of HDRD (hazard ratio [HR] 1.46, $p < 0.05$). When considering only candidates for definitive therapy, RT remained predictive of HDRD on univariate (HR 1.53, $p < 0.05$) and multivariate (HR 1.62, $p < 0.05$). **Conclusions:** RT plays an important part of the current treatment paradigm for EC, but the use of RT leads to increased risk of HDRD that is detectable as early as eight months from diagnosis. More research is needed to define optimal dose volume parameters to prevent cardiac death. Consideration should be given to this risk in relation to the patients expected survival.

4026 Poster Session (Board #135), Mon, 8:00 AM-11:30 AM

Phase I/II study of a combination of capecitabine, cisplatin, and intraperitonealdocetaxel (XP ID) in patients with advanced gastric cancer with peritoneal metastasis. *First Author: Hyungwoo Cho, Departments of Internal medicine, Asan Medical Center, University of Ulsan College of medicine, Seoul, Korea, Seoul, South Korea*

Background: More than one third of patients with advanced gastric cancer (AGC) have peritoneal metastasis, and their prognosis is poor. This study was conducted to determine the recommended dose (RD) of intraperitoneal docetaxel (ID) in combination with systemic capecitabine and cisplatin (XP), and to evaluate its efficacy and safety at the RD in AGC patients with peritoneal metastasis. **Methods:** AGC patients with peritoneal metastasis received XP ID, which consists of 937.5 mg/m^2 of capecitabine twice daily on days 1-14, 60 mg/m^2 of intravenous cisplatin on day 1, and ID at 3 different dose levels (60, 80, or 100 mg/m^2) on day 1, every 3 weeks. In the phase I study, the standard 3+3 method was used to determine the RD of XP ID. For the phase II study, patients received RD of XP ID until disease progression, unacceptable toxicity, or consent withdrawal. A maximum of 8 cycles of ID was provided. **Results:** In the phase I study, 3 patients experienced no dose limiting toxicity (DLT) at each of 60 or 80 mg/m^2 of ID. ID 100 mg/m^{2}was determined as the RD with 1 DLT (ileus) out of 6 patients. Between June 2011 and December 2013, 39 AGC patients with definite peritoneal metastasis were enrolled in the phase II study and received RD of XP ID. With a median follow-up duration of 20.8 months (range, 13.1-40.3) in surviving patients, median progression-free survival was 11.0 months (95% CI, 6.9-15.1), and median overall survival was 15.1 months (95% CI, 9.1-21.1). Among 30 patients with ascites, complete resolution of ascites was observed in 12 patients (40.0%), and more than 10% reduction in amount of ascites was observed in 8 patients (26.7%). The most frequent grade 3 or 4 adverse events were neutropenia (38.6%), abdominal pain (30.8%), and anemia (25.6%). Of these adverse events, the incidence of abdominal pain cumulatively increased in the later treatment cycles. There was no treatment-related mortality. **Conclusions:** Our study indicated that XP ID was effective with manageable toxicities in AGC patients with peritoneal metastasis. Considering cumulative incidence of abdominal pain probably related to bowel irritation by ID, it may be necessary to modify the dose of ID. Clinical trial information: NCT01525771.

4027 Poster Session (Board #136), Mon, 8:00 AM-11:30 AM

Masitinib plus irinotecan for second line treatment of esophagogastric adenocarcinoma: An open label phase Ib/II trial. *First Author: Aziz Zaanan, Department of Gastroenterology, HEGP, Paris, France*

Background: Masitinib (MAS) is a selective c-Kit inhibitor that efficiently inhibits mast cell function. In vitro studies have shown that MAS could enhance efficacy of 5-fluorouracil (5-FU) and irinotecan (IRI) for treatment of gastric cancer cell lines. **Methods:** Patients (pts) with measurable locally advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction were eligible to receive MAS (6 mg/kg/day) in combination with 5-FU (400 mg/m^2 bolus then 2400 mg/m^2, 46h/2w), or IRI (350 mg/m^2/3w), or FOLFIRI, after progression to platinum based first line chemotherapy. The phase I study evaluated safety with "Dose Limiting Toxicity" (DLT) defined as grade 3 for non-hematological adverse event (AE), or any grade 4 AE related to MAS. The phase II study evaluated efficacy. **Results:** Thirty-six pts from 6 centers in France were included. The MAS + 5-FU arm was closed after 6 pts were included due to lack of efficacy on PFS (1.7 months). Reduction of dose (-25%) was performed for IRI and FOLFIRI regimens due to occurrence of DLT. In the MAS + IRI arm (n = 15), median OS and PFS was 13.4 and 3.9 months, respectively. Partial response (PR) and stable disease (SD) were reported for 1 pt and 5 pts, respectively, leading to a disease control rate (DCR) of 33%. In the MAS + FOLFIRI arm (n = 15), median OS and PFS was 10.9 and 2.4 months, respectively. SD was reported for 4 pts with 31% of DCR. No treatment related deaths occurred. In the MAS + IRI arm, 9/15 pts (60%) reported grade 3-4 AE (neutropenia, 20% and gastrointestinal disorders, 20%); and 4/15 pts (27%) reported serious AE (3 pts with neutropenia). In the MAS + FOLFIRI arm, 10/15 pts (67%) reported grade 3-4 AE (neutropenia, 47%); and 2/15 pts (13%) reported serious AE (1 pt with neutropenia). **Conclusions:** MAS + IRI seems to be active in advanced gastric cancer pts (*c.f.* median OS ~7.5 months; average from 7 studies reporting second-line IRI*) with an acceptable safety profile. A confirmatory phase III trial evaluating MAS at 6 mg/kg/day in combination with IRI in second line has been initiated.

Treatment	n	OS (months [95%CI])	PFS (months [95%CI])
MAS + IRI	15	13.4 [3.0;15.6]	3.9 [1.9;11.8]
MAS + FOLFIRI	15	10.9 [3.7;22.5]	2.4 [1.8;5.4]
Benchmark 2nd line IRI*	-	7.5	2.7

4028 Poster Session (Board #137), Mon, 8:00 AM-11:30 AM

Prognostic factor analysis of overall survival (OS) in gastric cancer from two phase III studies of second-line ramucirumab (RAM) (REGARD and RAINBOW) using pooled individual patient (pt) data. *First Author: Charles S. Fuchs, Dana-Farber Cancer Institute, Boston, MA*

Background: From 2009-2012, 1020 pts were enrolled in two phase III, randomized, double-blind studies of RAM in metastatic gastroesophageal junction and gastric adenocarcinoma following progressive disease (PD) on first-line platinum- and/or fluoropyrimidine-containing therapy: REGARD (N = 355, RAM + best supportive care [BSC] vs placebo [PL] + BSC) and RAINBOW (N = 665, RAM + paclitaxel [PTX] vs PL + PTX). **Methods**: Individual pt data were pooled, and 41 key baseline covariates, common in both studies, were examined (19 clinical characteristics; 22 lab parameters). Lab tests were parameterized in two ways based on local lab abnormality assessments (high/normal/low): high vs normal or low; low vs normal or high. To identify prognostic factors for OS, univariate Cox models were first used to select covariates with $p \leq 0.05$. For these covariates, a multivariate Cox model was used to make stepwise selection with both entry and exit p=0.01. All models were stratified by treatment and geographic region. **Results**: Of 1,020 pts, 953 (93%) were included in the stepwise Cox regression, after excluding pts with missing covariate values. We identified 12 independent prognostic factors (5 clinical; 7 lab). **Conclusions**: We identified 12 independent prognostic factors for pts with second-line gastric cancer from the largest randomized, controlled, global trial dataset. A simple prognostic index using these factors to divide pts into risk groups will be constructed and presented. This information may help clinical decision-making, pt risk stratification, and planning future clinical studies. Clinical trial information: NCT01170663 and NCT00917384.

Poor Prognostic Factors	HR (99% CI) for Mortality
Peritoneal metastasis	1.49 (1.22, 1.83)
Time-to-PD on prior therapy < 6 months	1.35 (1.10, 1.66)
ECOG PS ≥ 1	1.39 (1.12, 1.73)
Tumor differentiation (poor/unknown)	1.33 (1.08, 1.64)
Primary tumor present	1.31 (1.05, 1.62)
Alkaline phosphatase (high)	1.28 (1.03, 1.60)
Sodium (low)	2.04 (1.54, 2.71)
Lactate dehydrogenase (high)	1.31 (1.05, 1.63)
Aspartate Aminotransferase (high)	1.37 (1.06, 1.76)
Albumin (low)	1.33 (1.07, 1.65)
Lymphocytes (low)	1.31 (1.05, 1.63)
Neutrophils (high)	1.52 (1.17, 1.99)

4029 Poster Session (Board #138), Mon, 8:00 AM-11:30 AM

Candidate biomarker analyses in gastric or gastro-esophageal junction carcinoma: REGARD trial of single-agent ramucirumab (RAM) vs. placebo (PL). *First Author: Charles S. Fuchs, Dana-Farber Cancer Institute, Boston, MA*

Background: Vascular endothelial growth factors (VEGFs) are key regulators of tumor angiogenesis. RAM, a recombinant human IgG1 monoclonal antibody specific for VEGF receptor 2 (VEGFR2), inhibits VEGF-A, -C and -D binding to VEGFR2 and inhibits ligand-induced mitogenesis of human endothelial cells. We evaluated candidate tumor (HER2, VEGFR2) and serum (VEGF-C, -D, and soluble [s] VEGFR1 and 3) biomarkers for correlation with overall survival (OS) and progression-free survival (PFS) in patients from the randomized phase 3 REGARD trial (NCT00917384) that demonstrated survival benefits for RAM vs. PL. **Methods:** Of 355 patients randomized to RAM or PL in REGARD, there was at least one evaluable biomarker result for 152 (43%) patients using VEGFR2 immunohistochemistry (IHC) or HER2 (IHC or fluorescence in situ hybridization [FISH]) in baseline tumor tissue samples. For 32 (9%) patients, baseline serum samples were analyzed using VEGF-C, -D, sVEGFR1 or 3 validated assays. Assay analyses were blinded. **Results:** The table provides the results of the HER2 analyses in tumor tissue (N = 147) and VEGFR2 analyses in tumor blood vessels (N = 143). The small number of patients with serum samples limited interpretation for candidate circulating biomarkers. **Conclusions:** Exploratory candidate biomarker analysis of tumor biopsies and serum from REGARD patients did not identify a significant predictive marker for RAM efficacy. Further examination of the role of VEGFR2 pathway biomarkers is warranted in ongoing RAM trials. Clinical trial information: NCT00917384.

4030 Poster Session (Board #139), Mon, 8:00 AM-11:30 AM

Phase I study of GS-5745 alone and in combination with chemotherapy in patients with advanced solid tumors. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute, Nashville, TN*

Background: GS-5745 is a monoclonal antibody that inhibits matrix metalloproteinase 9 (MMP9), an extracellular enzyme involved in matrix remodeling, tumor growth, and metastasis. Inhibiting MMP9 is expected to block paracrine signaling and metastasis and to alter the immune environment within the tumor. **Methods:** The safety, pharmacokinetics (PK), and efficacy of GS-5745 alone and in combination with chemotherapy are being evaluated in a phase I dose escalation and expansion study in patients (pts) with advanced solid tumors. Dose escalation occurred at doses up to 1800 mg of GS-5745 IV every 2 weeks followed by a dose expansion at 800 mg IV every 2 weeks in pts with pancreatic adenocarcinoma combined with gemcitabine/nab-paclitaxel and pts with esophagogastric adenocarcinoma combined with mFOLFOX6. All pts continued until disease progression or unacceptable toxicity. **Results:** As of January 13, 2015, 88 pts were treated. Treatment-emergent AEs (TEAEs) in > 30% of pts included nausea (38%), dyspnea (31%), and fatigue (31%). No DLTs were observed after monotherapy treatment. Non-linear PK, suggestive of target-mediated disposition, was observed with a mean half-life of ~8 days at doses of 600 and 1800 mg. When combined with chemotherapy, the most common TEAEs were diarrhea (59%), fatigue (47%), and nausea (38%). There were no observed responses in the monotherapy escalation phase. In the expansion phase, objective response rates in pts with measurable target lesions were 64% (7/11 esophagogastric) and 41% (7/17 pancreatic) based on investigator evaluation. Two complete responses in the esophagogastric cohort were noted by central radiology review. **Conclusions:** Preliminary safety data demonstrate a manageable safety profile for GS-5745 alone and in combination with chemotherapy. The study has been expanded to enroll additional subjects with pancreatic and esophagogastric cancer to identify potential pharmacodynamic and predictive biomarkers of response.

4031 Poster Session (Board #140), Mon, 8:00 AM-11:30 AM

Adaptive immune resistance in gastro-esophageal cancer: Correlating tumoral/stromal PDL1 expression with CD8$^+$ cell count. *First Author: Ronan Joseph Kelly, The Sidney Kimmel Comprehensive Cancer Center of Johns Hopkins, Baltimore, MD*

Background: In adaptive resistance, tumors use PDL1 induction as a protective mechanism against an antitumor immune response implying underlying immuno-surveillance. By upregulating the expression of ligands for inhibitory receptors on tumor specific lymphocytes in the tumor microenvironment a growing malignancy can avoid immune elimination. Here we report the interaction between PDL1 status and the density of CD8$^+$ at the tumor stromal interface in gastric and gastroesophageal junction adenocarcinomas (G/GEJ). **Methods:** 34 invasive G/GEJ were stained for PDL1 using the 5H1 clone both at the tumor cell and associated tumor infiltrating lymphocyte/macrophages (TILs/TAMs). Tumors with greater than 5% membranous staining were considered PDL1 positive. TILs/TAMs were scored as no significant staining (0), less than 50% (focal) or greater than 50% (high). CD8$^+$ density was determined using image analysis. Survival was evaluated according to PDL1 and CD8$^+$ status. **Results:** 4/34 tumors (12%) showed membranous PDL1 expression. 45% of G/GEJ demonstrated PDL1 expression among TILs with 27% showing focal interface expression and 18% high expression. Patients whose tumors were defined as stroma high (CD8$^+$ > 500 cells/m^2) had a worse PFS, HR = 3.91 (95% CI: 1.32, 11.59) p = 0.01, and OS, HR = 3.46 (95% CI: 1.09, 10.96) p = 0.03, compared to stroma low (CD8$^+$< 500 cells/mm^2). Interestingly in the stroma, 8/9 tumors (89%, CI: 51.8%, 99.7%) with high CD8$^+$ were also positive for PDL1 while only 7/24 (29%, CI: 12.6%, 51.1%) with low CD8+ were PDL1 positive (p = 0.004). PDL1 stromal expression was identified in 33.3% stage I, 53.9% stage II, 37.5% stage III, and 66.7% of stage IV tumors (p = 0.51). Stromal PDL1 expression occurred in 60% of intestinal and 38.5% of diffuse tumors (p = 0.45). **Conclusions:** PDL1 is expressed on both tumor cells and TILs across all stages and histologies of G/GEJ. Patients with higher CD8$^+$ levels have higher PDL1 expression indicating adaptive resistance is occurring in the tumor microenvironment. Phase II and Phase III clinical trials investigating the efficacy of PD1/PDL1 inhibitors either alone or in combination with CTLA-4 inhibitors are currently ongoing in patients with advanced G/GEJ.

4032 Poster Session (Board #141), Mon, 8:00 AM-11:30 AM

Laparoscopic D2 distal gastrectomy versus conventional open surgery for advanced gastric cancer: The safety analysis from a multicenter prospective randomized controlled trial in China (CLASS-01 Trial). *First Author: Yanfeng Hu, Department of General Surgery, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: The safety and efficacy of laparoscopic D2 distal gastrectomy for the treatment of advanced gastric cancer (AGC) with curative intent is still controversial. Thus, the Chinese Laparoscopic Gastrointestinal Surgery Study (CLASS) group conducted a multicenter prospective randomized controlled trial, aiming to evaluate the surgical safety and long-term outcomes of laparoscopic D2 gastrectomy compared with conventional open surgery for AGC. (NCT01609309) **Methods:** The patients with tumor located at distal stomach at clinical T2-4a, N0-3, M0 stage were eligible for enrollment, treated by either laparoscopic D2 distal subtotal gastrectomy (LG) or open D2 gastrectomy (OG) after randomization. Fifteen qualified surgeons at 14 institutions finally participated in the study. The morbidity and mortality within postoperative 30 days were compared between the two groups. **Results:** A total of 607 consecutive patients were recruited and randomly assigned into either LG group (n = 308) or OG group (n = 299) between September 2012 and January 2014. The LG group and OG group were similar in the compliance rates of D2 lymphadenectomy (97.4% vs. 98.3%; $P = 0.591$). The rate of conversion to open surgery was 4.5%. There was no significant differences between the LG group and OG group in the incidence of intraoperative complication (5.8% vs. 4.3%; $P = 0.402$), morbidity (18.8% vs. 14.7%; $P = 0.175$), and mortality (0.6% vs. 0; $P = 0.499$). The patterns of severity grading were also comparable between the two groups. ($P = 0.372$). **Conclusions:** Laparoscopic D2 distal gastrectomy for AGC could be safely performed by experienced surgeons. Thus, our multicenter prospective study on long-term outcomes justifies continued exploration. Clinical trial information: NCT01609309.

4033 Poster Session (Board #142), Mon, 8:00 AM-11:30 AM

Pazopanib and 5-FU/oxaliplatin as first-line treatment in advanced gastric cancer: PaFLO, a randomized phase II study from the AIO (Arbeitsgemeinschaft Internistische Onkologie). *First Author: Peter C. Thuss-Patience, Charité-Universitätsmedizin Berlin, Campus Virchow-Klinikum, Med Klinik m. S. Hämatologie, Onkologie u. Tumorimmunologie, Berlin, Germany*

Background: Pazopanib is an oral tyrosine kinase inhibitor which selectively inhibits angiogenesis via VEGFR-1, -2, -3, ckit and PDGF-R. Recent positive trials show that angiogenesis is an effective target in gastric cancer. In this randomized phase II trial we treated patients (pts) with FLO +/- Pazopanib. **Methods:** Pts with metastatic or locally advanced gastric or gastro-esophageal junction adenocarcinoma, HER2 negative and with measurable disease were randomized in a 2:1 ratio to 5-FU (2,6g/m²/24h, d1) + Leukovorin (200mg/m², d1) + Oxaliplatin (85mg/m², d1) (FLO) + Pazopanib (800mg/d d1-14, q2w) (arm A) or the same chemotherapy without Pazopanib (arm B). Analysis was planned with a Simon Minimax design with PFS rate at 6 month in arm A as the primary endpoint expecting a minimum of 40% of pts progression free. **Results:** 87 pts were randomized, eligible and evaluable were 51 pts in arm A and 27 in arm B. Pts characteristics in % (arm A/arm B): male: 72/63%, female: 28/37%; median age: 65/60 yrs; ECOG 0: 44/44%, 1: 50/48%, 2: 6/7%; localization GEJ: 59/30%, gastric body 41/70%; histology intestinal: 31/33%, diffuse or mixed: 28/30%, not specified: 41/37%. Treatment was tolerated well with possibly treatment related SAE in arm A in 12 of 51 pts + 4 SAE of special interest (ALT elevation) and arm B 4 of 27 pts. Median chemotherapy cycles administered were similar in both arms (8 cycles). Necessary dose reduction of chemotherapy were similar, arm A 37%, arm B 33% of pts. Pazopanib dose reductions were necessary in 22% of pts. PFS rate at 6 months was 31.4% in arm A and 25.9% arm B. Median PFS: 5.1 months arm A and 3.9 months arm B (HR 0.93, 95%CI 0.56-1.54). Median OS was 10.1 months in arm A and 7.0 months in arm B (HR 0.80, 95%CI 0.44-1.48), Median follow up is 12 months. **Conclusions:** Both arms had an inferior PFS than expected from the literature. Pazopanib in combination with 5-FU/Oxaliplatin showed marginal efficacy in this randomized phase II study regarding PFS. Further follow up for interesting OS data is needed. Histology specimen and multiple serum samples were collected from each pt and need to be analyzed for potential subgroups that may benefit most from Pazopanib. Clinical trial information: NCT01503372.

4034 Poster Session (Board #143), Mon, 8:00 AM-11:30 AM

MET as a prognostic biomarker of survival in a large cohort of patients with gastroesophageal cancer (GEC). *First Author: Daniel Virgil Thomas Catenacci, University of Chicago, Chicago, IL*

Background: Estimates of the frequency of genomic/proteomic alterations in MET in solid tumors vary widely, but a growing body of evidence suggests that *MET* amplification and/or Met expression are biomarkers for poor prognosis. We examined both *MET* gene copy number and Met protein expression as potential prognostic biomarkers for survival in a large set of GEC samples with full clinical annotations (staging, HER2 status, treatment, and overall survival). **Methods:** Formalin-fixed, paraffin-embedded (FFPE) GEC samples (N = 394) primarily from early-stage tumors were collected in the United States and Italy. Samples were analyzed by fluorescence in situ hybridization (FISH) for *MET* gene amplification (Dako *MET* IQFISH probe mix, research use only) and by immunohistochemistry (IHC) for Met protein expression (Dako Met IHC assay, MET4 antibody, investigational use only). All assays were performed according to the manufacturer's instructions. Samples with a *MET*/CEP 7 ratio ≥ 2.0 were considered amplified, whereas samples with ≥ 25% Met tumor membrane staining by IHC (≥ 1+ intensity) were considered Met positive. Spearman's rank correlation coefficient was used to assess correlations between parameters. Cox proportional hazards models and Kaplan-Meier estimates were applied to explore relationships between MET, overall survival, and other clinical characteristics. **Results:** *MET* gene copy number variation (≥ 5 copies) was observed in 18 of 344 samples (5.2%), and *MET* gene amplification (*MET*/CEP 7 ≥ 2.0) was observed in 16 of 344 samples (4.7%). Of the 332 evaluable IHC samples, 117 (35.2%) were positive for Met protein expression. There was considerable overlap between *MET* amplification and Met expression; 12 of 15 *MET*-amplified samples (80.0%) were positive for Met expression. Survival analyses showed that both *MET* gene amplification and Met IHC positivity were prognostic of poor outcomes. **Conclusions:** *MET* amplification was observed in ~5% of this large set of GEC samples. Prevalence of *MET* amplification and Met expression were similar to those found in previously published studies. Our results indicate that *MET* gene amplification and Met protein expression are prognostic of poor outcomes in GEC.

4035 Poster Session (Board #144), Mon, 8:00 AM-11:30 AM

Randomized phase II study of recombinant human endostatin combined with definitive chemoradiotherapy in locally advanced esophageal squamous cell carcinoma. *First Author: Jiahua Lv, Department of Radiation Oncology, Sichuan Cancer Hospital & Institute, Chengdu, China*

Background: Recombinant human endostatin (endostar) has been documented to be an inhibitor of tumor angiogenesis. The aim of this randomized phase II study was to assess the efficacy and safety of endostar combined with chemoradiotherapy (CRT) in locally advanced esophageal squamous cell carcinoma (ESCC). **Methods:** Locally advanced ESCC with a performance status of 0-1 were randomly assigned to endostar group (endostar 7.5mg/m2 D1-D14 with CRT) or the control group (CRT only). Patients in both groups were treated with docetaxel (75 mg/m2 on D1)/CDDP (25 mg/m2 on D1-D3)-based intensity-modulated radiation therapy (IMRT, 60-66 Gy/30-33f/6-7wks). CT perfusion imaging and immunohistochemical staining of tumor microvessel density (MVD) were assessed before and after the treatment of endostar. The primary end point was overall survival (OS). The secondary end points were the effect of endostar on angiogenesis, progression-free survival (PFS) and object response rate (ORR). **Results:** Between Oct. 2012 and Sep. 2014, 63 patients were enrolled and divided into endostar group (n = 32) or the control group (n = 31). The endostar group resulted in a slight improvement in ORR (62.3% vs 55.1% in the control group), and a significant increase in the 1-year and 2-year overall survival rates (78.1% vs 67.7% and 56.2% vs 45.1%, respectively). The median PFS was extended to 16.5 months in the endostar group vs 9.3 months in the control group ($P < 0.05$). Endostar combined with CRT led to a marked decrease in tumor blood flow (BF) and blood volume (BV) with correction of MVD, compared to CRT alone ($P < 0.05$). There was no significant difference in toxicities in two arms. No new or unexpected endostar-related toxicities were observed. **Conclusions:** Recombinant human endostatin combined with CRT can reduce tumor angiogenesis. The short- and long-term effects of endostar combined with CRT were an improvement over that of CRT alone in this study. Clinical trial information: ChiCTR-TRC-13003908.

4036 Poster Session (Board #145), Mon, 8:00 AM-11:30 AM

Estrogen receptor beta (ERβ) gene polymorphisms as a predictor of overall survival in patients with gastric cancer (GC) from Japan and Los Angeles County (LAC). *First Author: Anish Parekh, University of Southern California/ Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Use of menopausal hormones has correlated with a lower risk of colon cancer in women. Prostate cancer patients (pts) treated with estrogen have a reduced risk of developing GC as a second primary. Several ERβ gene (*ESR2*) polymorphisms have been associated with colorectal cancer survival (Cancer Res 2013;73:767). To better understand the role of ERβ in relation to GC outcome, we tested whether *ESR2* polymorphisms will be associated with overall survival (OS) in GC pts from 2 different regions. **Methods:** We analyzed genomic DNA extracted from blood or tumor tissues of 169 pts from Japan (64% men, stage IB-IV of AJCC-6th, median age 67, median follow-up 3.6 years, median survival 5.7 years) and 214 pts from LAC (68% men, stage 0-IV of AJCC-6th, median age 62, median follow-up 8.2 years, median survival 2.6 years), using PCR-based direct sequencing. *ESR2* polymorphisms, which were shown to be of biological significance (rs2978381, rs3020443 and rs1271572), were analyzed for association with OS in both cohorts. Multivariate Cox proportional hazard regression was conducted to test the association after adjustment for age, sex, primary tumor site, stage and other covariates. **Results:** *ESR2* rs1271572 and rs3020443 had uni- and multivariate associations with OS in the Japanese but not LAC cohort. Any C allele of *ESR2* rs2978381 (T > C) was associated with longer OS than T/T genotype in the Japanese cohort (5-year survival 63 % vs 41 %, p= 0.021) but shorter OS in the LAC cohort (5-year survival 30 % vs 51 %, p= 0.049) although these findings did not remain significant in multivariate analysis. In analysis restricted to distal GC, the *ESR2* rs1271572 (C > A) correlated with OS but the effect of A allele was in the opposite direction between the Japanese (n= 121, adjusted HR 2.19, p= 0.019) and LAC cohort (n= 116, unadjusted HR 0.62, p= 0.031). **Conclusions:** *ESR2* polymorphisms have prognostic value in pts with GC. These data also suggest that ERβ pathway may play a key role in tumor progression of GC and its prognostic impact may differ depending on histopathologic, ethnic or epidemiologic differences. Further studies to evaluate the association among different races are warranted.

4037 Poster Session (Board #146), Mon, 8:00 AM-11:30 AM

A phase I dose-escalating and safety study of AZD8931 in combination with oxaliplatin and capecitabine chemotherapy in patients with oesophagogastric adenocarcinoma. *First Author: Anne L. Thomas, Leicester Royal Infirmary, Leicester, United Kingdom*

Background: AZD8931 is a novel small-molecule inhibitor which has equipotent activity against signalling by three members of the erbB family; EGFR, erbB2(HER2), and erbB3. Our hypothesis is that combining AZD8931 with chemotherapy will be effective not just in oesophago-gastric cancer patients (pt) who overexpress high levels of HER2, but those with low HER2 expression as well. This study seeks to establish the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) of AZD8931 with oxaliplatin and capecitabine (XELOX) in patients with oesophagogastric cancer (OGC). **Methods:** Chemonaive patients with metastatic OGC were recruited into this rolling 6 dose escalating study to determine MTD, safety (NCI-CTC version 4.0) and pharmacokinetics of the combination. Patients received oxaliplatin (130 mg/m^{2}day(d) 1 every 21 days (q21) and capecitabine (X) (1250mg/m2/d) d1-21, for a maximum of 8 cycles. AZD8931 dosing was planned at 3 cohorts (20mg bd, 40 mg bd, 60 mg bd continuously). With emerging toxicity at 20mg bd, AZD8931 was also investigated at 2 intermittent schedules (14d on and 7d off, 4d on and 3d off, from d1, q21). **Results:** 24 pts (median age 60 years) were enrolled in 4 cohorts and 4 DLTs within cycle 1 were observed: diarrhoea, vomiting and skin rash (Table 1). 58% (14/24) patients showed SAE grade ≥ 3 (mostly GI disorders and infections). 95% (18/19) patients had at least stabilisation of disease as best tumour response from cycle 3 (8 stable disease, 9 partial and 1 complete response). PK data, full demographic data including HER2 status and justification of RP2D dose will be presented. **Conclusions:** In this pt group the RP2D of AZD8931 in combination with XELOX is 20mg bd 4d on and 3d off q21. We are now recruiting pts with operable disease into the randomised phase of the study with XELOX versus XELOX and AZD8931. Translational studies are ongoing. Clinical trial information: 2011-003169-13.

Dosing cohorts and DLTs.

Dose of AZD8931 bd	No of Pts enrolled (evaluable for dose escalation)	DLTs
20 mg continuous	6 (6)	1 G2 diarrhea*
20 mg 14d on and 7d off q21	7 (6)	1 G3 diarrhea*
20 mg 4d on and 3d off q21	7 (6)	0
40 mg 4d on and 3d off q21	4 (4)	1 G3 vomiting & 1 G3 skin rash

*Requiring stoppage of X

4038 Poster Session (Board #147), Mon, 8:00 AM-11:30 AM

Multicenter phase 2: Capecitabine (CAP) + oxaliplatin (OX) + bevacizumab (BEV) + trastuzumab (TRAS) for patients (pts) with metastatic esophagogastric cancer (MEGCA). *First Author: Peter C. Enzinger, Dana-Farber Cancer Institute, Boston, MA*

Background: In MEGCA, cisplatin+CAP has RR 46% and OS 12.1 mos with BEV (AVAGAST) and RR 47% and OS 13.8 mos with TRAS (ToGA). We sought to improve these results by combining CAPOX with both BEV and TRAS. **Methods:** Pts with HER2/neu IHC 3+ or FISH+ MEGCA, with 0-1 prior chemo, received a loading dose of TRAS 4mg/kg, day (d) 1. One week later, pts received BEV 7.5mg/kg/d1, TRAS 6mg/kg/d1, OX 130mg/m2/d1 and then q21d. CAP d1-14/q21d was decreased from 1700mg/m2/d to 1200mg/m2/d after 4 of the first 5pts developed G3 diarrhea. Consenting pts underwent identical research biopsies prior to and 7 days after TRAS loading dose. Primary endpoint was RR by RECIST 1.1, scored by independent Harvard Tumor Imaging Metrics Core. **Results:** Of 35 pts enrolled, median age 58 (32-80), 4F/31M, HER2/neu IHC3+: 25/FISH+: 10, ECOG PS 0: 18/ 1: 17, prior chemo 10, primary: esophagus 16/GEJ 10/gastric 9, sites of mets: LN 26, liver 19, lungs 9, bone 2, other 6. Pts have received mean 16 cycles (2-50+). Of 34 pts (1 too early), PR 24 + CR 2 = 76.5% RR (95% CI, 0.59 – 0.88) by blinded review. For all 35pts, median PFS = 13.93 mos (95%CI, 8.5 - 22.33); median OS = 26.92 mos (95%CI, 11.31 – 36.36). Safety for 30pts (enrolled after CAP dose change): 16 pts required dose modification: CAP 12, OX 14, BEV 2, TRAS 0. Pts w grade 3-4 AE: periph neuropathy 3, bleeding 3, thromboembolic event 2, hypertriglyceridemia 2, ANC 2, HTN 1, plts 1, diarrhea 1. One pt died of cardiac arrest after 3yrs on tx. **Conclusions:** CAPOX+BEV+TRAS is well tolerated in pts with MEGCA. There appears to be at least additive effect between BEV and TRAS. Combinations of anti-VEGF and anti-HER2/neu agents should be considered in future randomized studies of HER2/neu+ MEGCA. Clinical trial information: NCT01191697.

4039 Poster Session (Board #148), Mon, 8:00 AM-11:30 AM

Prognostic impact of Forkhead box-F1 (FOXF1) polymorphisms on the clinical outcome in gastric cancer patients. *First Author: Satoshi Matsusaka, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: A recent genome-wide association study reported associations between risk of Barrett's esophageal and esophageal adenocarcinoma and seven single-nucleotide polymorphisms (SNPs) in region 16q24 on chromosome 16 near the Forkhead box-F1 (FOXF1) gene. The FOXF1 gene is known to regulate mesenchymal-epithelial interactions of the lung and gut morphogenesis and to regulate cancer-associated fibroblasts to stimulate cancer cell migration. We tested whether these SNPs are associated with clinical outcome of gastric cancer (GC) patients from Japan and Los Angeles County (LAC). **Methods:** We isolated genomic DNA from blood or tissue of GC patients from two independent cohorts. A total of 150 patients with advanced GC from Japan [107 male/43 female; median age 61 year-old; median follow-up time, 3.1 years; median overall survival (OS), 13.8 months; median progression-free survival (PFS), 6.6 months] who were treated with 1st line fluoropyrimidine-based chemotherapy and 214 patients with stage IA-IV GC from LAC [146 male/68 female; median age 62 year-old; median follow-up time, 8.2 years; median OS, 2.6 years] were included. Genomic DNA was analyzed using PCR-based direct DNA sequencing. Multivariate Cox proportional hazard regression was conducted to investigate the relationship between these SNPs with clinical outcome of gastric cancer patients. **Results:** One FOXF1 SNP, rs3950627, was associated with outcome in patients from Japan and LAC. Japanese patients who had C/C genotype experienced better outcome than those with any A allele (PFS: C/C 8.2 months, any A allele 5.3 months; p = 0.037 and OS: C/C 16.4 months, any A allele 12.2 months; p = 0.043). Similarly, patients in LAC with C/C genotype showed better outcome (OS: C/C 46.8 months, any A allele 27.6 months, p = 0.022). Results were consistently strong when we restricted the analysis to male patients and those with gastric cardia cancer. **Conclusions:** Our data show for the first time that rs3950627 is a promising a prognostic marker in two cohorts of GC patients. Furthermore, rs3950627 may be useful as a predictive marker in patients treated with fluoropyrimidine-based chemotherapy, which may be gender dependent.

4040 Poster Session (Board #149), Mon, 8:00 AM-11:30 AM

The role of panitumumab in combination with ECX in perioperative chemotherapy of unselected patients with locally advanced gastroesophageal adenocarcinomas: Randomized phase II study of the German Cancer Society. *First Author: Markus H. Moehler, Johannes-Gutenberg University Mainz, Mainz, Germany*

Background: Perioperative chemotherapy (pCT) significantly improved survival of patients (pts) with locally advanced esophagogastric adenocarcinoma (la EGC). However, ~60% of pts will later die from their disease. Thus, targeted drugs are worthwhile to be investigated to further improve survival (OS). **Methods:** To evaluate the role of the EGFR-antibody panitumumab with pCT, we performed an open randomized phase II study in 22 German centres. Untreated pts with la EGC (cT3-4 N0-3 M0) were eligible and treated with standard ECX therapy with (arm 1) or without (arm 2) panitumumab (9 mg/kg body weight iv, q 3 weeks). Three cycles were given prior to and after surgery. 163 from 171 pts (83 arm 1, 80 arm 2) were eligible from 11/2010 to 7/2013. Results: Compliance and dose intensity of pCT was equal in both arms, however 49% started and only 31% completed postop. CT in arm 1 versus 50% and 40% in arm 2, respectively. The cumulative capecitabine dose was lower in arm 1 (58% vs. 70% of planned dose). No death was observed until 30 days after postop. CT. Local efficacy was slightly increased with panitumumab (75% vs. 68% without progression/death or with downstaging, p = 0.24). PFS (HR 1.21; 0.78-1.89) and OS (HR 1.30; 0.79-2.13) was not significantly lower in arm 1. Molecular analyses were possible in 76 / 163 pts (47%): c-MET overexpression was high (53%); however c-MET amplification (4%), EGFR-amplification or overexpression (7%), HER2-positivity (8%) or RAS-mutations (3%) were rarely observed. 117 plasma samples were analyzed for 25 EGFR signaling markers and ligands. At baseline, patients had slightly higher levels vs. healthy controls for BDNF , EGF, HGF, PDGF, PlGF, SCF, VEGF-A, and -D. Conclusions: Similarly to metastatic disease, adding EGFR-antibody panitumumab to ECX did not improve the results in unselected locally advanced EGC pts. The rare pt numbers with possible predictive molecular alterations made it unlikely to define subgroups who may have benefitted from the addition of panitumumab to perioperative CT. Clinical trial information: 2008-007798-18.

4041 Poster Session (Board #150), Mon, 8:00 AM-11:30 AM

Analysis of patients with esophageal cancer following trimodality therapy: Pathological complete remission (PathCR) versus non-PathCR. *First Author: Mariela A. Blum, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Trimodality therapy (chemoradiation followed by surgery) continues to be the cornerstone treatment for localized esophageal cancer; predictive models for pathCR have been not been clinically validated. The purpose of this study was to determine the association of pathCR with baseline clinical factors, overall survival (OS), and recurrence free survival (RFS) in a large population. **Methods:** We analyzed the data of 911 consecutive patients treated for esophageal cancer with trimodality therapy. Logistic regressions were used to identify independent baseline factors associated with pathCR. We applied log rank testing and univariable and multivariable Cox models to determine the association between pathCR and the time-to-event outcomes (OS and RFS). **Results:** Of 911 patients studied, 218 (23.9%) achieved pathCR. Lower clinical T stage (T1/T2) was more likely to achieve pathCR (p = 0.0006). Advanced age (OR = 0.984, p = 0.0297), poorly differentiated tumors ((OR = 0.48), p = < 0.0001), and signet ring cell histology (p = < 0.0001) were associated with lower rate of pathCR. OS and PFS rates were higher for pathCR patients (p = 0.0021 and p = 0.0011). The estimated median OS was 71.28 (95% CI: 51.71-91.63) months in pathCR patients and 35.87 (95% CI: 31.23-42.19) months in non-pathCR patients. Distant recurrences were less common in pathCR patients (p = 0.0036). **Conclusions:** Poor prognostic indicators associated with decreased rate of pathCR and OS were: older age, poorly differentiated tumors, and the presence of signet ring cell histology. Our data is the largest data set showing that pathCR confers better prognosis in patients with esophageal cancer. While recurrences were still seen in pathCR patients, distant metastases were more common in non-pathCR patients. Further biomarker-based approach might help to identify patients who are more likely to achieve pathCR.

4042 Poster Session (Board #151), Mon, 8:00 AM-11:30 AM

Prognostic significance of tumor infiltrating immune cells and PD-L1 expression in gastric carcinoma in Chinese patients. *First Author: Ruixuan Geng, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Programmed death-1 receptor (PD-1) and its ligand (PD-L1) play an integral role in the immune response against cancer. This study in Chinese patients (pts) with gastric carcinoma (GC) investigated the prognostic significance of PD-L1 expression on tumor cells and its association with tumor-infiltrating lymphocytes (TILs). **Methods:** 398 archived, formalin-fixed, paraffin-embedded GC samples were collected Oct 2007–Feb 2010 at a single institution from pts with stage I–IV GC after gastric resection and no prior chemo- or radiotherapy. The median age was 60 years (range 21–87 y). TILs were phenotyped and PD-L1 expression on tumor cells was assessed immunohistochemically, using a pre-defined cutoff (≥ 5% tumor cells with ≥ 1+). Associations of TIL and PD-L1 expression with clinico-pathologic features were evaluated using a non-zero correlation test. Survival distribution among different subgroups was compared by Kaplan-Meier and a log-rank test. A multivariate Cox regression model was used to investigate prognostic factors (TNM stage, Lauren type, TIL density, PD-L1 expression) for overall survival (OS). The median follow-up time was 44.3 months (range 0.1–79.9 m). **Results:** PD-L1 expression was observed in 14% of pts. The median OS for PD-L1(-) pts was 61.1 m. The median OS time for the PD-L1(+) pts had not yet been reached. In specimens with PD-L1(+) tumor cells, 96% (55/57) were associated with TILs, and PD-L1 expression on tumor cells was positively associated with TIL densities (*P*= 0.0018). There was no correlation between PD-L1 expression and Lauren type or TNM stage. Multivariate analysis identified both moderate (HR 0.585; 95% CI, 0.346–0.989; *P*= 0.045) and high TIL densities (HR 0.109; 95% CI, 0.026–0.462; *P*= 0.003) as independent factors associated with OS. The association between PD-L1 expression and OS did not reach statistical significance (HR 0.766; 95% CI, 0.452–1.299; *P*= 0.322). **Conclusions:** Within the tumor microenvironment, a moderate to high number of TILs is associated with a better clinical outcome and elevated tumor PD-L1 expression. These observations support a possible therapeutic role for PD-L1 inhibitors in a subset of GC pts.

4043 Poster Session (Board #152), Mon, 8:00 AM-11:30 AM

Clinical characteristics and treatment outcomes of patients with metastatic, *MET*-amplified esophagogastric cancers. *First Author: Eunice Lee Kwak, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: The Cancer Genome Atlas (TCGA) reported *MET* gene alterations in 6% of gastric cancers (Nature 2014; 513: 202–209). Though rare, *MET* amplification is a biomarker for dramatic responses to single-agent MET inhibitors in esophagogastric cancer (J Clin Oncol 33, 2015, suppl 3; abstr 1). Clinical characteristics and outcomes were evaluated in patients (pts) with *MET*-amplified esophagogastric cancers (EGC) to facilitate identification of pts and establishment of treatment paradigms. **Methods:** Pts with metastatic *MET*-amplified EGC were identified between 2007 and 2014. *MET* amplification was determined in paraffin-embedded tissue using fluorescence in-situ hybridization (FISH), with a gene to control ratio of > 2.2 defined as positive. Clinical characteristics, treatment factors, and survival were recorded. A cohort of pts diagnosed between 8/2002 and 10/2012 with metastatic non-*MET*-amplified EGCs was evaluated as a comparison group. **Results:** We identified 23 pts with *MET*-amplified EGCs, 15 of whom were identified between 2012-2014. Compared to 37 non-*MET*-amplified tumors, *MET*-amplified EGCs were more typically poorly differentiated and located in the distal esophagus or gastroesophageal junction rather than distal stomach. Patterns of metastases did not differ between *MET*-amplified and non-*MET*-amplified pts. In the 17 pts for whom HER2 status was obtained, 4/17 EGCs showed co-amplification of *MET* and *HER2*. One EGC had concurrent *MET* and *EGFR* amplification. Additionally, 1/17 genotyped tumors harbored a *PIK3CA* mutation. Progression-free survival (PFS) from the time of metastatic diagnosis was 5 months for pts with *MET*-amplified EGCs. Including 7/23 pts who had received MET-directed therapy, overall survival (OS) was 13.2 months (3.4-7.8 and 6.0-21.1, 95% CI estimate of PFS and OS, respectively). Updated OS and comparison to the non-*MET*-amplified cohort will be presented. **Conclusions:** This series represents the largest cohort of clinically annotated *MET*-amplified EGCs and highlights this subgroup as a distinct clinical entity characterized by rapid progression. Patients should be identified early and directed to appropriate MET-targeted clinical trials.

4044 Poster Session (Board #153), Mon, 8:00 AM-11:30 AM

A phase II single-arm pilot study of second-line icotinib treatment in advanced esophageal cancer with EGFR over-expression or amplification. *First Author: Jing Huang, Cancer Hospital and Institute, Chinese Academy of Medical Sciences, Beijing, China*

Background: Epidermal growth factor receptor (EGFR) has been reported to be overexpressed in esophageal cancer, suggesting EGFR-directed treatment is a potential option. Here we report the antitumor activities of icotinib, a selective EGFR tyrosine kinase inhibitor (TKI), as second-line treatment for advanced esophageal cancer with EGFR over-expression or amplification. **Methods:** In this phase II, single-arm study, eligible patients were adults with advanced esophageal cancer confirmed by histology, who had received at least first-line chemotherapy, with EGFR over-expression [immunohistochemistry (IHC), 3+] or amplification [positive fluorescence in-situ hybridisation (FISH)]. Participants were treated with oral icotinib (250 mg, three times daily).The primary endpoint was objective response rate (ORR). **Results:** Between December, 2013 and January, 2015, 38 patients were enrolled (37 with squamous cell carcinoma, 1 with adenocarcinoma) with a median age of 60, in which 36 were IHC 3+ (94.7%) and 2 were IHC 2+ with positive FISH. And as of the December 31, 2014 cutoff, 33 patients were evaluable for response. The ORR was 15.2% (5/33), consisting of 1 CR and 4 PRs, and the disease control rate was 54.5% (18/33). The median duration of treatment in 18 patients (CR + PR + SD) is 12.3 weeks with the longest being 28+ weeks. Twenty-three out of 33 patients (69.7%) experienced at least one adverse event (AE) with rash (42.4%), diarrhea (24.2%), pain (21.2%), fatigue (15.2%) and vomiting (12.1%) as the most common ones. Most AEs were mild and reversible and no grade 3 or 4 AEs were reported. **Conclusions:** Second-line icotinib treatment in advanced esophageal cancer with EGFR over-expression or amplification demonstrated favorable outcome along with a high safety profile. However, the role of EGFR over-expression or amplification as predictive biomarker still needs further exploration. Clinical trial information: NCT01855854. Clinical trial information: NCT01855854..

4045 Poster Session (Board #154), Mon, 8:00 AM-11:30 AM

Patterns of local-regional relapse after complete response by definitive chemoradiotherapy for stage II/III (non–T4) esophageal squamous cell carcinoma. *First Author: Kazuki Sudo, National Cancer Center Hospital, Tokyo, Japan*

Background: Definitive chemoradiotherapy (dCRT) has been recognized as one of treatment options for esophageal squamous cell carcinoma (ESCC) patients who are not fit for surgery. Recent studies revealed that surveillance after dCRT was important in an adenocarcinoma dominant population. However, clinical utility of surveillance for ESCC is not clear. **Methods:** The subjects of this retrospective study were patients who underwent dCRT for stage II/III (excluding T4 disease) ESCC from 2000 to 2011 at National Cancer Center Hospital in Tokyo, Japan. We reviewed the patterns of relapse after clinical complete response (cCR). Each patient was generally surveyed with computed tomography (CT) and esophagogastroduodenoscopy (EGD) every 3-6 months. We also recorded new cancers (NC) diagnosed by EGD during surveillance after cCR. Local-regional relapse (LRR) without distant metastasis was classified into luminal-only relapse (LR) and other type of regional relapse (RR) with or without luminal relapse. Overall survival (OS) was estimated using the Kaplan-Meier method. **Results:** Among 351 patients treated with dCRT, 233 (66%) achieved cCR. The median follow-up time was 64.0 months. A total of 94 (40% of 233) patients had relapse after cCR: 45 (19%) with distant metastasis and 49 (21%) with LRR including 33 with LR and 16 with RR. Of the remaining 139 patients without relapse, 20 (14%) had NC: 17 with new esophageal cancer, 2 with hypopharynx cancer and 1 with esophagogastric junction cancer. Of 49 LRR, 31 (63%) were diagnosed within 1 year of dCRT and 46 (94%) within 3 years. Fifty-three of 69 patients (77%) with LRR or NC underwent local treatment (salvage surgery, endoscopic treatment or radiation). For these 53 patients with local treatment, the median OS from diagnosis of LRR or NC was 57.1 months (95% CI, 25.3-88.9). **Conclusions:** Our data suggest that 94% of LRR occurred within 3 years of dCRT. Of patients without relapse after cCR, 14% were diagnosed with NC by EGD. Outcome of local treatment for LRR or NC was excellent.

4046 Poster Session (Board #155), Mon, 8:00 AM-11:30 AM

Multicenter retrospective analysis for elderly patients with advanced gastric cancer (AGC) received first-line chemotherapy in clinical practice. *First Author: Kenji Kunieda, Department of GI Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Indication of elderly patients (pts) to intensive chemotherapy has not been established. We hypothesized that a survival benefit of doublet chemotherapy with fluoropyrimidine plus platinum, standard treatment might be attenuated in elderly AGC pts with decreased physiological function due to their low tolerability. **Methods:** We retrospectively investigated clinical outcomes of the elderly AGC pts, 70 years or older, who were treated with S-1 or S-1 + CDDP (SP) as the first-line chemotherapy between 2009 and 2011 at 29 medical centers participating West Japan Oncology Group. Among these pts we selected the pts considered to be fit for SP, and the efficacy and toxicity of S-1 with SP therapy was compared, calculating the propensity scores for receiving each treatment and conducted survival analyses by inverse probability of treatment weighting. **Results:** Among 464 pts enrolled this study, 446 pts were eligible for the criteria. Patient characteristics were: median age 75 years old (range 70-86); PS 0/1/2 38%/54%/8%; male/female 71%/29%; some co-morbidity +/- 68%/32%; CCr $<$ 50 ml/min/ $>=$ 50 ml/min 21%/79%; received S-1/SP 47%/53%. Between the S-1 and SP groups, there was a large imbalance in PS, better in the SP group ($p < 0.001$). Limited to the 170 pts with PS 0, 56 pts (33%) and 114 pts (67%) received S-1 and SP, respectively. Between the two groups in this subset of PS 0 showed no significant differences in gender and co-morbidity rate, but SP group showed better background such as age, ($p < 0.001$), CCr ($p < 0.05$). The median PFS in the S-1 and SP group, were 8.0 months and 7.9 months (HR = 0.999, 95 % CI 0.698-1.429, p = 0.999), and median OS were 15.0 months and 17.2 months (HR=1.116, 95 % CI 0.760-1.640, p = 0.574). The results were consistent after background factors were statistically adjusted by propensity score. Hematologic toxicities ($p < 0.001$), G3/4 adverse event ($p < 0.001$) and hospitalization due to AE ($p < 0.001$) were more frequent in the SP group. **Conclusions:** It is suggested optimal treatment strategy for elderly AGC patients should be established separately from younger patients, we are now planning the clinical trial for elderly AGC patients.

4047 Poster Session (Board #156), Mon, 8:00 AM-11:30 AM

A phase I dose expansion trial of avelumab (MSB0010718C), an anti-PD-L1 antibody, in Japanese patients with advanced gastric cancer. *First Author: Yasuhide Yamada, National Cancer Center Hospital, Tokyo, Japan*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. Here we present preliminary results from a phase Ib dose expansion study (NCT01943461) evaluating safety and clinical activity in a cohort of Japanese patients (pts) with advanced gastric cancer (GC). **Methods**: Pts with previously treated progressive GC, ECOG PS 0-1, received avelumab at 10 mg/kg, Q2W. Responses were assessed according to RECIST 1.1 and modified immune-related RECIST (irRECIST). Adverse events (AEs) were evaluated by CTCAE v4.0. Initial data from a prespecified analysis are reported here. A total of 20 pts in this expansion cohort were enrolled. **Results**: As of Oct 8, 2014, 11 pts were treated with avelumab. Pts were followed-up for at least 3 weeks (wks) and the median treatment duration was 9.9 wks (range 4-12). Median age was 69 years (range 38–76) and all pts had an ECOG-PS of 0 or 1, with a median of 3 prior lines (range 1–4) of therapy. Drug-related treatment-emergent AEs (TEAEs; all grades) occurred in 10/11 pts (90.9%). The most frequently observed treatment-related TEAEs ($>$ 1 case; all grade 1 or 2) were infusion-related reactions (IRRs) (3 pts, 27.3%), hyperthyroidism, and pruritus (2 pts each, 18.2%). There were no treatment discontinuations from AEs. One pt had grade 3 anemia; it was assessed as not drug-related. At data cutoff, 2 pts (18.2%) have come off study due to disease progression. Nine patients were still on treatment. To date, partial responses according to RECIST have been observed in 3 pts. **Conclusions**: Avelumab at 10 mg/kg Q2W can be safely administered in Japanese pts with heavily pretreated, metastatic GC. Additional studies to evaluate the efficacy of avelumab in Japanese pts with GC are planned and biomarkers from tumor tissue and blood samples including PD-L1 expression and soluble factors related to immune response will be evaluated. *Proposed INN. Clinical trial information: NCT01943461.

4048 Poster Session (Board #158), Mon, 8:00 AM-11:30 AM

Evaluation of tumor MET protein expression, *MET* gene amplification, and HER2 expression in Chinese patients with advanced gastric or gastroesophageal junction (G/GEJ) cancer. *First Author: Rui-hua Xu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Gastric cancer is a disease with high unmet medical needs in China. MET and its ligand, hepatocyte growth factor, are potential targets in G/GEJ cancer. This study evaluated overall survival (OS) according to tumor MET expression, *MET* gene amplification, and the association between MET and HER2 status in Chinese patients with advanced G/GEJ cancer. **Methods:** Baseline tumor biopsy samples (formalin-fixed, paraffin-embedded primary tumor) from patients with stage IV unresectable G/GEJ cancer, archived at Sun Yat-Sen University Cancer Center, were assessed for MET and HER2 protein levels and *MET* and *HER2* gene amplification by IHC and FISH, respectively. MET-positive: membrane protein staining in $\geq$ 25% or $\geq$ 50% of tumor cells. HER2-positive: IHC 2+ and a confirmatory *HER2* FISH-positive result (*HER2*:centromere 17 ratio $\geq$ 2.0), or IHC 3+. *MET*-amplified: *MET*:centromere 7 ratio $>$ 2.0. We evaluated associations between Kaplan-Meier OS and MET status (log-rank test), MET expression and *MET*gene amplification, and MET and HER2 status (Fisher exact test). **Results:** Of 289 eligible patients, 271 had evaluable IHC samples, and MET-positive rates were 42.1% and 25.1% by 25% and 50% cutoffs, respectively. Median OS by different levels of MET-positive expression is shown in the Table. Of 183 patients with evaluable FISH samples, 8 (4.4%) were *MET*-amplified. In 171 patients with IHC and FISH data, MET-positive expression by 25% and 50% cutoffs was associated with *MET* amplification ($P <$ 0.005, both cutoffs). In 145 patients with MET IHC, FISH, and HER2 data, the HER2-positive rate was 13.8%. Of patients who were MET-positive by 25% and 50% cutoffs, 8/48 (16.7%) and 4/29 (13.8%), respectively, were also HER2-positive. Additionally, 1/8 (12.5%) *MET*-amplified patients was HER2-positive. **Conclusions:** MET-positive status was associated with shorter OS in this population of Chinese patients with advanced G/GEJ cancer. MET high expression or *MET* amplification was not associated with HER2 expression.

Patients evaluable for IHC	MET-positive	MET-negative	*P* value

4049 Poster Session (Board #159), Mon, 8:00 AM-11:30 AM

Prospective phase II trial of pazopanib plus CapeOX (capecitabine and oxaliplatin) in previously untreated patients with advanced gastric cancer. *First Author: Min-Young Lee, Samsung medical center, Seoul, South Korea*

Background: We designed a single-arm, open label phase II study to determine the efficacy and toxicity of the combination of pazopanib with CapeOx (capecitabine and oxaliplatin) in metastatic and/or recurrent advanced gastric cancer (AGC) patients. **Methods:** Previously untreated AGC patients received capecitabine (850 mg/m^2 bid, day 1–14) plus oxaliplatin (130 mg/m^2, day 1) in combination with pazopanib (800 mg, day 1–21) every three weeks. Treatment was continued until progression of the disease or intolerable toxicity was observed. **Results:** In all, 66 patients were treated with pazopanib plus CapeOx. The median age of the patients was 51.5 years (range, 23.0–77.0 years), and the median ECOG performance status was 1 (0–1). Among all 66 patients, one complete response and 37 partial responses were observed (overall response rate, 57.6%; 95% confidence interval (CI), 46.7–67.9%). Stable disease was observed in 22 patients (33.3%), revealing a 90.9% disease control rate. The median progression free survival and overall survival were 6.5 months (95% CI, 5.6–7.4 months) and 10.5 months (95% CI, 8.1–12.9 months), respectively. Thirty-four patients (51.5%) experienced a treatment-related toxicity of grade 3 or more during the study. The most common toxicities of grade 3 or more were neutropenia (15.1% of all patients), anemia (10.6%), thrombocytopenia (10.6%), anorexia (7.6%), nausea (3.0%), and vomiting (3.0%). There were no treatment-related deaths. **Conclusions:** The combination of pazopanib and CapeOx showed moderate activity and an acceptible toxicity profile as a first-line treatment in metastatic and/or recurrent AGC patients (ClinicalTrials.gov NCT01130805). Clinical trial information: NCT01130805.

4050 Poster Session (Board #160), Mon, 8:00 AM-11:30 AM

Quantitative measurement of HER2 levels by multiplexed mass spectrometry to predict survival in gastric cancer patients treated with trastuzumab. *First Author: Chan-Young Ock, Seoul National University Hospital, Seoul, South Korea*

Background: Trastuzumab-based chemotherapy is standard treatment for HER2-positive advanced gastric cancer (AGC). Although increased *HER2* gene amplification by fluorescent *in situ* hybridization (FISH) has been correlated with sensitivity to trastuzumab, the predictive value of HER2 protein expression levels for trastuzumab sensitivity has not been reported. In this work, we quantitate levels of HER2 using a mass spectrometry-based assay and identify a cutoff for HER2 protein levels that is predictive of enhanced response to trastuzumab. **Methods:** A multiplexed, selected reaction monitoring (SRM) mass spectrometry assay was used to determine the absolute level of the HER2 protein in patient tumors. HER2 immunohistochemistry (IHC) status, *HER2/CEP17* ratio, *HER2* gene copy number, and HER2 protein levels were compared in 249 AGC tumors, 95 of which were treated with trastuzumab. Overall survival (OS) in the trastuzumab cohort was correlated with HER2 protein levels and a predictive cutoff was determined by the lowest *p* value of log rank test. **Results:** While HER2 protein quantitation by mass spectrometry positively correlated with both FISH and IHC, a wide range of HER2 protein levels was observed in tumors classified as HER2-positive by conventional methods. Ninety five trastuzumab treated patients were stratified into two groups based on HER2 protein level: HER2 high expressers and HER2 moderate expressers. Patients classified as HER2 high expressers (n = 48), with HER2 levels above 2383 amol/ug, had twice the overall survival (OS) of patients (n = 47) classified as moderate expressers (OS: 35.0 vs. 17.5 months, HR 0.5, p= 0.007). **Conclusions:** We used a non-antibody based assay to quantify absolute levels of HER2 protein in samples from AGC patients. We found high variability in HER2 expression within a patient population that had been classified as 3+ by IHC. High levels of HER2 correlated with increased overall survival following trastuzumab. This study demonstrates the HER2 measurement by SRM could guide physicians in their patient's selection for trastuzumab-based chemotherapy.

4051 Poster Session (Board #161), Mon, 8:00 AM-11:30 AM

First-line capecitabine (X) monotherapy versus capecitabine plus oxaliplatin (XELOX) in elderly patients with advanced gastric cancer (AGC): results from the first interim analysis. *First Author: In Gyu Hwang, Division of Hematology/Oncology, Department of Internal Medicine, Chung-Ang University Hospital, Chung-Ang University College of Medicine, Seoul, South Korea*

Background: While doublet combination with fluoropyrimidines and platinum is currently considered standard first-line chemotherapy in AGC, there has been a price to pay in terms of toxicity. Since the main goal of AGC treatment remains palliation, this multi-center randomized phase III trial compared efficacy and safety of X monotherapy with those of XELOX combination in elderly patients with AGC. **Methods:** Patients with chemotherapy-naïve, measurable AGC, aged 70 years or older were randomized 1:1 to receive X (capecitabine 1,000 mg/m2 bid po on D1-D14) or XELOX (X plus oxaliplatin 110 mg/m2 iv on D1). Treatment was repeated every 21 days until disease progression, unacceptable toxicity, or withdrawal. Primary end point was overall survival (OS). The present report contains the results from the first interim analysis conducted at Dec 2014. **Results:** As of Oct 2014, 50 patients with a median age of 77 (range, 70 to 84) were enrolled (X, n = 26; XELOX, n = 24). The two treatment arms were well balanced with respect to baseline characteristics. No treatment-related serious adverse events or unexpected toxicities were observed. The most frequently observed toxicities were nausea and hand-foot syndrome, with fatigue and peripheral neuropathy more common in XELOX than in X patients. Median PFS was significantly longer in XELOX arm than in X arm (7 v 3 months, respectively; HR 0.33, 95% CI 0.17-0.64). OS was also longer with XELOX (14 v 6 months; HR 0.60; 95% CI 0.29-1.23). **Conclusions:** XELOX combination chemotherapy results in improved efficacy but does not increase toxicities compared with X monotherapy in elderly patients with AGC. Although HR for OS did not achieve predefined margin, an independent data monitoring committee recommended early stopping of the trial based on the evidence of superiority with XELOX. Clinical trial information: NCT01470742.

4052 Poster Session (Board #162), Mon, 8:00 AM-11:30 AM

Comparison of open esophagectomy with minimally invasive esophagectomy: An observational nationwide study in Japan. *First Author: HIROYA TAKEUCHI, Department of Surgery, Keio University School of Medicine, Tokyo, Japan*

Background: To date, there has been a very limited number of prospective multicenter trials to verify the benefits of minimally invasive esophagectomy (MIE) such as thoracoscopic esophagectomy for esophageal cancer. In this study, we focused on the comparison of MIE and open esophagectomy (OE) using a Japanese nationwide database. **Methods:** Patient registration for the National Clinical Database (NCD) commenced in January 2011. It is a nationwide project that is linked to the surgical board certification system in Japan. Propensity score matching was performed to compare the MIE with the OE by use of the 2011-2012 NCD database. **Results:** Esophagectomy for 9584 patients with thoracic esophageal cancer were categorized into MIE (n = 3589) with OE (n = 5995) in the NCD 2011-2012 database. Propensity score matching created a matched cohort of 3515 pairs of patients with MIE and with OE. The operative time was significantly longer in the MIE group than in the OE group ($P < 0.001$), whereas blood loss was markedly lesser in the MIE group than in the OE group ($P < 0.001$). There was no significant differences in overall morbidity between the MIE (42.0%) and OE groups (43.1%). In particular, the incidence of the patients who needed prolonged respiratory ventilation more than 48 hours after surgery was significantly less in the MIE group than the OE group ((8.9% vs 10.9%, $P = 0.006$). Moreover, the incidence of superficial surgical site infection was significantly less in the MIE group compared with the OE group (6.7% vs 8.1%, $P = 0.037$). However, the reoperation rate within 30 days was significantly higher in the MIE group than in the OE group (7.0% vs 5.3%, $P = 0.004$). There were no significant differences in 30-day or operative mortality rates between the MIE and OE groups (30-day mortality: MIE 0.9% vs OE 1.1%, operative mortality: MIE 2.5% vs OE 2.8%). **Conclusions:** Our results suggest that MIE is comparable with conventional OE in terms of short-term outcome after surgery and is regarded as a desirable surgical option for patients with esophageal cancer although MIE was associated with higher reoperation rates and there were no marked benefits in operative mortality.

4053 Poster Session (Board #163), Mon, 8:00 AM-11:30 AM

Phase II study of FOLFOX plus regorafenib (REGO) in patients with unresectable or metastatic esophagogastric (EG) cancer. *First Author: Yelena Yuriy Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: REGO is a VEGFR2, FGFR2 and PDGFR small-molecule inhibitor with survival benefit in metastatic colorectal cancer. We performed a phase II trial of first-line FOLFOX+REGO in metastatic EG cancer. **Methods:** Patients (pts) with previously untreated metastatic EG adenocarcinoma with measurable or evaluable disease received mFOLFOX6 q14d and oral REGO 160 mg daily on days 4 to10 and 18 to 24 q28d. The primary objective was to improve historical 6-month progression-free survival (PFS) from 40% to 61% with REGO. With target accrual of 36 pts and 5% type I error rate, FOLFOX+REGO would be considered promising if $\geq$ 20 pts are progression free at 6 months. Tumor biomarker analysis was performed on samples using an on-site next generation sequencing (NGS) assay. Secondary endpoints included safety, partial response (PR) rate, disease control rate (DCR, PR+stable disease), exploratory biomarker analysis and overall survival. **Results:** Between 8/2013 -11/2014, 36 pts (10 esophageal/16 gastric/10GEJ) were accrued to this single-center study. Median age 59 and KPS 80%. Common adverse events included: Gr 2/3 hypertension (52%), Gr 2 neuropathy (39%), Gr 3/4 neutropenia (36%), Gr 2 fatigue (28%), Gr 2/3 diarrhea (17%), Gr 2 hand-foot syndrome (14%). 11 pts (31%) had one REGO dose reduction to 120mg; 5 pts (14%) were further reduced to REGO 80mg. In 27 pts with RECIST 1.1 measurable disease, the PR rate 56% (95% CI: 38%-73%). Overall DCR rate in pts with RECIST measureable and evaluable disease was 81% (95% CI: 67%-94%). 17 of 36 pts are progression-free at 6 mos, with 3 pts still on study for $<$ 6mos. NGS of 15 tumors completed to date. 94% of tumors harbored at least one genomic alteration, TP53 mutations (73%); amplifications in KRAS (13%), EGFR (13%), CDK12 (12%), MET (7%) and FGFR2 (7%). **Conclusions:** mFOLFOX in combination with one-week on/one-week off REGO dosing is well tolerated. NGS is ongoing on additional samples. Updated survival, response and correlative molecular analysis data will be presented. Clinical trial information: NCT01913639.

4054 Poster Session (Board #164), Mon, 8:00 AM-11:30 AM

Changing chemotherapy (C) with concurrent radiation (RT) followed by surgery after sub-optimal FDG-PET response to induction chemotherapy improves outcomes in locally advanced (LA) esophageal adenocarcinoma (EA). *First Author: Anuja Kriplani, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pre-operative CRT is a standard-of-care for LA EA. We showed that PET scan after induction C prior to CRT and surgery predicts outcomes (Cancer 118:2820; 2012). PET responders (PET+, defined as $>$ 35% decrease in mSUV of tumor) had superior pathologic complete response (pCR) rates and progression-free survival (PFS) vs. PET non-responders (PET-, $<$ 35% decrease). Some Pts with progression (PD) on PET after induction C had long-term overall survival (OS) when changed to alternative C during RT. **Methods:** We retrospectively reviewed all Pts with LA EA who received induction C and chemoRT prior to planned surgery. All Pts had PET scan before and after induction C. **Results:** 201 Pts were treated between 2002 to 2013, median age 62, 76% with uN+ disease. Induction C regimens included cisplatin/irinotecan ($\pm$ bevacizumab on study) in 63% and carboplatin/paclitaxel in 29%. 113 Pts (56%) were PET+ and 88 (44%) were PET-. All PET+ received same C during RT. Of PET-, 49 (56%) continued with same C during RT (PET-/no change) and 39 (44%) received different C with RT (PET-/change). 49 Pts (24%) did not undergo surgery because of PD (16%), medical inoperability (6%), or refusal given clinical CR (2%). Of 152 operated Pts, 13/86 PET+ (15%) achieved a pCR vs. 1/35 (3%) of PET-/no change ($p = 0.046$) vs. 3/31 (10%) of PET-/change ($p = 0.26$ for PET-/no change vs. PET-/change). Median PFS (23.4 vs. 10.1 mos, $p = 0.003$) and OS (38.7 vs. 25.3 mos, $p = 0.017$) for all Pts were significantly better for PET+ vs. PET-/no change. Median PFS for PET-/change was not reached and was superior to PET-/no change ($p = 0.02$) and not different from PET+ ($p = 0.73$). The 3-yr OS rates were 48% for PET-/change vs. 31% for PET-/no change ($p = 0.18$). Median OS for PET-/change was not different than for PET-/no change (25.8 vs. 25.3 mos, $p = 0.22$). **Conclusions:** PET scan after induction C predicts for outcomes in LA EA Pts who undergo CRT and surgery. Median PFS is improved, and trends toward improved pCR rate and OS appear possible in PET- who change C during RT. The ongoing CALGB 80803 study (NCT01333033) is evaluating this strategy.

4055 Poster Session (Board #165), Mon, 8:00 AM-11:30 AM

Clinical outcomes following neoadjuvant nab-paclitaxel and cisplatin chemotherapy for locally advanced esophageal squamous cell carcinoma. *First Author: Fan Yun, Zhejiang Provincial Cancer Hospital, Hangzhou, Zhejiang, China*

Background: The combination of nab-paclitaxel and cisplatin as preoperative treatment for esophageal squamous cell carcinoma (ESCC) has not been investigated. We carried out a phase II feasibility and efficiency study of preoperative chemotherapy with nab-paclitaxel and cisplatin for locally advanced ESCC. **Methods:** Between January 2011 and October 2012, 35 patients, from stage IIA to IIIC, performance status 0-1, with 31 male and 4 females, were included in the study. All pts received nab-paclitaxel (100 mg/m^2, d1, d8, d22 and d29) and cisplatin (75 mg/m^2, d1 and d22) as neoadjuvant chemotherapy, followed by esophagectomy. Two cycles of adjuvant chemotherapy with same regimen was given in 4-6 weeks after the resection. **Results:** Thity-five enrolled patients including 31 males and 4 females, the clinical stage forIIA,IIB, IIIA, IIIB, IIIC were 3(8.6%), 5(14.3%), 10 (28.6%), 8 (22.9%) and 9 (25.7%) patients respectively. After two cycles of neochemotheray. 30/35 patients went to surgery (85.7%) and all had R0 resection (100%). Pathological complete response (pCR) was achieved in 4 patients (13.3%). Down-staging was observed in 19 of 30 patients (63.3%). 24/30 (80.0%) patients received adjuvant chemotherapy, including 7 patients (23.3%) received adjuvant chemoradiotherapy. Only 1 (3.3%) patient appeared surgical complication with anastomotic leaks. With median follow up of 27.1 months, the 16/30 patients (50.44%) still alive, and a median disease-free survival (DFS) of 22.5 months (95 % CI 14.2 - 29.8). The Median overall survival (OS) and DFS of Down-staging patients were significantly longer than non-down-staging patients (Hazard Ratio 0.30, 95% CI: 0.074 - 0.75 and Hazard Ratio 0.27, 95% CI: 0.071-0.59, respectively) ($P = 0.0158$ and $P = 0.0037$, respectively), and all of pCR patients were still DFS survival at the latest follow up. **Conclusions:** weekly nab-paclitaxel and cisplatin is effective as a neoadjuvant chemotherapy for local advanced ESCC, and its adverse effects are tolerable. Down-staging, especially the pCR patients have favorable outcome than non-down-staging patients. Clinical trial information: NCT01258192.

4056 Poster Session (Board #166), Mon, 8:00 AM-11:30 AM

Comprehensive characterization of PDL-1 and CTLA-4 in gastric cancer. *First Author: Hans Anton Schloesser, Department of General, Visceral and Cancer Surgery, University of Cologne, Cologne, Germany*

Background: Recently remarkable efficacy of immune checkpoint inhibition has been reported for several kinds of solid cancers. This study is the first comprehensive analysis of cytotoxic T lymphocyte antigen 4 (CTLA-4) and programmed death 1 ligand 1 (PD-L1) in gastric cancer and the first study integrating oncogenomic analyses. **Methods:** PD-L1 and CTLA-4 were stained on paraffin embedded tumor sections of 127 patients with gastric cancer by immunohistochemistry. Genetic driver mutations were identified by next-generation Sequencing and FISH analysis. Expression of PD-1, PD-L1 and CTLA-4 on lymphocytes in tumor sections, lymph nodes and peripheral blood were studied by 10-colour flow cytometry and 4-colour immune-fluorescence microscopy in an additional cohort. **Results:** PD-L1 and CTLA-4 were expressed on primary tumor cells by 44.9%(57/127) and 86.6%(110/127) of the analyzed gastric cancer samples, respectively. Correlation to clinical and pathological parameters revealed no correlation for PD-L1, whereas CTLA-4-negativity was correlated to higher grading and diffuse type according to Lauren. Positivity of PD-L1 or CTLA-4 on tumor cells was associated with inferior overall survival. Expression of PD-1 (52.2%), PD-L1 (42.2%) and CTLA-4 (1.6%) on tumor-infiltrating T cells was significantly elevated compared to peripheral blood lymphocytes. We could identify distinct genotypic profiles comparing the subgroups of checkpoint molecule expression. **Conclusions:** Our analysis revealed a great impact of PD-1/PD-L1 and CTLA-4 on the biology of gastric cancer. Hence corresponding checkpoint-inhibitors should be evaluated in this disease and approaches combining molecular targeted therapy and checkpoint inhibition could be of additional benefit. An extensive immune monitoring should be included in these studies.

4057 Poster Session (Board #167), Mon, 8:00 AM-11:30 AM

Phase II study of everolimus as a salvage treatment after failure of fluoropyrimidine and platinum in patients with metastatic gastric cancer positive for $pS6^{Ser240/4}$ expression. *First Author: Ji Hyun Park, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Everolimus is a macrolide derivative of rapamycin which inhibits mTOR. Our previous phase II study in 2nd line setting showed that everolimus had no significant activity with 1.7 months of median progression-free survival (PFS) in unselected population with gastric cancer (GC) and suggested that $pS6^{Ser\ 240/4}$ might be a potential predictive biomarker of everolimus (Yoon et al, Br J Cancer. 2012;106:1039). In this study, we aimed to evaluate the efficacy and safety of everolimus in 2nd line GC patients selected by $pS6^{Ser240/4}$ expression. **Methods:** The primary endpoint was 4-month PFS rate. Patients with metastatic or recurrent GC positive for $pS6^{Ser240/4}$ were enrolled after failure of fluoropyrimidine and platinum. $pS6^{Ser240/4}$positivity was defined as immunostain of 10% or more cancer cells with moderate or strong intensity. Patients received everolimus 10 mg p.o. once daily until disease progression or unacceptable toxicity. **Results:** Between December 2011 and May 2013, a total of 45 patients were enrolled. Median age was 58 years (range 34-78). Thirty-nine (86.7%) patients had ECOG performance status 0-1, and 6 (13.3%) had 2. In addition to fluoropyrimidine and platinum, 14 (31.1%) and 5 (11.1%) patients received docetaxel and irinotecan, respectively. One (2.2%) patient achieved a partial response and 26 (57.8%) showed stable disease. With a median follow-up of 13.3 months (range, 9.9-24.1) in surviving patients, the median PFS was 2.6 months (95% CI, 1.9-3.2), and 4-month PFS was 25.6%. The median overall survival was 5.8 months (95% CI, 5.1-6.6). Grade 3 or 4 drug-related toxicities in $>$ 5% of patients included neutropenia (13.3%), anemia (13.3%), stomatitis (8.9%), and pneumonia (6.7%). **Conclusions:** Everolimus was safe, and it showed better activity in the current study which included biomarker-selected patients, compared with our previous study in biomarker-unselected population. Currently, further biomarker analysis is ongoing. Clinical trial information: NCT01482299.

4058 Poster Session (Board #168), Mon, 8:00 AM-11:30 AM

The prognostic impact of extracapsular lymph node involvement after neoadjuvant therapy and esophagectomy . *First Author: Sjoerd M Lagarde, Academic Medical Center, Amsterdam, Netherlands*

Background: In patients with esophageal cancer, little attention has been paid to the biological significance of extracapsular lymph node involvement (LNI) in patients who underwent neoadjuvant treatment followed by esophagectomy. Therefore, the aim of the present study was to assess the incidence, extent of extracapsular LNI and prognostic significance in a consecutive multicenter series of patients with cancer of the esophagus or gastroesophageal junction who underwent neoadjuvant chemo (radio) therapy followed by surgery. **Methods:** From a prospectively collected database, a consecutive series of patients in two high volume centers in Europe was analyzed. All patients with potentially curable adeno- or squamous cell carcinoma of the oesophagus or gastroesophageal junction were treated with neoadjuvant chemotherapy or chemoradiation therapy followed by transthoracic esophagectomy and two-field lymphadenectomy. **Results:** Between January 2000 and September 2013 a consecutive series of 707 patients underwent an esophagectomy after neoadjuvant therapy. A mean number of 29 (5-77) nodes were resected and identified. 347 (49%) patients had no evidence of lymph node metastases (N0). There were 360 (51%) with positive nodes. Extracapsular LNI was identified in 197 (27%) patients. Five-year overall survival rates were 63% for N0 patients, 45% for patients with intracapsular LNI and 14% for patients with extracapsular LNI ($p < 0.001$). On multivariate analyses ypT, ypN and the presence of extracapsular LNI were independent factors. **Conclusions:** The presence of extracapsular LNI after neoadjuvant chemo(radiation) therapy identifies a subgroup of patients with a significantly worse long-term survival. Extracapsular LNI reflects a particularly aggressive biologic behavior and has significant prognostic potential and should be considered for the future edition of the TNM staging system for esophageal cancer.

4059 Poster Session (Board #169), Mon, 8:00 AM-11:30 AM

Comparison of *HER2* gene amplification (AMP) in primary esophageal and gastroesophageal junction adenocarcinomas (EAC) and their metastatic regional lymph nodes (MLNs). *First Author: Harry H. Yoon, Mayo Clinic, Rochester, MN, Rochester, MN*

Background: The status of *HER2* AMP in primary EACs compared to their MLNs is unknown. This is clinically important since selection of patients for HER2-targeted therapy is usually based on HER2 analysis in primary tumors. Here, we report the largest HER2 evaluation of MLNs in EACs to date. **Methods:** Resected primary tumors and MLNs (209 patients) were tested for *HER2* AMP (fluorescence in situ hybridization) and protein expression (immunohistochemistry; IHC 0, 1+, 2+, 3+). Primaries were designated AMP-positive (pos) or -negative (neg) using standard criteria (*HER2/CEP17* $\geq$ 2 in $>$ 5% tumor cells). *HER2*AMP status in primaries and MLNs were compared (Wilcoxon, Fisher's). **Results:** HER2 by AMP *vs* IHC within individual MLNs (726 MLNs; median 3 MLNs per patient) were 92% concordant ($P < .0001$). *HER2* AMP status was concordant in primaries *vs* MLNs in 89% (186/209) of patients (Table). Yet among AMP-neg primaries, 7% (10/146) had at least 1 AMP-pos MLN. Importantly, among AMP-neg primaries (n = 146), those with a small AMP subpopulation (*ie,* $<$ 1% tumor cells) were more likely than uniformly AMP-neg primaries to have an AMP-pos MLN (33% *vs* 4%; $P = .001$). Among AMP-pos primaries, those with non-uniform AMP (*ie,* 6% - 49% tumor cells) were more likely than uniform AMP primaries (*ie,* $\geq$ 50% tumor cells) to have entirely AMP-neg MLNs. Across the whole cohort, among patients with at least 1 AMP-pos MLN, an average of 95% of MLNs (standard deviation 17%) was AMP-pos. **Conclusions:** *HER2* status was generally concordant between primary EACs and MLNs. But the strength of concordance diminished significantly among primaries with a small *HER2*-amplified subpopulation, where a considerably higher rate of *HER2*-amplified nodal metastases was observed compared to uniformly non-amplified primaries. These novel data suggest that testing MLNs in this subgroup may identify new candidates for HER2-targeted therapy.

	MLNs		
Primary tumor	**All MLNs are AMP-neg**	**Any MLN is AMP-pos**	***P***
AMP-neg *n = 146*			
Uniform neg *n = 131*	96% (126)	4% (5)	0.001
Small AMP subpopulation *n = 15*	67% (10)	33% (5)	
AMP-pos *n = 63*			
Uniform pos *n = 54*	17% (9)	83% (45)	0.078
Non-uniform pos *n = 9*	44% (4)	56% (5)	

4060 Poster Session (Board #170), Mon, 8:00 AM-11:30 AM

A serum microRNA biomarker panel for detection of gastric cancer. *First Author: Jimmy So, Department of Surgery, National University Hospital, Singapore, Singapore*

Background: Gastric cancer is the 2nd most common cause of cancer deaths worldwide. Currently, endoscopy is the only reliable method for early diagnosis. However, the invasiveness and cost limit its usage as a screening test. MicroRNAs (miRNAs) have been shown to be important in the pathogenesis of cancers. They are exceptionally stable in body fluids, making them potential noninvasive biomarker for cancers. **Methods:** We screened 600 miRNAs using our MiRXES qPCR technology in the sera of 236 gastric cancer subjects and 236 matched high risk subjects, serving as the discovery set. 191 miRNAs were reliably detected in all the serum samples, out of which 75 informative ones were identified to be significantly (false discovered corrected P value lower than 0.01) altered between gastric cancer and high risk subjects. Multivariate miRNA biomarker panels were then formulated by sequence forward floating search and support vector machine using all the quantitative data obtained for the expression of 191 miRNAs. **Results:** Multiple iterations of two-fold cross-validation were performed in silico where the panels with 8 or more miRNAs consistently achieved high accuracy [areas under the curve (AUC) $\geq$ 0.87 in the receiver operating characteristic (ROC) curve]. A 24-miRNA model was optimized based on the discovery set [AUC = 0.92 (95% Confidence Interval [CI]: 0.88-0.95)] and validated in two blinded studies with fixed algorithm and threshold definition; Korean case-control cohort (n = 129, 74 cancer cases) and Singaporean Chinese case-control cohort (n = 89, 20 cancer cases). The 24-miR panel showed 90% sensitivity and 81% specificity in the Korean cohort (AUC = 0.91 (95% CI: 0.86-0.96)] and had 90% sensitivity and 75% specificity in the Singaporean Chinese cohort [AUC = 0.89 (95% CI: 0.79-0.99)]. Importantly, the 24-miR panel was able to distinguish stage 1 and 2 gastric cancer in both Korean [AUC = 0.88 (95% CI: 0.81-0.96)] and Singaporean Chinese [AUC = 0.91 (95% CI: 0.80-1.00)] cohorts. **Conclusions:** We have identified a serum miRNA panel which can confidently differentiate patients with gastric cancer including the early-staged cancers from controls. This may be able to serve as a non-invasive screening test for gastric cancer which warrants study in larger cohorts.

4061 Poster Session (Board #171), Mon, 8:00 AM-11:30 AM

NeoFLOT II: Multicenter phase II study with short time neoadjuvant chemotherapy (stNACT) with 5-FU, FA, oxaliplatin, and docetaxel in rectable adenocarcinoma of the gastresophageal junction and gastric adenocarcinoma (T3, T4, and/or LN+) with high R0 resection rate over 91.5%. *First Author: Karsten Ridwelski, Klinikum Magdeburg gGmbH, Magdeburg, Germany*

Background: Perioperative chemotherapy is standard of care in locally advanced gastroesophageal cancer (GEC included adenocarcinoma of gastroesophageal junction -GEJ- and gastric adenocarcinoma) in europe. the NeoFLOT II study had examined a short time neoadjuvant chemotherapy (stNACT) with only 4 cycles FLOT. Patients(pts.)3,T4 and/or nodepositive adenocarcinoma (GEC)were eligible for this multicenter phase II study. **Methods:** For stNACT, 5-FU 2600mg/sqm/24h on day (D) 1, FA 200mg/sqm/30min on D 1, oxaliplatin 85mg/sqm/1h on D 1 and docetaxel 50mg/sqm/2h on D 1 were admistrated every 2 weeks for two cycles. Application of adjuvant chemotherapy was not part of the protocol. Primary endpoint was the R0-resection rate. Secondary endpoints were toxicity, remission rate and rate of surgical complications. **Results:** A total of 49 pts. with a median age of 64years were enrolled in 5 centers. 46 pts. completed stNACT, 1 patient had only 1 cycle and 2 pts.had 3 cycles. 47 patients underwent surgery. R0-resection rate was 91,5% (43/47). We saw no pathological complete response (pCR) and 19 partial responses (pPR 45,2%). 3/49 pts. developed progressive disease (6,1%). Grade 3-4 toxicities included neutropenia (42,9%), febrile neutropenia 8,2% and diarrhea 22,4%. 2 pats. died after resection (4,3%). **Conclusions:** StNACT with 4 cycles of FLOT is effective and tolerable in resectable GEC. R0-resection rate was very high. Clinical trial information: EudraCT-Nr. 2009-01260820 Neoflot.

4062 Poster Session (Board #172), Mon, 8:00 AM-11:30 AM

Prognostic value of tumor infiltrating lymphocytes in Epstein-Barr virus-associated gastric cancer. *First Author: Shinkyo Yoon, Department of Oncology/Hematology, Kyungpook National University School of Medicine, Daegu, South Korea*

Background: It is well known that lymphocytic infiltration around tumor can be considered as a host immune reaction against tumor cells, although prognostic implication of lymphocyte infiltration in gastric cancer are not certain. Therefore, we investigated prognostic impact of tumor-infiltrating lymphocytes (TILs) in Epstein-Barr virus (EBV)-associated gastric cancer (EBVaGC), which can be sub-classified into 3 histological subtypes according to the host immune response: lymphoepithelioma-like carcinoma (LELC), carcinoma with Crohn's disease-like lymphoid reaction (CLR), and conventional-type adenocarcinoma (CA). **Methods:** In situ hybridization for EBV positivity was performed in 1318 cases that underwent surgery or endoscopic submucosal dissection at Kyungpook National University Hospital between January 2011 and November 2014. Histopathologic analysis of percentage of TILs was performed on hematoxylin and eosin–stained sections. TILs were defined as the percentage of tumor stroma containing infiltrating lymphocytes. A tissue with TILs over 20% was considered TILs-positive. EBVaGCs were also sub-classified into 3 histological subtypes: LELC, CLR, and CA . **Results:** EBVaGC was identified in 111 cases (8.4%) from a total of 1318 gastric cancer. The median age was 62 years (32-80), and 86 patients (77.5%) were male. The pathologic stages after resection were as follows: stage I (n = 69), stage II (n = 24), stage III (n = 16), and stage IV (n = 2). TILs-positive patients were 65 patients (58.6%). The number of histologic subtypes of EBVaGC was as follows: LELC (n = 35), CLR (n = 50), and CA (n = 26). In the univariate analysis, TILs score and EBVaGC sub-classification was significantly associated with disease-free survival (DFS), respectively (p = 0.016, p = 0.001). The LELC and CLR groups with TILs-positive showed an improved DFS compared to the CA group with TILs-negative (p = 0.002). This difference was also significant in the multivariate analysis (p = 0.018). **Conclusions:** TILs and sub-classification of EBVaGC may constitute prognostic factor in EBVaGC. As a result, this finding suggests that the host cellular immune response could be useful as a prognostic marker for EBVaGC.

4063 Poster Session (Board #173), Mon, 8:00 AM-11:30 AM

Knocking on molecular alterations in advanced gastric cancer (AGC). *First Author: Fabricio Racca, Vall d´Hebron University Hospital, Barcelona, Spain*

Background: AGC represents the third leading cause of cancer related deaths. Chemotherapy for AGC is active but still of limited efficacy and targeted agents Trastuzumab and Ramucirumab have shown modest activity. Expanded molecular profile may provide critical information on druggable molecular aberrations and treatment options for these patients (pts). **Methods:** From 11/2010 to 11/2014, 101 pts with AGC underwent genetic/proteomic tumor profiling as part of the VHIO Phase I Trial Molecular Prescreening Program. Detection of mutations (mt) was performed with Multiplex-Single base extension followed by Mass-spect detection (Sequenom) or NGS (Amplicon-seq) (Illumina). Immunohistochemistry was used to assess HER2, PTEN and PDL1 expression. Amplification of *HER2, PIK3CA, FGFR1, FGFR2*, and *MET*were analyzed by in situ hybridization. **Results:** Median age of pts was 59-year, 66% men. Median prior treatment lines were 3 (1-6). Median overall survival was 18 months. As expected, HER2 was deregulated in 20%. *PIK3CA* mt and PTEN low expression were respectively found in 9% and 30%, with one pt harboring both molecular alterations. *KRAS* mt were found in 5%. *PIK3CA, KRAS, FGFR4* and *MSH6* mt coexisted in one pt. Amplification in *FGFR2* (5%), *MET* (2%), and *PIK3CA* (1%) were also detected. One pt harbored amplification in 10 genes implicated in receptor tyrosine kinase- and cell cycle- pathways. PDL1 was positive in 6%; *PIK3CA* mt and PDL1 overexpression coexisted in 3%, *ARID1A* and *SMAD4* also coexisted in another pt. Twenty-seven pts (27%) were treated with targeted therapies according to their molecular profile, with modest efficacy. **Conclusions:** Our molecular data is consistent with TCGA data. Pts. with AGC considered for genetic/proteomic tumor profile seem to derive benefit from this expanded characterization and treatment in phase I/II clinical trials with targeted agents.

Molecular aberration	Treatment	Outcome
HER2 deregulated	Chemotherapy + HER2/ HER3 inhibitors (inhib)	4 SD (stable disease $\geq$ 6 months) + 1 PD (progressive disease)
	HER2/HER3 inhib	2 SD + 3 PD
***PI3KCA* mt**	Chemotherapy + PI3KCA inhib	2 SD + 2 PD
	PI3KCA inhib	2 SD + 3 PD
PDL1 positive	PDL1 inhib	1 SD + 3 PD
MET deregulated	Chemotherapy + MET inhib	1 SD
	MET inhib	3 PD
	HGF inhib	1 PD
***FGFR4* amplified**	FGFR4 inhib	2 PD

4064 Poster Session (Board #174), Mon, 8:00 AM-11:30 AM

Accuracy of EUS-FNA for distant regional lymph nodes in the initial staging of esophageal cancer (EC). *First Author: Yusuke Shimodaira, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Accurate clinical staging is essential for making immediate treatment decisions. The role of endoscopic ultrasound (EUS) and fine needle aspiration (FNA) in altering treatment has been debated in patients diagnosed with cStage II or III EC. The purpose of this study was to assess the yield of EUS-FNA for paratracheal and subcarinal lymph nodes in distal ECs. **Methods:** We analyzed278 EC patients who had baseline EUS-FNA between 2010 and 2014. A subgroup of 85 patients with Seiwert's type I or II EC had FNAs of the paratracheal or subcarinal nodes (far away from the primary EC) were carefully reviewed. The accuracy of EUS, PET, EUS+PET, and FNA were compared using FNA as the gold standard. A McNemar's test was used to determine whether EUS+PET or FNA performed differently in identifying positive nodes. **Results:** In the subgroup of 85 patients, FNA was positive for malignancy in 27 (32%) leading to modifications of the radiation field in upper thorax. Moreover, EUS, PET, and EUS+PET had an accuracy of 83.0% (EUS), 87.1% (PET), and 93.0% (EUS+PET), respectively. Comparing FNA to EUS+PET, FNA was positive whenever EUS or PET was positive. In 6 patients, PET-negative nodes were malignant by EUS-FNA ($p = 0.03$). Of 58 cases with negative initial FNA, only one was malignant, on follow-up, when surgically removed. **Conclusions:** Our data show that in distal ECs with suspicious paratracheal or subcarinal lymph node(s), EUS-FNA is a highly effective tool to help with appropriate treatment decisions. An extremely low false negative rate (1/58) suggests that EUS/FNA is highly complimentary to PET and can also identify malignant nodes that are not FDG-avid. From U. T. M. D. Anderson Cancer Center (UTMDACC), Houston, Texas, USA. (Supported in part by UTMDACC, and CA 138671 and CA172741 from the NCI).

4065 Poster Session (Board #175), Mon, 8:00 AM-11:30 AM

A phase II study of the c-Met inhibitor tivantinib (tiv) in combination with FOLFOX for the treatment of patients (pts) with previously untreated metastatic adenocarcinoma of the distal esophagus, gastroesophageal (GE) junction, or stomach. *First Author: Shubham Pant, Stephenson Cancer Center/SCRI, Oklahoma City, OK*

Background: C-Met protein is a receptor tyrosine kinase that is amplified in gastric and esophageal cancers causing downstream activation of multiple signaling pathways. Tivantinib is an orally bioavailable c-met inhibitor. This phase II study evaluated the response rate (RR) of the combination of tiv plus FOLFOX as treatment for pts with previously untreated metastatic adenocarcinoma of the distal esophagus, gastroesophageal (GE) junction, or stomach. **Methods:** Pts with advanced GE cancer received standard mFOLFOX6 day 1 and tiv (360mg PO BID) days 1-14 of each 2-week cycle. Restaging occurred every 4 cycles. The primary endpoint was RR. Secondary endpoints included progression-free survival (PFS), time to progression (TTP), overall survival (OS), and safety. **Results:** Thirty-four pts were enrolled: median age 65 yrs (range, 34-88), 76% male, 53% KPS 90. Forty-seven percent of pts underwent prior surgery, 32% received prior radiation, and 15% received prior systemic treatment. Two pts did not receive treatment due to patient request and anemia prior to cycle 1 day 1. 32 pts were treated for a median of 8 cycles (range, 1-38). Treatment-related toxicities (% G1/2; % G3/4) included neutropenia (9%; 53%), fatigue (47%; 9%), diarrhea (41%; 9%), nausea (44%; 0), and peripheral neuropathy (44%; 0). Of the 26 pts evaluable for response, 10 pts (38%) achieved objective response (1 CR, 9 PRs), with a best response of stable disease noted in 13 pts (50%). The overall RR was 29%. Median PFS was 6.1 months (95% CI: 3.6-8) with a median TTP of 6.1 months (95% CI: 5.2-11.5). Median OS was 9.6 months (95% CI: 7.2-NA). Three pts remain on study and have been on treatment for a median of 16 months (range, 14-19). Their best response was PR (2) and SD (1). One of these pts was met high by IHC. Met status by FISH is unknown at this time. **Conclusions:** The combination treatment of tiv plus mFOLFOX6 in pts with advanced GE cancer showed a RR and PFS in the range of historical controls for first-line FOLFOX therapy. However, 3 pts had extended time on study treatment, and these pts may represent pts with met-driven tumors. Clinical trial information: NCT01611857.

4066 Poster Session (Board #176), Mon, 8:00 AM-11:30 AM

The prognostic value of a modified tumor regression grade after neoadjuvant chemoradiotherapy and resection of esophageal carcinoma. *First Author: Maarten CJ Anderegg, Department of Surgery, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background: The tumor regression grade (TRG) is used to define the response to preoperative chemoradiotherapy for esophageal carcinoma. The aim of this study was to determine whether inclusion of the postoperative pathological nodal status could improve the prognostic value of TRG. **Methods:** All patients who underwent an esophagectomy after chemoradiotherapy between 2003 and 2013 were included in this retrospective study. Patients were classified according to a modified TRG consisting of the TRG by Mandard et al (TRG 1 = complete response in the esophagus; TRG > 1 = incomplete response) and the postoperative node category (N0 = no lymph node metastases; N+ = at least 1 lymph node metastasis). Based on the TRG by Mandard and this modified TRG Kaplan-Meier survival analyses were performed and compared. **Results:** 411 patients underwent neoadjuvant chemoradiotherapy followed by esophagectomy. After exclusion due to non-specific histology (n = 2), unknown TRG (n = 3), intraoperative detection of distant metastases (n = 3), salvage procedures (n = 17) and in-hospital mortality (n = 15) 371 patients were analysed (289 adenocarcinoma, 82 squamous cell carcinoma). A significantly improved median disease free survival was observed in patients with TRG 1 compared to patients with TRG > 1 (90.3 vs. 30.8 months, P = 0.004). After implementation of the modified TRG significant differences in median disease free survival were found between the four categories: TRG 1-N0 (n = 76) 90.3 months; TRG 1-N+ (n = 10) 20.8 months; TRG > 1-N0 (n = 146) 81.3 months; TRG > 1-N+ (n = 139) 18.1 months (P < 0.001). **Conclusions:** The TRG, determined in the primary tumor, provides insufficient information about the prognosis after chemoradiotherapy followed by resection of esophageal cancer. It is advisable to use a modified classification in which the postoperative pathological nodal status is considered.

4067 Poster Session (Board #177), Mon, 8:00 AM-11:30 AM

Signet ring cell (SRC) histology of localized gastric adenocarcinoma (LGAC) to predict response to preoperative chemoradiation. *First Author: Nikolaos Charalampakis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with LGAC, when treated with preoperative therapy, have heterogeneous and unpredictable outcomes. Currently, there are no clinical variables or biomarkers that can predict response to therapy. **Methods:** We analyzed 107 LGAC patients who were treated with chemoradiation followed by surgery. LGAC were grouped into categories based on: (1) presence of SRC (yes-SRC) or absence of SRC (no-SRC). LGACs with yes-SRC were further grouped by the % of SRC(s): 0%, 1-10%, 11-49%, and 50-100% and (2) histologic grade: moderately (G2) or poorly (G3) differentiated. These variables were correlated with pathologic complete response (pathCR) or < pathCR in the resected specimens. Descriptive statistics and survival analyses were utilized. **Results:** The patients were primarily males (60%), had clinical stage III LGAC (50%), and had received chemotherapy before chemoradiation (93%). Most had G3 tumors (78%) and yes-SRC (58%). Patients with yes-SRC had a lower rate of pathCR (11%) compared to no-SRC (36%, $p = 0.004$) and the association remained statistically significant even for a low percentage of SRC (1-10%) ($p = 0.014$). Higher the fraction of yes-SRC, the lower was pathCR ($p = 0.03$). The pathCR rate tended to be lower (18%) in G3 LGACs compared to G2 LGCAs (33%; $p = 0.125$). Patients with G3 tumors and yes-SRC had shorter overall survival (OS) ($p = 0.046$ and $p = 0.038$, respectively). Post-therapy pathologic stage was the only prognostic factor independently associated with OS and recurrence-free survival ($p < 0.001$). **Conclusions:** Our data suggest that yes-SRC LGACs are relatively chemoradiation resistant compared to no-SRC LGACs. A higher fraction of yes-SRC is associated with higher LGAC resistance. Validation and biomarker evaluation are warranted. From U. T. M. D. Anderson Cancer Center (UTMDACC), Houston, Texas, USA. (Supported in part by UTMDACC, and CA 138671 and CA172741 from the NCI). Dr. Nikolaos Charalampakis has been awarded a scholarship from the Hellenic Society of Medical Oncology.

4068 Poster Session (Board #178), Mon, 8:00 AM-11:30 AM

Association of high tumor infiltrating cytotoxic T cells with absence of lymph node involvement in resected colorectal and gastric cancer: Implications for immunosurveillance. *First Author: Tong Dai, Weill Cornell Medical College, New York, NY*

Background: Adaptive immune response can play an important role in restricting tumor growth, and the presence of tumor infiltrating lymphocytes (TIL) is associated with lower cancer stage and improved survival. However, the characterization of TILs with gastrointestinal malignancies, and their clinical implication, remains poorly understood. **Methods:** To characterize TIL subpopulations in different gastrointestinal cancer types, we performed immunohistochemistry (IHC) staining of CD3, CD8, CD45RO, and CD4/FOXP3 markers for all T cells, cytotoxic, memory, and regulatory T cells, respectively. Tissue microarray(TMA) from 122 colorectal, 37 gastric, and 59 esophageal cancer were included in the study, and IHC staining for each immune marker was scored as low ($<$ 5 cells/hpf), intermediate (5-50 cells/hpf), and high ($>$ 50 cells/hpf). **Results:** LN- colorectal and gastric cancer was associated with higher $CD3^+$ and $CD8^+$ cell infiltration, when compared with LN+ disease (Table 1). This was not observed in esophageal cancer. Increased memory T cell infiltration is also associated with LN- disease in gastric cancer. In addition, increased $FOXP3^+$ regulatory T cells are associated with LN- disease in colorectal cancer. **Conclusions:** Across a panel of gastrointestinal malignancies, we found that for both gastric and colorectal cancer, increased infiltration of cytotoxic T cells ($CD3^+/CD8^+$) was associated with LN- disease. These findings suggest high cytotoxic T cells may protect from LN metastasis in colorectal and gastric cancer. Regulatory $FOXP3^+$ regulatory T cells may have similar function in colorectal cancer. Understanding the spatial distribution of proteins that regulate the immune response in the tumor microenvironment will have implications for subsequent immunomodulatory treatments.

Percentage of tumor with high expression of CD3, CD8, and CD45RO.

Cancer Type	LN Status	$CD3^+$	$CD8^+$	$CD45RO^+$
Colorectal	LN+	22.6%	17.1%	52.6%
	LN-	37.7%	42.3%	44.0%
Gastric	LN+	37.0%	42.8%	43.5%
	LN-	70.0%	75.0%	80.0%
Esophageal	LN+	28.9%	36.4%	52.6%
	LN-	14.3%	41.2%	40.0%

4069 Poster Session (Board #179), Mon, 8:00 AM-11:30 AM

Phase Ib/II study of cancer stem cell (CSC) inhibitor BBI608 combined with paclitaxel in advanced gastric and gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Carlos Becerra, Texas Oncology-Baylor Sammons Cancer Center, Dallas, TX*

Background: BBI608, a first-in-class CSC inhibitor that works through inhibiting Stat3, has shown potent synergistic anti-tumor and anti-metastatic activity with paclitaxel in vivo. In a phase Ib dose escalation study in patients with advanced solid tumors, BBI608 + weekly paclitaxel was well tolerated and a RP2D of BBI608 500 mg BID was determined. **Methods:** Patients with advanced, pre-treated gastric and GEJ adenocarcinoma were enrolled in a phase Ib/II extension study to assess safety, tolerability, and preliminary anti-cancer activity in patients with advanced gastric/GEJ adenocarcinoma. Eligible patients received $\geq$ 1 line of prior treatment in the metastatic setting with a platinum + fluoropyrimidine/TS inhibitor. BBI608 was administered orally at 480 mg or 500 mg twice daily with paclitaxel 80 mg/m^2 IV weekly 3 of every 4 weeks. A sample size of 40 set the bounds of the 90% CI at $\pm$10% to 14%, assuming a DCR of 60% to 80%. **Results:** 46 patients (87% Caucasian, 7% Black, 6% Asian) were enrolled in US and Canada; 10 (22%) had 1 line of prior therapy, 16 (35%) had 2 prior lines, and 20 (43%) had 3 or more prior lines. Common adverse events (AE) were grade 1 to 2 diarrhea, abdominal cramps, nausea, and vomiting. Grade 3 AE included vomiting (10%), diarrhea of 5 days or longer (7%), fatigue (7%), and abdominal cramps, nausea, dehydration (2% each). In 20 patients who had not received a taxane in the metastatic setting, the per-protocol ORR was 31% (5/16) and DCR was 75% (12/16); median PFS was 20.6 wks and mOS was 39.3 wks. In 26 patients who failed a prior taxane (median 3 prior lines), per-protocol ORR was 11% (2/19), and DCR was 68% (13/19); mPFS was 12.6 wks and mOS was 33.1 wks. In a subset of evaluated patients who received only 1 prior line of therapy without a taxane, the ORR was 50% (3/6) and the DCR was 83% (4/6). **Conclusions:** In this first known clinical study of a CSC inhibitor in gastric/GEJ adenocarcinoma, BBI608 and weekly paclitaxel were combined safely at the full-intended doses. Encouraging signs of anti-cancer activity were observed. A phase 3 study of BBI608 in combination with weekly paclitaxel in patients with gastric/GEJ cancer who had failed first line therapy is underway. Clinical trial information: NCT01325441.

4071 Poster Session (Board #181), Mon, 8:00 AM-11:30 AM

Randomized phase II crossover trial exploring the clinical benefit from targeting EGFR or VEGF with combination chemotherapy in patients with non-resectable biliary tract cancer. *First Author: Lars Henrik Jensen, Vejle Hospital and University of Southern Denmark, Vejle, Denmark*

Background: Non-resectable biliary tract cancer (BTC) is chemosensitive but there are no clear signals of effect from inhibiting any specific molecular target. The most promising targets are EGFR and VEGF. This trial evaluated the effect of adding panitumumab or bevacizumab to chemotherapy in a crossover design. **Methods:** Eligible patients with biopsy proven non-resectable BTC, 18+ years (y), KRAS wild-type and performance status (PS) 0-2 were randomized 1:1. Patients in arm A received panitumumab 6 mg/kg + gemcitabine 1,000 mg/m^2 + oxaliplatin 60 mg/m^2 on day 1 and capecitabine 1,000 mg/m^2 b.i.d. on days 1-7 of a 2 weeks cycle. In arm B the chemotherapy was similar but added bevacizumab 10 mg/kg on day 1. At progression patients crossed over to bevacizumab in arm A and to panitumumab in arm B with the same chemotherapy backbone. The primary endpoint was the fraction of patients with PFS at six months (PFS6m). Secondary endpoints were PFS and overall response rate (ORR) both before/after crossover, overall survival (OS), toxicity, translational analysis and of second line treatment. Results: Three centres recruited 88 patients with a median age of 66 y (range 35-84). Selected base line characteristics were PS 0 (n = 23), 1 (n = 47), 2 (n = 18) and 73 metastatic/15 locally-advanced disease. Cases of grade $>$ 2 toxicity were equal with more skin toxicity in arm A and more hypertension and infection in arm B. PFS6m in arm A/panitumumab was 43% (95%CI 29-58) and in arm B/bevacizumab 55% (95%CI 40-70). ORR was 46% (95%CI 30-62) in arm A and 18% (95%CI 6-31) in arm B. Median PFS was 6.1 m (95%CI 5.8-8.1) vs 8.2 m (95%CI 5.3-10.6) and OS 9.5 m (95%CI 8.3-13.3) vs 12.3 m (95%CI 8.8-13.3) in arm A vs B. OS was 17.7, 9.5 and 5.6 m in PS 0, 1 and 2, respectively. As a phase II study, comparisons between treatment arms were exploratory and revealed no differences in PFS6m (p = 0.39), median PFS (p = 0.13) or OS (p = 0.47), but ORR was superior in arm A (p = 0.01). Conclusion: Signals of clinical benefit with respect to PFS and OS were equal for targeting EGFR and VEGF, but ORR was higher with EGFR inhibition. This might have implications for potentially resectable disease in the neoadjuvant setting. Clinical trial information: NCT01206049.

4072 Poster Session (Board #182), Mon, 8:00 AM-11:30 AM

Pazopanib (P) and trametinib (T) in advanced cholangiocarcinoma (CC): A phase Ib study. *First Author: Rachna T. Shroff, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CC is an aggressive disease with a dismal prognosis and no clear therapy in the refractory setting. Mek inhibition and anti-angiogenic therapies have shown modest activity in advanced CC, while dual inhibition of these pathways has not been evaluated. We investigated the safety of combining of P+T in a phase I trial (previously reported). 2 patients (pts) with CC were enrolled during dose escalation with 1 prolonged partial response (PR) and the other with stable disease (SD). Based on this possible signal, we evaluated the safety and efficacy of this combination in an expansion cohort of 25 advanced, pre-treated CC pts. **Methods:** P+T were administered daily for a 28-day cycle with radiographic imaging performed every two cycles. Patients were monitored for toxicity throughout. The primary endpoint was progression-free survival (PFS) with secondary endpoints including overall survival (OS), response rate (RR) and disease control rate (DCR, partial response + stable disease). **Results:** 25 patients were enrolled (median age = 62, 20 evaluable for response). The median follow-up was 8.9 months with pts having received a median number of 2 prior therapies (range 1-9). The most common grade 3/4 toxicities attributable to study drugs included: rash, thrombocytopenia, hypertension, fatigue (all n = 3), and elevated LFT's (n = 2). ORR was 5% with a DCR of 75% (15/20 pts). Median PFS was 4.3 mths (95% CI: 3.5-7.6) with a 4-mth PFS of 56% ($p < 0.002$ compared with a pre-specified null hypothesis rate of 25%). Median OS was 6.7 mths. **Conclusions:** P+T was well tolerated with evidence of activity in refractory CC. Further studies are needed to assess the benefit of combining anti-angiogenic therapy with Mek inhibition and to explore a potential molecular phenotype in which this combination may provide a clinically meaningful benefit. *This study was approved and funded by the National Comprehensive Cancer Network (NCCN) Oncology Research Program from general research support provided by GlaxoSmithKline.* Clinical trial information: NCT01438554.

4073 Poster Session (Board #183), Mon, 8:00 AM-11:30 AM

A phase II clinical trial on combined axitinib and transarterial chemoembolization (TACE) for hepatocellular carcinoma (HCC): Final results and evaluation of clinical predictor for response. *First Author: Stephen Lam Chan, Sir YK Pao Center for Cancer, State Key Laboratory in Oncology in South China, Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Axitinib is a potent and specific inhibitor of VEGFRs. Elevation of VEGF level in plasma and tumor is frequently observed after TACE treatment for HCC. We hypothesize that combining axitinib and TACE has synergism by inhibiting the VEGF surge after TACE. We conducted a phase II clinical trial to study the combination for treatment of inoperable HCC. **Methods:** This is an investigator-initiated, single-arm, phase II study. Key eligibility criteria include: diagnosis of inoperable HCC; Child's A function; without main portal vein thrombosis/distant metastases. Patients (pts) were started axitinib 5mg bid followed by TACE at 5thweek. Assessment of further TACE is conducted every 2 months (m). TACE is given if there is viable HCC and pts are suitable for TACE. Axitinib is withheld 24 hours before and resumed 24 hours after TACE. CT Imaging is arranged every 8 weeks (mRECIST). The primary endpoint is 2-year survival rate. Secondary endpoints include determination of response, toxicity and clinical predictors of outcome. The sample size is 50. **Results:** From May 11 to Apr 14, 50 pts have been recruited. Data cut-off date was 31 Dec 14. The median follow-up is 21.6m. Median age: 61.8 years; median tumor diameter: 6.8cm. BCLC Stage B/C: 38/12. Median cycle of TACE given is 2. The median OS is 15.9m (95% CI 13.7-31.9m) with 2-year OS rate of 41.9%. The median time-to-progression is 10.4m. Amongst 45 evaluable pts, 30 (68.2%) have partial or complete response. Total 6 pts underwent surgical resection after downstaging of HCC with 5 of the specimens showing complete tumor necrosis. Common $\geq$ grade 3 toxicities include: ALT elevation (40%), hypertension (24%) and hand-foot skin reaction (12%). The median dose density of axitinib is 90.6%. Development of hypertension (any grade) during the treatment course is associated with better OS (25.0 vs. 13.7m; p = 0.03). **Conclusions:** The combination of axitinib and TACE is efficacious with high response rate. The regimen is well tolerated without significant safety concern. Selected pts could be converted to operable state after downstaging. Further clinical development is indicated. (NCT01352728) Clinical trial information: NCT01352728.

4074 Poster Session (Board #184), Mon, 8:00 AM-11:30 AM

Efficacy and safety of nintedanib (N) versus sorafenib (S) in Caucasian and Asian patients with advanced hepatocellular carcinoma (HCC): Pooled analysis of two randomized phase II trials. *First Author: Tim Meyer, University College London Cancer Institute, London, United Kingdom*

Background: N is an oral, triple angiokinase inhibitor of vascular endothelial growth factor, platelet-derived growth factor, and fibroblast growth factor receptors. Two randomized, open-label, Phase II studies evaluated the efficacy and safety of N versus S in patients with advanced HCC in Europe (NCT01004003; 1199.37) and Asia (NCT00987935; 1199.39). **Methods:** Patients with unresectable, advanced HCC, ECOG-PS $\leq$ 2, Child–Pugh score A, alanine/aspartate aminotransferase (ALT/AST) $\leq 2 \times$ upper limit of normal and $\geq$ 1 untreated measurable lesion or previously treated lesion with progression (by RECIST 1.0) were randomized 2:1 to N 200 mg bid or S 400 mg bid continuously in 28-day cycles, until intolerable adverse events (AEs) or disease progression (PD); treatment beyond PD was allowed if clinical benefit was perceived. The primary endpoint was time to progression (TTP) by independent central review (ICR; RECIST 1.0); secondary endpoints included overall survival (OS) and objective tumor response (OR) by ICR. **Results:** 188 patients received N (1199.37: n = 62; 1199.39: n = 63) or S (n = 31; n = 32). Main patient demographics/baseline characteristics were balanced between treatments in both trials except for macrovascular invasion (N vs S; 48% vs 31%) in 1199.39. TTP was comparable between N and S (median 3.7 vs 3.9 months; HR 1.31 [95% CI: 0.89–1.91]), as were OS (median 11.4 vs 11.0 months; HR 0.91 [95% CI: 0.65–1.29]) and OR rate (4% vs 5%). The rate of Grade $\geq$ 3 AEs (62% vs 87%) and AEs leading to dose reduction (19% vs 51%) was lower with N than S; more N-treated patients had AEs leading to drug discontinuation (34% vs 29%). The most frequent ($>$ 5% of patients in any group; N vs S) Grade $\geq$ 3 AEs were diarrhea (10% vs 5%), fatigue (7% vs 2%), increased AST (8% vs 13%) and ALT (6% vs 8%), anemia (7% vs 6%), thrombocytopenia (5% vs 8%), skin reaction (1% vs 6%) and hand-foot skin reaction (0 vs 19%). **Conclusions:** Pooled analysis of two trials in Caucasian and Asian patients showed similar efficacy between N and S. AEs were as expected based on the safety profile of both agents. Further studies of N in patients with advanced HCC are warranted. Clinical trial information: NCT01004003 and NCT00987935.

4075 Poster Session (Board #185), Mon, 8:00 AM-11:30 AM

Proposal of a new staging system for intrahepatic cholangiocarcinoma: Analysis of surgical patients from a nationwide survey of Liver Cancer Study Group of Japan. *First Author: Yoshihiro Sakamoto, Hepato-Biliary-Pancreatic Surgery Division, The University of Tokyo, Tokyo, Japan*

Background: In the current AJCC/UICC staging system 7thed. for intrahepatic cholangiocarcinoma (ICC), tumor size was excluded and "periductal invasion" was added as a new factor determining T-category. However, prognostic significance of tumor size and periductal invasion remains unclear. **Methods:** Of a total of 1216 patients who underwent surgical resection for ICC between 2000 and 2005 on Japanese nationwide database by Liver Cancer Study Group of Japan (LCSGJ), 756 patients with histologically confirmed mass-forming dominant ICC were studied. A multivariate analysis of the clinicopathological factors on the survivals of patients were performed using the data of 419 patients with complete set of the valid data. A new staging system was customized based on the results of the multivariate analyses. **Results:** The overall survivals were best stratified with a cut-off value of 2 cm with the minimal p-value to discriminate the survivals of patients. The 5-year survival rate of the 15 patients with ICC $<$ / = 2cm without nodal metastasis or vascular invasion was 100%, suggesting surgical resection offers cure of the disease and these cohort can be defined as T1. Multivariate analysis of prognostic factors for all 419 patients showed that tumor size (HR = 2.487, CI = 0.912-6.780), tumor number (HR = 2.570, CI = 1.814-3.643), nodal metastasis (HR = 2.818, CI = 1.992-3.987) and distant metastasis (HR = 2.940, CI = 1.258-6.869) were independent and significant prognostic factors. The survival curves of N0M0 patients were well-stratified using a new T classification regulated by the 1) tumor size ($<$ / = 2cm, $>$ 2cm), 2) tumor number and 3) portal vein, arterial or major biliary invasion. The survivals of patients with T1-3N1M0 were as good as those of T4N0M0 patients, and thereby categorized as Stage IVA, discriminating from Stage IVB, a group of T4N1M0 or M1. **Conclusions:** Tumor size with a cut-off value of 2cm and major biliary invasion were important prognostic factors for survival. The proposed new staging system would be useful for assigning surgical indication for selected patients even with nodal metastasis.

4076 Poster Session (Board #186), Mon, 8:00 AM-11:30 AM

Sorafenib plus intra-arterial cisplatin versus sorafenib alone in patients with advanced hepatocellular carcinoma: A randomized phase II trial. *First Author: Masafumi Ikeda, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Intra-arterial cisplatin therapy for advanced hepatocellular carcinoma (HCC) has been reported a favorable tumor-shrinking effect and long-term survivals even in pts with highly advanced HCC. The aim of this trial was to evaluate the efficacy and safety ofsorafenib plus intra-arterial cisplatin (SP) vs. sorafenib alone (S) for advanced HCC. **Methods:** In this multicenter open-labeled randomized phase II trial, advanced HCC pts with no prior chemotherapy and Child Pugh A or B7 were randomly assigned 2:1 to receive SP (sorafenib: 800 mg, twice daily; intra-arterial cisplatin: 65 mg/m2, day 1, every 4 to 6 weeks up to a maximum of 6 cycles) or S (800 mg, twice daily) with portal vein tumor thrombosis and extrahepatic metastasis as dynamic allocation factors. The primary endpoint was overall survival. If the median survival of S is assumed as 7.0 months and that of SP as 9.5 months, the hazard ratio (HR) is 0.74. SP would be judged as favorable if HR is 0.74 or lower. A total of 105 pts was needed to estimate the 1-year survival rate with an accuracy of $\pm$10%. **Results:** From June 2011 to December 2013, 108 pts were randomized (SP, n = 66; S, n = 42) and followed up to December 2014. In the full analysis set of 106 pts, the patient characteristics were well-balanced, except for portal vein tumor thrombosis and hepatitis C viral infection. The median survivals in the SP and the S arms were 10.6 and 8.7 months, respectively (crude HR [95% CI], 0.68 [0.44-1.04], p = 0.073; and stratified HR by the allocation factors [95% CI], 0.60 [0.38-0.96], p = 0.031). The median time to progression was 3.1 and 2.8 months in the SP and S arms (HR [95% CI], 0.78 [0.52-1.16], p = 0.212; stratified HR [95% CI], 0.78 [0.59-1.21]). The following adverse events were more frequent in the SP arm than in the S arm, (percentage in the SP/S arms): neutropenia, 60.0/43.9; leukocytopenia, 75.4/43.9; hemoglobin, 89.2/73.2; thrombocytopenia, 89.2/80.5; hyponatremia, 81.5/53.7; nausea, 41.4/19.5; and hiccups, 9.2/0.0, respectively. **Conclusions:** According to the prespecified HR of 0.74, SP yielded favorable overall survival as compared to S in pts with advanced HCC. A further phase III trial is warranted to confirm these results. Clinical trial information: UMIN000005703.

4077 Poster Session (Board #187), Mon, 8:00 AM-11:30 AM

Ramucirumab (RAM) as second-line treatment in patients (pts) with advanced hepatocellular carcinoma following first-line therapy with sorafenib: Patient-focused outcome (PFO) results from the phase 3 REACH study. *First Author: Ian Chau, Royal Marsden, London & Surrey, United Kingdom*

Background: REACH did not demonstrate a significant improvement in overall survival (OS) in the ITT population, but pts in the RAM group with an elevated baseline alpha-fetoprotein (AFP) ≥400ng/mL (pre-specified) had meaningful improvement in OS (HR 0.67, $p < 0.05$). Here we present PFOs (pt-reported FACT Hepatobiliary Symptom Indexes [FHSI-8] and clinician-reported Eastern Cooperative Oncology Group [ECOG] performance status [PS]) from the REACH study. **Methods:** Eligible pts had advanced HCC; Child-Pugh A; ECOG PS 0 or 1; and prior sorafenib. Pts were randomized 1:1 to receive RAM (8 mg/kg) or placebo (PBO) on day 1 of an every 2 week cycle. The FHSI-8 was completed at baseline, cycles 4, 10, 16, and end of treatment. PS was assessed at baseline, each cycle, and end of treatment. Time to deterioration (TtD) in FHSI-8 was defined as the time from the randomization date to the first date with a ≥3-point decrease (based on 32-point scale) from baseline. TtD in PS was defined as the time from the randomization date to the first date a change to PS ≥2 was observed. Kaplan-Meier method and Cox regression were used to assess TtD. **Results:** Compliance with FHSI-8 was balanced between treatment arms. In the ITT population, TtD in FHSI-8 and PS were similar between RAM and PBO. In the elevated AFP population, there was a strong trend toward a delay in the deterioration of symptoms in FHSI-8 ($p = 0.054$) and PS ($p = 0.057$) for RAM treated pts compared to PBO. **Conclusions:** In the ITT population, symptom score and TtD were comparable between treatment arms; RAM did not result in the detriment in symptoms or pt functioning. Delay in symptom and PS deterioration coupled with survival benefit was observed in pts treated with RAM in the elevated AFP population. Clinical trial information: NCT01140347.

	ITT		AFP ≥400 ng/ml	
	RAM	PBO	RAM	PBO
FHSI-8 Compliance Baseline, %	96.5	94.7	99.2	94.7
FHSI-8 Compliance End of Treatment, %	62.1	72.5	67.2	76.6
FHSI-8 Score Change from Baseline, mean	-2.44	-2.86	-2.21	-3.73
TtD FHSI-8, mo				
HR (95% CI)	1.04 (0.80-1.34)		0.69 (0.47-1.01)	
P value	0.78		0.054	
TtD ECOG PS ≥2, mo				
HR (95%CI)	0.89 (0.65-1.22)		0.64 (0.41-1.02)	
P value	0.47		0.057	

4078 Poster Session (Board #188), Mon, 8:00 AM-11:30 AM

Gemcitabine (G), capecitabine (C) and bevacizumab (BV) in patients with advanced biliary cancers (ABC): final results of a multicenter phase II study. *First Author: Renuka V. Iyer, Roswell Park Cancer Institute, Buffalo, NY*

Background: Role of antiangiogenic therapy is still undefined in ABC. We examined BV combined with G + C, a standard chemotherapy for ABC when the study began. **Methods**: Pts with ABC (inoperable stage III or IV), ECOG PS 0-1, normal organ and marrow function. Schema: BV 15 mg/ kg q 21 days; C 650 mg/m2 bid x 14 days, both starting day 1; G 1000 mg/m2 days 1 & 8; cycles repeated q 21 days. Primary objective was progression free survival (PFS), secondary objectives were overall survival (OS) toxicity, quality of life (QOL) using the FACT HEP tool and circulating tumor cell (CTC) number. **Results:** Fifty pts enrolled at 2 sites; 11(22%) gall bladder (GB), 29(58%) intrahepatic cholangiocarcinoma (IHC) and 10(20%) extrahepatic cholangiocarcinoma (EHC). Median age 63 (range 25- 84 years), 52% male, inoperable 16% and metastatic 84%. Cycles: median 8 cycles/patient (range 1- 33), median time on treatment was 5.8 months. Responses (RECIST): PR 12(24%), SD 24 (48%), PD 6(12%) and 8 (16%) 2 too early/6 clinical progression (nonevaluable). Clinical benefit rate (PR + SD) = 72 %. Median PFS: 8.1months (95% CI:5.3, 9.9). Median OS: 11.3 months (95% CI:8.1, 13.1). One year survival rate was 0.47 (95%CI: 0.32-0.60). Grade 3/4 toxicities (> 5%): hematologic 28(58%), GI 18 (36%), infections 14 (28%) and thromboembolic events 6 (12%). Treatment discontinuation for toxicity (10%), progression (64%), death (4%), or other reasons (22%). Median OS in 21 (46%) pts with detectable CTCs was 9.4 months compared to 13.7 months in the 25(54%) pts without detectable CTCs at baseline.Patients with QOL scores after one and two cycles of therapy that were above median score at baseline for the whole group had higher OS of 13 months compared to 11.3 months. **Conclusions**: PFS and OS in ABC with the combination of gemcitabine, capecitabine and bevacizumab is relatively comparable to that reported with gemcitabine and cisplatin with acceptable toxicity. Lack of detectable CTCs and higher than median QOL score after one/two cycles of therapy may serve as biomarkers to predict improved outcome. **Acknowledgement**: Study is supported by a grant from Genentech. Clinical trial information: NCT01007552.

4079 Poster Session (Board #189), Mon, 8:00 AM-11:30 AM

Evaluation of the value of serum glycomics (GlycoCirrhoTest) for risk prediction of hepatocellular carcinoma in compensated cirrhosis. *First Author: Xavier Verhelst, Department of Hepatology and Gastroenterology, Ghent University Hospital, Ghent, Belgium*

Background: Cirrhosis is a major risk factor for the development of hepatocellular carcinoma (HCC) with a yearly incidence ranging from 1 to 8%. EASL and AASLD guidelines recommend systematic screening with liver ultrasound at 6 months interval in cirrhotic patients. A glycomic based test, called GlycoCirrhoTest, based on to the respective abundance of bisecting GlcNAc residues and triantenarry glycans on serum proteins, has shown a 79% sensitivity and 86% specificity for the diagnosis of cirrhosis among patients with chronic liver diseases. The aim of the present study was to determine whether serum glycomics are predictive for the development of HCC in compensated cirrhotics. **Methods:** Blood samples of 132 cirrhotic (Child A or B) patients collected between 1995 and 2005 were analysed. Seventy percent suffered of Hepatitis C. In the remaining patients, the cause of cirrhosis was HBV infection, alcohol and autoimmune diseases. Cirrhosis was confirmed by liver biopsy. The patients were followed until the appearance of a HCC, death or liver transplantation. At the moment of serum sampling there was no evidence of HCC. GlycoCirrhoTest was performed using capillary electrophoreses as previously described by Callewaert et al. (Nature Medicine 2004). **Results:** After a median follow up of 4 years (IQR: 3.6–8.06), 35 (26.5%) of the patients developed a HCC. Mean follow up in the patients who did not develop HCC was 3.7 years (IQR: 3.4-9.9; ns) . There was a significant increase of the mean baseline GlycoCirrhoTest value in the patients who developed a HCC during follow up ($p < 0.001$) as compared to those who did not. ROC Curve analysis showed an AUC of 0.716 (95% CI: 0.611-0.820) for the prediction of HCC in the patients with a follow up of at least 1 year. An 0.1 increase in the value of the GlycoCirrhoTest was associated with a 27% increase in the risk for developing HCC (OR 1,27; 95%CI: 1,098-1,475). **Conclusions:** This study suggests that an analysis of the serum protein glycome could generate a useful biomarker for the identification of cirrhotic patients at high risk for the development of HCC. GlycoCirrhoTest may help to stratify cirrhotic patients according to the risk of HCC and optimize screening.

4080 Poster Session (Board #190), Mon, 8:00 AM-11:30 AM

A multicenter cohort study on transarterial chemoembolization with or without sorafenib for intermediate-stage hepatocellular carcinoma: Reconsidering combination-therapy trial design. *First Author: Yan Zhao, Department of Liver Disease and Digestive Interventional Radiology, Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China*

Background: The proof of the superiority of combination therapy with sorafenib and transarterial chemoembolization (TACE) over TACE alone for hepatocellular carcinoma (HCC) in term of survival is lacking. We conducted this multicenter retrospective study to evaluate the efficacy of combination therapy over TACE alone, and to compare the overall survival (OS) between patients with ≥ grade 2 sorafenib-related dermatologic adverse events (AEs) in the combination therapy group and patients treated with TACE alone. **Methods:** From January 2009 to December 2012, 606 consecutive patients with intermediate stage HCC, Eastern Cooperative Oncology Group performance status 0-1, and Child-Pugh class A-B (≤ 7) were included. Of them 202 received combination therapy and 404 received TACE alone therapy, respectively. **Results:** There was no significant difference between the two groups in median OS although a trend toward longer survival was observed in the combination therapy group (22.3 vs. 18.1 months, *P*= 0.281). After propensity score matching the difference in OS was still not different (22.3 vs. 17.9 months, *P*= 0.343). Of note, in the combination therapy group, 119 patients with ≤ grade 1 dermatologic AEs within the first two months of sorafenib initiation, which were defined as non-responders, had increased risk of death compared with 83 patients with ≥ grade 2 dermatologic AEs which were defined as responders (HR = 1.85; 95%CI 1.27-2.68; *P*= 0.001). By using the second propensity score matching to balance the baseline differences between responders subgroup and TACE alone group, a significantly prolonged median OS was observed in the responders subgroup (27.9 vs.18.3 months, *P*= 0.046). **Conclusions:** Combination therapy, not in all, but in responders to sorafenib, results in longer overall survival than TACE alone. Sorafenib-related dermatologic AEs may be considered a possible clinical marker to stratify responders from all patients. Before the appearance of any assured biomarkers, the design of prospective comparative studies needs to focus on the responders to treatment who are evaluated by clinical markers.

4081 Poster Session (Board #191), Mon, 8:00 AM-11:30 AM

A pilot study of tremelimumab – a monoclonal antibody against CTLA-4 – in combination with either trans catheter arterial chemoembolization (TACE) or radiofrequency ablation (RFA) in patients with hepatocellular carcinoma (HCC). *First Author: Austin G. Duffy, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Tremelimumab is a fully human monoclonal antibody that binds to CTLA-4 expressed on the surface of activated T lymphocytes and results in inhibition of B7-CTLA-4-mediated downregulation of T-cell activation. Both transcatheter arterial chemoembolization (TACE) and radiofrequency ablation (RFA) have been shown to induce a peripheral immune response which may enhance the effect of anti-CTLA4 treatment in patients with advanced HCC. **Methods:** Patients with HCC [Childs Pugh A/B7; Barcelona Clinic Liver Cancer Stage B/C; ECOG 0/1; sorafenib refractory/intolerant (BCLC stage C only)] were enrolled in a pilot study of Tremelimumab at 2 dose levels (DL1 and DL2) until PD (irRECIST). Subtotal TACE or RFA was performed during study week 6 with DLT evaluation period encompassing first 8 weeks of study. Tumor biopsy at baseline and at time of RF/TACE. **Results:** 20 pts were enrolled with N = 18 evaluable for primary endpoint. Baseline characteristics: M:F 15:3; Median age = 54(range 42-76); Cirrhosis present in 13pts; BCLC Stage B/C: 4/14; Hepatitis B/C/neg: 4/10/4. 8 pts received TACE, 10 underwent RFA during week 6 of tremelimumab therapy. No DLT encountered. Most common toxicity was pruritus. One patient developed pulmonitis and was taken off study but remains disease-free at 16months. Of N = 10 pts evaluable for response outside of TACE/RFA-treated lesion 4 (40%) achieved confirmed partial responses. 5 of 7 pts with quantifiable HCV experienced a marked reduction in viral load. 6-week tumor biopsies showed immune cell infiltration on all evaluable patients. Median PFS for the study population (N = 17) was 7.4months. **Conclusions:** Tremelimumab in combination with subtotal TACE or RFA in patients with advanced HCC is safe and feasible. Obtaining tumor biopsies at baseline and at the time of RFA/TACE is safe. Evidence of immune cell infiltration was seen on evaluable patients. Encouraging clinical activity has been seen with objective confirmed responses, TTP 7.4m and possibly surrogate reductions in HCV viral load. Clinical trial information: NCT01853618.

4082 Poster Session (Board #192), Mon, 8:00 AM-11:30 AM

Panitumumab in combination with gemcitabine/cisplatin (GemCis) for patients with advanced kRAS WT biliary tract cancer: A randomized phase II trial of the Arbeitsgemeinschaft Internistische Onkologie (AIO). *First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany*

Background: Biliary tract cancer encompasses a group of genetically heterogeneous tumors. Panitumumab is a human EGFR inhibitor and has shown anti-tumor activity in RAS WT colorectal cancer. **Methods:** Pts with advanced KRAS wild type biliary tract or gallbladder adenocarcinoma were 2:1 randomized to receive Cis (25mg/m2) followed by Gem (1000mg/m2) on days 1 and 8 of a 21-day cycle, plus Panitumumab (6mg/kg) in arm A until disease progression. Primary endpoint was the progression-free survival rate at 6 months. For genetic profiling, massive parallel multigene sequencing was done by using a custom designed cholangiocarcioma multigene panel on an IonTorrent Proton. Mutations (21 genes) as well as amplifications and deletions (19 genes) were identified by panel tailored bioinformatic algorithms. **Results:** 93 pts were enrolled (63 per arm A and 30 arm B). Pts characteristics (panitumumab vs. control): median age 61.5 vs. 58.5 years; 59% vs. 50% male; intrahepatic, extrahepatic, gall bladder (%): 63, 16, 17 vs. 71, 11, 11; ECOG PS 0, 1, 2 (%): 64, 33, 2 vs. 45, 55; prior resection (%): 46 both arms. The most common grade 3-4 non-haematological adverse event (AE) was skin toxicity (39% vs 0%). Distribution of other grade 3-4 haematological and non-haematological AEs were not significantly different between both arms. 6-months PFS rate was not significantly different (55% vs 73%), mPFS was 6.7 vs. 8.2 mo, HR (95% CI, Gem/Cis ref.): 0.73 (0.43 – 1.24), p = 0.24; mOS was 12.8 vs. 21.4 mo, HR (95% CI, Gem/Cis ref.): 0.74 (0.39 – 1.4), p = 0.35; response rate (in evaluable pts): panitumumab (28/63 [45%] vs. control 11/28 [39%]. The most frequent genetic variations were detectable in p53 (34%), IDH1/2 (19%) and SMAD4 (11%) with up to 9 events per patient. The prognostic and predictive role of the variants is currently under investigation and will be presented. **Conclusions:** Panitumumab in combination with chemotherapy does not improve response rate, PFS and OS in patients with advanced bilary tract cancer. Further investigations of chemotherapy in combination with anti-EGFR antibodies are not warranted. Clinical trial information: NCT01320254.

4083 Poster Session (Board #193), Mon, 8:00 AM-11:30 AM

A phase 1/2 study of TRC105 in combination with sorafenib in hepatocellular carcinoma (HCC). *First Author: Austin G. Duffy, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Endoglin (CD105) is an endothelial cell membrane receptor highly expressed on proliferating tumor vasculature, including in HCC. CD105 is essential for angiogenesis and its expression is upregulated by hypoxia and VEGF inhibition. TRC105 is a chimeric IgG1 anti-CD105 monoclonal antibody that inhibits angiogenesis and causes ADCC and apoptosis of proliferating endothelium. Sorafenib is the only FDA-approved drug in HCC and anti-endoglin antibody potentiates sorafenib in preclinical models **Methods:** Patients with HCC (Childs Pugh A/B7), ECOG 0/1, were enrolled in a phase I study of TRC105 at 3, 6, 10, 15mg/kg q 2wks plus sorafenib 400mg bid. Correlative biomarkers included DCE-MRI, color Doppler ultrasonography, circulating endothelial and endothelial progenitor cells, plasma levels of angiogenic factors, soluble CD105 and tumor IHC for CD105. Samples were also collected for analysis of immune subsets and pharmacokinetics. **Results:** 21 pts were enrolled (N = 2 inevaluable); 12 with cirrhosis; Hep B/C/NA: 2/10/7; M:F 13:6; Mean age of 60 (range 18-76); 1 DLT (increased AST) occurred at 10mg/kg. The most frequent toxicity was low grade epistaxis. One patient experienced an infusion reaction and was replaced. One patient with coronary stenosis developed a fatal myocardial infarction and one patient developed G3 cerebral tumor hemorrhage. Four of sixteen (25%) pts evaluable for response achieved PR by RECIST (3/6 at Dose Level 4). Four patients had confirmed stable disease, one of whom was treated for 22 months. Median PFS was 4.1 months for first N = 18 patients, 5 months at dose level 4. **Conclusions:** TRC105 combined with sorafenib was well tolerated at the recommended single agent doses of both drugs. Encouraging evidence of activity (PR rate 25%) was observed and the study is now in the phase 2 stage. Full correlative and clinical data will be presented. Clinical trial information: NCT01306058.

4084 Poster Session (Board #194), Mon, 8:00 AM-11:30 AM

Objective response by mRECIST to predict survival in hepatocellular carcinoma: A multivariate, time-dependent analysis from the phase III BRISK-PS study. *First Author: Josep M. Llovet, Liver Cancer Program, Division of Liver Diseases, Mount Sinai School of Medicine, New York, NY*

Background: mRECIST (modified Response Evaluation Criteria In Solid Tumors) was developed to overcome the limitations of standard RECIST in hepatocellular carcinoma (HCC) response assessment. Retrospective studies have correlated objective response (OR) by mRECIST with overall survival (OS) in patients treated by loco-regional therapies. We investigated whether OR by mRECIST predicted OS using data from a double-blind, placebo-controlled, randomized phase III trial. **Methods:** In the BRISK-PS study, 395 patients with advanced HCC who progressed on/after or were intolerant to sorafenib were randomly assigned (2:1) to receive brivanib plus best supportive care (BSC) or placebo plus BSC. Tumor assessments were performed every 6 weeks by contrast-enhanced computed tomography or magnetic resonance imaging. Assessment of response was done by central radiological review using mRECIST. Multivariate models using time-dependent covariate analysis defined variables with independent prognostic value (SPSS 18 and SAS 9.2). **Results:** 210/226 (93%) patients in the brivanib arm and 101/108 (94%) in the placebo arm, who had baseline and on-study scans available for central blinded review, were evaluable according to mRECIST. 26/210 patients on brivanib and 2/101 on placebo achieved partial response ($p < 0.01$). At the end of follow up, 284 patients had died, the median OS for the brivanib arm being 9.4 months. As per mRECIST response assessment, median OS was 16.4 months (n = 26; 95% CI, 15.7 – NA) for brivanib responders and 8.3 months (n = 237; 95% CI, 7.2 – 9.7) for brivanib non-responders (hazard ratio, 0.28; 95% CI, 0.14 – 0.55, $p < 0.01$). Independent predictors of OS at multivariate time-dependent analysis were ORR by mRECIST, vascular invasion/extrahepatic spread, AFP > 200 ng/mL and bilirubin > 1.5 mg/dl. **Conclusions:** ORR by mRECIST is an independent predictor of OS in HCC patients receiving a systemic multikinase inhibitor, brivanib. mRECIST response is a marker of antitumor activity and warrants further evaluation in prospective clinical trials exploring novel agents in HCC patients. Clinical trial information: NCT0901901.

4085 Poster Session (Board #195), Mon, 8:00 AM-11:30 AM

Changes in plasma biomarkers over time in patients (pts) with advanced biliary tract cancer (ABC) treated in the UK ABC-03 randomized phase II trial. *First Author: Alison Catherine Backen, University of Manchester (Institute of Cancer Sciences), Manchester, United Kingdom*

Background: ABC-03 was a randomized phase II trial of cediranib (C; AZD2171) [inhibitor of VEGFR-1, -2 and -3 tyrosine kinase and VEGF-induced signaling] or placebo (P) in combination with cisplatin/gemcitabine for pts with ABC. Changes in plasma biomarkers including angiogenic proteins and a marker of cell death (CK18) have not been reported in ABC. **Methods:** ELISA was performed for 15 angiogenesis or inflammatory-related proteins and CK18 in plasma of pts with repeated sampling during treatment and at disease progression. Tumor markers were also evaluated. Overall survival (OS) was analyzed using Cox model for baseline (BL) biomarkers and time-varying covariate Cox model (TVC) for biomarkers with serial measurements. **Results:** Plasma samples were available from 117 of 124 pts (59 in C arm, 58 in P). After adjusting for treatment and pt characteristics, higher BL VEGFR2 ($p = 0.02$), CK18 ($p = 0.005$), CEA ($p < 0.001$), CA19-9 ($p = 0.03$) and CA125 ($p = 0.001$) correlated with shorter OS, as did incremental increases in CK18 (HR 1.08, 95%CI 1.05-1.11, $p < 0.001$) and IL-6 (HR 1.02, 95%CI 1.00-1.03, $p = 0.008$) using TVC. There was evidence for interaction between treatment and BL CA19-9 and PDGFbb for OS: incremental increases in CA19-9 were associated with an increased risk of death (C: HR 1.44, 95%CI 1.16-1.80; P: HR 1.03, 95%CI 1.00-1.05, $p = 0.001$) and higher values of PDGFbb were associated with a decreased risk of death with C (HR 0.82, 95%CI 0.68-1.00) and an increased risk of death with P (HR 1.15, 95%CI 0.99-1.34, $p = 0.01$). In TVC, there was evidence of interaction between treatment and VEGFA ($p = 0.03$), PDGFbb ($p = 0.08$), VEGFC ($p = 0.06$) and SDF1b ($p = 0.06$). Higher values of VEGFA were associated with increased risk of death with P (HR 1.31, 95%CI 1.06-1.62) but not with C (HR 0.99, 95%CI 0.86-1.15) ($p = 0.03$). **Conclusions:** High BL VEGFR2, CK18 and tumor markers are associated with a poor outcome in pts with ABC. Increasing levels of CA19-9 and PDGFbb from BL were associated with increased and decreased risk of death, respectively, in C-treated pts. Changes in VEGFA correlated with OS for pts on P but not C. These findings may inform future clinical trial stratification and design. Clinical trial information: NCT00939848.

4086 Poster Session (Board #196), Mon, 8:00 AM-11:30 AM

Molecular characterization of 350 hepatocellular carcinomas to identify biomarker aberrations with potential novel therapeutic options. *First Author: Celina Ang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Effective treatment strategies for hepatocellular carcinoma (HCC) remain limited. Identification of additional therapies remains paramount as currently available agents have resulted in marginal improvements in overall survival or are not appropriate for this patient population. **Methods:** 350 HCC sampleswere evaluated on a commercial platform, for both genetic and proteomic aberrations. Tests included Sanger or next generation sequencing (NGS), protein expression by immunohistochemistry (IHC) and gene amplification by in situ hybridization (ISH). **Results:** TP53 was mutated in 34%, CTNNB1 in 20%, and BRCA2 in 18%; other gene mutation rates were < 5%.TP53-mutated tumors show significantly higher TOP2A (89% vs. 39%, $p<0.0001$), TS (70% vs. 32%, $p=0.0067$) and RRM1 expression (40% vs. 12%, $p=0.017$), implying high rates of proliferation and DNA synthesis. CTNNB1-mutated tumors showed significantly higher SPARC (67% vs. 21%, $p=0.0013$) and AR expression (53% vs. 22%, $p=0.025$). Changes in protein expression are shown. Metastatic HCC ($N=124$) exhibited significantly higher PD-1 (79% vs. 50%, $p=0.047$) and TS expression (31% vs. 14%, $p<0.0008$) than non-metastatic ($N=226$). Analysis of outcomes in a subset of patients treated based on biomarker-therapy associations is ongoing. In 1 patient an EGFR mutation (predictive of response to erlotinib in NSCLC) was identified, and the patient has begun treatment with erlotinib. **Conclusions:** The molecular profile in HCC suggests potential targeted therapies, such as tyrosine kinase inhibitors, anti-PD1 agents, or PI3 kinase pathway inhibitors. Immuno-modulatory agents may be an option, particularly in metastatic HCC, based on levels of PD-1. Concurrent protein changes in CTNNB1-mutated tumors suggest potential benefit of combination therapies when targeting the WNT pathway. Review of responses to targeted therapies, such as is being tried with erlotinib in the patient with EGFR mutation may provide additional insight into efficacious therapies.

4087 Poster Session (Board #197), Mon, 8:00 AM-11:30 AM

The influence of tumor-infiltrating lymphocytes (TILs) and their prognostic value in cholangiocarcinoma. *First Author: Yaman Suleiman, Moffitt Cancer Center, Tampa, FL*

Background: Cholangiocarcinoma is a malignancy arising from the epithelial cells of the biliary tract with poor prognosis. Tumor-infiltrating lymphocytes (TILs) have a prognostic impact in various solid tumors. We aimed to investigate TIL expression and programmed cell death ligand PD-L1 and their clinical relevance in cholangiocarcinoma. **Methods:** Formalin-fixed paraffin-embedded tumor samples from 47 pts with resected and histologically verified cholangiocarcinoma between 1990 and 2011 were immunohistochemically (IHC) stained with anti CD8, anti CD45RO and the anti-PDL1 mouseIgG1 (clone 5H1; Thompson) antibodies on a Leica automated IHC platform. The stains were semiquantitatively analyzed using the AllRed score system (range 1 to 8). IHC score > 3 considered positive. The association between PDL1, CD45R0, OS and PFS was investigated using Kaplan-Meier survival and COX proportional hazard regression analyses. **Results:** Median age was 65 (41-85) with 51% male. 24%, 45%, 24% and 7 % were stage I, II, III, and IV respectively, CD8 was positive in 11/47 (23%), PD-L1 was positive in 42/47 (89 %), CD45R0 (lymph node like structure) was positive in 18/47 (38%), 17/18 (95%) of CD45R0+ tumors were PD-L1 positive. Pts with tumors exhibiting lymph node (LN) like structures (CD45R0+) has better median OS (63 months vs 18 months, $P = 0.003$) and median PFS (29 months vs 14.7 months, $P = 0.06$) than patients lacking LN like structures (CD45R0-). 5 yrs. OS in CD45R0+ was 61% vs 26% in CD45R0- (P 0.005) whereas 5 yrs. PFS in CD45R0+ was 44% vs. 18% in in CD45R0- pts (P value 0.02). Correlating PDL1 with OS and PFS was not feasible due to high expression of PD-L1 (89 %). **Conclusions:** Presence of LN like structures (CD45R0+) was associated with significant better outcome reflecting the immune-mediated killing of tumor cells. This LN like structures need to be further characterized to understand how they escaped the inhibitory effect of PD-L1. The high expression of PD-L1 on cholangiocarcinoma cells represents a potential therapeutic target which may enhance the immunologic response and improve the prognosis of this dismal cancer. Future trials involving PD-L1 inhibitors are warranted.

4088 Poster Session (Board #198), Mon, 8:00 AM-11:30 AM

A phase II trial of bevacizumab and erlotinib as second line therapy for advanced hepatocellular carcinoma. *First Author: Ahmed Omar Kaseb, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The objective of the study was to evaluate the efficacy and tolerability of bevacizumab (B) and erlotinib (E) combination as second line therapy for advanced hepatocellular carcinoma (HCC). **Methods:** Patients who had advanced HCC that was not amenable to surgical or regional therapies, had shown progression with sorafenib therapy; Childs-Pugh score A or B liver function; Eastern Cooperative Oncology Group performance status 0, 1, or 2 received bevacizumab 10 mg/kg every 14 days and erlotinib 150 mg orally daily, continuously, for 28-day cycles. The tumor response was evaluated every 2 cycles by using Response Evaluation Criteria in Solid Tumors Group criteria. The primary objective will be to assess progression-free survival (PFS) measured at 16 weeks following initiation of therapy .The secondary objective will be to assess time to progression (TTP) and overall survival (OS). **Results:** A total of 44 patients were included. PFS at 16 weeks was 43% (95% CI 28% -59%), the Median TTP was 3.9 months (95% CI 2.0-8.3) and median overall survival (OS) was 9.9 months (95% CI, 8.3-15.5). Grade 3-4 adverse events included fatigue (13.3%), acne (11.1%), diarrhea (8.8%), anemia (6.6%), upper gastrointestinal hemorrhage (6.6 %). **Conclusions:** Bevacizumab and Erlotinib combination showed promising activity in this first US study in the second line setting. Validation studies are warranted. Clinical trial information: NCT01180959.

4089 Poster Session (Board #199), Mon, 8:00 AM-11:30 AM

Prognostic score in high-grade gastrointestinal neuroendocrine tumours (GI-NETs). *First Author: Angela Lamarca, Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Outcomes of patients with high-grade GI-NETs are poor; prognostic markers for risk-stratification are needed. **Methods:** Consecutive patients, diagnosed with high-grade GI-NETs between 1997-2014, were included. Prognostic factors were identified by the Log-rank test, Cox regression and logistic regression and ROC curve comparisons performed for prediction accuracy. Internal validation of the score by Bootstrap-corrected Harrell Concordance Index (C-index) and Resampling Model Calibration were performed. **Results:** One-hundred and nine patients were eligible for analysis. Median follow-up time was 9.7 months (1.3-102.9). Median age: 67.7 years (16.3-84.1); 62% male, 84% metastatic; 19% foregut, 5% midgut, 19% pancreas, 28% hindgut and 29% unknown primary. Median ki67: 70% (20-100); ECOG PS 0: 26%, 1: 52%; 70% received chemotherapy. Baseline median alkaline phosphatase (ALK) and LDH were 109 IU/l (45-2035) and 70 IU/l (258-11069), respectively. The maximum model included stage, PS, LDH, Na, ALK, ki67, number of metastatic sites, presence of liver and presence of lung metastases. The score, selected by the lowest Akaike Index Criterion, included liver metastases, PS, ki67, LDH and ALK with 0-6 points assigned to each, resulting in 4 risk groups (A-D) with predicted risk of death, detailed in Table. There was no difference in the survival prediction accuracy between the maximum model and the score. On multivariable analysis, the score was prognostic for overall survival (HR 1.95, 95%CI 1.55-2.47; $p < 0.001$) and had good discrimination (C-index, 0.76) and calibration (mean error, 0.021; percentile 90, 0.037). **Conclusions:** This simple score identified high-grade GI-NET patients with meaningful differences in survival and may inform clinical decision-making and trial design.

Prognostic group (points)	Risk of death at 3 months (%)	Risk of death at 6 months (%)	Risk of death at 9 months (%)	Risk of death at 12 months (%)	Risk of death at 18 months (%)	Risk of death at 24 months (%)
A (0-1)	0.9	10.1	20.3	32.1	58	71.9
B (2)	4.2	26.01	43.6	57.3	79.7	88.2
C (3)	16.4	52.4	70.3	79.3	91.8	95.6
D (4-6)	46.9	77.5	87.8	91.6	96.9	98.5

4090 Poster Session (Board #200), Mon, 8:00 AM-11:30 AM

Association of progression-free survival with overall survival (OS) in patients (pts) with neuroendocrine tumor (NET) treated with somatostatin analogs. *First Author: Monica Ter-Minassian, Dana-Farber Cancer Institute, Boston, MA*

Background: Progression-free survival (PFS) is commonly used as a primary endpoint in NET clinical trials. Whether PFS is associated with OS is uncertain. We assessed the association between PFS and OS in a large observational cohort of pts with NETs treated with somatostatin analogs (SSA). **Methods:** We enrolled 1330 pts to a prospective observational study, beginning in 2003. Of these pts, we identified 440 with metastatic NETs who had received single-agent SSA and were evaluable for tumor progression, based on medical record review. We used a landmark analysis to assess OS in pts with progression (PD) or without PD at 6 month intervals, from 6 to 24 months after treatment initiation. Adjusted hazard ratios were assessed with Cox proportional hazards models. Kaplan-Meier estimates were used to calculate median OS for pts with PD vs. those without PD at each landmark time. PFS was defined as time of treatment initiation to time of first progression or death. OS was defined as time of treatment initiation plus the landmark time to time of death. **Results:** Of the 440 pts, 224 had small bowel NETs, 93 had pancreatic NETs and 123 other NETs. 311 pts progressed and 215 died. Median follow-up was 7.6 yrs. PFS was associated with OS at the 6, 12, 18, and 24 month landmarks: those who progressed by each landmark time had shorter median OS times than those who did not progress (see table). A trend suggesting association of PFS with OS was seen across tumor subgroups. **Conclusions:** In this observational cohort of pts with metastatic NETs treated with SSA, PFS was associated with OS. Our findings support the use of PFS as an endpoint in NET clinical trials.

PFS and OS in NET patients treated with SSA (N = 440).

Landmark time	No PD (N)	No PD (Median OS)	PD (N)	PD (Median OS)	Adjusted HR[a] (95%CI)
6 mo	327	7.52 yrs	107	3.62 yrs	1.72 (1.25, 2.37), p = 0.0009
12 mo	249	7.02 yrs	169	4.71 yrs	1.47 (1.07, 2.00), p = 0.017
18 mo	181	7.10 yrs	220	3.97 yrs	1.77 (1.25, 2.51), p = 0.0014
24 mo	147	6.79 yrs	219	4.21 yrs	1.58 (1.07, 2.32), p = 0.02

4091 Poster Session (Board #201), Mon, 8:00 AM-11:30 AM

Everolimus in patients with advanced, progressive pancreatic neuroendocrine tumors: Overall survival results from the phase III RADIANT-3 study after adjusting for crossover bias. *First Author: Marianne E. Pavel, Charité Berlin Campus Virchow-Klinikum, Berlin, Germany*

Background: In the RADIANT-3 study, everolimus (EVE) improved progression-free survival (PFS) by 6.4 mo versus placebo (PBO; HR, 0.35; 95% CI, 0.27-0.45; $P < 0.001$) in patients (pts) with advanced, progressive pancreatic neuroendocrine tumors (pNET). Here we present final overall survival (OS) results of the RADIANT-3 study with updated safety and also report OS adjusted for confounding due to crossover. **Methods:** A total of 410 pts with advanced, progressive, low-/intermediate-grade pNET were randomized to EVE 10 mg/d (n = 207) or PBO (n = 203), both with best supportive care. Upon disease progression in double-blind phase, crossover from PBO to open-label EVE was allowed at investigator's discretion. At the end of core phase, ongoing pts from both arms were unblinded and switched to open-label EVE. OS was analyzed by one-sided stratified log-rank test. Rank-preserving structural failure time (RPSFT) analysis was performed to estimate treatment effect corrected for crossover bias. **Results:** A total of 225 pts received open-label EVE; including 85% (172 of the 203) pts randomized to PBO arm. Median OS (95% CI) was 44.0 (35.6-51.8) mo for pts initially randomized to EVE and 37.7 (29.1-45.8) mo for those randomized to PBO (HR, 0.94; 95% CI, 0.73-1.20; P= 0.30). RPSFT analysis showed a relative survival benefit of 3.27 (95% CI, 0.10-13.93) with survival rates of 82.6% vs 74.9% and 67.7% vs 55.6% at 12 and 24 mo, respectively for EVE vs RPSFT corrected PBO arm. The most frequently reported drug-related adverse events included stomatitis (45%), rash (37%), and diarrhea (26%) in open-label EVE arm. **Conclusions:** The randomized, placebo-controlled, phase III RADIANT-3 study reports unprecedented median OS of 44 mo with EVE in advanced, progressive pNET. Although statistically not significant, a survival benefit of 6.3 mo with EVE was observed, consistent with PFS benefit reported previously. A stronger OS advantage with EVE after a correction for crossover effect confirms that crossover of majority of PBO pts (85%) likely confounded the survival results. The safety profile of EVE remained consistent with earlier experience. Clinical trial information: NCT00510068.

4092 Poster Session (Board #203), Mon, 8:00 AM-11:30 AM

Phase Ib study of pasireotide (P), everolimus (E), and selective internal radioembolization therapy (SIRT) for unresectable neuroendocrine hepatic metastases. *First Author: Bassel F. El-Rayes, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Pasireotide (P) is a somatostatin (SST) analogue active against receptors 1, 2, 3, and 5. Everolimus (E) is an mTOR inhibitor. mTOR and SST pathways activate angiogensis, survival and increase radio-resistance. **Methods:** Major eligibility criteria: unresectable bilobar liver metastasis from low or intermediate grade NET, prior therapy with octreotide LAR 30mg, evidence of disease progression by RECIST 1.1, hemoglobin A1C less than 7, and adequate liver functions. A 3+3 dose escalation design was used. Everolimus dose levels were 2.5 mg, 5 mg, and 10 mg every day. Standard dosing and administration was used for Sir-sphere$^{(R)}$. E and P (600mcg BID) were given 1 week prior to SIRT and until 29 days after second SIRT when E (10mg daily) and P LAR (60 mg q 28days) were started. Dose limiting toxicities (DLT) were defined as the occurrence of any treatment related grade 4 hematologic or grade 3 non-hematologic toxicities lasting more than 7 days or grade 4 non-hematologic toxicity. Serum pharmacodynamic markers (VEGF, FGF, PIGF, Il-8, IGF-1, IGF-2, IGF binding proteins) were collected at baseline, prior to and 24 hours after first SIRT. QOL patients were assessed monthly by the Norfolk QOL-NET questionnaire. **Results:** 13 patients (pts) were enrolled in the study. 1 pt was in-evaluable for toxicity. Pt characteristics were median age 61 yrs, 7 males, primary site (midgut 4 pts, pancreas 3, lung 2, unknown 2, gastric 1, colon 1), and low grade (11). 3 pts had liver only disease. No DLT was observed. The grade 3 toxicities throughout the study were: hyperglycemia (6 pts) and thrombocytopenia (2pts). Liver toxicities observed in the first 28 days were bilirubin grade 1 (1 pt), bilirubin grade 2 (1 pt), and AST/ALT elevation grade 1 (8 pts). Best response was PR (6 pts), SD (3 pts), PD (3 pts- 2 had extrahepatic progression). 6 pts (50%) are still with no progression and median PFS is 9 months (95%CI 4-21). **Conclusions:** The RP2D is everolimus 10 mg QD and pasireotide 600 mcg BID. **P**, E and SIRT was well tolerated with minimal liver toxicity. The preliminary results for activity appear promising and control of liver disease is excellent with only 1 pt (8%) having progressive disease in the liver. Clinical trial information: NCT01469572.

4093 Poster Session (Board #204), Mon, 8:00 AM-11:30 AM

Novel score to predict outcome in resected pancreatic neuroendocrine tumors (pNET). *First Author: Antonio Viudez, Department of Medical Oncology, Complejo Hospitalario de Navarra-Fundacion Navarrabiomed, Pamplona, Spain*

Background: MGMT expression can predict response to temozolomide-based treatment. In pNET PHLDA-3 silencing is a common event while the expression of NDRG-1 and its functional role is unknown. We conducted a retrospective review of immunohistochemistry (IHC) expression of MGMT, NDRG-1 and PHLDA-3 in pNET and investigated their potential role as prognostic biomarkers. **Methods:** IHC nuclear staining for MGMT and PHLDA-3 was scored as 0, 1-5%, 6-50% and ≥ 51%. For NDRG-1, we used a cytoplasmic score from 0 to 3 based on staining intensity. Based on the long-rank test result between 2 clusters for each IHC staining, we designed an IHC score (IHC-S, score from 0 to 3). Finally a Global Score (GS) was developed with those variables that showed most significant differences in the univariate analysis (IHC-S and margin). **Results:** 92 samples from patients (pts) with resected pNET and follow-up > 24 moths were analyzed. Median follow-up was 55.5 months (mo). Pts had a median age of 56.5 y (16-88) and R0 resection occurred in 84.8%. Median DFS was 77 mo while median OS has not been reached yet. Significant statistical differences were observed in DFS based on surgical margin status (R0: 118 m vs R1: 34 m; p = .005), ypN0 vs ypN1 (p = .004) and ki67 < 2% (< 2% vs 2-20% p = .015). DFS was significantly poorer in pts without any expression of MGMT (p = 0.045), in pts with low-expression of NDRG-1 (0 or 1, p = 0.03), and in pts with high-expression of PHLDA-3 (≥ 51%, p = 0.01). Significant differences were observed between pts with IHC-S = 0 vs IHC-S = 1 (p = 0.009), IHC-S = 2 (p = 0.012) or IHC-S = 3 (p = 0.0001). Pts with IHC-S = 0 never recurred while up to 70% of pts with IHC-S = 3 progressed during follow up. Using the Cox proportional hazards regression, GS was found as independent prognosis factor for DFS (HR: 5.043; 95%CI: 1.278-19.901). **Conclusions:** Our results suggest the potential use of MGMT, NDRG-1 and PHLDA-3 IHC expression as predictor of outcome in pNET. Our Global Score may be able to discriminate between pts that will be cured after surgery from those with high risk of relapse.

4094 Poster Session (Board #205), Mon, 8:00 AM-11:30 AM

Study of the therapeutic management of gastric carcinoid tumors from data of the French national cohort of neuroendocrine tumors: CARGAS study. *First Author: Sylvain Manfredi, CHU Pontchaillou, Rennes, France*

Background: 4 types of gastric NETs are described: type 1 developed on atrophic gastritis (70-80% of cases), type 2 (5-6% of cases) as part of MEN 1, sporadic type 3 (14-25% of cases), and Type 4 corresponding to poorly differentiated NETs (6-8%) (1). The natural history of types 1 and 2 is usually benign, while type 3 and 4 are more aggressive. Treatments of these four types are different and based on European guidelines (2). Those recommendations are based on data of small series. **Methods:** The objective of this study was to study of the treatment and monitoring of gastric NETs registred prospectively in a national cohort. Secondary objectives: epidemiology, overall survival. The National Register of GTE records all TNE via e-crf. **Results:** At the end-point of the study 197 gastric NETs were recorded (2.5% of all the NETs registred, 11th frequency tumor). A study of each case, on site, was conducted. 181 (91.9%) complete records were analyzed. The characteristics of these tumors are presented in the table below. Gastrin was measured in 31% of patients and chromogranin A in 36.9%. A somatostatin analogue was administered to 16 patients (8.8%). **Conclusions:** This cohort represents the largest cohort known to date. It provides us important data on epidemiology of these tumors and their management. There are very likely over-reporting of type 3 and 4 in this register.

4095 Poster Session (Board #206), Mon, 8:00 AM-11:30 AM

Characteristics, prognosis and treatments of 294 patients with poorly differentiated neuroendocrine carcinoma: The FFCD-GTE national cohort. *First Author: Thomas Walter, Hopital Edouard Herriot, St Didier Au Mont D'or, France*

Background: Data on poorly differentiated neuroendocrine carcinoma (NEC) are limited or retrospective. We designed a French cohort to describe characteristics, prognosis and treatments of NEC **Methods:** All patients with a diagnosis of NEC (WHO 2010) performed between 01/01/2010 and 31/12/2013 could be included in this national prospective cohort. Patients with small-cell NEC from lung, mixed tumors, and well-differentiated neuroendocrine tumors (NET) were not included **Results:** 294 patients from 49 centers were included: median age was 66 (range: 23-92) years, 6 (2%) had functional tumors, performance status (PS) was 0-1 in 79% of patients, fortuitous diagnosis was done in 10 (3%) patients. Main primary locations were pancreas (18%), colorectal (24%), oeso-gastric (15%), large-cell lung NEC (15%), and unknown (17%). Most of the patients were metastatic (75%). At that time, 85 (29%) pathological specimens have been reviewed by the French national referent pathological network (TENpath). Pathological data showed: small/large cell NEC in 38%/62%, with necrosis in 79%, and a median Ki67 index of 70% (range: 10%-100%). Median overall survival (OS) was 15.7 months (95% CI: 13.9-17.8). GEP-NEC had similar characteristics and survival than other NEC. Factors associated with worse OS in multivariate analysis were PS > 1 (HR = 2.9, p < 0.001), metastatic disease (HR = 2.2, p < 0.001), NSE > 2 ULN (upper limit of normal) (HR = 4.1, p < 0.001), and LDH > 2ULN (HR = 2.7, p < 0.001). Ki67 index > 55% and primary location were not significantly associated with different OS. OS were 11.8 months from first-line (L1) systemic palliative chemotherapy (n = 202 pts), 7.6 months from L2 (n = 117), and 5.9 months from L3 (n = 58). The type of L1 was mainly platinum-etoposide (n = 176), whereas folfiri (79 patients) and folfox (37 patients) were mainly given in L2 or further lines. Efficacy of these treatments will be presented at the meeting **Conclusions:** This is the largest prospective series of NEC showing that worse prognosis factors are performance status, tumor burden, and elevated biologic markers (NSE and LDH). Further prospective studies are needed to improve treatment in L2

4096 Poster Session (Board #207), Mon, 8:00 AM-11:30 AM

Multicenter prospective phase II trial of bevacizumab (bev) for progressive pancreatic neuroendocrine tumor (PNET). *First Author: Timothy J. Hobday, Department of Oncology, Mayo Clinic College of Medicine, Rochester, MN*

Background: Single agent trials of mTOR inhibitors and VEGF receptor TKIs in PNET yield response rates < 10%. We previously demonstrated a 39% PR rate in PNET with the combination of temsirolimus and bev in patients with progressive PNET. There are no data regarding the efficacy of single agent bev in PNET. **Methods:** We conducted a multicenter phase II trial of bev at a dose of 10 mg/kg IV q 2 weeks in patients (pts) with well or moderately differentiated PNET, adequate organ function, and ECOG PS of 0-1. Important eligibility criteria included requirement for progression of disease by RECIST within 7 months of study entry. No prior anti-VEGF pathway inhibitor therapy was allowed. Ongoing octreotide was allowed at stable dose if required for symptom control. Primary endpoint was response with null hypothesis of 10% and promising result was defined as 30%. Planned enrollment was 21 pts. **Results: :** 22 pts enrolled from 10/2012 through 6/2014 were eligible for The primary endpoint of response assessment. 9 patients remain on therapy. Confirmed PR rate is 9% (2/22). 6 month progression free survival (PFS) was 95% (20/22). 15 out of 22 pts have follow-up on study > 12 months. The Kaplan-Meier 12 month PFS was 54% (95% CI: 34-85%). Median PFS is 13.6 months (95% CI 10.6-NA). Therapy was well tolerated with no grade 3-4 AEs except 36% grade 3 hypertension. **Conclusions:** Bev therapy for PNET is associated with a 9% PR rate in this trial. For a population required to have RECIST criteria progression within 7 months prior to study enrollment, the 6 and 12 month PFS rates of 95% and 54% are promising with minimal systemic toxicity. Clinical trial information: NCT01010126.

4097 Poster Session (Board #208), Mon, 8:00 AM-11:30 AM

Bronchial neuroendocrine neoplasms: A Surveillance Epidemiology and End Results (SEER) database review of demographics and survival in 187,991 cases. *First Author: Mark Andrew Lewis, MD Anderson Cancer Center, Sugar Land, TX*

Background: Bronchial neuroendocrine neoplasms (NENs) are a biologically heterogeneous group of malignancies whose differences are incompletely understood. We aimed to study the demographics and survival of patients with these neoplasms by reviewing the SEER database. **Methods:** We identified 945,331 cases in the SEER database with malignancies of the lung and extracted 187,991 bronchial NENs to examine patient characteristics & clinical outcomes by histology and stage. **Results:** By histology and grade, there were 130,092 cases of small cell carcinoma, 44,520 cases of large cell carcinoma, 3,349 cases of neuroendocrine carcinoma (grade 3/4), 9,135 cases of typical bronchial carcinoid (grade 1), and 895 cases of atypical bronchial carcinoid (grade 2). The ethnic predilection was Caucasian (87%, with 9% black and 4% other). Overall there were more cases in men (55% of the entire cohort), but women accounted for 66% of the carcinoid cases. Mean age at diagnosis for all NENs was 66, with typical carcinoids having the youngest mean age (60) than any other type. By SEER stage, 13% of NENs were localized, 24% were regional, and 63% were metastatic, with median survivals of 39.7, 14.4, and 4.3 months, respectively. Survival by histology is summarized in the table below. **Conclusions:** Bronchial NENs vary widely in their clinical behavior. By histology, large cell carcinomas carry the worst prognosis, whereas typical carcinoids are associated with the longest survival, as well as lowest age at diagnosis & female sex, Atypical carcinoids bear more semblance to typical carcinoids than to small cell, large cell, or neuroendocrine carcinomas in their biology.

Tumor type	Median survival (months) [95% CI]
Large cell carcinoma	6.0 [5.9-6.1]
Small cell carcinoma	7.0 [6.9-7.1]
Neuroendocrine carcinoma	9.0 [8.5-9.5]
Atypical carcinoid	101.0 [80.8-121.2]
Typical carcinoid	201.0 [191.7-210.3]

4098 Poster Session (Board #209), Mon, 8:00 AM-11:30 AM

Bronchial neuroendocrine neoplasms: A Surveillance Epidemiology and End Results (SEER) database review of treatment outcomes. *First Author: Mark Andrew Lewis, MD Anderson Cancer Center, Sugar Land, TX*

Background: Bronchial neuroendocrine tumors (NENs) are a biologically heterogeneous group of malignancies with varied approaches to treatment. We queried the SEER database about outcomes of surgery and radiation. **Methods:** We identified 945331 cases in the SEER database with malignancies of the lung and extracted 187991 bronchial NENs – 130092 cases of small cell carcinoma, 44520 cases of large cell carcinoma, 3349 cases of neuroendocrine carcinoma (grades 3/4 [G3/4]), 9135 cases of typical bronchial carcinoid (grade 1 [G1]), and 895 cases of atypical bronchial carcinoid (grade 2 [G2]) – to examine clinical outcomes by treatment modality, including radiation in 82157 cases and surgery in 21352. **Results:** Surgical intervention on the primary NEN became less frequent as SEER stage become more extensive; operations were performed in 56.0% of cases of localized disease, 19.9% of regional disease, and 4.5% of distant disease. Proportionately more surgery was performed on lower-grade histologies (e.g. 84% of all-stage G1 NENs vs. 27% of large cell carcinomas). Significantly higher median survivals were seen across all SEER stages and histologies with surgical intervention vs. none (e.g. $>$ 240 vs. 68 mos. for localized G1 NENs, $p < .001$). Across SEER stages, large cell carcinoma was the histology treated proportionately the most often with radiation, given to 52.3% of all cases, followed by 44.8% of small cell, 38.9% of G3/4 NENs, 15.3% of G2 NENs and 4.9 % of G1 NENs. Typical carcinoids did not benefit from radiation regardless of SEER stage, with the largest decrement in median survival in localized disease receiving radiation (37 mos.) vs. none (232 mos., $p < .001$). **Conclusions:** Patients undergoing surgery for bronchial NENs had longer survivals than those who did not undergo surgery, regardless of histology or SEER stage. G1 NENs treated with radiation had median survivals poorer than those who did not receive radiation. It is unclear if those patients receiving radiation had positive margins after surgery, initially inoperable disease, or other prognostic factors associated with worse outcomes. Nonetheless, there is no evidence of benefit for radiation administered to G1 NENs of any SEER stage.

4099 Poster Session (Board #210), Mon, 8:00 AM-11:30 AM

Identification of response predictors to capecitabine/temozolomide in metastatic pancreatic neuroendocrine tumors. *First Author: Jonathan R. Strosberg, Moffitt Cancer Center, Tampa, FL*

Background: Capecitabine and temozolomide are active in the treatment of metastatic pancreatic neuroendocrine tumors (pNETs), with response rates ranging from 30% to 70%. Several small retrospective series have suggested that MGMT deficiency may predict response to temozolomide, however expression of MGMT has not been validated as a predictive biomarker. Cytotoxic chemotherapy is thought to be most active in aggressive tumors, however the ki-67 index has not been formally evaluated as a predictive factor. It is unclear whether chromosomal instability (which correlates with alternate lengthening of telomeres) predicts response. **Methods:** 144 patients with pNET who underwent treatment with capecitabine/temozolomide were retrospectively evaluated for radiographic response. The predictive role of ki-67% and MGMT by immunoistochemestry as well as ALT activation by FISH was assessed on up to 59 evaluable archival specimens. Frequently altered genes in pNETs were also sequenced and their status was correlated to the radiographic response. **Results:** The ORR was 63%. Response to treatment was significantly higher in tumors with ki-67 $>$ 5% ($n = 28$) as compared to tumors with ki-67 $\leq$ 5% ($n = 31$) (ORR: 64% vs 29%; $p = 0.006$). MGMT status ($p = 0.358$) and ALT pathway activation ($p = 0.174$) were not predictive of response. **Conclusions:** pNETs with ki-67 $>$ 5% are more likely to respond to capecitabine/temozolomide. MGMT status appears to have no correlation with response.

4100 Poster Session (Board #211), Mon, 8:00 AM-11:30 AM

A phase II study of axitinib in advanced carcinoid tumors: Preliminary results. *First Author: Mauro Cives, Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Neuroendocrine tumors (NETs) are highly vascular neoplasms overexpressing VEGF as well as VEGFR. Axitinib is an inhibitor of receptor tyrosine kinases with picomolar potency against VEGFR-1, -2 and -3 and nanomolar potency against PDGFR-β. **Methods:** We performed a phase II trial of axitinib 5 mg twice daily in patients with unresectable or metastatic low to intermediate grade carcinoid tumors. Prior antiangiogenic therapy with a dedicated VEGF pathway inhibitor was not permitted. The primary endpoints were PFS and 12-month PFS rate. H_0= 12 mo PFS rate of 36% (corresponding to median PFS of 8.1 months); H_a= 12 mo PFS rate of 56.5% (corresponding to median PFS of 14.6 months). Preliminary findings are reported. **Results:** 30 patients were enrolled and assessable for toxicity; 22 were assessable for response. Primary sites included small intestine (19 patients), lung (3), unknown (3), colon (2), rectum (2), and thymus (1). 21 patients had low-grade and 9 patients had intermediate-grade tumors. Carcinoid syndrome was diagnosed in 16/30 patients. Median TTF was 8.99 months (SD $\pm$7.18) and the 12 mo PFS rate was 65% (SD $\pm$13%). Median PFS not yet determined due to small number of events. The 1-year OS rate was 93% (SD$\pm$4.9%). Best radiographic response was PR in 1/30 (3.3%) and stable disease in 21/30 (70%); 8/30 patients (27%) unevaluable due to toxicity (4/30) and consent withdrawn (4/30). Among 25 patients with baseline elevated chromogranin A levels, 4 (16%) experienced major reductions ($>$ 50%) of the tumor marker. 90% of patients experienced hypertension (any grade). Grade 3 and 4 hypertension were seen in 18 (60%) and 2 (7%) patients respectively. Hypertension led to treatment discontinuation in two cases, however, axitinib interruption prompted a fast recovery without sequelae. **Conclusions:** The 12 mo PFS rate associated with axitinib in advanced carcinoid tumors appears promising when compared to results observed in phase II studies of other antiangiogenic TKIs such as sunitinib or pazopanib. Although associated hypertension is common, axitinib treatment was overall well tolerated. Clinical trial information: NCT01435122.

4101 Poster Session (Board #212), Mon, 8:00 AM-11:30 AM

Randomized, phase III trial of adjuvant adefovir vs. therapeutic lamivudine in post-operative BCLC stage 0 or A HBV-related HCC: The Taiwan Cooperative Oncology Group T1206 study. *First Author: Li-Tzong Chen, National Institute of Cancer Research, National Health Research Institutes, Tainan City, Taiwan*

Background: To investigate the role of adjuvant anti-viral nucleoside in tertiary prevention of HCC relapse in post-operative BCLC stage 0 or A HBV-related HCC. **Methods:** Patients with curative resection of BCLC stage 0 or A and solitary tumor < 5 cm, HBV-related (HbsAg+/anti-HCV-) HCC were eligible. Accruals were stratified by HBV genotype (C vs. non-C) and serum viral titer (< 20,000 vs. > 20,000 IU/mL) and randomly assigned to receive either 3 years of adefovir treatment from study entry or observation alone, in which 18 months of lamivudine would be given when their HBV DNA titer > 20,000 IU/mL and ALT > 2.0 x UNL. The primary endpoint was late RFS. **Results:** Between April 2007 and August 2010 (early terminated because lamivudine was no longer the standard care for chronic HBV infection), a total of 117 patients were enrolled. The demographic characteristics were well-balanced between adefovir (N = 58) and control (N = 59) arms. At a median follow-up of 57.9 months, 53 (45.3%) had recurrence and 17 (14.5%) were deceased. The cumulative 5-year FRS and OS rates of ITT cohort were 52.6% and 86.4%, respectively. The median RFS were not reached yet in adefovir arm and 6.4 years in control arm; while the 5-year RFS rate in corresponding arm was 53.8% (95% confidence interval [CI], 38.8% to 66.6%) and 51.6% (95% CI, 37.4% to 64.0%), respectively (P = 0.692, log-rank test). In Cox's regression univariate analysis, only baseline HBeAg and HBV DNA titer significantly affected RFS, with a HR of 2.988 (95% CI: 1.489 - 5.994, p = 0.0021) and 1.916 (95% CI: 1.083 - 3.388, p = 0.0255), respectively. Late RFS in those with RFS > 2 years was also similar between two study arms. **Conclusions:** Despite earlier trials showed adjuvant anti-HBV nucleoside (*vs.* no treament) can significantly improve the RFS and OS in post-operative HBV-related HCC (JCO 2013 and Ann Surg 2015). In current study, 3 years of adjuvant adefovir did not reduce the postoperative recurrence as well as late recurrence of HBV-related HCC as compared to observation followed by lamivudine when their HBV DNA titer > 20,000 IU/mL and ALT > 2.0 x UNL. This study is registered at ClinicalTrials.gov, identifier NCT00455091 Clinical trial information: NCT00455091.

4102 Poster Session (Board #213), Mon, 8:00 AM-11:30 AM

Phase II studies of BEZ235 in patients with advanced pancreatic neuroendocrine tumors (pNET). *First Author: Ramon Salazar, Institut Català d'Oncologia-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain*

Background: The PI3K/AKT/mTOR signaling pathway is upregulated in pNET. Everolimus (EVE) is an mTOR inhibitor (mTORi) approved to treat advanced pNET, but resistance occurs. PI3K pathway activation is associated with mTORi resistance. The dual mTOR/PI3K inhibitor BEZ235 (BEZ) may provide enhanced antitumor effects. **Methods:** Ph II studies (Study [S]1 [NCT01628913]; S2 [NCT01658436]) investigated BEZ in patients (pts) with advanced pNET. S1 enrolled pts with disease progression within 12 months (mo) and no prior mTORi, who were randomized 1:1 to BEZ (400 mg BID) or EVE (10 mg QD). Stage 1 of S2 (single arm) enrolled pts with advanced pNET after mTORi failure, who received BEZ (400 or 300 mg BID [starting dose reduced]). Primary endpoint for S1 was progression-free survival (PFS) assessed only for descriptive purposes, and 16-week (wk) PFS rate for S2. Interim futility analysis was performed after stage 1 of S2 (31 pts observed ≥16 wk). Futility rejection criteria: ≥60% 16-wk PFS rate and ≥0.9 posterior probability of 16-wk PFS rate ≥40%. **Results:** At database lock, treatment discontinuation was 87% of pts in BEZ arm and 71% in EVE arm of S1, and 94% in S2, mainly due to progressive disease (S1: BEZ 36% vs EVE 45%; S2: 48%) and adverse events (AEs [S1: BEZ 39% vs EVE 16%; S2: 36%]). All-grade AEs regardless of study treatment relationship (≥35%) are listed. Median PFS in S1 was 8.2 mo (95% CI: 5.3–NE) and 10.8 mo (95% CI: 8.1–NE), for the BEZ and EVE arms, respectively; hazard ratio 1.53 (95% CI: 0.72–3.25). In S2, 16-wk PFS rate was 52% (90% CI: 35.7–64.3); posterior probability that 16-wk PFS rate is ≥40% was 0.9 (futility criteria met). **Conclusions:** BEZ as 1st- and 2nd-line (post-mTORi) therapy had limited clinical activity. S1 showed BEZ was not better tolerated than EVE; in S2, poor tolerability after EVE led to dose reduction. Clinical development of BEZ in pNET was terminated, but targeting the PI3K pathway warrants further exploration. Biochemical response data in S1 will be presented at the meeting. Clinical trial information: NCT01628913 and NCT01658436.

4103 Poster Session (Board #214), Mon, 8:00 AM-11:30 AM

Lanreotide depot/autogel (LAN) vs. placebo (PBO) for carcinoid syndrome (CS) in patients with neuroendocrine tumors (NETs): Subgroup analysis of the ELECT study. *First Author: Aaron Vinik, Eastern Virginia Medical School, Norfolk, VA*

Background: ELECT, a large phase 3 study of the long-acting somatostatin analog (SSA) LAN for symptomatic control of CS in NET patients showed significant improvement over PBO in % days with short-acting octreotide use as rescue medication. Here, we investigate reduction in use of rescue medication for LAN vs PBO in subgroups defined by baseline characteristics. **Methods:** Patients with histologically confirmed NETs and history of CS received double-blind LAN 120 mg (n=59) or PBO (n=56) every 4 wks for 16 wks, with access to short-acting octreotide for breakthrough symptoms (NCT00774930). Least-squares mean differences in % of days rescue octreotide use for LAN vs PBO were calculated by ANCOVA within subgroups. **Results:** The significant reduction for LAN vs PBO in rescue medication use in the overall population (Table; approximately one-third lower for LAN group relative to PBO group) was generally consistent with reductions favoring LAN over PBO across subgroups, except small subgroups in which CIs were wide (e.g. BMI ≥30). **Conclusions:** Beneficial effects of LAN for CS symptom control in NET patients are consistent regardless of baseline characteristics. Clinical trial information: NCT00774930.

		Short-acting octreotide use, % days*

4104 Poster Session (Board #215), Mon, 8:00 AM-11:30 AM

Lanreotide depot/autogel (LAN) in midgut neuroendocrine tumors (NETs): A subgroup analysis from the CLARINET study. *First Author: A. Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In CLARINET, progression-free survival (PFS) was significantly prolonged with the somatostatin analog LAN 120 mg vs. placebo in patients with metastatic grade 1 or 2 (Ki-67 <10%) non-functioning intestinal and pancreatic NETs (hazard ratio [HR] for progressive disease [PD]/death: 0.47 [95% CI: 0.30, 0.73]. Here, we more fully characterize treatment effects in the midgut subgroup (tumors of small intestine/appendix). **Methods:** CLARINET was a 96-week randomized double-blind trial. Patients received LAN 120 mg or placebo every 4 weeks, administered by deep subcutaneous injection (NCT00353496). Subgroup analyses were undertaken to investigate only the consistency of treatment effects as the study was not otherwise designed or powered for such analyses. **Results:** 73 patients with midgut NETs received LAN (n=33) or placebo (n=40). At baseline, mean age was 64 yrs, 34% had liver burdens >10% (19% with burdens >25%), 96% had stable disease, 88% had received no previous treatment, and 48% had undergone previous NET surgery. Median PFS in the midgut subgroup was not reached at study end with lanreotide vs. 21 months with placebo; treatment response was consistent in midgut NETs with liver tumor burdens above or below 10% (Table). Adverse events occurred at similar rates with lanreotide vs placebo (overall: 85 vs 93%; treatment-related: 42 vs 33%). Few patients on LAN or placebo had serious AEs (n=5 vs n=7; none treatment-related) or AE-related withdrawal (n=0 vs n=1). **Conclusions:** These data indicate antitumor effects and a favourable safety/tolerability profile that support LAN as a first-line midgut NET treatment. This is consistent with previous reports in the overall CLARINET study population. Clinical trial information: NCT00353496.

Midgut NET patients	N	LAN PFS*	PBO PFS*	Logrank p-value	HR (95% CI)
All	73	Not reached	85 wks	p=0.009	0.35 (0.16, 0.80)
Liver burden ≤10%	48	Not reached	98 wks	p=0.044	0.30 (0.08, 1.04)
Liver burden >10%	25	Not reached	60 wks	p=0.007	0.21 (0.06, 0.72)

*Median PFS estimated by Kaplan-Meier method.

4105 Poster Session (Board #216), Mon, 8:00 AM-11:30 AM

Low objective response and high toxicity to single-agent mitotane in patients with metastatic adrenocortical carcinoma (ACC): A 25 year experience at MSKCC. *First Author: Betty Y Lung, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ACC is a rare but devastating disease, with short life expectancy in the setting of metastatic, unresectable disease. Mitotane, an oral adrenocorticolytic agent, is often used as a systemic treatment though its therapeutic window is narrow. We retrospectively assessed outcomes of patients (pts) with metastatic ACC who received single-agent mitotane therapy to determine treatment toxicities and effectiveness. **Methods:** In this retrospective IRB-approved study, we identified 35 pts with metastatic ACC treated with single-agent mitotane at MSKCC from 3/15/1989-9/18/2014. All pts had follow-up at MSKCC and all imaging was reviewed according to RECIST 1.1 by reference radiologists. We reviewed pt demographics, clinical symptoms, toxicity (based on CTCAE Version 4), and treatment outcomes. **Results:** 35 pts were identified with mean age of 53 years (range, 23-87), 60% female. 18/35 tumors (51%) were functional: estradiol (n = 1), cortisol (n = 12), testosterone (n = 3), or both testosterone and cortisol (n = 2). Grade 3 toxicities were observed in 15 of the 35 pts (43%). Severe toxicities included anorexia (9%), depression (6%), fatigue (20%), rash (6%), nausea (11%), vomiting (11%), and abdominal pain (6%). Radiographic progression of disease occurred in 30 of 35 pts (86%) and 1 pt (3%) experienced clinical progression. 2 pts (6%) had a complete response, 1 pt (3%) had partial response, and 1 pt (3%) had stable disease. The 3 pts (9%) with response (CR+PR) were asymptomatic prior to initiating mitotane; all had low volume indolent disease limited to one site (1 pt lung only; 1 pt retroperitoneal LN; 1 pt liver). All 3 pts experienced grade 3 toxicities on mitotane requiring treatment interruption and/or discontinuation. **Conclusions:** Among pts with ACC treated with mitotane-based therapy, 43% experienced grade 3 toxicities and 89% experienced POD. Response was noted in only 9% of pts and came with significant toxicity. The tumors in these responders are currently undergoing next generation sequencing analysis and results will be reported at the annual meeting. More effective and less toxic therapies are desperately needed in this rare disease.

4106 Poster Session (Board #217), Mon, 8:00 AM-11:30 AM

Clinical diagnostic utility of a blood-based multi-transcriptome assay for gastroenteropancreatic disease. *First Author: Irvin Mark Modlin, Yale School of Medicine, New Haven, CT*

Background: Current blood-based biomarkers for the diagnosis and follow-up of neuroendocrine tumors (NETs) do not achieve acceptable metrics of sensitivity and specificity. We report the sensitivity and selectivity of the PCR-based test, the NETest, to detect tumors with reference to other benign and malignant gastrointestinal diseases. We report the utility of a 51 transcript peripheral blood signature, the NETest, in comparison to Chromogranin A (CgA) measurement in pancreatic NETs. **Methods:** One hundred and seventy nine cases (Set 1: gastrointestinal tumors: n= 81 including NETs (n= 41) and gastrointestinal carcinomas (n= 40); Set 2: pancreatic disease: n= 98 including NETs (n= 45), pancreatitis (n= 4), cysts (n= 31) and adenocarcinoma (n= 14)) were prospectively collected and analyzed by the NETest (disease activity index > 20% [0-100 score]) or by chromogranin A (CgA) ELISA to determine metrics for detecting small intestinal and pancreatic NETs. Marker gene expression (qPCR) and CgA (DAKO) were compared (χ^2, non-parametric) in Set 1. For Set 2, selectivity was assessed; sensitivity and specificity metrics were calculated for the entire cohort (n= 179). **Results:** Set 1: For intestinal disease, the accuracy of the NETest was 93% (all NETs positive, .CgA was positive in 80% but 29% (n= 7) of colorectal cancers were CgA positive and 3 (7.5%) colorectal tumors were NETest positive)). Set 2: For pancreatic disease, the NETest accuracy was 92% (96% NETs positive, 2 (6%) *intraductal papillary mucinous neoplasms (*IPMN) positive) while for CgA it was 56% (29% of pancreatic NETs were CgA positive). Overall, the NETest was significantly more sensitive than CgA for the detection of small intestinal (AUC 0.98±0.01 versus 0.75±0.06 $p<$ 0.0001) and pancreatic NETs (0.95±0.02 vs. 0.5±0.06, $p<$ 0.0001). When CgA was normal, The NETest was elevated (93%). **Conclusions:** This "real-world" study comparing NETs to unknown gastroenteropancreatic diseases demonstrates the sensitivity and specificity of a blood-based multianalyte NET gene transcript measurement for identifying small intestinal and pancreatic neuroendocrine tumor disease.

4107 Poster Session (Board #218), Mon, 8:00 AM-11:30 AM

Recurrence following surgical resection of gastroenteropancreatic neuroendocrine tumors (NETs): An analysis from the NCCN oncology outcomes database. *First Author: Katherine Van Loon, University of California, San Francisco, San Francisco, CA*

Background: Resection of gastroenteropancreatic NETs is known to prolong survival. Current NCCN guidelines recommend that complete surgical resection of the primary tumor and metastases should be performed if possible. However, large multicenter studies of recurrence patterns following resection have not been performed. **Methods:** Patients ≥18 years who presented to 7 participating NCCN institutions after 2004 with a new diagnosis of a small bowel, pancreas, or colorectal NET were included. All underwent complete (R0) resection of the primary tumor and of synchronous metastases if present. Descriptive statistics were used to determine recurrence rates. Kaplan-Meier estimates were used to calculate time-associated endpoints. Comparisons were assessed by the log-rank test. **Results:** Of 1,125 patients with small bowel, pancreas, or colorectal NETs in the database, 301 patients underwent R0 resection. 50% of patients included in the analysis were male, 88% were Caucasian, and 99% had an ECOG PS 0-1. The median age was 55 years (range 20-90); however, patients with a colorectal NET were younger (p<0.001). Median follow-up time from R0 resection was 62.1 months. Among patients with small bowel NET (n=110), 18% recurred. Among patients with pancreatic NET (n=141), 26% recurred. Among patients with colorectal NET (n=50), 10% recurred. The proportion of patients without recurrence and the proportion alive at 12, 24, 36, 48, and 60-month follow-up are below. Stratification according to stage will be presented. **Conclusions:** R0 resection was associated with variable risk of recurrence across subtypes during 5 years of follow-up. Greater than 90% of patients who underwent an R0 resection were alive at 5-year follow-up; similarly, the majority of patients were disease-free. Further inquiry into appropriate surveillance strategies following R0 resection is needed.

	Small bowel	Pancreas	Colon/rectum
Follow-up (months)		Proportion without recurrence following R0 resection (p=0.01)	
12	95%	96%	95%
24	93%	86%	90%
36	87%	74%	90%
48	83%	69%	90%
60	78%	62%	90%
		Proportion alive following R0 resection (p=0.5)	
12	98%	98%	100%
24	97%	96%	100%
36	92%	96%	96%
48	92%	95%	96%
60	92%	94%	96%

4108 Poster Session (Board #219), Mon, 8:00 AM-11:30 AM

Ramucirumab (RAM) as second-line treatment in patients (pts) with advanced hepatocellular carcinoma (HCC): Analysis of REACH pts by Child-Pugh (CP) score. *First Author: Andrew X. Zhu, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: REACH was a global, randomized, double-blind, phase III study evaluating the efficacy and safety of RAM as a single-agent treatment of pts with advanced HCC after prior sorafenib therapy. The primary outcome for the ITT population was presented at ESMO 2014. The overall survival (OS) HR for the ITT population (RAM 283; placebo [PBO] 282) was 0.866 (95% CI 0.717, 1.046; p = 0.1391). In pts with baseline alpha-fetoprotein (AFP) ≥ 400 ng/mL (RAM 119; PBO 131), OS HR was 0.67 (95% CI 0.51–0.90; p = 0.0059). **Methods**: Efficacy and safety of RAM based on CP score are presented for all pts enrolled in REACH inclusive of ITT (n = 565) and CP B (n = 78) population. **Results**: In REACH, pts with CP5 (N = 177 RAM, N = 180 PBO), CP6 (N = 108 RAM, N = 100 PBO), and CP7+8 (CPB) (N = 39 RAM, N = 39 PBO) were enrolled. Baseline pt characteristics were generally balanced between treatment arms by CP score. The table below shows OS, PFS, ORR and DCR according to CP score. The safety profile of RAM in pts with CP5 and CP6 was similar, and consistent with that observed in the ITT analysis of CP A pts. In pts with CP7+8 (CP B), an increase in liver events grade ≥ 3 was observed on the RAM vs PBO arm (56% vs 41%), including an increase in hepatic encephalopathy grade ≥ 3 (10% vs 0%). This observation led to exclusion of CP B pts from enrollment after 441 total pts were randomized during the study. **Conclusions**: A greater RAM treatment benefit was observed in pts with lower CP scores. In the CP B pt population, an increase in liver adverse events was observed for RAM, specifically hepatic encephalopathy. A consistent and clinically meaningful improvement in OS, regardless of CP score, was observed in pts with elevated baseline AFP levels (≥ 400 ng/mL). Clinical trial information: NCT01140347.

4109 Poster Session (Board #220), Mon, 8:00 AM-11:30 AM

A phase I/II study of bavituximab and sorafenib in advanced hepatocellular carcinoma (HCC). *First Author: Adam Charles Yopp, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Bavituximab, a first-in-class immunomodulator targeting phosphatidylserine (PS), a membrane lipid externalized on tumor and endothelial cells. In preclinical HCC models, sorafenib upregulated PS externalization providing more bavituximab targets altering the tumor environment from immunosuppressive to immunoreactive. **Methods:** In the 3+3 phase I trial, adults with advanced HCC, ECOG PS $\leq$ 2, and Child-Pugh class A or B7 received escalating doses of bavituximab weekly (0.3, 1, and 3 mg/kg) and sorafenib 400 mg bid for one 4-week cycle to determine the MTD of bavituximab. In the phase II trial with the same eligibility, patients received 3 mg/kg bavituximab and sorafenib until progression or toxicity. The primary endpoint was radiologic time to progression (TTP). Secondary endpoints included safety, 4-month progression free survival (PFS), overall survival (OS), and response rates. Correlative studies from pre- and post-treatment tumor biopsies included IHC analysis of immune infiltrates. **Results:** Ten patients were enrolled in the phase I trial without DLTs, demonstrating a MTD of 3 mg/kg of bavituximab and 400 mg PO of sorafenib. In the phase II trial, 38 patients were accrued, with 4 remaining on treatment at the time of this submission. Median follow-up is 6.1 months. Patient characteristics: median age: 60.5 years, male: 74%, HCV: 79%, macrovascular invasion: 84%, previous treatment: 40%, and metastases: 24%. Median TTP is 6.7 months (95%CI 4,14). Median OS is 6.2 months (95%CI 5,7). Four month PFS is 61% and two patients achieved partial response. Treatment related AEs include seven grade 3 but no grade 4 or 5 events. Most common all grade events were diarrhea (32%), fatigue (26%), and anorexia (24%). Six patients had tissue analyzed pre- and post-treatment, two of the six had significant increase tumor infiltration of CD4+, CD8+, and macrophages with a corresponding decrease in T regulatory cells. **Conclusions:** Bavituximab and sorafenib were well tolerated in advanced HCC. When compared with historical controls, combination therapy in a patient population with more unfavorable disease biology demonstrated an improvement in TTP and 4-month PFS. Combination therapy increased immune tumor infiltrates. Clinical trial information: NCT01264705.

4110 Poster Session (Board #221), Mon, 8:00 AM-11:30 AM

Prospective identification of potentially actionable molecular alterations in cancers of unknown primary. *First Author: Anna M. Varghese, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with cancers of unknown primary (CUP) represent a heterogeneous population, and the frequency of actionable molecular alterations in their tumors remains unknown. These patients are frequently excluded from most Phase II/III studies as most require a histologic diagnosis with a primary site of disease; consequently, little progress has been made in developing targeted therapies for these patients. **Methods:** We prospectively identified patients with CUP seen for initial consultation at MSKCC from 01/2013 through 11/2014. We excluded patients with a likely primary disease site based on subsequent pathologic and radiographic tests. Tumors and matched normal samples underwent testing by MSK-IMPACT, a comprehensive molecular profiling platform performed in a CLIA-compliant laboratory using targeted deep sequencing of 341 cancer-associated genes to identify sequence mutations, copy number alterations, and select rearrangements. We collected tumor histology and defined potentially actionable molecular alterations as those for which investigational or FDA-approved targeted agents exist. **Results:** Of 34 patients identified with CUP, pathologic review demonstrated 44% adenocarcinoma (15/34) and others, including carcinoma (Ca), squamous cell Ca, neuroendocrine Ca, and sarcoma. 334 alterations were identified with a median 7 alterations / patient (range 0-41). Alterations were seen most commonly in *TP53* (19/34), *CDKN2A* (7/34), *ARID1A* (7/34), *KRAS* (7/34), and *SMARCA4* (7/34). Potentially actionable alterations were present in 41% (14/34) of patients and included *BRAF* V600E, *AKT1* E17K, and *ERBB2* S310F, among others. Actionable alterations identified in 10 patients made them eligible for inclusion in targeted therapy studies available at our institution. Updated treatment and response information will be presented at the meeting. **Conclusions:** CUPs harbor potentially actionable mutations. Patients with CUPs might benefit from expanded treatment opportunities and possibly improved outcomes through increased access to clinical trials in which eligibility criteria is based on molecular status rather than histologic diagnosis based on a primary site of disease.

4111 Poster Session (Board #222), Mon, 8:00 AM-11:30 AM

Long-term outcomes of cytoreduction and HIPEC for malignant peritoneal mesothelioma. *First Author: Gleneara Elizabeth Bates, Mesothelioma Center Columbia College of Physicians and Surgeons New York-Presbyterian Hospital, New York, NY*

Background: The prognosis of malignant peritoneal mesothelioma (MPM) has improved over the past decade in patients undergoing operative extirpation and intraperitoneal chemotherapy (IC). This study investigates the largest reported cohort of patients operated on for MPM. **Methods:** Kaplan-Meier curves and univariate cox proportional hazards model was used to estimate survival and significant treatment and prognosis factors, for 195 patients who underwent cytoreductive surgery and or HIPEC treatment between 1995-2014; patients were not excluded for bicavity disease or for unresectable disease. **Results:** The median survival time was 3.21 years with (95% CI: 2.38- 5.53), with median follow-up of 3.44 years (SD = 3.4, minimum = 0.014 and maximum = 16.752) years from first operation. The mean age at diagnosis was 54.8 years [HR: 1.027 (95% CI: 1.012-1.042)] with 111 men (57%) and 84 women (43.1), with female gender having favorable survival [HR: 0.442 95% CI: 0.296-0.659)]. Asbestos exposure was reported in 77 patients (39.5%) with n = 80 (41.0%) having no known asbestos exposure and in 38 patients (19.5%) asbestos exposure was not documented. The majority of patients had epithelioid histology (n = 161(82.6%), with the remainder biphasic/sarcomatoid (n = 34, 17.4%), with increased risk of death with non-epithelioid histology [HR: 2.46(95%CI 1.59-3.82)], (P = 0.001). Of the 195 patients who received cytoreductive surgery, 71(36.1%) received 1 HIPEC treatment, while 124 (63.9%) received 2 HIPEC treatments, with completion of protocol having an associated favorable prognosis [HR: 0.161 (95%CI 0.109-0.237)] (p = 0.001). Of those who received a full treatment course of cytoreductive surgery and 2 HIPEC treatments, 66 (33.8% CI: 95%) were still alive at the median follow-up. **Conclusions:** This large cohort illustrates that long-term survival is possible in MPM, although there is continued significant decline after 3 years from diagnosis. While the treatment of MPM continues to evolve, a comprehensive treatment approach may give the best chance for long-term survival.

4112 Poster Session (Board #223), Mon, 8:00 AM-11:30 AM

Importance of tumor grade in stage III mucinous appendiceal carcinoma: An analysis of the SEER Database. *First Author: Olivia Fukui, Carolinas Healthcare System, Charlotte, NC*

Background: Appendiceal cancers are rare tumors with prognostic heterogeneity and treatment-responses dependent upon histologic characteristics. In the 7th edition AJCC manual, mucinous tumors were separated from non-mucinous. Histologic grade was used to distinguish stage IVa from IVb in mucinous tumors. We examined SEER data to investigate the impact of cancer grade on all stages of appendiceal cancer. **Methods:** We identified patients (pts) with primary appendiceal cancer from the SEER data. Disease-specific survival (DSS) was analyzed based on histologic subtype, stage, and grade. Hazards ratios were calculated using Cox models. Tumor grades were grouped according to AJCC criteria (Grade 1 vs. Grade 2 and above). **Results:** From 1988-2011 a total of 4491 appendiceal adenocarcinomas were identified in the SEER database; 2026 (45%) pts had mucinous histology and 1578 (35%) had non-mucinous histology. Tumor grade had no impact on DSS in stage I and II tumors. However, in Stage III and IV mucinous tumors higher tumor grade was significantly correlated with worse survival. In pts with Stage III mucinous disease, those with grade 1 tumors had significantly longer DSS than those with tumors $\geq$ grade 2, with 5-year survival of 75% vs. 44%, respectively (p = 0.02, HR 3.15, 95% CI 1.11 - 8.96). Survival for mucinous stage III grade 1 tumors was similar to stage II tumors. **Conclusions:** Tumor grade is a strong prognostic indicator in pts with stage III mucinous appendiceal carcinoma. We propose that tumor grade should be included in AJCC staging for stage III mucinous appendiceal cancers, and should not be limited to Stage IV disease as in the AJCC 7th staging manual. Continued investigation into the clinical implications of the observed difference in survival in patients with Stage III appendiceal mucinous adenocarcinoma is warranted, and may potentially alter adjuvant treatment recommendations in selected pts.

4113 Poster Session (Board #224), Mon, 8:00 AM-11:30 AM

Prognostic impact of different FDG-PET uptake according to histology in advanced gastric cancer. *First Author: Hong Jae Chon, Yonsei Cancer Center, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: This study aims to investigate the role of preoperative FDG-PET/CT as a prognostic factor in advanced gastric cancer (AGC). **Methods:** A total of 953 AGC patients who underwent FDG-PET/CT and subsequent curative surgical resection were enrolled from 2003. Afterward, 548 patients with pathologically proven T stage 3 or 4 were visually reassessed and, in patients with positive FDG-PET/CT findings, SUVmax were evaluated as prognostic factors according to histologic subtype for cancer recurrence and death. **Results:** Of 548 patients, 497 (90.1%) showed positive FDG-cancer uptake. In terms of WHO classification, well or moderately differentiated adenocarcinoma (WMD) demonstrated the highest mean SUVmax, followed by poorly differentiated (PD) and signet ring cell carcinoma (SRC) (WMD: 9.3; PD: 6.4; SRC: 4.8; $P < 0.001$). Based on Lauren's classification, intestinal type displayed significantly higher mean SUV_{max} than diffuse type (Intestinal: 8.5; Diffuse: 5.3; $P < 0.001$). While mean SUV_{max} of WMD or intestinal type GC were well correlated with primary tumor size (both $P < 0.001$), those of SRC or diffuse type GC were not well correlated. TNM stage was not associated with SUV_{max} regardless of histologic subtype. When patients were divided into two groups (low vs. high SUV_{max}) based on median SUV_{max}, High SUV_{max} group had significantly shorter disease-free survival (DFS; SRC: $P = 0.004$; Diffuse: $P < 0.001$) as well as shorter overall survival (OS; SRC: $P = 0.007$; Diffuse: $P < 0.001$) than low SUV_{max} group in SRC or diffuse type GC. However, WMD or intestinal type GC did not demonstrate significant survival difference between low and high SUV_{max} groups. Multivariate modeling confirmed that high SUV_{max} patients with diffuse type GC had a significantly increased risk of recurrence and death than those with low SUV_{max} after adjusting for age, sex, pathologic stage (DFS: HR, 1.73; $P < 0.001$; OS: HR, 1.84; $P < 0.006$). **Conclusions:** FDG uptake of gastric cancer is different according to histologic subtype.FDG PET/CT could provide prognostic information on the prognosis after surgical resection of gastric cancer in SRC or diffuse type GC.

4114 Poster Session (Board #225), Mon, 8:00 AM-11:30 AM

Safety, pharmacokinetics, pharmacodynamics, and antitumor activity of necuparanib combined with nab-paclitaxel and gemcitabine in patients with metastatic pancreatic cancer: Phase 1 results. *First Author: Eileen Mary O'Reilly, David M. Rubenstein Center for Pancreatic Cancer Research, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Preclinical studies have shown necuparanib (necu)'s ability to bind growth factors, adhesion molecules, and chemokines to inhibit tumor progression, invasion, metastasis, and angiogenesis. Necu is being evaluated in a phase I/II trial with nab-paclitaxel (nabP) + gemcitabine (gem) in patients (pts) with metastatic pancreatic cancer (ClinicalTrials.gov NCT01621243). Part A is an open-label safety/pharmacokinetic (PK)/pharmacodynamic (PD) study to determine a Part B dose; Part B will evaluate efficacy, safety, and PK/PD relative to nabP + gem. **Methods:** In Part A, necu was given as daily escalating s.c. doses in combination with i.v. 125 mg/m^2 nabP and 1000 mg/m^2 gem (Days 1, 8, 15 of each 28-day cycle). The necu start dose was 0.5 mg/kg, with escalation via a modified 3+3 design until the maximum tolerated dose (MTD) was determined. The protocol was amended to include nabP after 2 necu + gem cohorts were completed. **Results:** As of January 15, 2015, 39 pts in 7 cohorts (0.5 and 1 mg/kg + gem; 1, 2, 4, 6, and 5 mg/kg + nabP + gem) received necu. Two dose-limiting toxicities (DLTs) occurred: increased AST/ALT at 0.5 mg/kg necu (N = 1) and cellulitis at injection site at 6 mg/kg (N = 1). Mild aPTT increases were observed at 4-6 mg/kg. There were no increases in known AEs of chemotherapy across doses. PK data (C_{max}, AUC) increased linearly from 2 mg/kg. Release of heparin-binding proteins (e.g. HGF, a PD marker) from heparan sulfate stores increased with dose and plateaued at 4-5 mg/kg. Given the cellulitis and mild aPTT increases at 6 mg/kg, 5 mg/kg was considered MTD. 16 pts treated with necu + nabP + gem completed Cycle 1 and had ≥ 1 scan on treatment; 8 (50%) achieved RECIST partial response and 6 (38%) more achieved stable disease, for an overall disease control rate of 14/16 (88%). Of 15 CA19.9 evaluable pts, 15 (100%) had > 20%, 14 (93%) had > 50%, and 7 (47%) had > 90% decreases from baseline. **Conclusions:** The MTD was necu 5 mg/kg combined with nabP + gem. Acceptable tolerability and encouraging signals of activity were observed with the combination. These results supported the initiation of the randomized, double-blind, phase II trial. Clinical trial information: NCT01621243.

4115 Poster Session (Board #226), Mon, 8:00 AM-11:30 AM

A multicenter, phase II trial of preoperative gemcitabine and nab-paclitaxel for resectable pancreas cancer: The AGITG GAP study. *First Author: Andrew Barbour, University of Queensland, Brisbane, Australia*

Background: Recent pancreatic cancer (PC) series show 41% (95%CI 40-43%) of patients (pts) achieve an R0 resection (margin clearance ≥ 1mm). In neoadjuvant chemotherapy trials for resectable PC, only 54-89% undergo pancreatic resection with R0 rates of 74-80%. Nab-paclitaxel(nab-pacli) and gemcitabine(GEM) chemotherapy(CX) is an active regimen in metastatic disease. We aimed to determine feasibility and R0 resection rate of 85% with peri-operative nab-pacli and GEM for resectable PC. **Methods:** Pts with operable PC received 2 cycles of neo-adjuvant nab-pacli 125mg/m^2 followed by GEM 1000mg/m^{2}CX on days(D) 1, 8 and 15(28D cycle) followed by resection and then post-operative CX(4 cycles). **Results:** Forty-one pts were enrolled (2012-14). Median age = 65 (range 43-79), 41% male. Thirty-six (88%) pts underwent surgery, while five (12%) did not (2 disease progression, 2 refused surgery, 1 cholangitis). Only 4/36 (10%) had grade ¾ septic events, no grade ¾ pancreatic leak, and no treatment related deaths. Thirty pts had pancreatic resection (73%; 29 had evaluable cancer and 15/29 (52%) had grade 0-2 tumour regression; one did not have cancer on central pathology review). Six (15%) pts had unresectable disease at surgery. Pre-operative nab-pacli and GEM produced an R0 rate of 52% (15/29; 95%CI 34-69%) with a minimum 1mm margin and an R0 rate of 86% (25/29; 95%CI 68-96%) with a 0mm margin. 39/41 (95%) completed planned induction CX (although dose modifications/omission were required - mostly omission of D15). Post-operatively, eighteen pts (18/30, 60%) commenced CX, with 14/18 (78%) completing all 4 cycles of planned CX; whilst four pts commenced chemoradiation, but 2 withdrew due to disease progression. **Conclusions:** Pre-operative nab-pacli and GEM was delivered safely and achieved an R0 resection rate clinically significantly higher than the mean of surgical series using similar pathology criteria. Our pre-operative regimen was delivered to 95% of patients, but in contrast post-operative CX was less achievable with only 60% commencing treatment. Neoadjuvant nab-pacli and GEM is an encouraging strategy to improve outcomes in resectable PC and merits testing in a randomised setting. Clinical trial information: ACTRN12611000848909.

4116 Poster Session (Board #227), Mon, 8:00 AM-11:30 AM

Randomized phase II study of S-1 and concurrent radiotherapy with versus without induction chemotherapy of gemcitabine for locally advanced pancreatic cancer (JCOG1106). *First Author: Akira Fukutomi, Divison of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Most patients (pts) with locally advanced pancreatic cancer (LAPC) are treated with chemotherapy (CT) alone in Japan. Chemoradiotherapy (CRT) is also a treatment option, but the role of radiotherapy (RT) remains controversial. Recently, induction CT followed by CRT is recognized as one potentially promising strategy. The aim of this study is to evaluate the efficacy and safety of CRT with and without induction CT to determine which is more promising CRT strategy. **Methods:** LAPC pts with an ECOG PS of 0-1, aged 20-80, and adequate organ function were randomized to CRT (Arm A) or induction CT followed by CRT (Arm B). Pts in Arm A received RT (50.4 Gy/28 fr over 5.5 weeks) with concurrent S-1 (40 mg/m^2/dose, b.i.d. on the day of irradiation). Pts in Arm B received induction gemcitabine (GEM) (1,000 mg/m^2, iv, days 1, 8 and 15, every 4 weeks) for 12 weeks, and then, only pts with controlled disease received same CRT as Arm A. After CRT, GEM was continued until disease progression or unacceptable toxicity in both arms. Primary endpoint was overall survival (OS). The sample size was 100 to detect ≥10% difference in 1-year OS with a probability of at least 0.9. Arm B will be considered to be more promising if point estimate of hazard ratio (HR) of OS for Arm B to Arm A is smaller than 1.186. **Results:** From 12/2011 to 9/2013, 102 pts were randomized, but 2 pts were ineligible because of metastasis. Therefore, 100 pts (Arm A/B n=51/49) were evaluated in this analysis. 50 pts received CRT in Arm A, while 34 pts in Arm B. 1-year OS for Arm A/B were 66.7/69.3% (HR 1.16 [95%CI 0.71-1.89]; p=0.56), and 1-year PFS were 39.2/46.6% (HR 1.05 [0.68-1.61]; p=0.84). Incidences of grade 3/4 toxicities in Arm A/B were leukopenia 62/61%, neutropenia 54/57%, anemia 18/12%, thrombocytopenia 10/14%, anorexia 16/4%, fatigue 8/4%, nausea 8/2%, diarrhea 6/4%, gastroduodenal (GD) hemorrhage 8/6%, GD ulcer 6/4%, and biliary infection 20/27%. Two treatment-related deaths occurred in Arm A (pneumonitis, duodenal hemorrhage). **Conclusions:** Induction CT followed by CRT was considered more promising as the test arm for a subsequent phase III trial comparing with CT alone. Clinical trial information: 000006811.

4117 Poster Session (Board #228), Mon, 8:00 AM-11:30 AM

A phase II/III randomized study to compare the efficacy and safety of rigosertib plus gemcitabine versus gemcitabine alone in patients with previously untreated metastatic pancreatic cancer. *First Author: Aaron James Scott, University of Colorado Denver, Aurora, CO*

Background: Rigosertib (ON 01910.Na), a first-in-class Ras mimetic and small molecule inhibitor of multiple signaling pathways including polo-like kinase 1 (PLK1) and phosphoinositide 3-kinase (PI3K), has shown efficacy in preclinical pancreatic cancer models. In this study, rigosertib was assessed in combination with gemcitabine in patients with treatment-naïve metastatic pancreatic adenocarcinoma. **Methods:** Patients with metastatic adenocarcinoma of the pancreas were randomized in a 2:1 fashion to gemcitabine 1000 mg/m^2 weekly for 3 weeks of a 4-week cycle plus rigosertib 1800mg/m^2 via 2-hr continuous IV (CIV) infusions given twice weekly for 3 weeks of a 4-week cycle (RIG+GEM) versus gemcitabine 1000mg/m^2 weekly for 3 weeks in a 4-week cycle (GEM). **Results:** A total of 160 patients were enrolled globally and randomly assigned to RIG+GEM (106 patients) or GEM (54). The most common grade 3 or higher adverse events were neutropenia (8% in the RIG+GEM group vs. 6% in the GEM group), hyponatremia (17% vs. 4%), and anemia (8% vs. 4%). The primary outcome of the study, median overall survival (OS), was 6.1 months for RIG+GEM versus 6.4 months for GEM (hazard ratio (HR), 1.24; 95% confidence interval [CI], 0.85-1.81). The median progression-free survival (PFS) was 3.4 months for both groups (HR = 0.96; 95% CI, 0.68-1.36). The partial response rate by Response Evaluation Criteria in Solid Tumors (RECIST) v.1.1 was 19% versus 13% for RIG+GEM versus GEM, respectively. Of 64 tumor samples sent for molecular analysis, 47 were adequate for multiplex genetic testing and 41 were positive for mutations. The majority of cases had *KRAS* gene mutations (40/47, 85%). Other mutations detected included *TP53* (13 cases) and *PIK3CA*(1 case). No correlation between mutational status and efficacy was detected. **Conclusions:** The combination of RIG+GEM failed to demonstrate an improvement in survival or response compared to GEM in metastatic pancreatic adenocarcinoma. Rigosertib had a similar safety profile to that observed in other trials of the IV formulation. Clinical trial information: NCT01360853.

4118 Poster Session (Board #229), Mon, 8:00 AM-11:30 AM

A phase Ib study of the anti-cancer stem cell agent demcizumab (DEM) & gemcitabine (GEM) +/- paclitaxel protein bound particles (nab-paclitaxel) in pts with pancreatic cancer. *First Author: Manuel Hidalgo, Centro Integral Oncológico Clara Campal, Madrid, Spain*

Background: Delta-like ligand 4 (DLL4) activates the Notch pathway. DEM is a humanized IgG_2anti-DLL4 antibody that inhibits tumor growth & decreases cancer stem cell frequency in human tumor xenograft models. In addition, DEM has an antiangiogenic effect & synergistic activity when combined with GEM & nab-paclitaxel in pt derived xenograft models of pancreatic cancer. **Methods:** Pts with 1st line pancreatic cancer were enrolled. Pts in cohorts 1-3 received DEM (2.5 every 2 or 4 wks or 5 mg/kg every 4 wks including 3 truncated pts) & GEM 1000 mg/m^2 7 of 8 wks, then 3 of 4 wks. Pts in cohorts 4, 5 & 6 received truncated DEM (2.5, 3.5 or 5 mg/kg every 2 wks through Day 70) & nab-paclitaxel 125 mg/m^2 + gemcitabine 1000 mg/m^{2}3 of 4 wks. The primary objective was to determine the MTD. Other objectives were safety, efficacy, immunogenicity, PK & biomarkers. **Results:** 47 pts were enrolled; 8, 8, 8, 6, 8 & 9 pts received 2.5 mg/kg every 2 wks, 2.5 mg/kg every 4 wks, 5 mg/kg every 4 wks, 2.5 mg/kg every 2 wks (truncated), 5 mg/kg every 2 wks (truncated) & 3.5 mg/kg every 2 wks (truncated), respectively. Related AEs in $>$ 20% of pts were fatigue (38%), nausea (34%), vomiting (28%), decreased appetite (21%), hypertension (21%) & diarrhea (21%). Hypertension was managed with anti-hypertensives. Increased BNP is an early indicator of the cardiac effects of DEM & mildly elevated values were used to initiate cardioprotective therapy with an ACE inhibitor or carvedilol. One pt who received 5 mg/kg continuously developed reversible pulmonary hypertension & heart failure on day 143. As a result, DEM was limited to 70 days in cohorts 4, 5 & 6. In cohorts 1-3, 4 of 16 (25%) pts had a PR & 7 had SD. In cohorts 4, 5 & 6, 9 of 22 (41%) pts had a PR & 10 had SD. The median PFS for 2.5 & 5 mg/kg every 4 wks & 2.5 mg/kg, 2.5 mg/kg (truncated), 3.5 (truncated) & 5 mg/kg (truncated) every 2 wks were 1.7, 7, 3.4, 9.1, not reached & not reached, respectively. **Conclusions:** This therapy was generally well tolerated with fatigue, nausea & vomiting being the most common related AEs. Encouraging clinical activity was observed. Biomarker analysis showed pharmacodynamic modulation of the Notch pathway. Final data will be presented. Clinical trial information: NCT01189929.

4119 Poster Session (Board #231), Mon, 8:00 AM-11:30 AM

SWOG S1115: Randomized phase II trial of selumetinib (AZD6244; ARRY 142886) hydrogen sulfate (NSC-748727) and MK-2206 (NSC-749607) vs. mFOLFOX in pretreated patients (Pts) with metastatic pancreatic cancer. *First Author: Vincent M. Chung, City of Hope, Duarte, CA*

Background: Over 90% of pancreatic cancers (PC) have mutant *KRAS* that is at present not druggable. Activating mutations lead to signaling through RAF/MEK/ERK and PI3K/AKT/mTOR pathways leading to cell growth, proliferation and survival. Pre-clinical data suggest that simultaneously blockade of these pathways is effective in treating *KRAS*mutant tumors. Our trial evaluated this novel, molecularly targeted treatment approach in pancreatic cancer versus mFOLFOX chemotherapy. **Methods:** 113 pts (PS 0-1) with metastatic PC failing gemcitabine-based therapy were randomized to MK-2206 135 mg weekly plus selumetinib 100 mg daily (MS) or mFOLFOX6 (without bolus 5FU) every 2 weeks. Overall survival (OS) was the primary endpoint with secondary objectives evaluating toxicities, objective tumor response and progression free survival (PFS). **Results:** Pt characteristics and results are in the table. 34 pts had grade 3 toxicities in the MS arm vs. 19 in the mFOLFOX arm. The most common grade 3 toxicities in the MS arm include rash, mucositis, dehydration and fatigue while for mFOLFOX arm, hematologic toxicities, fatigue, nausea and vomiting. In the MS arm vs. mFOLFOX, there were 0 vs 3 pts with a partial response and 8 vs 9 pts with stable disease, respectively. Shorter survival was observed in the MS arm (median OS 4.0 vs 7.5 mos, hazard ratio (HR) 1.46, 95% CI 0.90-2.38; median PFS 2 mos for each, HR 1.43, 95% CI 0.93-2.20). Approximately 50% of the patients on the mFOLFOX arm went on to receive additional therapy as compared to 30% on the MS arm. **Conclusions:** MS did not improve OS in pts who previously failed gemcitabine chemotherapy. Collected tissue will be analyzed for potential biomarkers. Clinical trial information: NCT01658943.

Effectiveness and tolerability of maintenance capecitabine administrated to patients with metastatic pancreatic cancer treated with first line FOLFIRINOX. *First Author: Juliette Reure, Centre Antoine Lacassagne, Nice, France*

Background: Treating metastatic pancreatic cancer (MPC) remains a challenging issue. Significant improvement was achieved recently by combining 4 drugs with Folfirinox regimen at the cost of increased toxicities compared to Gemcitabine. Maintenance therapy is a growing concept used in many different types of cancer. Our retrospective analysis aims to evaluate effectiveness and tolerability of early maintenance capecitabine administrated to patients with MPC treated with first line Folfirinox. **Methods:** 103 patients treated for MPC between November 2009 and July 2014 were retrospectively identified. Among them, 31 patients initially treated with a minimum of 4 cycles of Folfirinox, without sign of progression, received maintenance therapy with capecitabine until progression. Upon first progression (PFS1), patients were retreated with Folfirinox until second progression (PFS2). Survival was estimated with Kaplan Meier method. **Results:** Median numbers of cycles achieved for Folfirinox and capecitabine were respectively 6 and 4.5. Initial median dose of capecitabine was 2000mg/m^2, we recorded dose reduction in 11 cases (35,4%), mostly due to cutaneous and digestive toxicities. Median overall survival (OS) was 19 months. Survival rates were 74% at 1 year (95% CI [0.59 to 0.91]) and 24% at 2 years (95% CI [0.12 to 0.47]). Median PFS1 was 11 months (95% CI [0.22 to 0.58]). 30 patients have relapsed during capecitabine treatment (96,7%). After disease progression, Folfirinox could be reintroduced in 14 cases. Other patients received FOLFIRI, Gemcitabine and Folfox due mainly to persistence of neuropathy and asthenia. Median PFS 2 was 16 months (95% CI [0.22 to 0.65]). **Conclusions:** Maintenance with capecitabine seems effective and safe without compromising Folfirinox efficacy and allows obtaining very promising overall and progression free survival. Role of maintenance therapy in MPC will soon be addressed in a French multicenter phaseII/III study. PANOPTIMOX/PRODIGE 35.

4121 Poster Session (Board #233), Mon, 8:00 AM-11:30 AM

A prospective, single-arm, phase I/II trial of RAS peptide vaccine TG01/GM-CSF and gemcitabine as adjuvant therapy for patients with resected pancreatic adenocarcinoma. *First Author: Daniel H. Palmer, University of Liverpool Cancer Research UK Centre, Liverpool, United Kingdom*

Background: TG01 targets oncogenic mutations in RAS genes that are present in 80-90% of pancreatic cancers. TG01 is a mixture of 7 RAS peptides and previously, as monotherapy in patients with pancreatic cancer, induced specific cellular immune responses in 100% of patients. This study evaluated safety and whether induced immune responses are maintained with standard adjuvant chemotherapy. **Methods:** Patients were eligible after an R0 or R1 pancreatic adenocarcinoma resection and expected to receive gemcitabine (1000 mg/m^2 for 3/4 weeks x 6 cycles) started within 12 weeks of surgery. For gemcitabine toxicity 5-FU/ leucovorin could be substituted. TG01 0.7 mg id was given on days 1, 3, 5, 8, 15, 22 and 2-weekly until end of chemotherapy, 4-weekly up to 1 year and 12-weekly thereafter. GM-CSF 0.03 mg id was given 15 minutes prior to TG01. TG01 was used for the DTH test. **Results:** 18 patients were included from 3 sites (Norway and UK). 6 patients are ongoing 3 to 50 weeks from the start of vaccinations. 5 patients were withdrawn due to recurrent disease, 1 for an unrelated death, 3 for related AEs and 2 for other reasons. 10 SAEs in 6 patients occurred; 3 related to gemcitabine (pulmonary infection and fever) and 2 related to TG01 (anaphylaxis) the others were unrelated to gemcitabine or GM-CSF/TG01. The main AEs related to GM-CSF/TG01 were local reactions in 4/18 patients (8 events), allergic reactions in 4/18 patients (6 events); one occurring before gemcitabine (Grade 1). Anaphylaxis only occurred after gemcitabine completion. Other adverse events were flu-like symptoms and single cases of fatigue, arthralgia, fever, nausea and vomiting. 14/16 patients (87.5%) had a positive DTH by week 11 persisting after gemcitabine and to date 7/8 patients (87.5%) generated positive T cell responses. **Conclusions:** TG01/ GM-CSF generated immune responses in 87.5% of patients with resected pancreatic cancer, these responses were maintained with chemotherapy and persisted with booster injections. The regimen was generally well tolerated although some late allergic reactions were seen. Clinical trial information: NCT02261714.

4122 Poster Session (Board #234), Mon, 8:00 AM-11:30 AM

DocOx (AIO-PK0106): A phase II trial with docetaxel and oxaliplatin as a second-line systemic therapy for patients with advanced and/or metastatic adenocarcinoma of the pancreas—Final results. *First Author: Thomas Jens Ettrich, Department of Internal Medicine I, University of Ulm, Ulm, Germany*

Background: Pancreatic ductal adenocarcinoma still remains a major cause of cancer related deaths in the western world. The current study was conducted to confirm the activity and feasibility of docetaxel/ oxaliplatin combination in 2nd-line treatment of advanced pancreatic ductal adenocarcinoma. **Methods:** Prospective single arm, non-randomized, multi-center, Simon's two stage phase II trial using docetaxel (75 mg/m2, 60 min, d 1) and oxaliplatin (80 mg/m2, 120 min, d 2) in 21-day cycles. Duration of the trial was scheduled up two 8 cycles. Primary endpoint was tumor response according to RECIST 1.0. Secondary endpoints were progression free survival, overall survival, safety/toxicity, QoL and clinical benefit. **Results:** Data represents the intention to treat analysis of 44 patients included between 2008 and 2012. The majority of patients received a gemcitabine based first-line chemotherapy (95.5%). The primary endpoint of tumor response was achieved in 15.9% (7 partial remissions, no complete remission), with a disease control rate of 48% after the first two treatment cycles. Median progression free survival was 7 weeks (CI 6-15.9 weeks) and overall survival 40 weeks (CI 20.4-56.4 weeks). No unexpected adverse events occured. The recorded AEs were mainly hematologic (neutropenia grade 3/4 63.6%, febrile neutropenia 4.6%), gastrointestinal (29.6% grade 3/4 AEs) and infectious (18.2% grade 3/4 AEs). **Conclusions:** In this single-arm 2nd-line trial for the treatment of advanced PDAC, the combination of docetaxel and oxaliplatin shows promising results comparable with other 2nd-line protocols such as OFF (oxaliplatin, 5-FU, leucovorin) or liposomal irinotecan (MM-398) plus 5-FU/leucovorin (NAPOLI 1-trial). Some patients seem to benefit particularly as indicated by long periods of treatment in this setting. Even after 8 cycles of treatment with DocOx, partial response was observed in 2 patients and stable disease in another 6 patients corresponding to a disease control rate of 18%. The toxicity profile was quite tolerable and comparable to other 2nd-line studies. Clinical trial information: NCT00690300 Clinical trial information: NCT00690300.

4123 Poster Session (Board #235), Mon, 8:00 AM-11:30 AM

Nab paclitaxel plus gemcitabine for metastatic pancreatic adenocarcinoma after failure of folfirinox: Results of an AGEO multicenter prospective cohort. *First Author: Alix Portal, Hopital Européen Georges Pompidou, Paris, France*

Background: Both Folfirinox and Nab-paclitaxel plus Gemcitabine showed a benefit in terms of survival in first-line treatment of metastatic pancreatic adenocarcinoma (MPA) when compared to gemcitabine. It could be of interest to use them consecutively, knowing that there is currently no standard for 2nd line treatments for MPA and that median Progression free survival (PFS) is consistently less than 4 months in this setting. The aim of this study was to evaluate the efficacy and tolerability of gemcitabine plus Nab-paclitaxel after Folfirinox failure in MPA. **Methods:** From February 2013 to July 2014, all consecutive patients (pts) from 12 French centers treated by Nab-paclitaxel plus Gemcitabine for a histologically proven MPA after failure of Folfirinox were prospectively recorded. Nab-paclitaxel plus Gemcitabine was delivered on days 1, 8, and 15 every 4 weeks, as previously reported, until disease progression, patient refusal or unacceptable toxicity **Results:** Nab-paclitaxel plus Gemcitabine was administered to 57 pts. They received a median number of 4 cycles (1–12). Disease control rate was 58% (n = 33) with a 18.5 % (n = 18) objective response rate (RECIST). Within the whole cohort, median overall survival (OS) was 8.8 months (95% CI: 6.2-9.7) and median PFS was 5.1 months (95% CI : 3.2-6.2). Since the start date of first line chemotherapy with Folfirinox, median OS was 18 months (95% CI: 16-21). No toxic death occured. Grade 3–4 toxicities were reported in 40% of patients and were neutropenia (12%), neurotoxicity (12%), asthenia (8%) and thrombocytopenia (8%). **Conclusions:** With median PFS and OS of respectively 5.1 and 8.8 months Nab-paclitaxel plus Gemcitabine seems promising with a manageable toxicity profile after folfirinox failure, in selected patients able to receive second line treatment for a MPA. These promising results have now to be confirmed in a phase III randomized trial.

4124 Poster Session (Board #236), Mon, 8:00 AM-11:30 AM

Multiplatform molecular profiling of pancreatic adenocarcinomas to identify BRCA1/2 mutations and PD-1/PD-L1 status with therapeutic implications. *First Author: Sherri Z. Millis, Caris Life Sciences, Phoenix, AZ*

Background: Pancreas adenocarcinoma (PAC) is a challenging disease with overall single digit 5-year survivorship. BRCA1 and BRCA2 germline mutations are associated with increased risk of PC. Recent retrospective studies have described response of BRCA patients to platinum agents and PARP inhibitors. Additionally, immune therapies targeting the programmed cell death pathway in other cancers have shown promise; evaluating the incidence of aberrations of these markers in PAC impact therapeutic decisions. **Methods:** 450 PAC's were evaluated at a commercial CLIA laboratory using a combination of sequencing (Sanger or next generation sequencing (NGS)) and protein expression (immunohistochemistry). BRCA1/2 mutations that could be germline or somatic, coincidence with other mutations identified in the tissue, and expression levels of PD-L1 and PD-1 tumor infiltrating lymphocytes (TIL's) were evaluated. **Results:** Mutations (MT) in BRCA1 and BRCA2 were identified in 5 and 17% percent of tissues, respectively. BRCA1 and BRCA2 MT had different rates of concurrence with other gene alterations, which was also different from the general PC population (table). Overexpression of PD-L1 and PD-1 TIL's were also identified in 7% and 37% of PAC cases, respectively. BRCA1 MT cases had a higher incidence of PD-1 TIL's, while BRCA2 MT cases had a higher percent of overexpressed PD-L1 than the overall population. **Conclusions:** The different frequencies of KRAS, TP53, PIK3CA and SMAD4 MT between the overall PAC population and BRCA MT populations may inform driver differences and may help select drugs and refine treatment decision making for certain patients. Evaluating the profiles of the BRCA MT populations with clinical outcomes will provide valuable insight into the clinical behavior in genomically defined subsets and may facilitate in developing rational combinations of targeted agents in PAC.

Biomarker MT	BRCA1 MT	BRCA2 MT	Overall PC Population
		% Coincidence	
APC	14	0	3
BRAF	0	0	1
KRAS	71	77	85
PIK3CA	14	0	3
SMAD4	0	10	16
TP53	43	60	59
PD-1	38	50	37
PD-L1	13	8	7

4125 Poster Session (Board #237), Mon, 8:00 AM-11:30 AM

A retrospective single institution review of 90 pancreatic adenosquamous cancer (PASC) patients (pts). *First Author: Jennifer Brooke Goldstein, The University of Texas MD Anderson Cancer Center, Medical Oncology Fellowship, Houston, TX*

Background: PASC is a rare and aggressive subset of pancreatic cancer. PASCs are more likely to have poorly differentiated histology and positive lymph nodes. No separate treatment guidelines exist for PASC, however platinum-based therapy (tx) is commonly used based on a few published case series. The molecular signature of PASC has been reported in small studies and mirrors that of pancreatic adenocarcinoma (PA), with genetic mutations commonly involving TP53, CDKN2A, KRAS and loss of SMAD4 and the recently reported UPF1. These genomic analyses have been limited to genes known to be important in PA. **Methods:** We retrospectively reviewed the medical records of pts with PASC that were seen at M.D. Anderson Cancer Center from 1990 to 2014. Pts were chosen based on a pathologic diagnosis of PASC either in the primary tumor or metastasis. Descriptive statistics and survival analysis were performed using Stata 13.1. **Results:** A total of 90 pts were identified as having PASC, 75 diagnosed from the primary tumor and 15 from a metastatic site. Median age was 65 years (40-86), 62% were male, and 67% had locally advanced or metastatic disease at presentation. The median overall survival (OS) was 8.8 mths [95%CI (6.8-10.3)]. Of 29 pts who underwent surgical resection, the median time to recurrence was 6.7 mths [95%CI (3.4-Not Estimable)]. First line platinum-based tx did not impact OS (HR 1.07, 95% CI 0.66-1.75, P=0.785). 6 pts had genomic testing performed. All 6 had mutations in codon 12 of KRAS (three G12D, two G12R, and one G12V), 4 had mutations in TP53, all at different loci. One pt had CDKN2A loss, while another had a point mutation in the gene. Additionally, 2 of 6 pts showed FGF 3 and 19 amplification. **Conclusions:** Our results demonstrate that PASC has a poor prognosis. Pts undergoing surgical resection are at a high risk for relapse and neoadjuvant tx may be utilized to stratify pts who would benefit from resection. Next generation sequencing of tumors show the classically described KRAS and TP53 mutations seen in PA, but a potentially novel amplification of FGF 3 and 19, which could play a role in tumorigenesis. Further molecular profiling may demonstrate potential targets for tx not traditionally seen in PA.

4126 Poster Session (Board #238), Mon, 8:00 AM-11:30 AM

A quantitative analysis of funding for pancreatic cancer research. *First Author: Andrew Eugene Hendifar, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Although pancreatic cancer is the fourth most common cause of cancer death, it only receives approximately 2.5% of federal dollars distributed by the NCI. Recognizing the need for research support, patient advocacy groups, private institutions, and public institutions are working together to correct this funding gap. **Methods:** The International Cancer Research Partnership (ICRP) is an alliance of governmental and charitable organizations funding regional, national and international cancer research. The ICRP maintains a database of grants and awards that its members have provided. We interrogated the ICRP database to review the number of grants and their monetary value for pancreatic cancer and liver cancer ($>$ 50% relevance) awarded from 2002 to 2012 in the United States. In addition, we received private funding data from the Pancreatic Cancer Action Network, Lustgarten Foundation, and the American Association for Cancer Research. We compared private and public funding for pancreatic cancer and then benchmarked against the funding for liver cancer. Wilcoxon-Mann-Whitney test was used to compare private and public funding from 2002 to 2012. **Results:** Between 2002 and 2012 total funding for pancreatic cancer has increased nearly ten-fold from $11 million (60 grants) to $92 million (347 grants). Private and charitable funding makes up 27% of the total funding and the mean difference per award (public minus private) has decreased from $139,425 to $6,396 ($p < 0.001$). Funding for liver cancer has also increased over this time period, from $10.5 million to $59.5 million; however, the contribution from private and charitable organizations is significantly less as compared to pancreatic cancer (13% vs 27% $p < 0.001$). **Conclusions:** Funding for pancreatic cancer has increased significantly from 2002-2012. Private and charitable contributions comprise an increasingly larger portion of these funds. As federal funding for research has become increasingly constrained, private and charitable organizations have assumed a growing role in the funding landscape and are helping fill the gap.

4127 Poster Session (Board #239), Mon, 8:00 AM-11:30 AM

Discovery of new potentially actionable mutations in pancreatic ductal adenocarcinoma by next generation sequencing. *First Author: Mariacristina Di Marco, "L & A Seràgnoli" Department of Hematology and Oncological Sciences, University of Bologna, Bologna, Italy*

Background: Advances in chemotherapy, represented by FOLFIRINOX and Gemcitabine plus Nab-paclitaxel regimens, have resulted in a modest outcome improvement and Gamcitabine-based chemotherapy remains the treatment of choice especially in metastatic disease. Therefore, there is an urgent need to develop accurate markers of pre-invasive pancreatic neoplasms in order to help disease diagnosis at an earlier stage and to apply the best treatment. We aimed to better understand PDAC biology and genomic alterations of invasive phenotype by whole genome sequencing (RNAseq and WES). **Methods:** We analyzed 27 PDAC samples together with their normal counterpart by HiScanSQ Illumina platform (15/27 by RNASeq and 12/27 by WES). All data were mapped with BWA on hg19, SNVs were called with either SNVMix2 (RNA-seq) or MuTect (WES) while Indels were called with GATK. All variants were filtered on dbSNP, 1000genomes and compared with Cosmic data base. Non-synonymous SNVs were analyzed with PROVEAN and SIFT to predict mutation effect on protein function. **Results:** Deleterious point mutations or Indels were found in *KRAS* (92%), *TP53* (63%), *SMAD4* (48%), and *CDKN2A* (52%) genes. Components of mTOR signaling pathway (*PTEN*, *MTOR*, *PIK3IP1*) were found mutated in 50% of patients with poor prognosis PDAC suggesting that mTOR signaling alterations might promote the development of metastatic PDACs. Furthermore, we found inactivating mutations in *PARP* and *ATM* genes (26%), that could confer sensitivity to DNA cross-linking agents and to poly(ADP-ribose) polymerase inhibitors. Moreover, it has been elsewhere reported that ATM mutant neoplasms may be more sensitive to PARP and protein DNA-PKcs inhibitors. **Conclusions:** Our results demonstrated that PDACs are tumors harboring an high number of mutations. Beyond conventional mutated genes, we identified shared mutations in mTOR signaling components as well as *PARP* and *ATM* genes. These are potentially targetable mutations. In particular, mTOR signaling inhibition is a promising strategy to increase the therapeutic efficacy of conventional chemotherapeutic drugs. In conclusion, our results provide novel insights into PDACs target therapy.

4128 Poster Session (Board #240), Mon, 8:00 AM-11:30 AM

Dendritic cells generated with PDL-1 checkpoint blockade for treatment of advanced pancreatic cancer. *First Author: Jan Nesselhut, Institut Fuer Tumortherapie, Duderstadt, Germany*

Background: The efficacy of immunotherapy with monocyte derived dendritic cells (MoDC) is controlled via immune checkpoints, among them the PD-1/PDL-1 pathway. PDL-1 expressed on DC delivers an inhibitory signal to T-cells upon binding to PD-1 expressed on activated T-cells. Blocking of PDL-1 on DC may lead to improved efficacy of DC therapy for pancreatic cancer. **Methods:** After isolating monocytes from peripheral blood of $n = 44$ patients with stage IV pancreatic cancer, who failed first-line chemotherapy, antigen primed MoDC were generated using standard protocols. Patients included in the follow-up analysis received a minimum of 3 vaccines. 10 patients received MoDC modified by PDL-1 blockade after failure of previous DC therapy. PDL-1 blockade was performed by adding soluble CD80 or anti-PDL-1 to MoDC. Cytokine release and T-cell activity were measured exemplary using a mixed lymphocyte culture (MLC). **Results:** Median survival after onset of DC-therapy was 8 months with MoDC alone (18 months after primary diagnosis) with longest follow up of 36 months (49 months after primary diagnosis). We could induce a secondary stabilisation (4 to 8 months) in 5 from 10 patients, who failed to respond to previous DC therapy by using MoDC modified by PDL-1 blockade. Cytokine measurement using MLC, which was exemplarily performed, shows a change in the cytokine release upon PDL-1 blockade. **Conclusions:** An effective immune response requires both the inhibition of inhibitory signals and the activation of an antigen specific T-cell response. The efficacy of dendritic-cell based therapy may be improved by blockade of PDL-1 on dendritic cells to avoid an inhibitory signal and thus improve the T-cell specific response. Further investigations are necessary to ascertain whether the combination of systemic anti PD1-therapy with DC therapy using MoDC modified with PDL-1 blockade may further enhance therapeutic efficacy in solid tumors.

4129 Poster Session (Board #241), Mon, 8:00 AM-11:30 AM

Targeting Sema3D in pancreatic cancer: A novel therapeutic strategy. *First Author: Adrian Murphy, The Sidney Kimmel Comprehensive Cancer Center Johns Hopkins, Baltimore, MD*

Background: Pancreatic ductal adenocarcinoma (PDA) is known for its chemotherapy resistance and dismal survival rates. Little is known about the mechanisms of metastasis in PDA. We identified Annexin A2 (AnxA2), an essential mediator of metastasis using sera from patients with prolonged survival after GVAX treatment. AnxA2 regulates secretion of semaphorin3D (Sema3D) promoting invasion and metastasis of PDA cells. Sema3D and other axon guidance genes have been shown to be the cellular pathways most frequently altered in PDA. **Methods:** KPC mice, which spontaneously develop PDA, were generated with KRAS/P53 mutations. KPCA$^{-/-}$ mice were created by crossing AnxA2 knockouts with KPC mice. Cell lines were developed from primary tumors of these mice and gene expression profiling performed comparing KPC and KPCA$^{-/-}$ cells. Sema3D secretion was measured from KPC and KPCA$^{-/-}$ cells by ELISA. Anti-AnxA2 antibodies were used to see the effect of AnxA2 inhibition on Sema3D secretion. Sema3D knockdown KPC cells were used in a hemi-spleen model of liver metastasis to evaluate metastasis *in vivo*. Immunohistochemistry (IHC) was used to analyze Sema3D expression in resected human PDA tissue. **Results:** While PDA tumors spontaneously developed in both KPC and KPCA$^{-/-}$ mice, metastases were only seen in KPC (16/17) but not in KPCA$^{-/-}$ mice (0/23). Sema3D expression was down-regulated in KPCA$^{-/-}$ cells compared to KPC cells and Sema3D secretion was significantly lower from KPCA$^{-/-}$ cells (0.25 ng/ml) than KPC cells (17.5 ng/ml) ($p = 0.01$). Antibody blockade of AnxA2 suppressed Sema3D secretion in KPC cells suggesting its role in Sema3D secretion. Animals injected with KPC cells transfected with Sema3D-targeting shRNA had fewer metastases (5/13) and longer survival than mice injected with control (11/12) ($p = 0.01$). IHC on human PDA tumors showed that 15/20 patients with DFS < 1 year abundantly expressed Sema3D. Sema3D secretion can be measured in 96 well plates after 24 hours of incubation and this platform is optimized for drug testing. **Conclusions:** Sema3D secretion, which is regulated by AnxA2, is crucial for PDA metastasis. Targeting this pathway may lead to increased therapeutic options in PDA. We have established a platform to detect drugs that reduce Sema3D secretion.

TPS4131 Poster Session (Board #243a), Mon, 8:00 AM-11:30 AM

A randomized, double-blind, placebo-controlled phase III study of cisplatin plus a fluoropyrimidine with or without ramucirumab as first-line therapy in patients with metastatic gastric or gastroesophogeal junction (GEJ) adenocarcinoma (RAINFALL, NCT02314117). *First Author: Charles S. Fuchs, Dana-Farber Cancer Institute, Boston, MA*

Background: Ramucirumab, a human IgG1 monoclonal antibody directed to the ectodomain of VEGFR-2, prevents ligand binding to the receptor, blocking activation of downstream receptor-mediated pathways. Ramucirumab has demonstrated significant improvement in overall survival (OS) and progression-free survival (PFS) in 2 phase III registration studies (REGARD, RAINBOW) in patients in second-line treatment of gastric cancer. This global phase III trial will compare PFS in patients with HER2-negative, metastatic gastric or GEJ adenocarcinoma receiving ramucirumab with cisplatin/capecitabine (or 5-FU) versus placebo with cisplatin/capecitabine (or 5-FU) as first-line treatment. The trial is conducted in 139 sites in the Americas, Europe and Japan and is currently open to enrollment. **Methods:** Eligible patients will be randomized to receive a higher dose of ramucirumab (8mg/kg on days 1 and 8, based upon population pharmacokinetic modelling) or placebo with cisplatin/capecitabine every 21-day cycle until disease progression, unacceptable toxicity, or other withdrawal criteria are met. The primary endpoint is PFS; OS is the key secondary endpoint. Efficacy will be considered at 3 analysis points: futility analysis for PFS, primary analysis of PFS & final analysis of OS. A gatekeeping strategy will be used to assess PFS and OS. The OS endpoint will only be tested if the PFS test is significant to control Type I error at 5% across both endpoints. An exposure/safety analysis will be done after 30 patients in each cycle have started the 3rd cycle. The study has over 90% power to demonstrate a PFS advantage assuming HR = 0.70 and 80% power to demonstrate an OS advantage assuming HR = 0.77. Other secondary endpoints include PFS2 (the time from randomization to disease progression after the start of additional systemic anticancer treatment, or death from any cause, whichever occurs first), objective response rate, safety and quality of life. As of 1/28/2015, one patient has been enrolled in the US. Clinical trial information: NCT02314117.

TPS4132 Poster Session (Board #243b), Mon, 8:00 AM-11:30 AM

Perioperative chemotherapy and cytoreductive surgery with versus without HIPEC in gastric cancer with limited peritoneal metastases: A randomized phase III study (GASTRIPEC). *First Author: Beate Rau, Charite Campus Mitte University of Berlin, Berlin, Germany*

Background: Cytoreductive surgery (CRS) followed by hyperthermic intraperitoneal chemotherapy (HIPEC) can improve prognosis of patients with peritoneal metastases (PM) in colorectal cancer. In gastric cancer (GC) patients with PM this concept is under debate. Perioperative chemotherapy has been shown to improve survival in gastric cancer. In patients with limited PM systemic chemotherapy, a palliative gastrectomy and CRS may prolong survival compared to chemotherapy alone (Sun) in selected patients. It is unclear whether HIPEC has an additional benefit in this setting. The GASTRIPEC trial (NCT02158988) will clarify the role of HIPEC. **Methods:** It is an open label, multicenter randomized phase III trial. 180 patients with histological proven GC or GE-junction and PM will be included. All patients will receive 3 cycles of pre- and postoperative chemotherapy, dependent on the HER 2 status (Her 2 + ve: cisplatin, capecitabine, trastuzumab (CCT); HER 2 –ve: epirubicin, oxaliplatin, capecitabine (EOX). All patients will receive gastrectomy and peritonectomy. Patients randomized into **group B will be treated with additional intraoperative HIPEC** with Mitomycin C and Cisplatin for 60 minutes at 41-43°C. Main inclusion criteria: Histological proven PM in GC including adenocarcinoma of the GE-junction, no evidence of distant metastases in CT scan chest and abdomen other than PM (exception of Krukenberg tumors), estimation of peritoneal cancer index via staging laparoscopy or laparotomy, possibility of 80% tumor reduction at CRS, Karnofsky Index $>$ 70%, written informed consent. We hypothesize a hazard ratio for overall survival as the primary endpoint of 0.65 (9 months in None-HIPEC versus 13.8 months in HIPEC arm). With an alpha error of 0.05 and a power of 80 percent 180 patients need to be enrolled. Secondary endpoints are 30 days complication-rate, time to progression, quality of life, toxicity, adverse events. 18 patients are included since March 2014. Conclusion**:** The GASTRIPEC trial may help to clarify the role of HIPEC in addition to systemic chemotherapy, gastrectomy and CRS in GC patients with limited PM. Clinical trial information: NCT02158988.

TPS4133 Poster Session (Board #244a), Mon, 8:00 AM-11:30 AM

Perioperative chemotherapy vs. adjuvant chemotherapy for potentially resectable gastric cancer: A randomized and multicenter phase III study in locally advanced gastric cancer with D2 dissection. *First Author: Qun Zhao, The Fourth Hospital of Hebei Medical University, Shijiazhuang, China*

Background: The MAGIC and ACTS-GC/CLASSIC trials demonstrated benefit in resectable gastric cancer from both perioperative and postoperative adjuvant chemotherapy, although such management remains controversial for locally advanced gastric cancer (LAGC) after D2 lymph node dissection. **Methods:** A Phase III 1:1:1 randomized, open label, multicenter, trial comparing adjuvant (Arm A) or perioperative SOX (Arm B), and perioperative XELOX (Arm C) was initiated in February 2012, in T3/4, node+ gastric cancer patients after R0 resection. SOX included S-1 40 mg/m2 bid day 1-14, Oxaliplatin 130 mg/m2 on day 1, XELOX included Capecitabine 1000 mg/m2 bid day1-14, plus Oxaliplatin 130 mg/m2 on day, each cycle was 3 weeks, each patient received 8 cycles. Arm B and C patients received 2 cycles prior to surgery, and 6 cycles post op. Patients were stratified by tumor stage, ECOG PS and institution. The study was powered to show superiority of perioperative over adjuvant SOX, and non-inferiority of SOX to XELOX. Eligibility included histologically proven gastric cancer (including gastroesophageal junction), age 18-75, D2 or more extensive surgery with no residual disease, ECOG score ≤ 2, and no distant metastasis. Primary endpoint was R0-resection rate, secondary endpoints included overall survival, disease–free survival, safety. Up until January 2015, 638 subjects from 7 centers have been enrolled. Hematological toxicities included neutropenia, anemia, and thrombocytopenia. Non-hematological toxicities included fatigue, abnormal hepatic/renal function, neurotoxicity, and skin pigmentation, most adverse events were tolerable. No treatment related death was observed. Updated safety data will be presented. This study was registered with Clinicaltrials.gov, NCT01516944. Clinical trial information: NCT01516944.

TPS4134 Poster Session (Board #244b), Mon, 8:00 AM-11:30 AM

The Nationwide Cancer Genome Screening Projects for Gastrointestinal Cancer in Japan (SCRUM-Japan GI-SCREEN): Efficient identification of actionable cancer genome alterations in advanced colorectal and non-colorectal gastrointestinal cancer (GI Screen 2013-01-CRC and 2015-01-Non CRC). *First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Several cancer genome alterations have been identified as important targets for treatment. Example of possible candidates in gastrointestinal (GI) cancer include *BRAF* mutations in colorectal cancer (CRC) or MET amplification in gastric cancer, for which corresponding targeting agents showed attractive activity in early phase clinical trials. Efficient screening systems for these relatively minor cancer genome alterations are necessary for the successful development of targeted therapies. We initiated a nationwide screening project in Japan (GI-SCREEN) in February 2014 to detect rare mutations from CRC (GI-SCREEN 2013-01-CRC). The patient's population will be expanded to non-CRC GI cancer (SCRUM-Japan GI-SCREEN 2015-01-Non CRC). The objective of these consecutive projects is to evaluate the frequency of oncogenic genome alterations in advanced GI cancers and to facilitate the enrollment of patients in IND registration trials for targeted therapies as well as optimal individualized treatment. **Methods:** These prospective observational studies are designed to enroll patients with CRC or non-CRC GI cancer (gastric, esophageal, small-intestinal, appendiceal, anal carcinomas and neuroendocrine carcinoma) who are planned to receive systemic chemotherapy. Tumor samples from surgical or biopsy specimens have been examined by Luminex technology so far. Starting from February 2015, it will be redesigned to analyze more than 140 kinds of alterations in cancer genome, which included mutations, copy number variations, and gens fusions, using next generation sequencing of the Oncomine Cancer Research Panel (OCP) at a quality-controlled central laboratory. Patient characteristics and treatment outcome are also planned to be collected. The targeted sample size is 2000 patients with CRC and 1000 patients with non-CRC. As of January 26, 2015, a total of 844 CRC patients were enrolled and non-CRC study will be opened in April 2015 with planned participation of 18 major cancer centers in Japan. Clinical trial information: UMIN000016344.

TPS4135 Poster Session (Board #245a), Mon, 8:00 AM-11:30 AM

Multicohort phase II KEYNOTE-059 study of pembrolizumab (MK-3475) for recurrent or metastatic gastric or gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Charles S. Fuchs, Dana-Farber Cancer Institute, Boston, MA*

Background: Many tumors suppress immune control via the programmed death receptor 1 (PD-1) pathway. Pembrolizumab is an anti–PD-1 monoclonal antibody designed to block the interaction of PD-1 with its ligands PD-L1 and PD-L2. In 39 patients (pts) with PD-L1–positive metastatic gastric cancer enrolled in the phase I KEYNOTE-012 trial, 67% of whom had $\geq$ 2 prior lines of therapy, pembrolizumab 10 mg/kg every 2 wk (Q2W) provided a 22% confirmed ORR (RECIST v1.1, central review) and an acceptable safety profile. KEYNOTE-59 (NCT02335411) is an ongoing, international, 3-cohort, phase II study designed to further assess pembrolizumab in pts with gastric cancer. **Methods:** All cohorts of KEYNOTE-059 will enroll pts with recurrent or metastatic gastric or GEJ adenocarcinoma, $\geq$ 1 measurable lesion, and ECOG PS 0 or 1. All pts must provide a newly collected (preferred) or archival tumor biopsy sample for immunohistochemical determination of PD-L1 expression at a central laboratory. In cohort 1, up to 180 pts with any PD-L1 status who progressed on $\geq$ 2 prior chemotherapy regimens that included a fluoropyrimidine and platinum doublet and, if $HER2^+$, trastuzumab, will receive pembrolizumab 200 mg Q3W. In cohort 2, approximately 20 non-Asian and 20 Asian treatment-naive, $HER2^-$ pts with any PD-L1 status will receive pembrolizumab 200 mg Q3W plus infusional 5-FU or capecitabine and 6 cycles of cisplatin. In cohort 3, approximately 50 treatment-naive, $HER2^-$ pts with PD-L1–positive tumors will receive pembrolizumab 200 mg Q3W. In all cohorts, pembrolizumab will be given for 24 mo or until disease progression, intolerable toxicity, or investigator decision; treatment may be discontinued for complete response. Eligible pts may continue pembrolizumab beyond initial RECIST-defined progression. AEs will be monitored. Response will be assessed at wk 9 and every 6 wk thereafter per RECIST v1.1 and RECIST adapted to account for response patterns observed with immunotherapies. Primary end point is ORR per RECIST v1.1 by central review; secondary end points include PFS, OS, disease control rate, and duration of response. KEYNOTE-059 enrollment began in February 2015. Clinical trial information: NCT02335411.

TPS4136 Poster Session (Board #245b), Mon, 8:00 AM-11:30 AM

A randomized phase III study of neoadjuvant chemotherapy with docetaxel(D), oxaliplatin(O), and S-1(S) (DOS) followed by surgery and adjuvant S-1 vs. surgery and adjuvant S-1 for resectable advanced gastric cancer (PRODIGY). *First Author: Yoon-Koo Kang, Department of Oncology, Asan Medical Center, Seoul, South Korea*

Background: Although adjuvant chemotherapy with S-1 is now considered a standard after D2 resection in stage II or III locally advanced gastric cancer (LAGC) in Asia, many patients still experience recurrence of disease. Addition of neoadjuvant chemotherapy can be one method to further improve outcomes in LAGC. A previous phase II study of neoadjuvant DOS triplet regimen followed by surgery and adjuvant S-1 in LAGC demonstrated promising outcome with 98% of R0 resection rate, 90% of 2-year disease-free survival and manageable toxicity (Park et al, Cancer Chemother Pharmacol. 2013;72:815). On this background, a phase III randomized study has been initiated. **Methods:** Since Jan 2012, patients with newly diagnosed resectable gastric or gastroesophageal junction(GEJ) adenocarcinoma at clinical stage T2,3/N(+) or T4/N(any) by AJCC 7th edition have been recruited. Key exclusion criteria are Eastern Cooperative Oncology Group (ECOG) performance status $\geq$ 2, history of any malignancy other than gastric or GEJ cancer, or patients who have difficulties in oral ingestion/digestion/absorption. Patients are randomized 1:1 in open label to neoadjuvant DOS chemotherapy, surgery and then adjuvant chemotherapy (CSC) arm vs surgery and chemotherapy (SC) arm. Neoadjuvant DOS regimen consists of D 50mg/m^2 i.v. on day 1, O 100mg/m^2 i.v. on day 1 and S 40mg/m^2 twice orally on days 1-14 every 3 weeks for 3 cycles. Surgical method is D2 dissection. Adjuvant chemotherapy is S 40mg/m^2 twice orally on days 1-28 every 6 weeks for 8 cycles. Primary endpoint is 3 year progression free survival (PFS). Secondary endpoints include overall survival (OS), pathologic stage, R0 resection rate and safety profiles compared in two arms. With power of 80% and two-sided α- level of 5%, 244 events are required to detect 70% of 3 year PFS in CSC arm compared to 60% in SC arm (HR = 0.698). Considering 10% of drop-out rate, target enrollment is 530 subjects from 17 sites in Korea until July 2016. The first Independent Data Monitoring Committee meeting was held in October 2014 and the committee recommended continuing the study as planned. NCT01515748 Clinical trial information: NCT01515748.

TPS4137 Poster Session (Board #246a), Mon, 8:00 AM-11:30 AM

A randomized phase III study of adjuvant capecitabine vs observation in curatively resected stage IB (by AJCC 6th edition) gastric cancer (CATALYSIS; KCSG ST14-05). *First Author: Min-Hee Ryu, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: In stage I (by AJCC 6thedition) gastric cancer (GC), recurrence rate is generally low, and long-term outcomes are considered very good after curative resection. For this reason, only limited number of stage I GC patients (pts) were included in most previous studies of adjuvant treatment, and no stage I GC pts were included in ACTS-GC and CLASSIC trials which compared adjuvant chemotherapy vs observation after D2 dissection. However, a large scale retrospective study (Park et al, Gastric Cancer. 2015 Jan 23 [Epub ahead]) demonstrated that pts with stage IB GC with other risk factors showed high recurrence rate more than 20%. Considering more than 30% risk reduction of recurrence by adjuvant chemotherapy in stage II GC, stage I GC pts at high risk of recurrence may also get benefit from adjuvant chemotherapy. Moreover, in Korea, more than 50% of GC pts have stage I disease, which is increasing due to nationwide screening program. Based on this background, a phase III randomized study has been initiated and here we present the progress. **Methods:** Since November 2013, pts with curatively resected gastric or gastroesophageal junction adenocarcinoma at stage IB have been recruited from 12 sites in Korean Cancer Study Group (KCSG). Other key eligibility criteria include ECOG performance status 0-2, age of 18-74 years, at least one more other risk factors for recurrence-free survival (RFS) (i.e., age $\geq$ 65 years, male gender, lymphovascular invasion, and/or perineural invasion). Three to 6 weeks after curative surgery (D1 beta or D2 dissection), pts are randomized 1:1 in open label to adjuvant capecitabine arm vs observation arm. In adjuvant chemotherapy arm, pts receive capecitabine 1,250 mg/m^2 p.o. twice daily on days1-14 every 3 weeks for 8 cycles. Primary endpoint is 5-year RFS rate. Secondary endpoints include overall survival, safety, compliance, and pharmacokinetic study of capecitabine. With power of 80% and two-sided α level of 5%, 174 events are required to detect 7% difference in 5-year RFS rate, i.e., 85% in adjuvant capecitabine arm vs. 78% in observation arm (HR = 0.654). Considering 10% of drop-out rate, target enrollment is 870 subjects. NCT01917552 Clinical trial information: NCT01917552.

TPS4138 Poster Session (Board #246b), Mon, 8:00 AM-11:30 AM

A phase III study to compare efficacy and safety of DHP107 (oral paclitaxel) versus IV paclitaxel in patients with metastatic or recurrent gastric cancer after failure of first-line chemotherapy (DREAM). *First Author: Sang Cheul Oh, Korea University Guro Hospital, Seoul, South Korea*

Background: Paclitaxel is an antineoplastic agent widely used for treating cancer patients. However, only IV paclitaxel is available on the market. DHP107, a novel oral formulation, is composed of edible oils. Also, it is able to safely and effectively absorb paclitaxel to body via intestine without concomitant use of P-glycoprotein inhibitors. In the first-in-human study, DHP107 showed no dose limiting toxicity (DLT) at a single dose-escalating schedule and was considered safe and feasible in patients with advanced malignancies. In a phase I-IIa study which included advanced gastric cancer or metastatic solid tumors, the recommended dose (RD) of DHP107 was determined as 200mg/m^2 bid on days 1, 8, 15 at 4-weekly interval. In the study, the pharmacokinetic profiles of DHP107 were similar to IV paclitaxel, and 3 out of 10 gastric cancer patients who failed first-line chemotherapy showed partial response at the RD. Based on this background, a phase III randomized study has been initiated in gastric cancer and the progress is presenting here. **Methods:** Since April 2013, patients with metastatic or recurrent gastric cancer in second-line setting have been enrolled. Patients are randomized as 1:1 in open label to Arm A (DHP107) vs Arm B (IV paclitaxel). Arm A regimen consists of 200mg/m^2 po bid on day 1, 8, 15, every 4 weeks. In arm B, paclitaxel 175mg/m^2 was infused on day 1, every 3 weeks. Key inclusion criteria are ECOG performance status $\leq$ 2, failure of first-line chemotherapy including fluoropyrimidine and/or platinum, at least 1 measurable lesion by RECIST version 1.1. Response evaluation is performed every 6 ($\pm$1) weeks. Primary endpoint is progression free survival (PFS). Secondary endpoints include overall response rate, overall survival and safety. With power of 80% and one-sided type I error rate of 2.5%, 204 events are required to observe non-inferiority of DHP107 compared with IV paclitaxel in PFS. With 10% of drop-out rate, target enrollment is 238 subjects from 12 sites in Korea. For the efficacy analysis, test for non-inferiority will be performed sequentially, first with non-inferiority margin of 1.48, and then 1.25. Clinical trial information: NCT01839773.

TPS4139 Poster Session (Board #247a), Mon, 8:00 AM-11:30 AM

The BRIGHTER trial: A phase III randomized double-blind study of BBI608 + weekly paclitaxel versus placebo (PBO) + weekly paclitaxel in patients (pts) with pretreated advanced gastric and gastro-esophageal junction (GEJ) adenocarcinoma. *First Author: Manish A. Shah, Weill Cornell Medical College, New York, NY*

Background: BBI608 is an orally-administered first-in-class cancer stemness inhibitor. By targeting Stat3, BBI608 blocks cancer stem cell (CSC) self-renewal and survival through suppressing stemness pathways, including Stat3, β-catenin as well as immune checkpoint gene expression. Potent anti-tumor and anti-metastatic activity was observed in preclinical models, with marked synergy between BBI608 and paclitaxel. Moreover, cancer stemness genes, such as Stat3 and β-catenin, two poor prognostic biomarkers in many cancer types, predict sensitivity to BBI608. Encouraging anticancer activity in refractory gastric and GEJ adenocarcinoma was observed in a phase Ib (Stephenson et al, ASCO 2014 abstr) and a subsequent phase II study including 39 gastric or GEJ adenocarcinoma pts. On the basis of these data, a phase III trial is being conducted in North America, South America, Europe, Australia, and Asia. **Methods:** This study (ClinicalTrials.gov NCT02178956) will assess the efficacy of BBI608+paclitaxel *vs* PBO+paclitaxel in pts with pre-treated, advanced gastric and GEJ adenocarcinoma (target n=680). Pts must have failed one prior line of therapy containing a fluoropyrimidine/platinum doublet for unresectable disease. Pts are randomized in a 1:1 ratio to receive BBI608 480 mg or PBO twice daily continuously plus paclitaxel 80 mg/m^2 IV, weekly, for 3 of every 4 weeks. Treatment will continue until disease progression, death, intolerable toxicity, or patient/investigator decision to stop. Primary endpoint is overall survival (OS) in the general study population; secondary endpoints include progression free survival (PFS), OS and PFS in a predefined biomarker (β-catenin)-positive sub-population, objective response rate, disease control rate, and safety. In addition, blood, plasma, and archival tissue will be assessed for pharmacokinetic and biomarker analyses and quality of life will be measured. As of January 2015, 28 pts were randomized and recruitment is ongoing. Clinical trial information: NCT02178956.

TPS4140 Poster Session (Board #247b), Mon, 8:00 AM-11:30 AM

Adjuvant chemotherapy with gemcitabine and cisplatin compared to observation after curative intent resection of cholangiocarcinoma and muscle invasive gallbladder carcinoma (ACTICCA-1): A randomized, multidisciplinary, multinational phase III trial. *First Author: Alexander Stein, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany*

Background: Despite complete resection, disease free survival (DFS) and overall survival (OS) of patients with cholangiocarcinoma (CCA) or muscle invasive gallbladder carcinoma (GBCA) is poor. Thus, evaluation of adjuvant chemotherapy (CTx) in biliary tract cancer (BTC) in a large randomized trial is warranted. **Methods:** ACTICCA-1 is a phase III investigator initiated trial (EudraCT No 2012–005078-70). With respect to ABC-02 trial, cisplatin and gemcitabine for 24 weeks were selected as investigational treatment. Based on adjuvant trials in pancreatic cancer with a comparable postoperative recovery time, inclusion of patients within a maximum interval of 16 weeks between surgery and start of CTx was chosen. Due to the different prognosis and treatment susceptibility of gallbladder carcinoma, two separate cohorts for CCA and GBCA were included. Randomization will be stratified for lymph node status for both cohorts and localization for CCA. The primary endpoint is DFS and secondary endpoints include OS, safety, tolerability and quality of life. For CCA, DFS 24 months post surgery (DFSR@24) is expected to be 40% without CTx. CTx should increase DFS@24 to 55% to be regarded as clinically relevant. With a power of 80% and a significance level of 5%, 271 evaluable study patients have to be followed for 24-28 months to observe 166 events. For GBCA, adjuvant CTx should increase DFSR@24 from 35% to 55% to be relevant; thus, 154 evaluable patients and 90 events are needed. In both cohorts, randomization will be 1:1 with adjuvant CTx for 24 weeks and imaging every 12 weeks. The ACTICCA-1 trial has been started in Germany (funded by the Deutsche Krebshilfe and supported by medac) in 2014 and recently in the Netherlands (funded by the Dutch Cancer Society and supported by medac). Furthermore, Australia, Denmark and the United Kingdom (funded by Cancer Research UK) will particpate within the next months. **Conclusion:** The randomized, multinational, multidisciplinary phase III ACTICCA-1 trial will establish the role of adjuvant gemcitabine and cisplatin in patients with BTC. Clinical trial information: NCT02170090.

TPS4141 Poster Session (Board #248a), Mon, 8:00 AM-11:30 AM

Randomised phase III study of gemcitabine, cisplatin plus S-1 (GCS) compared with gemcitabine plus cisplatin (GC) for unresectable or recurrent biliary tract cancer (KHBO1401-MITSUBA). *First Author: Tatsuya Ioka, Hepatobiliary and Pancreatic Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan*

Background: Gemcitabine plus cisplatin (GC) therapy has been the standard palliative chemotherapy for patients with advanced biliary tract cancer (BTC). Our previous KHBO1002 trial, a single-arm phase II study of GC plus S-1 combination therapy (GCS), demonstrated a favorable survival benefit in BTC patients (Kanai M, et al. Cancer Chemother. Pharmacol. (2015) 75, 293-300). This phase III study aims to confirm the superiority of GCS to GC in terms of overall survival in patients with recurrent or unresectable BTC. **Methods:** Eligibility criteria include chemotherapy-naïve patients with recurrent or unresectable biliary tract adenocarcinoma (gallbladder, intrahepatic biliary tract, extrahepatic biliary tract, or ampulla of Vater), an Eastern Cooperative Oncology Group performance status of 0–2, and adequate organ function. Eligible patients are randomized into either GCS arm or GC arm. In the GCS arm, gemcitabine and cisplatin were administered intravenously at doses of 1,000 or 25 mg/m (2), respectively, on day 1, and oral S-1 was administered daily at a dose of 80 mg/m (2) on days 1-7 every 2 weeks. In the GC arm, 1000 mg/m2 of gemcitabine and 25 mg/m2 of cisplatin are infused on days 1 and 8 and repeated every 3 weeks. The primary endpoint is overall survival and the secondary endpoints are progression-free survival, %response rate, %planned dose, adverse events. The sample size was calculated to be 220 (110 patients per arm), assumed median survival time of 11.2 months in GC and of 16.2 months in GCS, an accrual period of 4 years, and a follow-up period of 1 year. Forty-nine institutions are participating in this study (NCT02182778□AUMIN 000014371). The study was activated in August 2014. Clinical trial information: NCT02182778.

TPS4142 Poster Session (Board #248b), Mon, 8:00 AM-11:30 AM

SWOG S1310: Randomized phase II trial of single agent MEK inhibitor trametinib vs. 5-fluorouracil or capecitabine in refractory advanced biliary cancer. *First Author: Richard D. Kim, Moffitt Cancer Center, Tampa, FL*

Background: No standard treatment options are available for patients with advanced biliary cancer (BC) who fail gemcitabine/platinum based regimen. The most commonly used second line regimens are 5-fluorouracil (5-FU) with leucovorin (LV), or capecitabine based on limited data. Trametinib is an orally bioavailable, potent, and specific allosteric inhibitor of MEK1/2. In cell lines, increased sensitivity to trametinib was observed especially in cells with mutations in the MAPK pathway. Aberrant activation of the Ras/Raf/MAPK pathway occurs in more than 60% of BC indicating the importance of these pathways. Furthermore other MEK inhibitors have been studied in advanced BC demonstrating promising results including complete responses (Bekkai-Saab et al JCO 2012, Finn RS GI ASCO 2011) **Methods: :** An open label phase II trial was designed to randomly assign patients to receive trametinib (2.0mg daily) versus 5-FU (400 mg/m^2 bolus and 2400 mg/m^2 infusion over 48 hours) with LV(400 mg/m^2) every 2 weeks or capecitabine (1000 mg/m^2 BID 14 days on 7 days off) in refractory BC. Eligible patients must have histologically or cytologically documented BC (excluding ampullary cancer) following progression of first line chemotherapy. The primary endpoint is overall survival. Secondary endpoints include progression-free survival and overall response rate. Additional endpoints will assess a 16 gene expression signature as a biomarker of MEK efficacy and to measure inflammatory cytokines. MRI or CT scan will also be obtained for all patients at the time of study entry and at 6 weeks into treatment to estimate lean soft tissue and fat mass weight gain according to treatment with trametinib. Analysis will compare randomized groups, stratified by 5FU/LV versus capecitabine and cholangiocarcinoma versus gall bladder. Assuming a one-sided type 1 error of 10%, 80% power, and 2 years of accrual with an additional year of follow-up, approximately 80 eligible patients (40 per arm) are needed to detect an improvement in median OS from 5 months to 8.25 months (corresponding to a 1.65 hazard ratio). As of Jan 2015, 33 of the planned 89 patients have been randomized. Clinical trial information: NCT 02042443.

TPS4143 Poster Session (Board #249a), Mon, 8:00 AM-11:30 AM

Randomized phase III study of etoposide plus cisplatin versus irinotecan plus cisplatin in advanced neuroendocrine carcinoma of the digestive system: A Japan Clinical Oncology Group study (JCOG1213). *First Author: Chigusa Morizane, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: According to the World Health Organization grading system for neuroendocrine neoplasms, neuroendocrine carcinoma (NEC) is a poorly differentiated, high-grade malignant tumor, including small and large cell carcinoma. The primary sites of NEC vary, and NEC arising in the digestive system accounts for 20%–68% of extra-pulmonary NEC. Treatment guidelines for advanced extra-pulmonary NEC recommend platinum-based chemotherapy regimens, which are suitable for small-cell lung carcinoma. We previously reported that etoposide plus cisplatin (EP) and irinotecan plus cisplatin (IP) are commonly used as community standard regimens for NEC of the digestive system in Japan (Yamaguchi et al. Cancer Sci. 2014;105(9)). However, no randomized controlled trial has ever been conducted, and it is unknown which is more effective. This phase III study compares EP and IP in terms of overall survival for patients with recurrent or unresectable NEC of the digestive system. **Methods:** Eligibility criteria include chemotherapy-naïve patients with recurrent or unresectable, histologically or cytologically confirmed NEC of the digestive system, an ECOG PS of 0-1, age of 20–75 years, and no history of platinum agents. Eligible patients are randomized into the EP arm or the IP arm. In the EP arm, 100 mg/m^2 of etoposide on days 1, 2, and 3 and 80 mg/m^2 of cisplatin on day 1 are infused every 3 weeks. In the IP arm, 60 mg/m^2 of irinotecan on days 1, 8, and 15 and 60 mg/m^2 of cisplatin on day 1 are infused every 4 weeks. The primary endpoint is overall survival. Due to scarcity of this disease, we set the sample size to be 140 (70 patients per arm), based on the assumption of median survival time (MST) of 8 months by the inferior regimen and 12 months by the superior regimen (6 years accrual, 1 year follow-up), with a two-sided alpha of 10%, a power of $\geq$ 70%. Seventy-eight institutions belonging to JCOG are participating in this study (UMIN000014795). This study was activated in Aug 2014 and the current enrollment is 17 as of Jan 2015. Clinical trial information: UMIN000014795.

TPS4144 Poster Session (Board #250a), Mon, 8:00 AM-11:30 AM

A randomized phase II trial of epigenetic therapy following adjuvant treatment in patients with resected pancreatic cancer and high risk for recurrence. *First Author: Kim Anna Reiss, Johns Hopkins Univ, Batimore, MD*

Background: Pancreatic ductal adenocarcinoma (PDAC) has the highest disease specific mortality-to-incidence ratio of any malignancy. Even patients who present with potentially curable disease have a median survival of $<$ 2 years. Those with positive nodes or margins at time of resection or with persistent CA 19-9 elevation have $>$ 90% chance of recurrence despite triple modality therapy. Epigenetic abnormalities in PDAC have been shown to increase malignant proliferation, metastasis and resistance to chemotherapy. Preclinical data has identified a number of specific genes that are commonly hypermethylated in PDAC and have an accompanying phenotypic change leading to a more aggressive tumor, greater chemotherapy resistance and increased epithelial mesenchymal transition. Methylation reversal with a DNA methyltransferase inhibitor (DNMTi) and subsequent gene retranscription has been preclinically demonstrated to result in a less aggressive PDAC phenotype. The effects of DNMTi therapy have been shown to persist even after the DNMTi exposure is removed and may prime for sensitization to chemotherapy, including gemcitabine and taxane therapies. We designed a randomized phase II study of oral 5-azacitidine (CC-486) for patients with resected PDAC and high risk of recurrence (node positive disease, margin-positive resection or rising CA 19-9 following resection). **Methods:** We have enrolled 11/60 patients. Patients must have completed adjuvant therapy (chemotherapy, radiation or a combination thereof) and have no evidence of recurrence at the time of enrollment. Patients are 1:1 randomized to receive standard-of-care (observation and surveillance) or CC-486 (300mg PO daily for days 1-21 of 28 day cycles) until there is evidence of recurrence. At recurrence, patients have fresh biopsies obtained. Correlative work evaluates for global methylation status as well as for the methylation status of a select group of genes known to be aberrantly methylated in PDAC and whose reversal may be associated with a phenotypic change in tumor behavior. These include: SLIT2/3, ROBO1/2, BRCA1, RAR-B, MGMT, hMLH1, EYA2, p16, RASF1A, FOXE1, NPTX2, Reprimo, ARID1B and Dkk3. Clinical trial information: NCT01845805.

TPS4145 Poster Session (Board #250b), Mon, 8:00 AM-11:30 AM

A randomized study of temozolomide or temozolomide and capecitabine in patients with advanced pancreatic neuroendocrine tumors: A trial of the ECOG-ACRIN Cancer Research Group (E2211). *First Author: Pamela L. Kunz, Stanford University School of Medicine, Stanford, CA*

Background: Patients with advanced pancreatic neuroendocrine tumors (NETs) have few treatment options that yield objective radiographic tumor regression. Somatostatin analogues and biologics yield prolonged progression-free survival (PFS) but minimal overall response rates (RRs). Historical studies reporting the highest RRs and longest PFS intervals include regimens with cytotoxic chemotherapy, such as streptozocin. Recent retrospective and small, prospective studies, suggest that temozolomide is similarly active but less toxic than streptozocin-based therapy. The proposed study will provide prospective data on response rates and progression-free survival associated with temozolomide or temozolomide in combination with capecitabine, and will also assess the relative efficacy of these two regimens. **Methods:** E2211 is a two-arm, multi-center, randomized phase II trial comparing temozolomide (200 mg/m2 PO QD days 1-5) vs. capecitabine (750 mg/m2 PO BID days 1-14) and temozolomide (200 mg/m2 PO QD days 10-14) in patients with advanced pancreatic NETs. Eligibility criteria include: metastatic or unresectable, low or intermediate grade pancreatic NETs, progression within preceeding 12 months, and no prior temozolomide, DTIC, capecitabine, or 5-FU therapy. Primary endpoint is PFS; secondary endpoints are Overall Survival (OS), RR, safety, and MGMT status as evaluated by immunohistochemistry and promoter methylation status. This study will require a minimum of 138 patients (or a maximum of 145 patients to allow for 5% ineligibility) to be accrued at the rate of 6 patients per month. With 23 months of accrual time and 13 months of follow-up (3 years total study time), this trial will have at least 81% power to detect a difference in median PFS between the treatment arms of 9 versus 14 months (hazard ratio of 0.64) using a two-sided log-rank test at the overall 0.20 significance level. First patient entered onto the study in August 2013. As of January 2015 a total of 67 (46% of target) patients have been recruited. Clinical trial information: NCT01824875. Clinical trial information: NCT01824875.

TPS4146 Poster Session (Board #251a), Mon, 8:00 AM-11:30 AM

JANUS 2: A phase III study of survival, tumor response, and symptom response with ruxolitinib plus capecitabine or placebo plus capecitabine in patients with advanced or metastatic pancreatic cancer (mPC) who failed or were intolerant to first-line chemotherapy. *First Author: Eileen Mary O'Reilly, David M. Rubenstein Center for Pancreatic Cancer Research, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The systemic inflammatory response characteristic of PC is mediated in part by JAK-STAT signaling and may contribute to local tumor growth and disease-related weight loss, decreased muscle mass, and poor performance status. In the phase II, randomized, double-blind RECAP study, the combination of the JAK1/JAK2 inhibitor ruxolitinib with capecitabine improved overall survival (OS) versus placebo + capecitabine in patients with mPC and elevated C-reactive protein (CRP) levels or a modified Glasgow Prognostic Score (mGPS) of 1 or 2 (Hurwitz et al. *J Clin Oncol*. 32:5s, 2014 [suppl; abstr 4000]). **Methods:** JANUS 2 is a phase III, randomized, double-blind, multicenter study. Eligible patients are ≥ 18 years of age and have histologically or cytologically confirmed pancreatic ductal adenocarcinoma, advanced and inoperable or metastatic disease; ECOG performance status of 0–2; only 1 prior chemotherapy regimen for advanced or metastatic disease (not including neoadjuvant and/or adjuvant therapy); no concurrent anticancer therapy; and an mGPS of 1 (CRP > 10 mg/L and albumin ≥ 35 g/L) or 2 (CRP > 10 mg/L and albumin < 35 g/L). Exclusion criteria are prior severe reaction to fluoropyrimidines, dihydropyrimidine dehydrogenase deficiency, or other sensitivity to 5-fluorouracil. Patients are randomized 1:1 to receive 21-day cycles of capecitabine 2000 mg/m^2/d (days 1−14) + ruxolitinib 15 mg twice-daily or capecitabine 2000 mg/m^2/d + placebo twice-daily. The primary endpoint is OS; secondary endpoints include progression-free survival, tumor response per RECIST 1.1, and duration of response. An exploratory endpoint is the assessment of change from baseline in PC symptoms using the Pancreatic Cancer Symptom Assessment Form electronic diary. Treatment will continue as long as it is tolerated and discontinuation criteria are not met. Patients who discontinue treatment will be followed for subsequent anticancer treatments and survival. Enrollment began in April 2014 and is ongoing. The planned enrollment is 270 patients. Clinical trial information: NCT02119663.

TPS4147 Poster Session (Board #251b), Mon, 8:00 AM-11:30 AM

JANUS 1: A phase 3, placebo-controlled study of ruxolitinib plus capecitabine in patients with advanced or metastatic pancreatic cancer (mPC) after failure or intolerance of first-line chemotherapy. *First Author: Herbert Hurwitz, Duke University Medical Center, Durham, NC*

Background: The systemic inflammatory response observed in PC is a negative prognostic factor and is mediated in part by JAK-STAT signaling. Treatment with the JAK1/JAK2 inhibitor ruxolitinib in combination with capecitabine was previously investigated as second-line therapy for patients with mPC and evidence of a systemic inflammatory response (elevated C-reactive protein [CRP] levels or a modified Glasgow Prognostic Score [mGPS] of 1 or 2) in the phase 2, randomized, double-blind RECAP study. Results showed improved overall survival (OS) relative to placebo + capecitabine (Hurwitz et al. *J Clin Oncol*. 32:5s, 2014 [suppl; abstr 4000]). Ruxolitinib has US Food and Drug Administration orphan drug status for the treatment of PC. **Methods:** JANUS 1 is a phase 3, international, multicenter, randomized, double-blind study. Eligible patients are ≥ 18 years of age with histologically or cytologically confirmed pancreatic adenocarcinoma that is advanced and inoperable or metastatic; have an ECOG performance status of 0–2; have received 1 prior chemotherapy regimen for advanced or metastatic PC not including neoadjuvant and/or adjuvant therapy; and have an mGPS of 1 (CRP > 10 mg/L and albumin ≥ 35 g/L) or 2 (CRP > 10 mg/L and albumin < 35 g/L). Patients are excluded for > 1 prior chemotherapy regimen for advanced or metastatic disease; radiation therapy; concurrent anticancer therapy; or prior severe reaction to fluoropyrimidines, dihydropyrimidine dehydrogenase deficiency, or other sensitivity to 5-fluorouracil. Patients are randomized 1:1 to receive 21-day cycles of capecitabine 2000 mg/m^2/d (days 1–14) + ruxolitinib 15 mg twice-daily or capecitabine 2000 mg/m^2/d + placebo twice-daily. The primary endpoint is OS. Secondary endpoints include progression-free survival, tumor response per RECIST 1.1, and duration of response. Treatment will continue as long as it is tolerated and discontinuation criteria are not met. Patients who discontinue treatment will be followed for subsequent anticancer treatments and survival. Enrollment was initiated in March 2014 and is ongoing. The planned enrollment is 310 patients. Clinical trial information: NCT02117479.

TPS4148 Poster Session (Board #252a), Mon, 8:00 AM-11:30 AM

Randomized phase II study of the safety, efficacy, and immune response of GVAX pancreas vaccine (with cyclophosphamide) and CRS-207 with or without nivolumab in patients with previously treated metastatic pancreatic adenocarcinoma (STELLAR). *First Author: Dung T. Le, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: A heterologous prime-boost vaccination strategy using GVAX pancreas vaccine and CRS-207 is showing promise in patients with pancreatic adenocarcinoma (PDA) (Le, JCO 2015). Furthermore, blockade of the immune checkpoint programmed death-1 (PD-1) is active in some cancers. Combinatorial strategies aimed at priming tumor antigen-specific T cells while simultaneously blocking negative checkpoints may be necessary to improve outcomes in PDA. GVAX is composed of allogeneic pancreatic cancer cells modified to express GM-CSF and induces a broad response against multiple tumor antigens. GVAX is given with low-dose cyclophosphamide (CY) to inhibit regulatory T cells. CRS-207 is live-attenuated *Listeria monocytogenes* engineered to express the tumor-associated antigen mesothelin. CRS-207 boosts responses against mesothelin and is unique in its capacity to stimulate both innate and adaptive immunity by activating T cells and NK cells. Nivolumab is an antibody against PD-1. **Methods:** This is a phase 2 study comparing CY/GVAX and CRS-207 with or without nivolumab in subjects with PDA who failed only one chemotherapy regimen for metastatic disease. Subjects are randomized in a 1:1 ratio to receive either 2 doses of CY/nivolumab/GVAX and 4 doses of nivolumab/CRS-207 (Arm A) or 2 doses of CY/GVAX and 4 doses of CRS-207 (Arm B). The primary objective is to compare OS between Arms A and B. Secondary/exploratory objectives include: assessment of safety and clinical responses (tumor assessments and CA19-9 levels) and correlation of *Lm*- and mesothelin-specific T cell and other immunological responses with OS, progression-free survival and best overall response. Clinical trial information: NCT02243371. Clinical trial information: NCT02243371.

TPS4149 Poster Session (Board #252b), Mon, 8:00 AM-11:30 AM

POLO: A randomized phase III trial of olaparib tablets in patients with metastatic pancreatic cancer (mPC) and a germline *BRCA1/2* mutation (g*BRCA*m) who have not progressed following first-line chemotherapy. *First Author: Hedy Lee Kindler, University of Chicago, Chicago, IL*

Background: Germline mutations in *BRCA1/2* define a molecular subgroup of PC that in some populations has a prevalence as high as 15%. g*BRCA*m-defective tumors are intrinsically sensitive to platinum and PARP inhibitors. In a Phase II trial (NCT01078662), 23 previously-treated g*BRCA*m mPC patients received the PARP inhibitor olaparib (Lynparza) as monotherapy. The tumor response rate was 22%, progression-free survival (PFS) was 4.6 months and overall survival (OS) was 9.8 months (Kaufman, JCO 2014). These data led to a double-blind, placebo-controlled Phase III trial (NCT02184195; POLO) of olaparib 'switch maintenance' monotherapy in patients with g*BRCA*m-associated mPC who have not progressed on first-line platinum chemotherapy. **Methods:** Eligible mPC patients must have documented disease control after completing at least 16 weeks of a first-line platinum-based regimen and must have a known or suspected deleterious g*BRCA*m, which will be confirmed by Integrated BRAC*Analysis* (Myriad Genetic Laboratories) during the trial. Patients are randomized (3:2) to olaparib (300 mg orally bid) or placebo. The primary endpoint is PFS, determined by blinded independent central review using RECIST 1.1. Disease will be assessed by CT scans at baseline, every 8 weeks for 40 weeks and every 12 weeks thereafter. Patients will receive treatment until objective disease progression unless toxicity is unacceptable. The primary PFS analysis will be performed after ~89 PFS events (~60% maturity) using a log-rank test. Secondary endpoints include OS, time from randomization to second progression (PFS2), HRQoL, safety and tolerability. Enrollment began in Q4 2014. The target number for randomization is ~145 patients across ~80 centers worldwide. Clinical trial information: NCT02184195.

TPS4150 Poster Session (Board #253a), Mon, 8:00 AM-11:30 AM

ACCEPT: Afatinib as cancer therapy for exocrine pancreatic tumors–An explorative randomized phase II trial. *First Author: Michael Haas, Department of Internal Medicine III and Comprehensive Cancer Center, Klinikum Grosshadern, Ludwig-Maximilians University of Munich, Munich, Germany*

Background: Metastatic pancreatic cancer still remains a disease difficult to treat. Since gemcitabine was established as a standard of care in the 1990s, the only targeted therapy which showed a moderate improvement in overall survival (OS) when applied along with gemcitabine was the tyrosine-kinase inhibitor erlotinib. Afatinib, a novel, oral irreversible ErbB family blocker has been approved for first-line-treatment in patients with non-small-cell lung cancer (NSCLC) bearing driver mutations of the epidermal-growth-factor-receptor (EGFR). Afatinib has shown superior progression-free survival and overall survival (in the prespecified subpopulation of Del 19 mutations) compared to standard of care chemotherapy. The combination of gemcitabine and afatinib was well tolerated with manageable adverse events (AEs) in patients with relapsed or refractory solid tumors in a phase I trial. **Methods:** ACCEPT is an open-label, controlled, randomized phase II trial for patients with histologically proven pancreatic adenocarcinoma previously untreated for metastatic disease. Patients are randomized in a 2:1 ratio to receive either gemcitabine 1000mg/m^2 intravenously over 30 minutes on days 1, 8 and 15 of a 28 day cycle in combination with oral afatinib, flat dose of 40mg daily, continuously (Arm A, experimental arm) vs. gemcitabine alone (Arm B). The study is designed to demonstrate a benefit in OS for the combination of gemcitabine and afatinib vs. gemcitabine alone. Estimating a hazard ratio (HR) of 0.60 for OS in favor of the experimental arm and expecting a drop-out rate of 15%, a total number of 117 patients to be recruited was calculated. The first patient was included in April 2013 and currently thirty high-volume centers are open for recruitment in Germany. The current recruitment status is 49/117 patients. The study has an explorative endpoint: tumor samples and peripheral blood are prospectively collected and centrally stored from all study participants. As part of this translational program analyses regarding tumor- and blood samples will focus on potential prognostic and predictive biomarkers associated with the EGFR pathway.Clinical trial information: NCT01728818 Clinical trial information: NCT01728818.

TPS4151 Poster Session (Board #253b), Mon, 8:00 AM-11:30 AM

Randomized phase II/III trial of neoadjuvant chemotherapy with gemcitabine and S-1 versus surgery-first for resectable pancreatic carcer (Prep-02/JSAP05). *First Author: Michiaki Unno, Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan*

Background: Despite the improvements in the surgery and postoperative adjuvant therapy for resected pancreatic adenocarcinoma (PDAC), its prognosis remains poor. Surgery-first and adjuvant increases survival for resected PDAC, but this strategy cannot be offered to a significant proportion of patients due to the unresectable cases found at laparotomy or postoperative morbidity. Neoadjuvant chemotherapy (NAC) with gemcitabine (GEM) and S1 is safe and effective strategy and has been reported 45.7% of 2-year survival rate in an intention-to-treat analysis. **Methods:** This is a prospective randomized phase II/III trial. Patients who planned resection with cytologically or histologically proven PDAC are eligible for this study. All patients must be at least 20 and under 80 years old with written informed consent. Abutment of major visceral arteries on radiological finding is considered exclusion criteria. Eligible patients will be randomized to surgery followed by adjuvant S1 (80 mg/m2/day for four weeks, repeated similarly every six weeks for a total of four courses) for 6 months or NAC (GEM 1000 mg/m2/week, S1 80 mg/m2/day) followed by surgery and the same adjuvant treatment. NAC is given a total of 4 doses of GEM and 4 weeks of S1 within 8 weeks. The primary study endpoint is resection rate for phase II (n = 80) and overall survival for phase III (n = 280). The secondary endpoints are adverse events and response of NAC, and recurrence-free survival. According to the sample size calculation, 180 patients in total need to be randomized to each treatment arm. For quality control, radiological staging and resected specimen will be centrally reviewed by dedicated radiologists and pathologists, respectively. In phase II part, no more than 14 cases of non-resection (90%CI: 22.6%-49.2%) in each arm (n = 40) is required to transit from phase II to phase III. Enrollment to cohort began in January 2013. **Discussion:**The Prep-02/JSAP05 study will provide the unbiased overall survival of all PDAC patients who were planned resection. Furthermore, this trial will determine the efficacy of NAC in PDAC and offers a potential for translational research. Clinical trial information: UMIN000009634.

TPS4152 Poster Session (Board #254a), Mon, 8:00 AM-11:30 AM

Randomized multicenter phase II/III study with adjuvant gemcitabine versus neoadjuvant/adjuvant FOLFIRINOX in resectable pancreatic cancer: The NEPAFOX trial. *First Author: Wael Hozaeel, Frankfurt A.M. Nordwest Krankenhaus GMBH, Frankfurt Am Main, Germany*

Background: The outcome of pancreatic cancer remains poor. Few patients (pts) can be assigned to surgery and 80% of resected pts experience a relapse. Currently, adjuvant ctx with gemcitabine is standard, but prognosis remains poor, with 5-year survival rates around 25%. FOLFIRINOX is superior to gemcitabine in the metastatic setting and may represent a valuable option in resectable stages. Therefore, we initiated this multicenter phase II/ III trial (NEPAFOX) to explore the efficacy of neoadjuvant FOLFIRINOX. **Methods:** This is a randomized phase II/III trial. Pts with locally limited, curatively resectable or borderline resectable adenocarcinoma of the pancreas without metastases are eligible. Eligible pts are randomized to (arm A) surgery followed by adjuvant gemcitabine (1000 mg/m^2) for 6 months or (arm B) perioperative FOLFIRINOX (irinotecan 180 mg/m^2, oxaliplatin 85 mg/m^2, 5-FU 400mg/m^2 bolus, 5-FU 2400 mg/m^2, sodium folinate 400 mg/m^2) with 6 cycles (12 weeks) pre and further 6 cycles post surgery. Staging includes CT of chest and abdomen and will be repeated after 3 cycles of neoadjuvant chemotherapy, before surgery and every 3 months after surgery. Follow-up will be two years for disease recurrence. As prophylaxis for neutropenia, pts will obtain Filgrastim (Nivestim) ($\leq$ 70 kg KG 30MioU/0,5 mL and $>$ 70 kg KG 48 MioU/0,5 mL) s.c. 1-0-0 d 5-7). The primary endpoint is median OS. Secondary endpoints are median PFS, perioperative morbidity and mortality, R0 resection rate, pathological complete remission and prevalence of iron deficiency anemia. 126 pts will be randomized 1:1. After an interims analysis, the trial can be continued as phase III (310 pts). Recruitment of the trial started in Nov 2014. Clinical trial information: NCT02172976.

TPS4153 Poster Session (Board #254b), Mon, 8:00 AM-11:30 AM

***nab*-paclitaxel (*nab*-P) plus gemcitabine (Gem) vs Gem alone as adjuvant treatment for resected pancreatic cancer (PC) in a phase III trial (APACT).** *First Author: Margaret A. Tempero, UC San Francisco Pancreas Center, San Francisco, CA*

Background: Adjuvant chemotherapy for resected PC has been shown to decrease recurrence and increase survival. Gem alone is a standard adjuvant therapy option. *nab*-P + Gem was superior to Gem alone as first-line treatment in a phase III trial in patients (pts) with metastatic PC, including the primary endpoint of overall survival (median, 8.5 vs 6.7 months; HR 0.72; $P < 0.001$). Toxicities were manageable. Based on these findings in the metastatic setting, the APACT trial will compare *nab*-P + Gem vs Gem alone in the adjuvant setting. **Methods:** Pts with histologically confirmed PC who underwent macroscopic complete resection (R0 or R1) within 12 weeks of randomization, with no evidence of metastasis at screening, are eligible for enrollment. Other eligibility criteria include staging of T1-3, N0-1, M0; Eastern Cooperative Oncology Group performance status of 0 or 1; acceptable hematologic function; CA19-9 $<$ 100 U/mL prior to randomization; and no prior neoadjuvant therapy or radiation for PC. Pts with neuroendocrine tumors, any other malignancy within 5 years of randomization, infection with HIV or hepatitis B or C, or prior neoadjuvant treatment or radiation therapy for PC are ineligible. The planned enrollment of $\approx$ 800 pts will allow 90% power to detect an HR for disease-free survival (DFS) of 0.74 at a 2-sided significance level of 0.05. One interim safety analysis and 2 interim efficacy analyses (the first for futility and the second for futility and efficacy) will be performed. Pt enrollment is ongoing. Clinical trial NCT01964430. Clinical trial information: NCT01964430.

Planned N	**$\approx$ 800**
Investigational arm	*nab*-P 125 mg/m^2 plus Gem 1000 mg/m^2 on days 1, 8, and 15 of each 28-day cycle $\times$ 6 cycles
Control arm	Gem 1000 mg/m^2 on days 1, 8, and 15 of each 28-day cycle $\times$ 6 cycles
Randomization	1:1
Stratification factors	Resection status (R0 vs R1) Nodal status (lymph node + vs lymph node −) Geographic region (North America vs Europe vs Australia vs Asia Pacific)
Primary endpoint	DFS (independently assessed)
Secondary endpoints	OS, safety
Exploratory endpoints	Molecular profiling of tumor tissue to correlate tumor heterogeneity with clinical outcome Quality of life as assessed by the EORTC questionnaires QLQ-C30 and QLQ-PAN26

4500 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Immunomodulatory activity of nivolumab in metastatic renal cell carcinoma (mRCC): Association of biomarkers with clinical outcomes. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: This prospective biomarker study in patients (pts) with mRCC treated with the programmed death-1 (PD-1) inhibitor antibody nivolumab assessed baseline (BL) and changes in serum chemokines, tumor T cell infiltrates (TIL), gene expression, T cell repertoire (TCR), and other biomarkers potentially associated with clinical outcomes (NCT01358721). **Methods:** Pts treated with 1–3 prior therapies received nivolumab 0.3, 2, or 10 mg/kg IV Q3W; treatment-naïve pts received 10 mg/kg IV Q3W. Biopsies were obtained at BL and cycle 2 day 8. Overall survival (OS) parameters were estimated by Kaplan-Meier method. Tumor PD-L1 expression was measured by immunohistochemistry (28-8 antibody; Dako). PD-L1 positivity was defined as ≥ 5% tumor membrane staining in ≥ 1 biopsy; tumor burden response as ≥ 20% reduction. Gene expression data were obtained on Affymetrix U219. **Results:** 91 pts were treated. Of 56 evaluable BL biopsies, 32% were PD-L1+. Median OS (95% CI) was 16.4 mo (10.1–not reached [NR]) for 0.3 mg/kg, NR for 2 mg/kg, 25.2 mo (12.0–NR) for 10 mg/kg, and NR for treatment-naïve pts. 1-yr and 2-yr OS rates (95% CI) were 75% (64–83) and 58% (46–68), respectively. OS by PD-L1 status is summarized (table). Pts with tumor burden response (n = 13) had ≥ 1.3-fold differential BL expression of 311 genes ($P < 0.01$, false discovery rate < 16%). Cell-mediated immune transcripts were elevated, including effector cell markers GZMB, NKG7, and CD7, NK/CD8-activating ligand MICB, inflammasome component AIM2, and activated macrophage marker IL-1a. Analysis of association between OS and serum chemokine levels, TCR and TIL is ongoing. **Conclusions:** Association of immune markers at BL with subsequent tumor burden response suggests that infiltrating immune activating cells may mediate response to nivolumab in mRCC pts. Consistent with the randomized phase II study of nivolumab in mRCC, OS appears longer in PD-L1+ pts but promising in both PD-L1+ and PD-L1– pts, especially when treatment-naïve. Clinical trial information: NCT01358721.

	PD-L1+ n = 18	PD-L1– n = 38
Median OS, mo (95% CI)		
Overall	NR	23.4 (13.1–33.3)
Previously treated	NR	22.3 (12.0–27.0)
Treatment-naïve	NR	33.3 (2.0–NR)
OS rate, % (95% CI)		
1-yr	71 (44–87)	71 (52–83)
2-yr	64 (37–82)	48 (30–64)

4501 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

A phase Ia study of MPDL3280A (anti-PDL1): Updated response and survival data in urothelial bladder cancer (UBC). *First Author: Daniel Peter Petrylak, Yale Cancer Center, New Haven, CT*

Background: PD-L1 may contribute to immune escape in UBC, a disease of high mutational complexity and immunogenicity. MPDL3280A was designed to restore T cell–mediated antitumor activity by blocking PD-L1 binding to PD-1 and B7.1 receptors. **Methods:** Previously treated, metastatic UBC pts were enrolled in an expansion cohort and received 15 mg/kg or 1200 mg IV MPDL3280A q3w. Efficacy-evaluable pts had ≥ 12 wk of follow-up (dosed by Jun 9, 2014; Sep 2, 2014 cutoff). ORR was assessed by RECIST v1.1 (unconfirmed), and archival biopsies were centrally evaluated for PD-L1 tumor-infiltrating immune cell (IC) expression by IHC. In-tumor gene expression and peripheral biomarkers were assessed as exploratory analyses in a subset of pts. **Results:** Updated analyses include 85 efficacy-evaluable, selectively enrolled UBC pts; 46 were PD-L1 IHC 2/3, 38 were IHC 0/1 and 1 had unknown IHC status. Median age was 66 y (36-89 y), and 75% were male. Baseline visceral mets were present in 77% of pts; 98% received ≥ 1 prior therapy (eg platinum in 93%). The ORR for IHC 2/3 pts was 46% (95% CI 31-61%; 6 CRs, 15 PRs), and for IHC 0/1 pts was 16% (95% CI 6-31%; 6 PRs) with median response durations not yet reached (IHC 2/3 pts, 0+ to 54+ wk; IHC 0/1 pts, 4+ to 33+ wk). Median PFS was 24 wk (95% CI 12-NE) for IHC 2/3 pts and 8 wk (95% CI 6-12 wk) for IHC 0/1 pts. 24-wk OS rates for IHC 2/3 and 0/1 pts were 85% (95% CI 74-96%) and 71% (95% CI 54-88%), respectively, with the medians not yet reached (3 to 72+ wk and 2+ to 51+ wk, respectively). Pts with visceral mets had ORRs of 32% (IHC 2/3: 3 CRs, 7 PRs; n = 31) and 12% (IHC 0/1: 4 PRs; n = 33). Median safety follow-up was 16 wk (3-73 wk). Drug-related AEs occurred in 64% of 87 safety-evaluable pts (most often fatigue, asthenia, nausea); 8% had a related G3-4 AE. 12% of pts had an immune-related AE. No related deaths were seen. Responders had lower myeloid gene expression at baseline (eg *Cox-2, IL8; IL1B*) and decreased circulating inflammatory and tumor markers (eg CRP; HCG, CA 19-9, CA-125) by cycle 2. **Conclusions:** MPDL3280A was well tolerated and had durable activity in UBC pts. Response, PFS and OS data are promising for IHC 2/3 and IHC 0/1 UBC pts vs historic controls. Response also correlated with in-tumor and blood-based biomarkers. Clinical trial information: NCT01375842.

4502 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Pembrolizumab (MK-3475) for advanced urothelial cancer: Updated results and biomarker analysis from KEYNOTE-012. *First Author: Elizabeth R. Plimack, Director, Genitourinary Clinical Research Fox Chase Cancer Center, Philadelphia, PA*

Background: Pembrolizumab, an anti–PD-1 antibody, demonstrated antitumor activity and acceptable safety in patients with recurrent or metastatic PD-L1–positive urothelial cancer enrolled in the phase 1b KEYNOTE-012 study (NCT01848834). We present updated efficacy and safety data for these patients, as well as an analysis of the relationship between PD-L1 expression and ORR. **Methods:** Eligible patients had recurrent, metastatic, or persistent urothelial cancer of the bladder, renal pelvis, ureter, or urethra. Patients received pembrolizumab 10 mg/kg every 2 weeks until complete response, progression, or unacceptable toxicity. PD-L1 expression was evaluated in baseline tumor samples at a central laboratory. Patients were enrolled if there were ≥1% PD-L1–positive cells in tumor nests or a PD-L1–positive band in stroma by a prototype immunohistochemistry assay. Samples were also analyzed with the clinical trial immunohistochemistry assay. Response was evaluated every 8 weeks per RECIST v1.1 by central review. **Results:** Thirty-three patients were enrolled (median age, 70 years; ≥3 prior therapies, 33%; visceral or osseous metastases, 66%). Median follow-up duration was 13 months (range, 1-16). Grade 3-4 drug-related adverse events occurred in 5 (15%) patients. In the 28 patients with measurable disease at baseline, ORR was 25% (95% CI 11-45), with 3 (11%) complete and 4 (14%) partial responses per central review. At the time of analysis, median duration of response had not been reached (range, 16-50+ weeks). The 12-month PFS rate was 19%. ORR in patients with tumors positive for PD-L1 expression as assessed with the clinical trial assay was 38%. **Conclusions:** Pembrolizumab demonstrates durable antitumor activity in patients with advanced urothelial cancer. A higher response rate was seen in patients with PD-L1 expression. Further analysis of the relationship between response and predictive biomarkers is ongoing. Clinical trial information: NCT01848834.

4503 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

First-line randomized phase II study of gemcitabine/cisplatin plus apatorsen or placebo in patients with advanced bladder cancer: The International Borealis-1 trial. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Heat shock protein 27 (Hsp27) is over-expressed in bladder cancer (BC) and postulated to increase tumor growth, metastasis, and chemotherapy resistance. Apatorsen (A; OGX-427), a novel antisense oligonucleotide, inhibits Hsp27 production and can potentially enhance the efficacy of chemotherapy. This trial was designed to evaluate efficacy and safety of A in combination with gemcitabine and cisplatin (GC) in patients (pts) with advanced BC. **Methods:** Chemotherapy naïve pts with advanced BC were randomized to GC+A 600 mg, GC+A 1000 mg, or GC + placebo. Pts were stratified by Karnofsky performance status (KPS) and visceral disease. The primary endpoint was overall survival (OS). Prognostic sub-groups were retrospectively evaluated using multiple variable modeling and hierarchical step down. A post hoc analysis was performed to explore the hypothesis that Hsp27 inhibition might be relevant to OS in poor prognosis disease. **Results:** A total of 179 pts were randomized/treated. Median OS was 15.2 months (m). When compared to GC + placebo, GC+A 600 demonstrated improved OS and PFS (OS HR = 0.856 and PFS HR = 0.830) versus GC+A 1000 (OS HR = 0.898; PFS HR = 0.927). Results from the post hoc model revealed that KPS, liver mets, alk phos, and hemoglobin were prognostic. A median prognostic score dichotomized pts into poor and good prognosis groups (50% each group). Pts with poor prognosis treated with GC+A 600 had a greater reduction in risk of death (HR = 0.717) than pts with good prognosis (HR = 1.44). The most significant prognostic factor was KPS ≤ 80% (35% pts in GC+A 600 vs GC) resulting in HR = 0.50 in favor of GC+A 600. Overall treatment was well tolerated. Most common Grade ≥ 3 adverse events (AEs) were neutropenia, anemia, thrombocytopenia and hypertension. Frequency of ≥ 3 Grade toxicities were: 89% (GC), 93% (GC+A 600) and 95% (GC+A 1000). GC+A 1000 had a higher treatment discontinuation rate due to AEs. **Conclusions:** Advanced BC pts with poor prognosis benefited from apatorsen 600mg combined with first line GC. Apatorsen may be impacting the intrinsic biology of patients with poor risk factors. Further evaluation is warranted in this pt population. Clinical trial information: NCT01454089.

4504 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Eribulin in advanced urothelial cancer (AUC) patients (pts): A California Cancer Consortium trial—NCI/CTEP 7435. *First Author: David I. Quinn, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: There is an unmet need for new agents in AUC. We previously reported that eribulin, a microtubule modulator derived from black Pacific sea sponge toxin, is highly active against metastatic UC in frontline and previously treated settings (ASCO 2010; ECC 2013). Here we report composite results of 150 AUC pts treated in a single phase II trial. **Methods:** Eligible pts with AUC, calculated CrCl ≥ 20mL/min were treated in 3 cohorts of first line, 2nd line with or without tubulin exposure. Eribulin 1.4mg/m2 IV on d1 & 8, q3 wks. In each cohort RR > 20% considered promising; 41 pts in a Simon 2-stage design. PFS & OS were secondary endpoints. **Results:** Pt characteristics: Median age 68 yrs (range: 25-90); Males: 71%; KPS ≥ 90%: 57%; Transitional cell histology: 90%; Lower tract 88%, Visceral mets 67%, Bajorin risk groups: 0: 30%, 1: 61%, 2: 9%. Bajorin risk group, visceral mets +/- KPS associated with OS & PFS ($p < 0.01$) while renal fn, age, line of therapy & prior tubulin exposure did not. Toxicities included Gr3/4 neutropenia: 57%, FN: 4%, Gr3 Hb: 13%, Gr1/2 sensory neuropathy: 45%. Age > 70 associated with Gr3+ neutropenia, no factors including tubulin exposure predicted neuropathy, developing any Gr3+ toxicity associated with age > 70 & KPS. **Conclusions:** Eribulin exceeded the prespecified benchmark in all strata with highly encouraging single agent activity in AUC. Phase III evaluation of eribulin in AUC is warranted. (NCT00365157; UM1 CA186717; U01 CA062505; P30 CA014089; P30 CA033572). Clinical trial information: NCT00365157.

Endpoint summary.

	Overall (n = 150)	Normal renal fn# (n = 121)	Moderate renal dysfn (n = 17)	Severe renal dysfn (n = 12)	First line (n = 52)	Tubulin naïve (n = 53)	Tubulin exposed (n = 45)
Median OS months (95%CI)	9.6 (7.6, 2.4)	9.2 (7.1,11.9)	16.8 (4.3,40.0)	11.3 (5.1,27.4)	11.3 (7.2,40.1)	9.6 (6.2,12.6)	8.7 (6.0,14.0)
Median PFS months (95%CI)	4.1 (3.5, 5.0)	4.0 (3.0, 5.0)	4.2 (2.8, 8.3)	6.1 (1.5,17.0)	4.2 (3.1, 5.6)	4.2 (2.8, 6.4)	3.9 (2.8, 5.1)
% Responded (95%CI)	32 (24, 40)	31 (22, 39)	41 (15, 67)	33 (2, 65)	42 (28, 56)	28 (16, 41)	24 (11, 38)

Normal renal fn: serum creat < 1.5 ULN or calc crcl > 60, Moderate 40-60, Severe 20-40

4505 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

A phase II/III, double-blind, randomized trial comparing maintenance lapatinib versus placebo after first line chemotherapy in HER1/2 positive metastatic bladder cancer patients. *First Author: Thomas Powles, Barts Cancer Institute, Barts Health and the Royal Free NHS Trust, London, United Kingdom*

Background: First-line chemotherapy for metastatic transitional cell carcinoma (TCC) is associated with clinical benefit. Further therapies are largely ineffective. The purpose of this trial was to establish if maintenance lapatinib after first-line chemotherapy was associated with clinical benefit in HER1/HER2 positive TCC patients. **Method:** During first-line chemotherapy, patients were screened for their HER1/HER2 status by centralised immunohistochemistry (IHC). HER1/2 positive patients with advanced/metastatic TCC who achieved clinical benefit after completing first-line chemotherapy (4-8 cycles) were potentially eligible for randomisation (1:1). The primary endpoint was to compare progression free survival (PFS). Secondary endpoints included adverse events (AE), overall survival (OS) and subset analysis for HER status. **Results:** Between 2007-2013, 455 patients were screened and 232 HER 1 or 2 positive patients were randomised to lapatinib (L) (n = 116) or placebo (P) (n = 116). 71.2% had visceral metastasis. 64.1% received cisplatin based chemotherapy. The median number of chemotherapy cycles was 6. The progression free survival for L and P was 4.6 months (95% CI: 2.8 – 5.4) and 5.3 months (95% CI: 3.0 – 5.9) respectively [HR: 1.04 (95% CI: 0.79 – 1.39) p = 0.77]. The overall survival for L and P was 12.6 months (95% CI: 9.5 – 16.2) and 11.9 months (95% CI: 10.6 – 15.8) respectively [HR = 0.98 (95% CI: 0.71 – 1.35) p = 0.89). The best response rate for L and P was 13.8% vs 7.8% (p = 0.14). The rate of grade 3-4 AEs for L and P was 24.3% vs. 15.5% (p = 0.09). Subset analysis of i) HER1/HER2 3+ positive patients on IHC ii) HER1 positive patients iii) HER2 positive patients showed no significant benefit in PFS (HR 0.94, 0.99 and 1.19 respectively: p > 0.05 for each) or OS (HR 0.76, 0.92 and 1.03 respectively: p > 0.05 for each) for lapatinib. A model predicting outcomes was constructed. **Conclusion:** This is the first personalised randomised trial in metastatic TCC. It shows maintenance lapatinib does not improve outcomes in HER1 or HER2 positive individuals. Clinical trial information: NCT00949455.

4506 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Randomized phase II, three-arm trial of lenvatinib (LEN), everolimus (EVE), and LEN+EVE in patients (pts) with metastatic renal cell carcinoma (mRCC). *First Author: Robert Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib (LEN), an oral tyrosine kinase inhibitor of VEGFR1–3, FGFR1–4, PDGFRα, RET, and KIT, in combination with EVE had manageable toxicity and antitumor activity in a phase 1 mRCC trial (*CCP* 2013;73:181). This phase II, open-label, multicenter study compared LEN, EVE, and LEN+EVE in pts with mRCC. **Methods**: Pts with progressive clear cell mRCC following 1 VEGF-targeted therapy were randomized 1:1:1 to LEN (24 mg/d), EVE (10 mg/d), or LEN+EVE (18+5 mg/d) in 28d cycles. The primary objective was progression-free survival (PFS) of LEN+EVE or LEN vs EVE. Secondary objectives included overall survival (OS), objective response rate (ORR), and safety. Primary analysis data cutoff was June 13, 2014. **Results**: One hundred and fifty-three pts were enrolled: 99% had one prior VEGF-targeted therapy, 1% had two; 18% had prior immunotherapy. LEN+EVE prolonged PFS vs EVE (Table; hazard ratio [HR] 0.40; 95% confidence interval [CI] 0.24–0.68; P < 0.001). LEN alone also prolonged PFS vs EVE (HR 0.61; 95% CI 0.38–0.98; P = 0.048). LEN+EVE and LEN improved ORR vs EVE (P < 0.001 and P = 0.007, respectively). Median duration of response (months) was longest in LEN+EVE, 13.1; LEN, 7.5; EVE, 8.5. OS analysis showed a trend favoring LEN+EVE vs EVE (HR 0.55; 95% CI 0.30–1.01; P = 0.062); this reached significance (HR 0.51; 95% CI 0.30–0.88; P = 0.024) in an updated analysis on Dec 10, 2014. For LEN+EVE, most common any-grade treatment-emergent adverse events (TEAEs) were diarrhea (84%), decreased appetite (51%), and fatigue (47%). Most common grade ≥ 3 TEAEs were diarrhea (20%), hypertension (14%), and fatigue (10%). **Conclusions**: LEN+EVE improved PFS and ORR versus EVE alone in this phase II trial of pts with mRCC following prior VEGF-targeted therapy. Updated OS also showed improvement with LEN+EVE. A phase III randomized trial of the combination in mRCC is planned. Clinical trial information: NCT01136733.

Primary analysis	LEN+EVE n = 51	LEN n = 52	EVE n = 50
Median survival, months (95% CI)			
PFS	14.6 (5.9–20.1)	7.4 (5.6–10.2)	5.5 (3.5–7.1)
OS	25.5 (20.8–25.5)	18.4 (13.3–NE)	17.5 (11.8–NE)

4507 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Final clinical results of a randomized phase II international trial of everolimus vs. sunitinib in patients with metastatic non-clear cell renal cell carcinoma (ASPEN). *First Author: Andrew J. Armstrong, Duke Cancer Institute, Duke University, Durham, NC*

Background: Limited evidence exists to guide therapeutic decisions in patients (pts) with metastatic non-clear cell RCC (NC-RCC). **Methods:** ASPEN was an international, randomized trial of pts with metastatic papillary, chromophobe, or unclassified histology; any MSKCC risk group, and no prior systemic therapy. Pts were randomized 1:1 to either everolimus (E) or sunitinib (S) until progression, stratified by histology and risk group. The primary endpoint was radiographic PFS by RECIST 1.1. With an expected 90 PFS events, there was 83% power to detect a 38% decrease in the hazard rate of progression/death assuming a two-sided type I error of 0.20 using a stratified log-rank statistic. **Results:** Between September 2010 and October 2013,we enrolled108 subjects across 17 sites and 3 countries. Median age was 63, 75/25% male/female, 66% papillary, 15% chromophobe, 19% unclassified; 27/59/14% good/intermediate/poor risk; 57 vs. 51 were randomized to E vs S. Treatment arms were well balanced at baseline. With 87 PFS events, 53 deaths, and 2 pts remaining on study treatment, S improved overall PFS, meeting the primary endpoint. S improved PFS in good/intermediate risk and papillary/unclassified pts, but E improved PFS in poor risk and chromophobe pts (**Table**). No unexpected safety signals emerged. **Conclusions:** Sunitinib prolonged rPFS as compared with everolimus in patients with NC-RCC, but resulted in higher rates of severe toxicity. This is the largest trial to date in NC-RCC and the first to demonstrate an mTOR-sensitive subgroup of NC-RCC pts as compared with VEGF inhibition in the front-line setting, including chromophobe and poor risk RCC pts. Clinical trial information: NCT01108445.

Endpoint	E (n=57)	S (N=51)	HR (80% CI) S as Reference	p-value

4508 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Dose analysis of ASSURE (E2805): Adjuvant sorafenib or sunitinib for unfavorable renal carcinoma, an ECOG-ACRIN-led, NCTN phase 3 trial. *First Author: Naomi B. Haas, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: E2805 is a phase III trial of sunitinib (SU), sorafenib (SOR) or placebo (PB) in patients (pts) with completely resected locally advanced renal cell carcinoma (RCC). There was no difference in DFS between the arms. Midway through the trial, starting doses were reduced. We analyzed the effect of this approach on drug dosing, toxicity and outcome. **Methods:** 1,943 pts stratified by risk, histology, ECOG PS, and nephrectomy type, were randomized to SU daily (4 of 6 wk cycle), SOR daily, or PB, for $\leq$ 1 yr. The primary endpoint was disease-free survival (DFS). After 1322 pts, starting doses of SU and SOR were reduced from 50 to 37.5 mg (25%) and from 800 to 400mg (50%), respectively, to mitigate the impact of pt discontinuation (DISC). Escalation to full dose after the first 2 cycles was mandatory when tolerated. Total dose of each agent over the entire yr, relative dose (actual/intended x 100), and number (no.) of cycles were related to DFS. **Results:** The redesign reduced the 3-month DISC rate from adverse events or refusal from 25%/30% in pts starting at full dose to 17%/11% in pts starting at reduced dose on SU/SOR (Gray's p = 0.01/0.0001). Total dose did not differ between groups on either SOR (p = 0.41) or SUN (p = 0.83). Most common grade $\geq$ 3 adverse events were hypertension, hand-foot reaction, rash and fatigue. There was no relationship between no. of cycles received or dose intensity and DFS. **Conclusions:** Dose titration reduced the DISC rate but not the total dose, with no impact on overall DFS by arm. Decreased DFS with reduced-dose SOR raises concern about the differential effects of multi-kinase inhibitors across a range of doses. Clinical trial information: NCT00326898.

Identification of efficacy biomarkers in a large metastatic renal cell carcinoma (mRCC) cohort through next generation sequencing (NGS): Results from RECORD-3. *First Author: James Hsieh, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Several large genomic analyses of RCC have recently identified prevalent mutations in epigenetic regulators with prognostic significance. However, the impact of these novel mutations on clinical outcomes of different classes of targeted therapies is unknown. We explored the potential correlations between somatic mutations and treatment efficacy in RECORD-3, a randomized phase 2 trial comparing 1st-line everolimus (EVE) then sunitinib (SUT) with 1st-line SUT then EVE at progression in 471 treatment-naïve mRCC patients (pts)(JCO 32:2764-72). **Methods:** Somatic mutations in exons of 341 cancer related genes were identified by an NGS assay (MSK IMPACT platform) at ~530X coverage on tumor (archival tissues, 260 pts) and matched germline (181 pts) DNA. Association between genotypes and 1stline PFS was assessed by Cox PH models and log-rank tests. **Results:** PBRM1 mutations were associated with longer PFS within EVE (median PFS [mPFS] 11.1 vs 5.3 months; unadjusted p=0.0031). Pts with PBRM1 mutations (41% of the cohort) derived comparable PFS benefit from EVE vs. SUT. KDM5C mutations were associated with longer PFS within SUT (mPFS 20.6 vs 8.4 months; unadjusted p=0.0511). Profiles of 227 clear cell RCC (ccRCC) pts showed a SETD2 mutation rate of 29%, substantially higher than the 10% seen in random tumor sample cohorts (842 pts, Nature Genetics 45:849-50), suggesting SETD2's role in ccRCC metastasis. **Conclusions:** Mutations in epigenetic regulators PBRM1 and KDM5C may represent novel mechanisms associated with sensitivity to EVE or SUT. These candidate predictive biomarkers could be considered as molecular entry criteria for prospective clinical studies in selecting mTORC1 or VEGFR inhibitors for genomically distinct mRCC pts. Clinical trial information: NCT00903175.

Association of genomic alterations with cisplatin resistance (cisR) in advanced germ cell tumors (aGCT). *First Author: Darren Richard Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: 20% of patients (pts) with aGCT progress after initial chemotherapy (chemo), displaying at least partial cisR. We sought to characterize the genetic alterations in aGCT and identify markers of cisR. **Methods**: aGCT pts with available tumor tissue (except pure teratoma or malignant transformation) were eligible. Cisplatin sensitive (cisS) pts had a CR to chemo +/- surgery (if pathology = necrosis or teratoma) or PR + negative tumor markers lasting one year or more. CisR pts had non-teratoma GCT at post-chemo surgery or at relapse. Cis status was inevaluable (IE) if followup (f/u) was too short (without progression) or standard initial chemo was not given. Whole exome sequencing (WES) in 19 pts (10 cisR, 9 cisS) identified several mutations and copy number changes, which we confirmed by targeted exon-capture sequencing of 341 cancer-related genes (MSK-IMPACT). MSK-IMPACT was then preformed for 69 additional pts. Results on all 88 pts were analyzed for associations with clinicopathologic features using Fisher's exact test and for progression-free survival (PFS) using Cox regression multivariable analysis (MVA). **Results:** Of 88 pts (65 nonseminoma [NS], 23 seminoma [SEM]), 23 (26%) were cisS, 59 (67%) cisR, and 6 (7%) IE. Primary site was testis in 77, mediastinum in 10, and retroperitoneum (RP) in 1. IGCCCG risk group was good in 39, intermediate in 9, and poor in 36 (4 IE). Forty-two primary and 46 metastatic tumors were sequenced; 47 were obtained pre- and 41 post-chemo. With median follow-up of 25 months, 59 pts progressed, with 10 dying from aGCT. On WES, cisR samples had more nonsynonymous mutations than cisS samples (mean 49 vs 15, p = 0.03). On MSK-IMPACT, *TP53* mutations were more common for pts with a mediastinal vs testis/RP primary (60 vs 3%, p < 0.0001) and KRAS mutations more common in SEM vs NS (26 vs 6%, p = 0.018). *TP53* mutations and *MDM2* amplifications were mutually exclusive and both occurred only in cisR pts (25 vs 0%, p = 0.008). On MVA adjusted for IGCCCG group, *TP53/MDM2*alteration independently predicted PFS (HR 2.6, 95%CI 1.4-4.8, p = 0.002). **Conclusions:** Genomic changes in aGCT differ by histology and primary site. As *TP53/MDM2* alterations correlate with cisR and predict PFS independent of IGCCCG risk, they may aid prognostic assessment.

4511 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM

Molecular drivers of the non-T cell-inflamed tumor microenvironment in urothelial bladder cancer. *First Author: Randy F. Sweis, University of Chicago, Chicago, IL*

Background: A T cell-inflamed tumor microenvironment is linked to response to immunotherapies and survival in malignancies including urothelial bladder cancer (UBC). We recently identified tumor-intrinsic β-catenin activation in melanoma as causally related to T cell exclusion. However, molecular mechanisms that prevent T cell infiltration in other cancers are incompletely defined. Using gene expression profiling and exome sequencing, we pursued targetable pathways associated with absence of T cells in UBC. **Methods:** RNA sequencing and exome somatic mutation data from 267 UBC samples in the cancer genome atlas were downloaded. Unsupervised hierarchical clustering was performed on 16,197 filtered genes. A 725-gene cluster contained 12 genes from a previously described T cell signature and was used to segregate samples. Differential gene expression was detected using ANOVA with a false discovery rate q < 0.01 and fold change > 2.0. Enriched pathways were identified by Ingenuity Pathways Analysis. Somatic variants were converted to VCF format and analyzed according to immune phenotype. **Results:** Expression of CD8A was positively correlated with inhibitory molecules PDL1, IDO1, FOXP3, TIM3, and LAG3 (all p < 0.0001). Based on a signature of T cell inflammation, 36% of bladder tumors showed a T cell-inflamed phenotype, 33% were non-inflamed, and the remainder intermediate. The non-inflamed group contained 730 over-expressed genes. Pathway analysis revealed the most significantly activated regulators were Wnt/β-catenin and peroxisome proliferator-activated receptor gamma (PPARG) (both p = 0.003). Exome mutation analysis revealed no difference in mutation number per patient for each group (p = 0.80). Genes mutated in two or more samples included 891 occurring only in non-inflamed tumors. FGFR3 was the most common mutation exclusive to non-inflamed tumors (p < 0.0001). Expression of WNT7B, PPARG, and FGFR3 were inversely correlated with CD8A (all p < 0.0001). **Conclusions:** Bladder tumors are characterized by T cell-inflamed and non-inflamed phenotypes. Mutational burden does not vary between these subsets. Activation of β-catenin, PPARG, and FGFR pathways are strongly correlated with T cell exclusion in UBC.

Association of p53-ness with chemo-resistance in urothelial cancers treated with neoadjuvant gemcitabine plus cisplatin. *First Author: Roland Seiler, Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada*

Background: Recent genomic analyses demonstrated that muscle-invasive bladder cancers can be grouped into intrinsic basal and luminal subtypes. Within the luminal subtype, tumors with "p53-like" gene expression were resistant to neoadjuvant chemotherapy (NAC) with methotrexate, vinblastine, doxorubicin, and cisplatin (MVAC). We investigated the response of these subtypes to gemcitabine plus cisplatin (GC), the other major frontline NAC regimen in this disease setting. **Methods:** Fifty-two bladder cancer patients received neoadjuvant GC followed by cystectomy. At diagnosis 44 (85%) and 36 (69%) patients had extravesical extension of the primary tumors and were clinically node-positive, respectively. At cystectomy, 37 (71%) patients did not respond to NAC (ypT $\geq$ 2 or any ypN1-3). RNA was isolated from pre-NAC transurethral resection (TUR) specimens and post-NAC cystectomy specimens using the RNeasy FFPE kit (Qiagen), amplified with the Ovation WTA FFPE system (NuGen) and hybridized to GeneChip Human Exon 1.0 ST microarrays (Affymetrix). A one nearest neighbor (oneNN) prediction model was used with the RNA normalized gene expression values to assign the tumors to intrinsic subtypes. **Results:** Unsupervised hierarchical clustering separated the tumors into clusters characterized by non-overlapping expression of basal or luminal biomarkers. Assignment of pretreatment TUR tumors to subtypes yielded the expected ratios of basal, p53-like, and luminal tumors. Rates of pathological down staging ($<$ ypT2), disease specific ($p = 0.013$), and overall survival ($p = 0.003$) were lower in the p53-like tumors compared to the other subtypes. An immune signature was enriched in the basal tumors that responded to NAC, although this did not reach statistical significance. Analyses of matched tumors before and after therapy revealed enrichment for p53-like tumors at cystectomy. **Conclusions:** Patterns of response and resistance to neoadjuvant GC appear to be very similar to those observed with MVAC, with p53-like tumors displaying chemo-resistance. If these results are confirmed prospectively, patients with p53-like tumors should not be treated with cisplatin-based chemotherapy.

Whole exome sequencing to reveal chemotherapy-driven evolution of platinum-resistant metastatic urothelial cancer. *First Author: Bishoy Faltas, Weill Cornell Medical College, New York, NY*

Background: First line platinum-based chemotherapy is the standard of care for metastatic urothelial carcinoma (UC). While a subset may achieve long-term disease control, the majority of patients will die of metastatic platinum-resistant UC (PRUC). Our objective was to understand chemotherapy-driven molecular evolution of metastatic PRUC by sequencing matched pairs of treatment-naive primary UC and metastatic PRUC from each patient. **Methods:** Following informed consent, 50 UC samples from 23 patients were analyzed (23 metastases, 37 PRUC and 18 trios of matched primary, metastatic and germline samples including 2 rapid autopsy cases yielding tumor samples from multiple sites).Germline samples were prospectively collected and matched archival formalin-fixed paraffin-embedded primary tumors from the same patients were retrieved. Whole exome sequencing was conducted. Data was analyzed using an integrated analysis of somatic single nucleotide variants and somatic copy number alterations (SCNA), and CLONET to estimate tumor purity and ploidy and to quantify corrected SCNAs for the inference of the clonal hierarchy of genomic aberrations; allele-specific SCNAs analysis was conducted with a focus on 9p21 locus across the cohort. **Results:** 414 recurrently mutated genes were identified, the most common in TP53 (45%), FOXD2 (33%), NIN (28%), TSC1 (19%) and PIK3CA (11%). Frequent SCNA included CDKN2A deletions (33%), E2F3 amplifications (10%) and ERBB2 amplifications (7%). Reconstructed phylogenetic trees from matched primary, metastatic and germline trios revealed evidence of divergent clonal evolution. Paired pre-chemotherapy and post-chemotherapy tumors from the same patients shared only an average of 33% of the total number of mutations. Allele-specific SCNA analysis revealed significant inter and intra-patient heterogeneity in the 9p21 region. **Conclusions:** This study generates a detailed molecular profile of the genomic landscape of PRUC revealing extensive heterogeneity and clonal selection underlying evolution of platinum-resistance and metastatic spread.

Defects in DNA repair genes and sensitivity to cisplatin based neoadjuvant chemotherapy (NAC) for bladder cancer. *First Author: Yu-Ning Wong, Fox Chase Cancer Center, Temple University Health System, Philadelphia, PA*

Background: Cisplatin based NAC prior to cystectomy is standard of care for MIBC, with 40-50% expected to respond with $\leq$ pT1N0M0. Biomarkers predictive of response are lacking. **Methods**: MIBC pts who received 3 cycles of cisplatin based NAC on 1 of 2 prospective multicenter clinical trials were included. Pts treated with accelerated methotrexate, vinblastine, doxorubicin + cisplatin (AMVAC) provided the discovery set [n = 34, 15/34 (44%) $\leq$ pT1N0M0]. Pts treated with dose dense gemcitabine + cisplatin (DDGC) provided the validation set [n = 24, 11/24 (46%) $\leq$ pT1N0M0]. DNA from pre-treatment tumor tissue underwent sequencing for all coding exons of 287 cancer-related genes and was analyzed for presence of base substitutions, indels, copy number alterations, and selected re-arrangements. The mean number of variants and variant status for each gene were correlated with response using two-sample t-test and Fisher's exact tests. Variant data were used to create a classification tree to discriminate responders vs. non-responders in the AMVAC discovery cohort. The resulting decision rule was then tested in the independent DDGC validation set. Overall survival analysis was performed using Kaplan-Meier. **Results**: Pts with pT0 had significantly more alterations than those with residual tumor in both the AMVAC discovery ($p = .024$) and DDGC validation ($p = 0.018$) set. In the AMVAC discovery set, alteration in $\geq$ 1 of the three DNA repair genes *ATM*, *RB1* or *FANCC* predicted for $\leq$ pT1N0M0 ($p < 0.001$, 87% sensitivity, 100% specificity) and improved overall survival (OS) ($p = 0.007$). This test remained predictive for $\leq$ pT1N0M0 in the DDGC validation set ($p = 0.033$), with a trend towards improved OS ($p = 0.055$) at short median follow up of 16.75 mo. **Conclusions**: Alterations in $\geq$ 1 of *ATM*, *RB1* and *FANCC* predict response to cisplatin based chemotherapy defined as $\leq$ pT1N0M0 in both our AMVAC discovery and DDGC validation sets. We hypothesize that defects in these genes, which are important for maintenance of chromatin structure and DNA repair, confer sensitivity to DNA damaging chemotherapy and explain the accumulation of alterations seen among pts with pT0. Further validation is planned.

4515 Poster Discussion Session; Displayed in Poster Session (Board #185), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Phase Ib/II study of an IL-2/T-cell receptor fusion protein in combination with gemcitabine and cisplatin in advanced or metastatic chemo-refractory urothelial cancer (UC). *First Author: Mayer N. Fishman, Moffitt Cancer Center, Tampa, FL*

Background: Although UC is sensitive to platinum-based chemotherapy such as gemcitabine (G) + cisplatin (C), patients who are refractory to GC have limited therapeutic options. ALT-801 is an IL-2/single-chain T-cell receptor fusion protein previously tested in various murine models. ALT-801 demonstrated potent activity against syngeneic and xenograft UC, suggesting sensitivity of this disease to IL-2 based immunotherapy. **Methods:** We report efficacy and safety results of co-administration of G (1000 mg/m^2/dose, d 1 & 8) + C (70 mg/m^2/dose, d 1) with ALT-801 (0.06 mg/kg/dose, d3, 5, 8, 12) on a 21 day schedule for 3 cycles in patients with advanced/metastatic chemo-refractory UC. The initial ALT-801 dose escalation and expansion study included chemo-naïve or refractory subjects of group 1. Group 2 are patients in a 2-armed Phase II dose expansion study of only chemo-refractory subjects receiving either 0.06 mg/kg ALT-801 + GC or 0.06 mg/kg ALT-801 + G based on the renal function. Those with at least stable disease (SD) after 3 cycles may receive addition cycles of study treatment. **Results:** To date, 62 were enrolled of whom 34 were chemo-refractory receiving ALT-801+GC (group 1, n = 17; group 2, n = 17). They were 82% male, had median age 62 y (47-74); 47% were ECOG PS = 1, and 76% had visceral metastases. Favorable responses including complete response (CR) were seen in both groups 1 and 2 with an overall response rate of 35% (95% CI: 20 - 54%) (3 CR, 9 PR, 6 SD, 12 PD, 4 non-evaluable). Median OS was 12.3 months for group 1; the group 2 results are pending follow-up. Grade 3/4 toxicities observed (n = 31) include thrombocytopenia (62%), neutropenia (48%), anemia (39%), lymphopenia (26%), hypophosphatemia (19%) and low WBC (13%). Evaluation of treatment-induced immune responses is ongoing. **Conclusions:** Based on responses seen in both groups, we conclude that ALT-801+GC has clinical activity in advanced/metastatic chemo-refractory UC patients. Observed toxicities are consistent with GC and with ALT-801 known pharmacological effects. Further evaluation of this regimen in randomized trials is warranted. Clinical trial information: NCT01326871 Clinical trial information: NCT01326871.

Expanded cohort results from CheckMate 016: A phase I study of nivolumab in combination with ipilimumab in metastatic renal cell carcinoma (mRCC). *First Author: Hans J. Hammers, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Nivolumab (N), a fully human IgG4 immune checkpoint inhibitor antibody, has shown durable response and encouraging overall survival (OS) in mRCC. Previously in CheckMate 016, N + ipilimumab (I) demonstrated manageable safety and promising antitumor activity in mRCC. Here, we report results from expansion cohorts in this study (NCT01472081). **Methods:** Patients (pts) with mRCC were randomized to N 3 mg/kg + I 1 mg/kg (N3 + I1), N 1 mg/kg + I 3 mg/kg (N1 + I3) or N 3 mg/kg + I 3 mg/kg (N3 + I3) IV Q3W for 4 doses, then N 3 mg/kg IV Q2W until progression or toxicity. Primary endpoint: safety. Other endpoints: objective response rate (ORR), duration of response (DOR), OS. DOR and OS were assessed by Kaplan-Meier method. **Results:** Pts randomized to N3 + I1 and N1 + I3 cohorts were expanded to 47 pts per arm; N3 + I3 (n = 6) arm showed early toxicity and did not proceed to expansion. 53% and 47% of pts were treatment naive and previously treated in N3 + I1; 45% and 55% were in N1 + I3. Median (range) follow-up was 34.3 (15.4 – 80.1) wks in N3 + I1 and 31.3 (4.6 – 79.9) wks in N1 + I3. Treatment-related AEs were seen in 88% of pts. Discontinuations for any grade AE occurred in 16% of pts. Grade 3-4 treatment-related AEs occurred in 34% and 64% of pts in N3 + I1 and N1 + I3, respectively; most common: ↑ lipase (13% and 26%), ↑ ALT (4% and 19%), diarrhea (2% and 15%), colitis (0 and 13%), ↑ AST (4% and 9%), and ↑ amylase (4% and 9%). Most common grade 3-4 select AEs were GI and hepatic (N3 + I1, N1 + I3); GI: 2%, 23%; hepatic: 4%, 21%. Efficacy is summarized in the table below. **Conclusions:** Updated results from expanded cohorts in CheckMate 016 confirm initial safety findings and promising antitumor activity for N + I in pts with mRCC. OS results for N + I in mRCC appear encouraging and support further development of this combination in the first-line setting. Clinical trial information: NCT01472081.

Effectiveness of adjuvant chemotherapy (AC) versus observation in patients with ≥ pT3 and/or pN+ bladder cancer (BCa). *First Author: Matt D. Galsky, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Though Level I evidence supports the use of neoadjuvant chemotherapy in BCa, the data supporting AC has been mixed. Experience suggests an adequately powered trial to definitely assess the role of AC is unlikely to be completed. Alternative approaches to evidence development are necessary. **Methods:** Patients undergoing cystectomy for ≥ pT3 and/or pN+ M0 BCa were identified from the National Cancer Database. Patients who received neoadjuvant chemotherapy and/or diagnosed after 2006 (most recent year with survival data) were excluded. Logistic regression was used to calculate propensity scores representing the predicted probabilities of assignment to observation versus AC based on: age, demographics, year of diagnosis, pT stage, margin status, lymph node density, distance to hospital, hospital cystectomy volume, and hospital type and location. Missing data were handled by multiple imputation. A propensity score-matched (1:1) cohort of AC versus observation patients was created using these variables. Stratified Cox proportional hazards regression was used to estimate the hazard ratio (HR) for the matched sample. Sensitivity analyses examined the impact of an alternative adjustment approach and comorbidities. **Results:** 4360 patients undergoing cystectomy alone and 1293 patients undergoing cystectomy plus AC met inclusion criteria.Patients receiving AC were significantly more likely to: be younger, have more lymph nodes examined and involved, have positive margins, reside in the Northeast, and have private insurance. HR are shown in the Table. Subset analyses explored the impact of nodal status [pN+ HR = 0.63 (0.56-0.70), pN- HR = 0.76 (0.63-0.90)] and age [<70 HR = 0.80 (0.72-0.88), ≥ 70 HR = 0.71 (0.61-0.82)]. The results were robust to sensitivity analysis for comorbidities. **Conclusions:** AC was associated with improved survival in patients with ≥ pT3 and/or pN+ BCa in this large comparative effectiveness analysis.

HR for overall survival with AC versus observation.

Model	HR [95% CI]
Matched Sample – Cox Model Stratified	0.71 [0.63-0.80]
Cox Model Weighted by Inverse Probability of Treatment Weight	0.78 [0.74-0.81]

4518 Poster Discussion Session; Displayed in Poster Session (Board #188), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

RECORD-4: A multicenter, phase II trial of second-line everolimus (EVE) in patients (pts) with metastatic renal cell carcinoma (mRCC). *First Author: Robert Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the pivotal RECORD-1 trial, EVE was superior to placebo in pts with mRCC previously treated with sunitinib, sorafenib, or both; prior treatment with cytokines, bevacizumab, and chemotherapy was permitted (*Cancer* 2010; 116:4256). The RECORD-4 study assessed EVE in pts with mRCC who progressed after 1 prior anti-VEGF or cytokine. **Methods:** RECORD-4 enrolled pts with clear cell mRCC into 3 cohorts based on prior first-line therapy: sunitinib, other anti-VEGF, or cytokines. Pts received EVE 10 mg/d until progression of disease (PD; RECIST, v1.0) or intolerance. Primary endpoint was PFS per investigator review. Data cutoff was Sept 1, 2014. **Results:** Enrolled pts (N = 134) previously received sunitinib (n = 58), other anti-VEGF therapy (n = 62: 23 sorafenib, 16 bevacizumab, 13 pazopanib, 10 other), or cytokines (n = 14). Demographics were balanced among cohorts; overall 90% of pts had good/intermediate MSKCC prognosis; most were white (56%) or Asian (41%). At data cutoff, 88% of pts had discontinued, mainly due to PD (54%). Median duration of exposure was 5.8 mo. Median overall PFS (95% CI) was 7.8 (5.7-11.0) mo, 5.7 (3.7-11.3) mo with prior sunitinib, and 7.8 (5.7-11.0) mo with prior other anti-VEGFs (Table). Overall response rate (ORR) was 7.5% (95% CI, 3.6-13.3%); most pts achieved stable disease (67%) as best overall response. Overall rate of grade 3 or 4 adverse events (AEs) was 56%. **Conclusions:** RECORD-4 results reinforce the clinical benefit of EVE in the second line setting after sunitinib and other first-line therapies. EVE safety profile was consistent with previous experience. (ClinicalTrials.gov ID, NCT01491672). Clinical trial information: NCT01491672.

Activating genomic mutations in the mTOR pathway to predict responses to everolimus and temsirolimus in patients with metastatic renal cell carcinoma (mRCC): Results from a large multi-institutional cohort. *First Author: Andre Poisl Fay, Oncology Service and Oncology Research Unit, HSL/PUCRS, Porto Alegre, Brazil*

Background: Mammalian target of rapamycin (mTOR) inhibitors are approved in mRCC, but only a subset of patients derives clinical benefit. Recently, case reports have suggested that mutations in mTOR pathway genes might be associated with response to everolimus and temsirolimus in several malignancies, including mRCC. **Methods:** We amassed a large international cohort of mRCC patients with available tumor specimens who received mTOR inhibitors and had distinct clinical outcomes: responders were defined as complete response (CR), partial response (PR) or stable disease with any tumor shrinkage or no tumor growth for at least 6 months (R); non-responders were defined as disease progression within the first 3 months of therapy (NR). Tumor DNA from 94 patients was analyzed using a targeted next-generation sequencing panel covering 504 cancer genes. We performed a blinded analysis to investigate the correlation between mutations in mTOR pathway genes and response status. **Results:** Samples from 79 of 94 patients were successfully sequenced and were included in the analysis. Mutations are summarized in **Table 1**. Mutations in *MTOR*, *TSC1* or *TSC2* were more common in R (12/43) than NR (4/36) (OR: 3.05; *p = 0.06; primary hypothesis*). Similarly, mutations in *TSC1* or *TSC2* were more common in R (9/43) than NR (2/36) (OR: 4.42; *p = 0.05; secondary hypothesis*). In an exploratory analysis, 5/12 with PR/CR had mutations in *MTOR*, *TSC1* or *TSC2* vs 4/35 NR (OR: 5.28; *p = 0.04*). **Conclusions:** In this large cohort of mRCC patients, mutations in *MTOR*, *TSC1* or *TSC2* were more common in patients with clinical benefit from everolimus or temsirolimus than in NR. Mutations in those 3 genes were associated with PR/CR to mTOR inhibitors. In contrast, neither PTEN nor PIK3CA mutations showed any association with response. These findings suggest that a personalized medicine approach has value for selection of mTOR inhibitors in mRCC.

Gene Mutation	NR(n = 36) n(%)	R(n = 43) n(%)	Total(N = 79) n(%)
MTOR(activating)	2(6)	3(7)	5(6)
PTEN(inactivating)	5(14)	5(12)	10(13)
TSC1(inactivating)	2(6)	8(19)	10(13)
TSC2(inactivating)	0	1(2)	1(1)
PIK3CA(activating)	0	1(2)	1(1)

Comprehensive genomic profiling of 443 patients with advanced renal cell carcinoma (RCC) to reveal clinically relevant genomic alterations and to aid in classification of rare subtypes. *First Author: Sumanta Kumar Pal, City of Hope, Duarte, CA*

Background: Large scale genomic sequencing studies in RCC (e.g., TCGA) have classically focused on localized disease, which is often curable. Advanced RCC represents a unique disease setting in which novel therapeutic targets may have a clinical impact. **Methods:** CGP for genomic alterations (GAs) was performed prospectively in 443 consecutive patients with advanced RCC (relapsed RCC or metastatic RCC at presentation). DNA was extracted from 40 microns of FFPE sections. CGP was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 646X for 3,230 exons of 182 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer (Frampton et al, Nat Biotechnol 2013). The CGP assay included base substitutions, INDELs, copy number alterations and fusions/rearrangements. Clinically relevant genomic alterations (CRGAs) were defined as alterations for which a selective inhibitor of the target or pathway is available. **Results:** There were 73% male and 27% female patients with a mean age of 56 years. 198 (44.6%) of the sequenced RCC cases were derived from metastatic sites. 400 patients (89%) had at least 1 GA with a mean 3.1 GA/case. Of the 400 RCC harboring GA, 396 (99%) had at least 1 CRGA involving 111 individual genes with a mean of 1.32 CRGAs/RCC case. The most common CRGA in order of frequency were: *ATM* (11%), *PTEN* (8.5%), *TSC1* (8.3%), *mTOR* (7%), *MET* (6.5%), *AR* (5.3%), *DNMT3A* (5%) and *TSC2* (5%). Other GAs such the ones with prognostic value in RCC included *CDKN2A* (21%) and *BAP1* (12%). Collecting duct carcinomas (CDCs) harbored an enrichment of *NF2* truncating alterations (>40%), distinct from renal medullary carcinoma (RMC). Multiple CDC cases harbored *SMARCB1* alterations suggesting these cases could be construed as RMC if a genomic criterion of *SMARCB1* loss of function is used for diagnosis. **Conclusions:** CGP can uncover a wide variety of CRGAs in advanced RCC with the potential to direct use of targeted therapies based on the tumor genotype. CGP can also refine the diagnosis of renal epithelial neoplasms.

Distinct MET alterations to induce a common phenotype and to define a MET-driven subset of papillary RCC: Results from the Cancer Genome Atlas (TCGA) Kidney Renal Papillary (KIRP) Working Group. *First Author: Laurence Albiges, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Papillary Renal Cell carcinomas (pRCC) are the most frequent non-clear cell RCC, commonly classified as type I and type II. *MET* oncogene mutations have been reported predominantly in type I. MET overexpression is a common feature in pRCC and correlates with copy number alteration (CNA). We aim to report the distinct molecular alterations of *MET* and their impact within the TCGA KIRP dataset. **Methods:** KIRP TCGA provides a comprehensive molecular evaluation of pRCC tumors. **Results:** Genomic analysis of 161 TCGA pRCC tumors revealed recurrent mutations in *MET* in 18 cases (11.2%): 3 germline and 15 somatic, and 72 cases (46%) with gain of chromosome 7. Analysis of RNA-Seq identified a new recurrent splicing isoform of *MET* in 8 cases (5%) skipping exons 1-2 (encoding the ligand binding domain) with inclusion of a new transcription start site prior to exon 3. Two new fusions (1.2%) involving the *MET* kinase domain and predicted to be constitutively activated were also identified. We further defined *MET* alterations as either a *MET* mutation, a splice variant or a *MET*-fusion. These alterations were mutually exclusive but tended to co-occur with CNA ($p < 0.001$). *MET* expression by RNA-seq was significantly elevated compared to the rest of the cohort ($p < 0.001$) when the alteration co-occurred with chromosome 7 gain. The *MET*-altered tumors exhibited a common phenotype associated with lower grade ($p < 0.001$), lower stage ($p < 0.001$), and better overall survival (log-rank $p < 0.001$) relative to all other pRCC. *MET* alterations were mostly observed in type I pRCC ($p < 0.001$). **Conclusions:** Overall, at least 17% of pRCC tumors included in the TCGA KIRP dataset present a *MET* alteration and display a common phenotype. A new splice variant is identified and may constitute a mechanism of ligand-independent *MET* activation. This report provides a survey of the diverse mechanisms of activation of the *MET* oncogene. Ongoing clinical trials of MET inhibitors in pRCC will hopefully help characterize the functional relevance of each proposed mechanism of activation involving *MET* in pRCC. *Funded in part by FNLCR Contract HHSN261200800001E.*

A phase II trial of everolimus (E) and bevacizumab (B) in advanced non-clear cell renal cell cancer (ncRCC) to show efficacy in patients (pts) with papillary features. *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: VEGF- and mTOR-directed therapies achieve inferior outcomes in pts with advanced ncRCC compared to clear cell RCC. Limited benefit from monotherapy supports study of combination regimens, prompting this phase II trial of E + B in pts with metastatic ncRCC. **Methods:** Treatment-naïve pts received concurrent E + B at standard doses until disease progression or intolerance to therapy. The primary endpoint was 6 month (mo) progression-free survival (PFS) with a planned sample size of 34 pts. Correlative analyses included ultra-deep next generation sequencing (NGS) from tumor and germline across 341 genes of interest. **Results:** 34 pts are evaluable (median follow-up 13.6 mo). The most common histologic subtype was unclassified RCC (URCC, n=23), the majority of which had papillary growth as a major component (n=14). 60% of pts achieved 6mo PFS; PFS varied significantly by histology ($p<0.001$). Objective response rates (ORR) were high in pts with significant papillary (7 of 18 pts) or chromophobe (2 of 5 pts) elements. Presence of a major papillary component was associated with treatment benefit across the entire cohort (table), particularly in pts with URCC, where this feature correlated with ORR (43 vs. 11%), median PFS (12.9 vs. 1.9 mo) and median OS (23.2 vs. 9.3 mo) (logrank $p<0.001$). NGS, performed on 33 cases, provides insight into the molecular background of disease phenotypes (e.g. frequent loss of chromosome 1p in tumors with papillary elements) and of treatment response (e.g. clonal convergence of activating alterations within the PI3K/mTOR pathway). **Conclusions:** Promising activity of E + B was seen in specific subtypes of ncRCC, particularly those with papillary features, justifying further study in a more defined population. The correlative analysis presented provides insight into the molecular basis of histologic phenotypes and response. Clinical trial information: NCT01399918.

	n	ORR (%)	Median PFS, mo (95% CI)	Median OS, mo (95% CI)
Full cohort	34	29	11.0 (3.8 – NR)	17.3 (14.6 – NR)
Cases with major papillary component	18	39	12.9(10.9 – NR)	19.7 (16.7 – NR)
Cases without major papillary component	16	19	1.9 (1.6 – NR)	10.3 (7.9 – NR)

CI: confidence interval; NR: not reached.

SWOG 1107: Parallel (randomized) phase II evaluation of tivantinib (ARQ-197) and tivantinib in combination with erlotinib in patients (Pts) with papillary renal cell carcinoma (pRCC). *First Author: Przemyslaw Twardowski, City of Hope, Duarte, CA*

Background: pRCC is associated with activation of MET signaling pathway and less favorable responses to VEGF inhibition than clear cell RCC. In SWOG 0317, the EGFR inhibitor erlotinib yielded a response rate (RR) of 11% and median overall survival (OS) of 27 months in pRCC pts. Tivantinib is a non-ATP competitive inhibitor of MET. In a preclinical pRCC model, combination erlotinib and tivantinib showed synergistic activity. A randomized multicenter phase II trial of tivantinib alone or with erlotinib was conducted in pts with either type I or II pRCC. **Methods:** Pts with histologically-confirmed advanced or metastatic pRCC and 0-1 prior systemic therapy were randomly assigned to tivantinib 360 mg BID (Arm 1) or tivantinib 360 mg BID plus erlotinib 150 mg daily (Arm 2). A RR of $\geq$ 30% was to be considered a promising outcome. Target accrual was 70 pts (35 per arm) with interim analysis planned after enrollment of 40 pts. Robust accrual resulted in 55 pts registered by the time of interim closure. **Results:** Of 55 pts enrolled, 50 were eligible: 25 in each arm. Median age was 64 years; most pts were male (68%). 33 pts (66%) had no prior systemic therapy; 6% of pts had type 1 pRCC, 42% had type 2, and 52% had no subtype assigned. The study was permanently closed at interim analysis when both arms yielded RR of 0%. Median progression free survival (PFS) was 2.0 and 5.4 months, and OS was 10.3 and 11.3 months in Arms 1 and 2 respectively. Most frequent adverse events: Arm 1- fatigue, nausea and anemia; Arm 2-rash, nausea, fatigue and diarrhea. Deep exome sequencing of archival tumor specimens is ongoing. **Conclusions**: Tivantinib - either alone or in combination with erlotinib has no clinical activity in pts with advanced pRCC. The addition of tivantinib to erlotinib may have reduced the latter's previously reported efficacy (although wide confidence intervals preclude a definite conclusion); this was not predicted by preclinical modeling. Although MET remains a reasonable therapeutic target in PRCC, more careful credentialing of proposed MET inhibitors, biomarkers, and patient subsets most likely to benefit would be required. (NIH/NCI NCTN CA180888;CA180819;CA180820). Clinical trial information: NCT01688973.

4524 Poster Session (Board #194), Mon, 1:15 PM-4:45 PM

Adjuvant chemotherapy for residual disease after neoadjuvant chemotherapy for muscle invasive urothelial cancer (MIUC). *First Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

Background: Neoadjuvant cisplatin-based chemotherapy (Neo) improves outcomes in MIUC. However, the benefit achieved with Neo correlates with pathologic downstaging and patients with residual disease (RD) remain at high risk for metastatic recurrence. The optimal management of such patients is unknown. We evaluated whether adjuvant chemotherapy (Adj) improves time to recurrence (TTR) in pts with RD after Neo. **Methods:** Data were captured from 23 sites participating in the Retrospective International Study of Cancers of the Urothelium (RISC). Pts with RD after Neo for UC were identified. Median (med) TTR was estimated by Kaplan-Meier method from 2 mo post-surgery to minimize lead time bias in non-Adj pts. The association between Adj and TTR was assessed using a multivariate Cox regression model. **Results:** From 11/1989 to 4/2013, 185 pts were identified who had RD despite Neo and had adequate follow-up time for data on Adj. Med follow-up time was 30 mo. 25 pts received Adj while 160 proceeded with surveillance. Both groups had similar performance status and med age at time of Neo. Med time to Adj was 1.5 mo. The majority changed regimens between Neo and Adj. Gemcitabine/cisplatin and dose dense MVAC were the most common regimens used in either setting. Use of Adj significantly correlated with higher path stage (p = 0.003). Med TTR was 17 mo with 95/185 experiencing relapse. After adjusting for path stage, type of Neo and age, Adj pts had a significantly decreased risk of relapse (HR = 0.35, 95% CI: 0.17,0.74). A subset analysis (Adj = 19, surveillance = 50) of pts with residual pathologic T4 and/or N+ after Neo also revealed a significant improvement with Adj: median TTR of 20 mo versus 9 mo, p = 0.02 (HR = 0.43, 95% CI: 0.21,0.89). **Conclusions:** In this international series, the use of Adj chemo for RD after Neo was rare. While limited by small numbers and the potential selection bias inherent to retrospective analyses, Adj may delay recurrence in pts with residual pT4 or N+ disease despite Neo. Overall survival analysis will be presented.

4525 Poster Session (Board #195), Mon, 1:15 PM-4:45 PM

JEVTCC: Phase II trial of cabazitaxel (Cbz) in patients (pt) with advanced or metastatic transitional-cell carcinoma (mTCC), who progressed before 12 months after cisplatin-based chemotherapy—A Spanish Oncologic Genitourinary Group (SOGUG) study. *First Author: Jose Angel Arranz Arija, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: Treatment of mTCC progressing to cisplatin is an unmet need. Prognostic factors (PF) for worse overall survival (OS) are ECOG >0, Hb <10 g/dL and liver metastases (Bellmunt, JCO 2010). Taxanes are active as 2nd-line in mUC. Cbz, a semi-synthetic taxane, is a poor substrate for the multidrug resistance system. **Methods:** Phase II study of Cbz 25 mg/m2/3w until progression, death or unacceptable toxicity, in each of the 3 subgroups of mTCC: very good, good or poor prognosis (VGP, GP, PP), defined by 0, 1 or > 1 of the above PF respectively. Primary endpoint of response rate ≥ 20% (RR, RECIST 1.1), required 35 pt in each group. Multinomial response and early progressions method (MREP, $\alpha = 0.05$, $\beta = 0.2$), and 2-stage Simon's optimal design (SOD, $\pi 0 = 10\%$, $\pi 1 = 30\%$ $\alpha = 0.05$, $\beta = 0.1$), were used for early stopping rules in an intermediate analysis (IA) in each group, after 15 and 18 evaluable pt respectively. Secondary endpoints: PFS, OS, and toxicity. Recruitment was not stopped until IA were available. **Results:** 71 pt were included (ITT population), 59 eligible and evaluable: 16/21 VGP, 28/34 GP, 15/16 PP. Mean age 65 y, 85% male, 94% ECOG 0-1, 77% bladder mTCC. Metastatic sites: 69% lymph nodes, 41% lung, 32% bone, 24% liver, 30% others. Toxicity is described in a separate abstract. Response (R), stable disease (SD), progression (PD), % RR, PFS and OS (months, with CI 95%) are summarized in the table below. **Conclusions:** In the IA, a RR ≥20% of Cbz after cisplatin in mTCC could be excluded in all prognostic subgroups, and the study was stopped. However, PFS and OS seem to be similar to those obtained with other active drugs in 2nd-line mTCC. EUDRACT 2011003498-27. Funding: Sanofi. Clinical trial information: 2011003498-27.

Group	N	# R	# SD	# PD	% RR (CI 95%)	Median PFS (CI 95%)	Median OS (CI 95%)
VGP	16	1	6	8	6.25 (1.1 – 28.3)	2.3 (1.9 - 3.9)	11.6 (4.5 - 20.1)
GP	28	0	11	17	0%	2.1 (1.9 - 4)	7.1 (3.6 - 8.3)
PP	15	1	2	12	6.7 (0.3 – 34)	2 (1.8 - 2.3)	3.7 (2.3 – 5.2)
ITT	71				4.9 [1.7 - 13.5]	2.1 (1.9 - 2.4)	5.3 (4.1 - 8.3)

4526 Poster Session (Board #196), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling of 295 cases of clinically advanced urothelial carcinoma of the urinary bladder to reveal frequency of clinically relevant genomic alterations. *First Author: Matthew J. Hawryluk, Foundation Medicine Inc., Cambridge, MA*

Background: Clinically advanced metastatic urothelial carcinoma (UC) is a devastating disease lacking effective systemic therapies. Herein, we present a comprehensive genomic profile-based (CGP) study of UC designed to detect clinically relevant genomic alterations (CRGA) that could inform the selection of established and novel targeted therapies. **Methods:** DNA was extracted from 295 consecutive cases of relapsed/metastatic UC. CGP was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 688X for 236 cancer-related genes. The CGP assay included base substitutions (SUB), INDELs, copy number alterations (CNA) and fusions/rearrangements. CRGA were defined as GA linked to drugs on the market or under evaluation in mechanism driven clinical trials. **Results:** There were 75% male and 25% female patients with a mean age of 66 years. 295/295 (100%) of UC were high grade and advanced stage (III and IV). 294/295 (99.7%) UC had at least 1 GA on CGP with a mean of 6.4 GA/UC with 61% SUB + INDEL, 37% CNA and 2% fusions. 275 (93%) UC had at least 1 CRGA involving 75 individual genes with a mean of 2.6 CRGA/UC. The most common CRGA involved *CDKN2A* (34%), *FGFR3* (21%), *PIK3CA* (20%) and *ERBB2* (16%). *FGFR3* GA were of diverse type and included 10% fusions. *ERBB2* GA were equally divided between amplifications (CNA) and SUB. *ERBB2* SUB were predominantly in the extracellular domain and were highly enriched in the micropapillary UC subgroup. Multiple clinical antitumor responses to therapies targeting *FGFR3* and *ERBB2* will be presented. **Conclusions:** Using a CGP assay capable of detecting all classes of GA simultaneously, an extraordinary high frequency of CRGA were identified in a large series of patients with clinically advanced UC. More than one-third of these relapsed/refractory cases of UC harbored alterations in *FGFR3* and *ERBB2* that are showing active responses to targeted therapies. Continued evaluation of CGP for UC and the development of genomic driven clinical trials designed to employ targeted agents potentially in combination with cytotoxic drugs for this challenging disease appears warranted.

4527 Poster Session (Board #198), Mon, 1:15 PM-4:45 PM

Externally validated improved 5-factor prognostic model in patients (pts) receiving salvage systemic therapy for advanced urothelial carcinoma (UC). *First Author: Guru Sonpavde, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: Prognostic factors in pts receiving salvage systemic therapy for advanced UC include performance status (PS), liver metastasis (LM), hemoglobin (Hb) and time from prior chemotherapy (TFPC). We investigated the impact of neutrophil count (N), lymphocytes (L), platelets (PLT) and albumin (Alb). **Methods:** Patient level data from phase II trials of salvage therapy on N, L, PLT and Alb were required in addition to TFPC, Hb, PS and LM status. Cox proportional hazards regression was used to evaluate their association with overall survival (OS). An optimal regression model was constructed using forward stepwise selection and risk groups defined using number of adverse factors. Trial was a stratification factor. External validation of significant factors was conducted in a separate dataset of 5 salvage phase II trials including 167 pts. **Results:** Data for discovery was obtained from 10 trials accruing 708 pts. After adjustment for TFPC < 3 months (mo), Hb < 10 g/dl, PS > 0 and LM status, PLT > ULN (upper limit of normal) and Alb < LLN were significant poor prognostic factors (Table). Only the addition of Alb < LLN was externally validated. Based on the 5 factor risk model, the median OS (mo) is 8.9, 6.4, 4.5 for 0-1, 2, 3+ risk factors (n = 207, 171, 113) in discovery dataset (n = 491), and 10.6, 10.0, 7.0 with n = 73, 47, 47 in the validation dataset (n = 167). The c-index improved from 0.631 to 0.638 in the discovery set and from 0.601 to 0.632 in the validation set by adding Alb < LLN to the previously identified 4 factors. **Conclusions:** A 5-factor model including TFPC < 3 mo, Hb < 10 g/dL, PS > 0, LM status and Alb < LLN was externally validated and enhanced the Bellmunt prognostic model in pts receiving salvage systemic therapy for advanced UC. Table

	Discovery (n = 491)		Validation (n = 167)	
Factor	**HR (95% CI)**	**p-value**	**HR (95% CI)**	**p-value**
TFPC < 3 months	1.49 (1.19, 1.87)	< 0.001	1.35 (0.87, 2.08)	0.18
ECOG PS > 0	1.39 (1.16, 1.67)	< 0.001	1.58 (1.06, 2.35)	0.023
Liver Metastases	1.45 (1.16, 1.81)	< 0.001	1.26 (0.83, 1.90)	0.27
Hb < 10 g/dl	1.73 (1.27, 2.35)	< 0.001	1.35 (0.94, 1.96)	0.10
Alb < LLN	1.61 (1.20, 2.15)	0.002	1.90 (1.27, 2.85)	0.002

4528 Poster Session (Board #199), Mon, 1:15 PM-4:45 PM

Molecular characterization of bladder cancer in smokers versus non-smokers. *First Author: Monika Joshi, Penn State Hershey Medical Center, Harrisburg, PA*

Background: Bladder cancer (BC) is one of the most common malignancies of the urinary tract and is 4thmost common cancer among men. It is estimated that by the end of 2015, the US will have approximately 74,000 new BC cases, accounting for 16,000 cancer related deaths. Smoking is considered an important risk factor for BC; recent data demonstrate an increase in BC incidence in non-smokers as well. Molecular characterization of BC in non-smokers has not been well studied. To the best of our knowledge, no retrospective or prospective study examining the correlation between smoking status (smokers vs non-smokers) and specific genetic alterations in BC has been published to date. **Methods:** 676 consecutive BC profiled at a CLIA certified laboratory were evaluated for differences in molecular characterization between smokers and non-smokers. Smoking status, patient characteristics, age, sex and survival data were collected on a subgroup; compilation of etiology is ongoing for additional patients. **Results:** 30 patients were confirmed lifetime nonsmokers (NS) and 39 were confirmed smokers or reformed smokers (R/S). Identified trends included differences in the PI3 kinase, WNT and EGFR pathways. Percentage of PIK3CA mutations was higher in NS (43%) vs. R/S (11%), whereas the WNT pathway aberration (CTNNB1 and APC mutations) occurred more frequently in R/S. EGFR amplification occurred in 22% NS and 11% in R/S, while HER2 was amplified only in R/S (23% vs. 0%, $p = 0.05$). Additionally, 3 of 8 R/S had an ALK 2p23 rearrangement, found in ~5% non-small cell lung cancers. TP53 did not differ between the populations. Survival data for 31 patients (14 NS, 17 R/S) showed overall average survival in the NS cohort was 175 days longer than in the R/S cohort. **Conclusions:** The difference in molecular biology between R/S and NS with BC suggests a different oncogenesis with potentially different treatment options. Increased incidence of PIK3CA mutations in NS may inform therapeutic options in this select group of BC patients with no smoking history. The results will need further verification in a larger group of BC patients in a prospective clinical study; more studies also need to be conducted to identify other mutational abnormalities between smokers vs. lifetime non-smokers.

4529 Poster Session (Board #200), Mon, 1:15 PM-4:45 PM

Maintenance vinflunine post cisplatin chemotherapy (CT) in patients with advanced urothelial carcinoma (UC): Preliminary analysis of a randomized placebo controlled phase II trial (MAJA trial)—SOGUG 2011-02. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Vinflunine (VFL) is a microtubule inhibitor approved by EMA as treatment after platinum progression, in metastatic bladder cancer. We evaluated whether maintenance VFL delays progression after response to CT. **Methods:** Patients (pts) with measurable disease, locally recurrent/metastatic UC and adequate organ function with radiological response or stabilization after 4-6 cy of a cisplatin/gemcitabine chemotherapy (carboplatin allowed after cy 4) were randomized 1:1 to receive VFL 320 mg/m^2 or 280mg/m^2(in case of PS 1, age $\geq$ 75 years, prior pelvic radiotherapy or CrCl $<$ 60ml/min) every 21 days vs best supportive care (BSC), until disease progression. The primary endpoint was progression free survival (PFS). With a median PFS considered unacceptable for the experimental arm 4 months (p0) and a very acceptable 6.5 (p1). 39 eligible pts per treatment arm were required to select better therapy with a type I error of 0.05 (α, one-tailed test), and a type II 0.1 (β) error. **Results:** 88 patients from 21 institutions of SOGUG cooperative group have been randomized between 04/2012 and 01/2015. At the time of present analysis 77 have confirmed eligibility and 66 pts (33 in the VFL arm and 33 in the BSC arm) have received at least 2 cy. Preliminary results based on these 66 pts are presented. Median age 63 years (range 42-78); PS 0/1, 50%/50%; CrCl $<$ 60 ml/min 24%; liver metastasis 25%; prior pelvic RT 10%. Primary location: bladder 82%. Metastatic/locoregional disease 77%/23%. Pure transitional 87%. 242 cy given in the VFL arm with a median of 4 cycles per patient (1–28). Most common G 3/4 (% pts) AEs were constipation (17.6%), neutropenia (17.6%), fatigue (11.7%), and 1 febrile neutropenia (2.9%). 2 deaths due to pneumonia not related to the treatment. With a median follow-up of 7.2 months (0.1-29.9), the median PFS was 10.4 months (0-24.6) in the VFL arm and 4.6 months (1.7-7.4) in the BSC arm ($p = 0.058$). **Conclusions:** Preliminary results indicate that maintenance VFL post CT has an acceptable tolerability profile in advanced UC pts and is associated with clinical activity. Further follow-up with mature results are needed. Clinical trial information: NCT01529411.

4530 Poster Session (Board #201), Mon, 1:15 PM-4:45 PM

Role of *miR-21*, *miR372*, and *E2F1* as biomarkers predicting outcome in cisplatin-treated bladder cancer patients. *First Author: Chensheng Willa Zhou, Dana-Farber Cancer Institute, Boston, MA*

Background: Cisplatin based chemotherapy is the gold standard for first line metastatic/locally advanced urothelial carcinoma (aUC). Variant expression of selected miRNAs and transcription factors (TF) are shown to correlate with and predict cisplatin efficacy in many types of cancers. In this study we aimed to confirm the role of selected miRNAs and TFs in patients receiving first line cisplatin combination therapy in aUC **Methods:** 82 clinically annotated patients with aUC (including N1 resected patients), with available tumor tissue, were identified, and total RNA was extracted from FFPE specimen. MicroRNA (miR21, miR106b, miR10b, miR146a, miR146b, miR371, miR372, miR373, miR1224, miR1248, miR200c, Let7i, miR27b, and miR26b) and TF panels (RELA, SMAD4, FOXO3, E2F1 and TWIST1) were identified using in silico data mining based on their roles in UC or in cisplatin response. Time to progression (TTP) was defined as time from chemotherapy start date to date of progression or censored on the last known without progression. For the TTP analysis, median miRNA expression levels were dichotomized and a cox regression model was used. For the extreme TTF phenotype, correlations were assessed by Wilcoxon's test ($P < 0.05$). Multivariate analysis was performed for all miRNAs, adjusting for ECOG status and visceral disease. **Results:** The median TTP was 12 mo, with 43 patients experiencing disease progression. In the TTP multivariate analysis, increased levels of E2F1 [$p = 0.02$, HR:0.49, (0.27, 0.89)], miR21 [$p = 0.03$, HR:0.53, (0.29, 0.97)] and miR372 [$p = 0.02$, HR: 0.49, (0.26, 0.90)], were associated with a shorter TTP. For the extreme phenotype, only miR21 and E2F1 were shown to be associated with TTP ($p = 0.055$). **Conclusions:** In this retrospective cohort of patients treated with cisplatin based therapy, higher levels of E2F1, miR21, and miR372 correlated with a shorter TTP. Biological validation of cisplatin effect on 6 bladder cancer cell lines that express different miR21 levels, from Cancer Cell Line Encyclopedia, is ongoing and results will be presented.

4531 Poster Session (Board #203), Mon, 1:15 PM-4:45 PM

The basal subtype to predict clinical benefit from neoadjuvant chemotherapy: Final results from a phase II clinical trial of DDMVAC + bevacizumab. *First Author: Arlene O. Siefker-Radtke, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Gene expression profiling (GEP) suggests 3 main subtypes of urothelial cancer: basal, which historically has the worst prognosis with high proliferation and HIF-1 expression; p53-like, with decreased proliferation and increased markers of extracellular matrix (ECM); and luminal which has increased proliferation compared to p53-like tumors. We hypothesized that GEP of transurethral resections (TUR) and cystectomy specimens from patients on a neoadjuvant trial would predict benefit from chemotherapy **Methods:** Sixty patients enrolled on a neoadjuvant trial of DDMVAC+B. TUR and cystectomy specimens were available for gene expression profiling in 39 and 33 patients, respectively, with matched specimens in 23 patients. The validation set consisted of 49 patients treated with perioperative MVAC on a previously published clinical trial **Results:** Chemotherapy was quite active with pT0N0 and $\leq$ pT1N0 down-staging rates of 38% and 53%, respectively. Basal tumors had improved survival compared to luminal and p53-like (5-year OS 91%, 73% and 36%, $p = 0.015$). A validation cohort of patients treated with perioperative MVAC confirmed this survival benefit (5-year OS basal, luminal, and p53-like 77%, 57%, and 57%, respectively, $p = 0.027$). The use of bevacizumab in basal tumors did not confirm evidence of significant benefit in these small numbers of patients (5-year OS bevacizumab: 91% vs MVAC: 77%, $p = 0.68$) Bone metastases within 2 years associated exclusively with the p53-like subtype (p53-like: 100%, luminal: 0%, basal 0%, $p \leq 0.001$). The p53-like subtype was enriched at cystectomy (basal to p53-like in 3/5 (60%), luminal to p53-like in 5/7 (71%), suggesting chemo-resistance in p53-like tumors **Conclusions:** In contrast to historical expectations, the basal subtype was predictive of clinical outcomes from neoadjuvant chemotherapy, reflecting the impact of chemotherapy on highly proliferative tumors. Bone metastases were associated with the p53-like subtype which is enriched for ECM. We can no longer think of urothelial cancer as one disease; subtyping should be considered for all tumors, and may have implications on selecting therapy Clinical trial information: NCT00506155.

4532 Poster Session (Board #204), Mon, 1:15 PM-4:45 PM

Association of somatic mutations in DNA damage repair (DDR) genes with efficacy of platinum-based chemotherapy in advanced urothelial carcinoma. *First Author: Richard Martin Bambury, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Platinum-based chemotherapy (PBC) is standard of care in the neoadjuvant and metastatic UC settings. Recent work identified mutations in *ERCC2*, *RB1*, *FANCC* and *ATM* as potential predictive biomarkers of response. We assessed response to PBC among patients with locally advanced or metastatic UC who underwent pre-treatment tumor genomic sequencing. **Methods:** 72 patients treated with PBC had exon sequencing of > 200 tumor suppressor/oncogenes using the MSK-IMPACT next generation sequencing assay. Deletions, truncations, frameshift, splice-site and missense alterations were recorded among 33 genes involved in the nucleotide excision repair, homologous repair and Fanconi anemia pathways (Table). Inactivating alterations in *RB1* and *TP53* were also investigated as potential predictive biomarkers. Baseline clinical parameters, investigator-assessed radiologic response and PFS were recorded. **Results:** 31(43%) patients had alterations in DDR genes and these were associated with improved PFS (median 11.3 v 6.1 months, HR 0.51, p 0.01). Among 65 evaluable patients, radiologic response was observed in 81% of those with DDR gene alterations vs. 58% in those without (p 0.06). DDR alterations remained a significant predictor for PFS on multivariate analysis (HR 0.45, p 0.004) after adjusting for ECOG performance status, visceral vs nodal metastases, chemotherapy type (cisplatin v carboplatin) and prior perioperative cisplatin. Among 9 patients with deletion, truncation, frameshift or splice-site alterations of DDR genes, 8 achieved PFS >11 months. There was no association between PFS and *RB1* (HR 1.37, p 0.32) or *TP53* (HR 0.93, p 0.79) alterations. **Conclusions:** Alteration of DDR genes is associated with improved efficacy in patients receiving 1st line PBC for advanced UC. Further refinement and validation could lead to prospective identification of patients who will respond to PBC, as well as identify patients unlikely to benefit and for whom alternative approaches are warranted.

Germ cell cancer and multiple relapses: Toxicity and survival. *First Author: Jakob Lauritsen, Rigshospitalet, Copenhagen, Denmark*

Background: A small fraction of patients with germ-cell cancer (GCC) receive more than one line of systemic treatment. The purpose of this study was to evaluate late-toxicity and survival in an unselected cohort of patients who relapsed after initial systemic treatment for disseminated disease. **Methods:** Based on the Danish DaTeCa database we identified all patients who received two or more lines of systemic treatment. Information on late-effects and mortality in GCC-survivors was obtained through linkage to national registers. Prognostic factors for relapse and death were identified and compared to the International Prognostic Factors Study Group (IPFSG). **Results:** In total, 268 patients received two or more lines of systemic treatment for disseminated GCC. Approximately half of the patients died of their disease (n = 136). The surviving patients (n = 132) had highly increased risk of death of other causes hazard ratio (HR): 2.5 (95% CI: 1.6-4.1), second cancer HR: 3.4 (2.0-5.7), major cardiovascular disease HR: 1.9 (1.0-3.3), pulmonary disease HR: 2.4 (1.3-4.4), gastrointestinal disease HR: 7.1 (3.5-14.3), renal impairment HR: 9.2 (3.4-25.5), and neurological disorders HR: 5.4 (2.7-10.8) compared to patients treated with orchiectomy only. We found a dose-response relationship with increasing number of treatment lines within most toxicities. The IPFSG-classification was confirmed in our population; however, we could not confirm primary site and hCG as independent factors. We identified increasing age as a possible new prognostic factor for treatment failure, hazard ratio (HR): 1.2 (1.2-1.5) per 10 years. **Conclusions:** GCC-survivors after second-line systemic treatment have a highly increased risk of severe late-toxicity and death, and should be candidates for life-long follow-up. The IPFSG-classification was confirmed in this unselected population.

4534 Poster Session (Board #207), Mon, 1:15 PM-4:45 PM

Wilms' tumor gene 1 (WT1) aberrations in testicular germ cell tumors (TGCTs). *First Author: Ludmila Boublikova, Department of Pediatric Hematology and Oncology, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic*

Background: Wilms' tumor gene 1 (WT1) is a transcription factor essential for normal development of the urogenital system and male gonadal formation. Its alterations have been found in Wilms' tumor, other malignancies and testicular dysgenesis syndromes. We studied WT1 aberrations to address its role in the pathogenesis of testicular germ cell tumors (TGCT). **Methods:** In fresh-frozen samples of 85 TGCT (48 seminomas, 37 non-seminomas), 3 stromal tumors and 88 non-neoplastic controls, expression of total WT1 and its four main isoforms was quantified by qPCR. WT1 mutations were detected by direct and next-generation sequencing (NGS). The presence of WT1 protein was evaluated by standard immunohistochemistry. **Results:** The total WT1 expression was significantly lower (1 log) in TGCT than in the controls and stromal tumors (Kruskal-Wallis $p < 0.0001$), and was lower in seminomas than non-seminomas. Testicular tissue surrounding TGCT and containing *in situ* lesions expressed similar WT1 levels like other controls. WT1 isoforms lacking the exon 5 ([EX5-] isoforms A and C) were highly overexpressed in TGCT and stromal tumors in comparison with controls (Kruskal-Wallis, $p < 0.0001$). The isoform D, containing both main splice sites, was down-regulated in the tumors and this altered expression pattern was independent of total WT1 expression. Direct sequencing of exon 7 and 9 (with clustered hot-spots) could identify only 2 types of SNPs – synonymous rs16754 (31% of TGCT) and intronic rs5030274 (2%). By NGS however, 1 – 3 mutations in WT1 newly occurring in TGCT and not present in the paired controls were found in 59% of 22 analyzed cases. Staining for WT1 protein was positive in controls and undetectable in TGCT cells. **Conclusions:** The finding of total WT1 down-regulation in TGCT with the difference between seminomas and non-seminomas, the alteration of the isoform pattern with a pronounced shift to [EX5-] variants in TGCT independent of total WT1 levels, and the new occurrence of WT1 mutations in a high proportion of TGCT samples support the role of WT1 as a local tumor-suppressor gene in testicular tissues. *Supported by grants IGA NT/12414-5, GAUK56413, UNCE204012 and CDRO00064203FNM*

4535 Poster Session (Board #208), Mon, 1:15 PM-4:45 PM

Impact of response to induction chemotherapy (CT) and prior paclitaxel (TXL)-based CT on the outcome of salvage high-dose chemotherapy (HDCT) for relapsed germ-cell tumors (GCT) in the modern era: An EBMT Solid Tumors Working Party study. *First Author: Andrea Necchi, Istituto Nazionale Tumori of Milan, Milano, MI, Italy*

Background: The prognostic impact of response to induction CT preceding salvage HDCT courses, and prior TXL-therapy for advanced GCT is unknown. This knowledge can inform trial design, stratification and eligibility criteria to HDCT. **Methods:** 23 European centers contributed data. Eligibility included adult male patients (pts) with GCT, and treatment with salvage HDCT between the years 2002 and 2012. Both TXL used in prior CT lines of therapy and in induction-mobilization regimens pre-HDCT were considered. Multivariable Cox analyses (MVA) evaluated the association of prespecified factors (prior TXL therapy, line of HDCT, primary site, prognostic category, response to induction CT and chemosensitivity), with progression-free (PFS) and overall survival (OS). **Results:** Since 10/2013, 324 of 442 registered pts were suitable for present analysis. 165 pts (51%) received HDCT in second-line, 102 (31%) in third and 57 (18%) beyond the third-line. 76 (23%) HDCT regimens were taxane-containing. 192 pts (59.3%) have received prior TXL-regimens. 61 pts (19%) had a progression (PD) to induction CT, 234 (72%) a response (29 [9%] missing or GCSF only). Median follow up was 36 months (IQR: 19-70). PD to induction CT and prior TXL were significantly associated with shorter OS in the univariable model ($p < 0.001$ and $p = 0.032$). However, on MVA while PD to induction CT was significantly prognostic for PFS and OS (HR: 1.92, 95%CI, 1.24-2.98, $p = 0.003$, and HR: 2.09, 95%CI, 1.27-3.42, $p = 0.003$), prior TXL-therapy was not: HR: 1.10 (95%CI, 0.70-1.73, $p = 0.674$) and HR: 1.09 (95%CI, 0.64-1.86, $p = 0.739$). Also, line of HDCT was not significant ($p = 0.338$ and $p = 0.340$ for PFS and OS). A separate model evaluated the interaction between prior TXL-therapy and taxane-containing HDCT: no significant interaction was found ($p = 0.221$ and $p = 0.077$ for PFS and OS). **Conclusions:** While PD to induction CT was independently prognostic for PFS and OS, prior TXL-regimens did not affect the outcome of HDCT. Stratification of trials for the latter factor did not appear to be required when accounting for the other clinical predictors.

4536 Poster Session (Board #209), Mon, 1:15 PM-4:45 PM

Prognostic significance of thromboembolic events in chemotherapy-treated germ cell tumors. *First Author: Enrique Gonzalez-Billalabeitia, Hosp G Universitario Morales Meseguer, Murcia, Spain*

Background: To evaluate the incremental prognostic value of thromboembolic events (TEE) in combination with the International Germ Cell Cancer Collaborative Group (IGCCCG). **Methods:** Patients with germ-cell cancer receiving first-line platinum-containing chemotherapy (CT-GCC) between 2000-2014 were pooled from the Spanish Germ-Cell Cancer Group (Grupo Germinal)/Spanish Oncology Genitourinary Group (SOGUG) registry and another 3 tertiary hospitals. We used the Cox-proportional hazard model with bootstrap resampling to identify prognostic factors for both overall survival (OS) and progression-free survival (PFS). Good risk IGCCCG was used as the reference category. **Results:** We included 683 consecutive patients from 17 centers. With a median follow-up of 50 months TEE were observed in 8% of the patients (n=65), of which 86% were venous and 14% were arterial. Venous TEEs (VTE) occurred before, during and after chemotherapy in 27%, 57% and 16%. All arterial thrombosis (ATE) ensued during or after chemotherapy. On Cox regression analysis, the IGCCCG risk category, as well as pre-chemotherapy venous and arterial events were independent prognostic variables (Table 1). Bootstrap bias-corrected Harrell's C-index was 0.74 (95% CI, 0.692-0.794) and 0.880 (95%CI, 0.837-0.922) for PFS and OS in the model combining the IGCCCG score and the presence of VTE and ATE. **Conclusions:** Thromboembolic events are clinically significant in CT-GCC. The classification of germ-cell tumors might be improved by incorporating surrogate variables of hipercoagulable states, such as the presence of early venous thromboembolisms and arterial thrombosis.

Explanatory covariates included in the Cox-Proportional Hazard Model for PFS and OS.

4537 Poster Session (Board #210), Mon, 1:15 PM-4:45 PM

Clinical outcomes of late relapse in stage I seminoma. *First Author: Ali Hosni, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: This study aimed to identify characteristics associated with late relapse (LR) in stage I seminoma and determine clinical outcomes according to timing of relapse. **Methods:** Between 1981 and 2011, 949 stage I seminoma patients were managed at our institution. Of these, 254 were treated with adjuvant radiotherapy (aRT) and 695 were managed by active surveillance (AS). LR was defined as tumor recurrence more than 2 years after orchiectomy. Treatment at relapse was dependent on initial treatment and disease extent at relapse. Progression free survival (PFS) from end of treatment of first relapse and overall survival (OS) were calculated. **Results:** At median follow-up of 10.9 years, 129 patients relapsed at median of 12 months; 14 after aRT and 115 on AS. There was no significant difference between the proportion of patients with LR for aRT (3/14; 25%) vs. AS (29/115; 21%) with no specific clinicopathological features were associated with LR. Paraaortic node(s) was the most common relapse site in AS patients either in LR (n = 28, 97%; median size: 2.1 cm) or early relapse (n = 79, 92%; median size: 2 cm), whereas in aRT patients; all LR were in mediastinum, and early relapse was inguinal (n = 4), scrotal (n = 3) and distant (n = 4). Most LR occurred between 2-3 years (n = 14, 44%; 13 of them were AS patients), and 8 of 9 patients who had LR beyond 5 years were on AS. Treatment of first relapse for aRT group consisted of chemotherapy (n = 10), RT (n = 3) and surgery (n = 1); and for the AS group: RT (n = 87), chemotherapy (n = 26) and surgery (n = 2).Only 1 aRT patient developed second relapse. Nine AS patients had second relapse (7 after RT and 2 after chemotherapy) at a median (range) time of 13 (2–48) months. Second relapse was predominantly distant (9/10), however all were successfully salvaged with chemotherapy. The 5-year PFS from end of treatment of first relapse for the whole, aRT and AS groups were similar, 93%. Among AS group, there was no significant difference between early and late relapse in 5-year PFS (91% vs 100%, p= 0.1) or 10-year OS (96%, for both). **Conclusions:** In stage I seminoma, the extent and pattern of LR is similar to that for early relapse. For AS patients, selective use of RT/chemotherapy for relapse results in excellent outcomes regardless of timing of relapse.

4538 Poster Session (Board #211), Mon, 1:15 PM-4:45 PM

Perioperative morbidity and mortality with bleomycin in primary mediastinal non seminomatous germ cell tumor (PMNSGCT). *First Author: Praveen Ranganath, Indiana University School of Medicine, Indianapolis, IN*

Background: PMNSGCT represents one of the most challenging subsets of malignant germ cell tumors. PMNSGCT has a distinctly worse prognosis and is appropriately categorized as poor risk disease. A phase III intergroup study in patients with poor risk germ cell tumors, including PMNSGCT demonstrated equivalent survival in patients with Etoposide, Ifosfamide and Cisplatin (VIP) compared to standard Bleomycin, Etoposide and Cisplatin (BEP) regimen. We have demonstrated that the magnitude of post chemotherapy surgery required for PMNSGCT is higher with potential for serious pulmonary complications including post operative pulmonary failure and death. This retrospective study from 1978-2013 compares perioperative morbidity and mortality associated with Bleomycin (BEP) vs. non Bleomycin (VIP) containing regimens. **Methods:** From 1978-2013, 221 PMNSGCT patients (mean age, 29 years; ranging from 12- 50 years) who underwent post chemotherapy surgery were reviewed. **Results:** Of the 221 patients who underwent post chemotherapy surgery, 55 were treated with VIP and 166 with BEP chemotherapy. Among patients who received BEP, 83% had ≥ 3 cycles of Bleomycin. Both groups were well balanced in respect to the number of patients requiring pulmonary resection, extent of pulmonary resection and surgical approach. Post operative complications including acute respiratory failure and/or pneumonia (22 vs. 0, p value 0.004) and prolonged ventilator requirement > 48 hrs (30 vs. 2, p value 0.004) were significantly higher in patients who received BEP compared to VIP chemotherapy respectively . There were 11 post operative deaths reported- 10 patients with post operative respiratory failure and 1 death from pulmonary embolism. All deaths were in BEP chemotherapy group and 0 post operative deaths were reported in patients who received VIP chemotherapy (p value 0.05). **Conclusions:** Bleomycin containing chemotherapy regimens have traditionally been the standard of care for patients with poor-risk NSGCTs, including PMNSGCTs. Given the high rate of post-operative pulmonary failure after BEP, these results support our present policy of preferring VIP in PMNSGCT patients prior to major thoracic surgical procedures.

4539 Poster Session (Board #212), Mon, 1:15 PM-4:45 PM

A retrospective analysis of patients with metastatic germ cell tumor (GCT) treated at Indiana University (IU) from 2000 to 2012. *First Author: Kimberly Ku, Indiana University School of Medicine, Indianapolis, IN*

Background: Metastatic GCT's have been classified by the International Germ Cell Cancer Collaborative Group (IGCCCG) in 1997 into good, intermediate, and poor risk with 5-year progression free survival (PFS) of 88, 75 and 41%, respectively and 5-year survival rate of 91, 79 and 48%, respectively. **Methods**: We conducted a retrospective analysis on outcomes of all patients with GCT who were diagnosed and received initial chemotherapy at IU between 2000-2012. We limited our analysis to patients with > 1 year of f/u. 5 years PFS and OS were analyzed using Kaplan Meier methods. **Results**: 403 patients were evaluable. 240 (58%) good, 46(11%) intermediate and 127 (30%) poor risk. Median time of f/u 5 years. Median age at diagnosis 29. The 5-year PFS of good, intermediate, and poor risk groups were 91, 80 and 52% (P value < 0.01) and 5-year survival rates were 95, 89 and 71%, (P value < 0.01) respectively. **Conclusions**: There was improvement in OS for men with poor risk metastatic GCT in this contemporary cohort of patients, possibly due to improved salvage chemotherapy compared to patients treated from 1975-1990 reported by the IGCCCG.

Bleomycin-induced pulmonary changes on restaging CT scans: Frequency and correlation with fibrosis markers. *First Author: Nico-Derk L. Westerink, University Medical Center Groningen, Groningen, Netherlands*

Background: Bleomycin-induced pneumonitis (BIP) is a well-known, potentially fatal, side-effect in metastatic testicular cancer (mTC). We prospectively investigated I: prevalence of lesions suspect for bleomycin-induced pulmonary changes on restaging CT scans; II: whether early changes of fibrosis markers Transforming Growth Factor β1 (TGF-β1) and Growth Differentiation Factor 15 (GDF-15) were predictive for these radiological changes. **Methods:** mTCpatients (pts), 18-50 years of age, treated with BEP (bleomycin, etoposide, cisplatin) chemotherapy were included from 2006 till 2012. Restaging CT scans were analyzed for bleomycin-induced pulmonary changes by 2 blinded radiologists and graded as minor, moderate or severe. Plasma samples were collected before, during and after chemotherapy and quantified for TGF-β1 and GDF-15. **Results:** 66 Pts were included. 45 Pts (68%) showed signs of bleomycin-induced pulmonary changes. 37 pts were classified as minor and 8 as moderate. Treatment and disease characteristics did not differ between the groups. 3 Pts had clinical signs of BIP (for which bleomycin was halted). Although there was a vast induction of both TGF-β1 and GDF-15 plasma levels (table), this was not different between pts with no and minor vs. pts with moderate radiological signs of bleomycin-induced pulmonary changes. **Conclusions:** Bleomycin-induced pulmonary changes are very common after BEP chemotherapy for mTC. TGF-β1 and GDF-15 plasma levels before and during treatment were not different between pts with and without radiological signs of bleomycin-induced pulmonary changes and therefore not helpful as predictive markers.

Biomarker levels in relation to bleomycin-induced pulmonary changes on restaging CT scan.

			No and minor changes (n=58)		Moderate changes (n=8)		
			Median	Range	Median	Range	P-value*
Cumulative dose bleomycin (USP)			270	150-360	270	240-360	.231
Biomarker	Course	Day					
TGF-β1	1	1	4788	550-24369	5268	2052-13361	.582
(pg/mL)	3	1	7889	1484-49897	8512	3878-20372	.765

4541 Poster Session (Board #214), Mon, 1:15 PM-4:45 PM

Early changes in renal function and late cardiovascular disease risk in testicular cancer survivors with 25 years follow-up. *First Author: Sjoukje Lubberts, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Cisplatin-based chemotherapy (CT) for testicular cancer (TC) leads to an increased cardiovascular disease (CVD) risk, related to endothelial damage by circulating platinum levels of which renal function is the main determinant (J Clin Oncol 30, 2012 (suppl- abstr 4528)). Aim was to investigate the role of pre-CT renal function and early treatment-related decrease of renal function in relation to late CVD development. **Methods:** We performed a retrospective study in TC patients (pts) treated with cisplatin-based CT from 1980-1989. Renal function was determined before and after completion of at least 1 course CT with ^{125}I-iothalamate clearance which is the gold standard for glomerular filtration rate (GFR). Follow-up regarding CVD was collected in 5-yr survivors from hospital records and via general practitioners. **Results:** 50 pts, median age of 28 yrs (17-53) at start of CT, were eligible. All pts started with a normal renal function (GFR $\geq$ 90 ml/min/1.73m^2), median GFR was 129 ml/min/1.73m^2 (93-185). After start of CT median GFR decrease was 43 ml/min/1.73m^2 (-90-+11). 52% ended up with GFR impairment classified as chronic kidney disease (GFR $<$ 90 ml/min/1.73 m^2). There were 38 5-yr survivors with a median follow-up of 20 yrs (6-32). 8 (21%) developed CVD median 14 yrs (8-26) after CT (3 strokes, 2 myocardial infarctions, 1 coronary artery disease, 2 peripheral artery disease). Pts with late CVD had lower pre-CT GFR. Pts who ended up with a GFR $<$90 ml/min/1.73m^2 developed more frequently CVD (7/19 (37%) vs 1/19 (5%); p=.042). **Conclusions**: A GFR $<$ 90 ml/min/1.73 m^2 after CT is associated with an increased risk of late CVD after median 14 yrs. Patients with impaired renal function after treatment should be monitored closely regarding (risk factors for) CVD.

Characteristics of 5-year survivors, n=38.

		CVD (n=8)	No CVD (n=30)	P*
Age pre-CT (yrs)	median	30 (24-53)	26 (17-52)	.037
Cum cisplatinum dose (mg/m^2)	(range)	400 (375-800)	400 (350-800)	.688
GFR pre-CT (ml/min/1.73m^2)		104 (93-154)	132 (100-185)	.013
Change in GFR (ml/min/1.73m^2)		-38 (-76-+11)	-49 (-77- -6)	.299
After CT GFR < 90 ml/min (n,%)		7/8 (88%)	12/30 (40%)	.042

4542 Poster Session (Board #215), Mon, 1:15 PM-4:45 PM

Bevacizumab (Bev) alone or in combination with TRC105 for metastatic renal cell cancer (mRCC): A California Cancer Consortium clinical trial. *First Author: Tanya B. Dorff, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Inhibition of vascular endothelial growth factor (VEGF) pathway is effective in mRCC, but resistance inevitably develops. CD105 (endoglin) is highly expressed on endothelial cells and has been shown in preclinical models to mediate resistance to VEGF pathway inhibitors, in part due to TGF-beta signaling. TRC105 is a monoclonal antibody against CD105 which has been shown to be tolerable in combination with Bev at full doses. **Methods:** Eligible mRCC patients (pts) with any histologic subtype may have received 1-4 prior systemic therapies including cytokines, VEGF, or mTOR agents. Bev was administered at 10 mg/kg IV on day 1 and 15 of 28-day cycles as a single agent (Arm A) or with TRC105 10 mg/kg IV on days 1, 8, 15, and 22 (Arm B). Primary endpoint was progression-free survival (PFS). A total of 88 pts were to be randomized to detect a halving of PFS with 80% power and α = 0.1. An interim analysis for futility was conducted after 44 pts had PFS evaluated. **Results:** Enrollment was halted after interim analysis with 61 pts randomized; 45 were men. Median age was 60 (24-83). 20 (32%) of pts had received 3 or more prior lines of therapy (median = 2 on both arms). 44 patients had clear cell RCC and 15 had non-clear cell histology. One subject on each arm had a confirmed PR (3%) and 2 patients on each arm had stable disease lasting $>$ 9 cycles. For the 56 evaluable pts, the PFS (including early treatment termination as progression) at 12 weeks was 48% +/- 9% on Bev compared to 50% +/- 9% on Bev + TRC105. Survival did not differ significantly (p = 0.5) between arms, being 81% at 24 weeks for both arms. Grade $>$ 3 toxicities were more common in Arm B and included anemia (8 vs 2 pts), electrolyte abnormalities (6 vs 2 pts), dyspnea (4 vs 2 pts), nausea/vomiting (4 vs 0 pts), hyperglycemia (2 vs 0 pts) and infusion reaction (2 vs 0 pts); hemorrhage, hypertension, and proteinuria were more common in Arm A. **Conclusions:** TRC105 failed to prolong PFS when added to Bev. Further analysis will examine biomarkers of potential TRC105 benefit in this population. TRC105 is being studied in combination with VEGF receptor tyrosine kinase inhibitors in mRCC to determine whether there is an additive effect on PFS. Clinical trial information: NCT01727089.

4543 Poster Session (Board #216), Mon, 1:15 PM-4:45 PM

HIF inhibition in metastatic renal cell carcinoma (mRCC): Final results of a phase Ib /IIa clinical trial evaluating the nanoparticle drug conjugate (NDC), CRLX101, in combination with bevacizumab (bev). *First Author: Stephen Michael Keefe, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: *VHL* inactivation occurs in most clear cell RCCs and results in expression of the HIF hypoxia response program and tumor angiogenesis. Antiangiogenic therapies are central to therapy for mRCC, but resistance develops in all patients (pts). We hypothesized that a dual inhibition strategy focused on HIF would be active in the refractory setting. CRLX101 (Cerulean Pharma, Inc., Cambridge, MA, USA), an NDC with a camptothecin payload, has been shown in preclinical models to durably inhibit both HIF1a and HIF2a. Synergy has been observed in the pre-clinical setting between this NDC and antiangiogenic agents including bev. **Methods**: Pts with refractory mRCC were treated every 2 weeks with bev (10 mg/kg) and escalating doses of CRLX101 (12 mg/m^2, 15 mg/m^2) in a 3+3 phase I design. A phase IIa expansion cohort of 10 pts was treated at the RP2D. Pts were treated until progressive disease (PD) or prohibitive toxicity. Adverse events (AEs) were assessed using CTCAE v 4.0 and clinical outcome using RECIST v1.1. Correlative assays, designed to translate clinical results in terms of HIF expression and inhibition, were performed in parallel with the clinical investigation on baseline tumor material and on pre- and post-treatment bone marrow and plasma. **Results**: 22 response-evaluable pts were enrolled on study at two AMCs (12 clear cell, 5 papillary, 3 unclassified, 2 chromophobe). Pts had a median of 2 prior therapies, and all had at least 1 prior standard (std) therapy. No dose-limiting toxicities were observed. CRLX101 at its RP2D (15 mg/m^2) combined safely with std bev. Grade 3 treatment-related AEs were observed - non-infectious cystitis (4) and hypertension (4). All other AEs were grade 1 or 2. The median PFS was 9.9 months. Overall response rate (ORR) was 23%, and 85% experienced either a PR or SD as best response. The 5 pts with a PR included 3 with clear cell and 2 with papillary RCC. The primary efficacy endpoint of this study was met. **Conclusions**: CRLX101 can be safely combined with std bev in mRCC. This two-drug combination demonstrated provocative PFS and ORR signals. A randomized phase II clinical trial in mRCC is enrolling pts. Clinical trial information: NCT01625936.

4544 Poster Session (Board #217), Mon, 1:15 PM-4:45 PM

Cardiovascular toxicity following anti-angiogenic therapy in persons over age 65 with advanced renal cell carcinoma. *First Author: Sekwon Jang, Inova Comprehensive Cancer and Research Institute, Fairfax, VA*

Background: Sunitinib and sorafenib are oral vascular endothelial growth factor receptor (VEGFR) tyrosine kinase inhibitors (TKIs) approved for treatment of patients with renal cell carcinoma (RCC) in 2005-2006. We conducted a population-based observational cohort study on the cardiovascular effects of VEGFR TKI therapy in elderly RCC patients. **Methods:** We analyzed patients with RCC diagnosed from 2000-2009 ages 66 and older using data from the Surveillance, Epidemiology, and End Results (SEER)-Medicare database. We examined the incidence of cardiovascular adverse events through December 2010 including congestive heart failure and cardiomyopathy (CHF/CM), acute myocardial infarction (AMI), stroke, and cardiovascular deaths. We performed Cox-proportional hazard model to estimate the risk of these events associated with sunitinib or sorafenib adjusting for age, sex, comorbidity, and use of other systemic therapy. **Results:** A total of 171 out of 670 patients who received either sunitinib or sorafenib had cardiovascular events. The incidence rates for CHF/CM, AMI, stroke, and cardiovascular death in those who received one of the two drugs were 0.87, 0.14, 0.14, and 0.05 per 1000 person-days, respectively. Sunitinib or sorafenib use was associated with an increased risk of stroke (adjusted HR = 2.72, 95% CI: 1.49 -4.97) compared with 788 patients diagnosed with advanced RCC from 2007-2009 eligible for Part D but did not receive either agent. There were no statistically significant increased risks of CHF/CM, AMI, or cardiovascular deaths. **Conclusions:** Sunitinib or sorafenib are significantly associated with an increased risk of stroke, and clinicians should be aware of these rare adverse events.

4545 Poster Session (Board #218), Mon, 1:15 PM-4:45 PM

Overall survival analysis from a randomized phase II study of axitinib with or without dose titration for first-line metastatic renal cell carcinoma. *First Author: Brian I. Rini, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: In a randomized phase II trial in treatment-naïve patients with metastatic renal cell carcinoma (mRCC), objective response rate (ORR) was significantly higher with axitinib versus placebo titration; the hazard ratio (HR) for progression-free survival (PFS) favored axitinib titration but was not statistically significant. Analysis of overall survival (OS; as of Nov 4, 2014) is reported. **Methods:** Previously untreated patients with mRCC (N = 213) received axitinib 5 mg twice daily (BID) for a 4-week lead-in period. Patients with 2 consecutive weeks of blood pressure ≤ 150/90 mmHg, no grade > 2 axitinib-related toxicities, no dose reductions, and ≤ 2 antihypertensive medications were randomized (double-blind) to axitinib 5 mg BID + dose titration to a maximum of 10 mg BID with axitinib or placebo (n = 56 each). Those ineligible for randomization continued the axitinib 5 mg BID dose (n = 91); 10 patients discontinued prior to randomization. Primary endpoint was ORR; PFS and OS were secondary endpoints. **Results:** As of the data cut-off date, 90 of 213 patients (42%) were censored for survival (45% in the axitinib titration arm vs 30% in the placebo titration arm; 46% in the nonrandomized arm); at least 75 censored patients were alive. Median OS (95% confidence interval [CI]) from first dose was 42.7 months (24.7–not estimable [NE]) in the axitinib titration arm versus 30.4 months (23.7–45.0) in the placebo titration arm (HR 0.785; 95% CI 0.485–1.272; *P*= 0.1616). Median OS (95% CI) in the nonrandomized arm was 41.6 months (33.0–NE). In all patients, median OS (95% CI) was 39.3 months (32.7–45.8). Safety data were consistent with previous reports. Following treatment periods > 3.5 years, 9 (16%), 1 (2%), and 10 (11%) patients remain on treatment in axitinib titration, placebo titration, and nonrandomized arms, respectively. **Conclusions:** Median OS exceeded 3 years in patients with mRCC treated with first-line axitinib. Median OS was numerically longer in patients receiving axitinib titration compared with placebo titration but did not reach statistical significance. A substantial percentage of patients remain on axitinib, and no new important safety signals were observed. Clinical trial information: NCT00835978.

4546 Poster Session (Board #219), Mon, 1:15 PM-4:45 PM

Analysis of real world treatment compliance in a cohort of 2,395 patients with metastatic renal cell carcinoma (mRCC). *First Author: Jay Margolis, Truven Health Analytics, Bala Cynwyd, PA*

Background: Given recent European data highlighting the importance of real world dose intensity, we sought to examine real world compliance in patients with mRCC from a US perspective (Cancer Med 2014; 3(6): 1517-26). **Methods:** In this retrospective cohort study, we used MarketScan Commercial and Medicare Supplemental administrative claims databases to select patients newly diagnosed with mRCC (index event) during 1/1/2006 to 3/31/2014. First line therapy (1L) was defined by first prescription record post-index for any approved mRCC therapy and a change in line of therapy was defined by therapy switch. Compliance was measured using the medication possession ratio (MPR) during each and all lines of therapy. MPR was defined as total days of supply during the treatment period divided by the total treatment period until the start of the last treatment. **Results:** A total of 2,395 mRCC patients were identified as initiating 1L therapy. Across all treatments the mean MPR was 0.77 ± 0.20, which increased over time from 0.73 in 2006 to 0.81 in 2013. More than 50% of patients were noncompliant, defined as MPR < 80%. During 1L, patients treated with sunitinib had significantly lower mean MPR compared with most other treatments (table). Compliance was found to increase during 2L (0.85 ± 0.18) vs 1L (0.80 ± 0.19). A larger proportion of patients who initiated therapy with temsirolimus were compliant compared with those who initiated with sunitinib (62% vs 38%). **Conclusions:** Over half of treated mRCC patients in this study were found to be noncompliant with therapy. There were differences found between individual drugs. Compliance was significantly better with IV administered temsirolimus relative to the reference oral therapy, sunitinib. Real-world analysis of adherence behaviors provides information for clinicians in monitoring and optimizing targeted therapy.

MPR in 1L and all lines.

Compliance	Sunitinib*	Sorafenib	Pazopanib	Everolimus	Temsirolimus
1L MPR, mean (SD)	0.76 (0.19)	0.84 (0.19)	0.86 (0.19)	0.89 (0.14)	0.83 (0.19)
All lines, MPR, mean (SD)	0.74 (0.20)	0.78 (0.23)	0.84 (0.20)	0.76 (0.24)	0.81 (0.19)

* Reference group. In 1L, all differences were significant at $P < 0.05$.

4547 Poster Session (Board #220), Mon, 1:15 PM-4:45 PM

Randomized phase II study of sunitinib + CXCR4 inhibitor LY2510924 versus sunitinib alone in first-line treatment of patients with metastatic renal cell carcinoma. *First Author: John D. Hainsworth, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: Sunitinib is a standard first-line treatment for patients (pts) with metastatic renal cell carcinoma (RCC). CXCR4 and its only known ligand, SDF-1, are both overexpressed in tumor and vascular cells of clear cell RCC. LY2510924 is a selective peptide antagonist of CXCR4. We compared the results of open-label treatment with LY2510924 + sunitinib vs sunitinib alone. **Methods:** Previously untreated metastatic clear cell RCC pts were randomized (2:1) to receive standard-dose sunitinib (50 mg qd for 4 weeks [wk], then 2 wk off) + LY2510924 (20 mg sc, qd) (Arm A) or sunitinib alone (Arm B). Pts were evaluated (per RECIST v.1.1) every 8 wk. The primary analysis was done when all pts completed 72 wk of treatment, discontinued, progressed, or died and compared progression-free survival (PFS) between arms using a Bayesian time to event analysis incorporating prior information about sunitinib along with the trial data. PFS was also analyzed using the hazard ratio (HR) with only trial data. The Bayesian design was simulated to size the trial. The objective response rates (ORR) in each arm were compared using the chi-squared test. **Results:** 72 and 36 pts were treated in Arms A and B, respectively. Key pt characteristics (ECOG PS, Motzer risk score, prior nephrectomy) were similar in Arms A and B. Median number of cycles administered in each arm was 5. Median PFS was 8.1 and 12.3 months in Arms A and B, respectively (HR [95% CI]: 1.19 [0.73, 1.94]). The ORR (95% CI) was 30.6% (19.9%, 41.2%) in Arm A and 38.9% (23.0%, 54.8%) in Arm B. The most frequent (> 5% Arm A) grade 3/4 AEs (Arm A, Arm B) were hypertension (13.9%, 19.4%), fatigue (9.7%, 13.9%), diarrhea (6.9%, 16.7%), thrombocytopenia (8.3%, 5.6%), and anemia (8.3%, 2.8%). Of interest, there were more bleeding-related events (mostly grade 1 or 2) in Arm A than B (39%, 14%). More pts in Arm A discontinued treatment due to AE (18.1%, 8.3%). Two deaths in Arm A were due to adverse events (pulmonary edema/respiratory arrest/cardiac arrest and intracranial tumour hemorrhage). **Conclusions:** Adding the CXCR4 inhibitor LY2510924 to sunitinib as first-line treatment for metastatic RCC was tolerated but did not improve efficacy. Clinical trial information: NCT01391130.

4548 Poster Session (Board #221), Mon, 1:15 PM-4:45 PM

***CYP3A5* and *ABCB1* polymorphisms as predictors for sunitinib outcome in metastatic renal cell carcinoma.** *First Author: Meta Diekstra, Leiden University Medical Center, Department of Clinical Pharmacy and Toxicology, Leiden, Netherlands*

Background: In our exploratory studies we have associated single nucleotide polymorphisms (SNPs) in candidate genes with efficacy and toxicities of sunitinib in metastatic renal cell carcinoma (mRCC). The aim of the present study is to test these SNPs for association with sunitinib treatment outcome in the largest patient cohort to date. **Methods:** mRCC patients treated with sunitinib and a DNA sample available were pooled from 3 exploratory studies conducted in the US, Spain and the Netherlands. A total of 22 SNPs and 6 haplotypes in 10 candidate genes related to pharmacokinetics and pharmacodynamics of sunitinib were tested for associations with toxicity, dose reductions, progression-free survival (PFS), overall survival (OS) and best objective response. **Results:** Three-hundred and thirty-three patients were included. The presence of *CYP3A5*1* was associated with dose reductions (OR = 2.0, CI = 1.0-4.0, *P*= 0.039). Presence of CGT in the *ABCB1* haplotype was associated with an increased PFS (HR = 1.9, CI = 1.3-2.6, *P*= 0.000275) and remained significant after Bonferroni correction. These associations are consistent with prior observations. Similar size and direction of effect were observed for the association of *VEGFA* rs1570360 with hypertension (OR = 1.9, CI = 0.8-4.5, *P*= 0.173) and *FLT3* rs1933437 with leukopenia (OR = 3.6, CI = 0.8-16.7, *P*= 0.088). **Conclusions:** The confirmation of previously reported associations between polymorphisms in *CYP3A5* and *ABCB1* with sunitinib toxicity and efficacy respectively indicates that genotyping of these genetic variants may be useful for guiding sunitinib treatment.

4549 Poster Session (Board #222), Mon, 1:15 PM-4:45 PM

Randomized phase II study of two different doses of AVE0005 (VEGF Trap, aflibercept) in patients (pts) with metastatic renal cell carcinoma (RCC): An ECOG-ACRIN study [E4805]. *First Author: Roberto Pili, Roswell Park Cancer Institute, Buffalo, NY*

Background: AVE0005 (VEGF Trap), or aflibercept, is a recombinantly-produced fusion protein consisting of human VEGF receptor extracellular domains fused to the F_c portion of human IgG_1 that has potent anti-VEGF activity. We tested whether aflibercept has clinical activity in clear cell RCC. The recommended Phase 2 dose was 4 mg/kg but several pts treated at 1 mg/kg demonstrated prolonged progression-free survival (PFS). We therefore tested both doses in a parallel group randomized trial. **Methods:** Eligible pts had metastatic clear cell RCC and previous treatments including prior exposure to a VEGF TKI. Pts were stratified on prior immunotherapy (IL2/IFN) and MSKCC Risk Category. Patients received aflibercept (either 1 mg/kg or 4 mg/kg) day 1 of a 14-day cycle until progression. Patients randomized to 1 mg/kg could crossover to 4 mg/kg at progression. The primary endpoint was proportion alive and progression-free at 8 weeks. A 2-stage design was used for each arm with 33 and 24 eligible pts/arm enrolled in stages 1 and 2. If 17 pts were alive and PF at 8 wks or an objective response was observed, an arm would continue to stage 2, and if 34 of 57 eligible pts were PF at 8 wks, the arm would be considered for further study. This design had 91% power and 10% Type I error. **Results:** 94 pts were enrolled, 59 and 35 to 4 mg and 1 mg doses respectively. Median age was 61 with 72% male, 96% white, and 72% with 1 prior tx (most commonly sunitinib). 16 eligible pts crossed over at progression to the 4 mg dose. The most common adverse events were hypertension, proteinuria, and fatigue. Only 4 pts reported Grade 4 or higher toxicity. With 36/59 (61%) pts PF at 8 wks, the 4-mg/kg dose met protocol specified efficacy criteria. **Conclusions:** At a dose level of 4mg/kg, 61% of patients were progression free at 8 weeks, meeting pre-specified criteria. Aflibercept at a dose of 4 mg/kg is active in previously treated ccRCC and may be worthy of further study. Clinical trial information: NCT00357760.

	Arm A (4 mg/kg)	Arm B (1 mg/kg)	Crossover
Enrolled	59	35	17
Eligible	59	32	16
PF at 8 Wks	36 (61.0%)	15 (42.9%)	
90% CI	49.5 – 71.7%	28.6 – 58.1%	
Median PFS (wks)	10.9	8.3	18.1
90% CI (wks)	8.7 – 15.4	7.9 – 9.6	8.0 – 24.1
ORR	1.7%	3.1%	
90% CI	0.1 – 7.8%	0.2 – 14.0%	

4550 Poster Session (Board #223), Mon, 1:15 PM-4:45 PM

Pancreatic metastases from renal cell carcinoma: Prognostic relevance and outcome in patients treated with targeted agents. *First Author: Paolo Grassi, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: Pancreatic metastases from renal cell carcinoma (PmRCC) are uncommon and their prognostic role in the era of targeted terapies (TTs) is not well defined. We evaluated the outcome of a cohort of PmRCC patients (pts) who were treated with either surgery and TTs **Methods:** PmRCC pts treated between 1993 and 2014 were identified from the databases of 11 European centers. Clinical records were retrospectively reviewed and clinical outcome was analyzed. Kaplan-Meier methods and log-rank test were used to evaluate progression-free survival (PFS) and overall survival (OS). Cox proportional hazard models were used to analyse covariates associated to OS **Results:** A total of 276 pts were evaluated. PmRCC were synchronous to the primary in 80 pts (29%). Pts treated with pancreatic local treatment (PLoT), including surgery, were 77 (28%) while pts receiving systemic treatment were 256 (93%). Pts with only PmRCC were 42 (15%) whereas lung (47%), lymph nodes (28%) and liver (23%) were the most common metastatic sites in the remaining pts. Most of pts (95%) received nephrectomy (Nx). Median time from Nx to PmRCC occurrence was 91 months (mo) (IQR 54-142). First-line TTs included: sunitinib (44%), sorafenib (12%), pazopanib (9%), interferon + bevacizumab (6%) and temsirolimus (1%); 37% of pts received cytokines and 53% received subsequent lines of TTs. Best response to first-line TTs were complete response (5%) partial response (40%) and stable disease (39%) with a disease control rate of 84% and a median PFS of 12 mo (IQR 10-14). Median OS (calculated from the time of PmRCC diagnosis to death) was 73 mo (IQR 61-86) with a 5-yr OS of 58%. Median OS for pts treated with PLoT was 106 mo (IQR 78-204) with a 5-yr OS of 75%. At univariate analysis MSKCC/Heng prognostic score (*p*= .0004), Nx (*p*= .0002) and PLoT (*p*= < .0001) were significantly associated with OS.At multivariate analysis these variables confirmed their prognostic role **Conclusions:** PmRCC are associated with long-term survival, usually occur many years after Nx and lead to an indolent growth thus initial observation might be an option for this pts subgroup. Surgery should be considered in oligometastatic pts while TTs are active in widespread disease

4551 Poster Session (Board #224), Mon, 1:15 PM-4:45 PM

Early tumor shrinkage (eTS) as a predictive and prognostic factor in metastatic renal cell carcinoma (mRCC). *First Author: Viktor Gruenwald, Medical School of Hannover, Hannover, Germany*

Background: Tumor shrinkage (TS) has predictive value in mRCC, and early TS has been reported to be associated with prognosis in small series with mRCC, but the optimal cut-off has not been defined. We therefore quantitated the degree of tumor shrinkage at first scan that has predictive or prognostic value in mRCC. **Methods:** Data from Pfizer-sponsored clinical trials with sunitinib, axitinib, sorafenib, IFN or temsirolimus in mRCC were included for this posthoc analysis (A6181006, A6181034, A6181061, A6181065, A6181110, RTKC-0511-014, A4061032, A4060146, A4061051, 3066K1-304, 3066K1-3311, 3066K1-404). Objective tumor response was captured by protocol-defined tumor imaging according to RECIST. Target lesions were followed for TS. eTS was assessed at first post-baseline scan and analyzed for sensitivity and specifity by receiver-operating characteristic (ROC) analyses to predict response measured by median progression free survival (PFS) or overall survival (OS). Patients were classified as responders if PFS (7 mo.) or OS (20 mo.) were above the median. **Results:** 4736 pts (71% male) with median age 59 years were identified within the database. Most patients were treatment naïve (67%), had clear cell histology (89%), and favorable performance status (ECOG 0/1: 53/47%). Overall, an eTS of 7% or 8% was identified as the optimal cut-off for prediction of PFS or OS, respectively. Subgroups were analyzed and are depicted in table. **Conclusions:** Using a large clinical trials database in mRCC, we explored the predictive value of eTS in mRCC. Our analyses showed that the conventional 30% tumor shrinkage threshold is too high and that a cut-off at approximately 10% early TS predicts PFS and OS in mRCC. This finding is confirmed by a recent report on observer variability of eTS in mRCC. eTS should be further explored as a novel endpoint for clinical studies in mRCC.

eTS as predictor in mRCC.

	PFS	sensitivity/specifity	OS	sensitivity/specifity

Novel chromosome copy number changes to predict clinical response to sunitinib in patients with advanced renal cell carcinoma. *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Sunitinib is a 1st-line therapy for clear cell Renal Cell Carcinoma (ccRCC); however, 20-30% of tumors show primary resistant disease (PRD) with progression as the best response. This study identifies the chromosomal copy number changes that are associated with sunitinib clinical response. **Methods:** Whole genome comparative genomic hybridization (aCGH) was performed on pretreatment tumor derived DNA from 76 sunitinib treated patients. Differential copy number alterations (CNAs) were identified using Fisher's exact test with p-values < 0.05 and a 15% minimum threshold difference. Identified CNAs were univariately tested for association with PFS, and compared to two publically available ccRCC SNP datasets, TCGA-436 (N = 436, TCGA, Nature, 2013, 499: 43) and University of Tokyo-240 (N = 240, Nature Genetics, 2013, 45: 860). **Results:** In patients with PRD gains of 22q and 6p were more common, and univariate PFS analysis for these CNAs showed a worse PFS (table). In patients with objective radiographic response (CR/PR), losses of 4q, 8p, and 10q were more common, and univariate PFS analysis identified loss of 4q and 8p trended toward improved PFS (table). Using databases comprising of largely sunitinib naïve patients (TCGA-436 and University of Tokyo-240), these CNAs were not correlated with overall survival, suggesting that these CNAs reflect sunitinib response, and not sunitinib-independent tumor biology. **Conclusions:** aCGH analysis of sunitinib treated ccRCC patients reveal multiple novel CNAs associated with clinical response. These CNAs warrant further investigation and may provide insight into mechanisms of sunitinib resistance.

Chromosome copy number changes.

Worse Prognosis		Improved Prognosis

4553 Poster Session (Board #227), Mon, 1:15 PM-4:45 PM

Updated survival results from a randomized, dose-ranging phase II study of nivolumab (NIVO) in metastatic renal cell carcinoma (mRCC). *First Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

Background: NIVO, a programmed death-1 immune checkpoint inhibitor, demonstrated encouraging clinical activity in a randomized phase II study in pts with mRCC pretreated with targeted VEGF pathway agents. Here we present updated survival results. **Methods:** NIVO was administered at 0.3, 2, or 10 mg/kg IV Q3W until progression or toxicity to pts with clear-cell mRCC ($\leq$ 3 prior systemic therapies, $\geq$ 1 agent targeting VEGF pathway). Treatment beyond progression was allowed in pts who tolerated NIVO and experienced clinical benefit. Primary endpoint (progression-free survival) was reported previously. Other endpoints included overall survival (OS), adverse event rate, and association of tumor PD-L1 expression with clinical outcomes. OS was calculated by Kaplan-Meier method. PD-L1 expression was measured in archival tumor tissue by immunohistochemistry (28-8 antibody; Dako). PD-L1 positivity was defined as $\geq$ 5% tumor membrane staining. Data cutoff, January 6, 2015. NCT01354431. **Results:** 168 pts were randomized.Of the treated pts (n = 59, 54, and 54 at 0.3, 2, and 10 mg/kg, respectively), 55 (33%) continue on study; 14 (8%) remain on treatment. Median doses given (range) was 6 (1–54), 7.5 (1–56), and 8 (1–59) for 0.3, 2, and 10 mg/kg, respectively. Median OS and OS rate are presented in the table. 64% of pts were evaluable for PD-L1 expression, 27% of whom had PD-L1 expression $\geq$ 5%. Median OS (80% CI) was 29.9 mo (13.4–not available [NA]) in the PD-L1+ subgroup and 18.2 mo (12.7–27.2) in the PD-L1– subgroup across doses. OS by MSKCC risk group and number of prior therapies, as well as long-term safety, will be presented. **Conclusions:** NIVO continues to demonstrate OS benefit across dose levels and in PD-L1+ and PD-L1– pts in this phase II mRCC study with 3 years minimum follow-up. Survival rates at 2 and 3 years compare favorably with other therapies in this setting of heavily pretreated pts with clear-cell mRCC and suggest potential for pts to achieve long-term survival with NIVO treatment. A phase III confirmatory study is underway. Clinical trial information: NCT01354431.

4554 Poster Session (Board #228), Mon, 1:15 PM-4:45 PM

Final overall survival analysis for the RECORD-3 study of first-line everolimus followed by sunitinib versus first-line sunitinib followed by everolimus in metastatic RCC (mRCC). *First Author: Jennifer J. Knox, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: RECORD-3 (ClinicalTrials.gov ID, NCT00903175) was a multicenter, randomized phase 2 trial that compared first-line everolimus followed by sunitinib (EVE→SUN) with first-line sunitinib followed by everolimus (SUN→EVE) at progression of disease (PD) in patients with mRCC. In the final primary analysis comparing PFS of EVE and SUN as first line therapy, the noninferiority margin was not achieved; therefore, the primary endpoint was not met (*J Clin Oncol* 2014;32:2765). The objective of this analysis was to evaluate mature data for secondary endpoints. **Methods:** Patients with mRCC (clear or non-clear cell) and without prior systemic therapy were randomly assigned 1:1 to either first-line EVE 10 mg/day or SUN 50 mg/day (4 weeks on, 2 weeks off) until first occurrence of PD (RECIST v1.0). Patients then crossed over and continued on the alternate drug until second occurrence of PD. For this final analysis, mature data for combined first- and second-line progression-free survival (cPFS) and overall survival (OS) were assessed. Data lock for final analysis was November 25, 2014. **Results:** From October 2009 to June 2011, 471 patients were enrolled (EVE→SUN, n = 238; SUN→EVE, n = 233) and most patients in both arms had clear cell RCC (~85%). Among patients who discontinued first line, 128 (55%) crossed over from EVE to SUN and 116 (51%) crossed over from SUN to EVE. The primary protocol-related reason for not crossing over was ineligibility related to poor performance status or PD-related decline in condition (~40%). Median duration of follow-up was ~3.7 years. At final OS analysis, median cPFS was 21.7 months for EVE→SUN and 22.2 months for SUN→EVE (hazard ratio [HR], 1.2; 95% confidence interval [CI], 0.91-1.59). Median OS was 22.4 months for EVE→SUN and 29.5 months for SUN→EVE (HR, 1.09; 95% CI, 0.87-1.37). The rate of grade 3 or 4 adverse events suspected to be drug related was 62% in the EVE→SUN arm and 71% in the SUN→EVE arm. **Conclusions:** Results of this final analysis are consistent with initial results and further support the standard sequence of SUN followed by EVE at PD. Safety profiles of EVE and SUN were consistent with those previously reported. Clinical trial information: NCT00903175.

4555 Poster Session (Board #229), Mon, 1:15 PM-4:45 PM

Phase II study of individualized sunitinib as first-line therapy for metastatic renal cell cancer (mRCC). *First Author: Georg A. Bjarnason, Sunnybrook Odette Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Higher sunitinib drug exposure is associated with better response (RR), progression free (PFS) and overall survival (OS). Retrospective data show poorer PFS and OS in patients (pts) with minimum toxicity on the 28 day (d)/14 d schedule vs pts needing dose/schedule changes. We hypothesized that toxicity-driven dose/schedule changes would optimize drug exposure. **Methods:** In a prospective phase II study (eligibility identical to EFFECT trial, JCO 30(12):1371) with the primary endpoint of improving PFS from 8.5 (EFFECT 4/2) to 14 months (mo), pts start on 50 mg/d for 28 d with treatment (Rx) breaks reduced to 7 d. Pts with grade-2 toxicity before d 28 stay on 50 mg with the d on Rx individually reduced aiming for $\leq$ grade-2 toxicity. Dose is reduced to 37.5 mg in pts that do not tolerate 50 mg for at least 7 d and to 25 mg in pts that do not tolerate 37.5 mg for 7 d with individualized duration of Rx. Pts with minimum toxicity on d 28 are dose escalated to 62.5 mg and then 75 mg on a 14/7 d schedule. Pts that develop grade-2 toxicity by d 28, stay on a 28/7d schedule. **Results:** With accrual completed and 116 pts entered at 12 centers, 83 pts are evaluable for RR (at least two CTs 2 mo apart) with median followup of 11.6 mo (Heng favorable 25%, intermediate 63%, poor 12%). Nine pts came off study early due to toxicity (5), non-compliance (2) or global deterioration (2). Of 61 pts still on therapy, 24 are too early for RR. Of 83 evaluable pts (37 still on Rx), 18 (21.7%) were dose escalated to 62.5 mg (11) and 75 mg (7). For 39 pts (47%), who would have been dose reduced by standard criteria, a 50 mg dose was continued for 7 - 24 d, while 7 pts (8.4%) stayed on a 28d schedule. Dose was reduced to 37.5 mg in 13 pts (15.7% vs 36 - 63% in 4 trials) and to 25 mg in 6 pts (7.2 % vs 15 - 19% in 4 trials). Rx was stopped due to toxicity in 7/116 pts (6% vs 15-19% in 4 trials). Best response was complete (CR) in 4 pts, partial (PR) in 38 pts, stable (SD, median 6.4 mo on Rx) in 32 pts and progression in 9 pts (10.8% vs 24.6% in EFFECT) for a CR+PR (median 14.3 mo on Rx) rate of 50.6% (vs 32% in EFFECT) and CR+PR+SD rate of 89.2% (vs 75% in EFFECT). **Conclusions:** Individualized dosing is safe and feasible in a multicenter setting and associated with improved dose intensity and one of the highest RR reported for mRCC. Clinical trial information: NCT01499121.

4556 Poster Session (Board #230), Mon, 1:15 PM-4:45 PM

Molecular analysis of sarcomatoid renal cell carcinoma (sRCC). *First Author: Thai Huu Ho, Mayo Clinic, Scottsdale, AZ, Scottsdale, AZ*

Background: Patients with sRCC have a have a poor prognosis and decreased likelihood of response to targeted therapy or IL-2. Predictive biomarkers of response are lacking in sRCC. We evaluated a cohort of RCC patients to identify potentially actionable recurrent molecular aberrations. **Methods:** 112 renal cases referred to Caris Life Sciences over 2 years were evaluated for sarcomatoid components with central pathology review. 91 cases were clear cell (ccRCC) and 21 were sRCC. Testing included sequencing (next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]), and gene amplification (CISH or FISH). For sequencing, DNA was isolated by microdissection of the sarcomatoid component. 20 RCC cases with sarcomatoid differentiation from Mayo Clinic Arizona were analyzed for external validation. **Results:** The sRCC cohort showed 54% aberrant expression of PD-L1 and all but 1 case was infiltrated with PD-1+ tumor infiltrating lymphocytes (TILs). 100% of ccRCC with sarcomatoid features (n = 4) showed aberrant expression of PD-L1 and were infiltrated with PD-1+ TILs; of ccRCC without sarcomatoid features, only 17% had PD-L1 and 62% had PD-1 involvement. ccRCC had a 54% loss of PTEN, while sRCC had a 33% loss (p value = 0.2). Loss of PBRM1 expression was observed in 30% of sRCC. Loss of histone 3 lysine 36 trimethylation (H3K36me3), associated with *SETD2* mutations, was observed in 19% of sRCC and 30% of ccRCC. Key differences are shown in the table below. **Conclusions**: Multiplatform molecular profiling of sRCC identifies numerous predictive biomarkers to cytotoxic agents and immunotherapies. In other solid tumors, overexpression of TOPO2A and loss of RRM1 are associated with sensitivity to anthracyclines and gemcitabine, respectively. sRCC have increased infiltration of PD-1+ TILs and may respond to PD1/PD-L1 targeted immunotherapies. Further evaluation of TOPO2A, RRM1 and PD-1/PD-L1 as predictive biomarkers in sRCC is warranted.

	% Overexpression			TILs	% Loss	
	TOPO2A	AR	PD-L1	PD-1	RRM1	PBRM1
ccRCC	25	26	17	62	100	58
sRCC	67	5	54	96	74	30
p value	0.0001	0.04	0.005	0.003	0.0001	0.02

4557 Poster Session (Board #231), Mon, 1:15 PM-4:45 PM

Tivozanib vs sorafenib targeted therapy for advanced renal cell carcinoma: Final results of a phase III trial (901) and efficacy results of a 2nd line tivozanib extension study (902). *First Author: Thomas Hutson, Texas Oncology–Baylor Charles A. Sammons Cancer Center, Dallas, TX*

Background: An extension and open access study allowed follow up of patients (pts) from TIVO-1 (301), an open label, phase III multinational trial in which pts with metastatic renal cell carcinoma (mRCC) were randomized to either tivozanib or sorafenib (both VEGF TKIs). TIVO-1 met its primary endpoint of improved median progression free survival (PFS) over sorafenib, but overall survival (OS) was shorter (*J Clin Oncol*. 2013; 31:3791). Follow up analysis of all pts from that trial is presented. **Methods:** Pts were treated until documented progression or unacceptable tolerability on both treatments. These pts were followed for OS, investigator assessed PFS, and long term safety. The majority of pts who received first line tivozanib had no subsequent therapy; the majority of pts initially treated with sorafenib were crossed over to tivozanib per protocol. **Results:** Few second line therapy options were available to pts who discontinued initial tivozanib. Of the 259 tivozanib pts, 69.3% received no subsequent therapy, 11.7% VEGF therapy (not tivozanib), 9.7% mTOR inhibitor therapy, and 10.0% non-targeted therapy. All 257 pts discontinued initial sorafenib therapy and 168 (65.4%) went on to subsequent VEGF therapy (163 treated with tivozanib), 1.2% to mTOR, 2.0% to non targeted therapy, and 31.5% to no additional therapy. Follow up PFS and OS from initial randomization for the 260 pts originally receiving tivozanib was 14.6 and 29.0 mos, and for the 257 pts originally receiving sorafenib was 9.7 and 34.1 mos, respectively (PFS HR = 0.77, OS HR = 1.18). Long term safety assessment of pts who continued tivozanib indicated that incidence of the most common on target AEs (hypertension and dysphonia) decreased over time. For the 163 pts who crossed over from sorafenib to second line tivozanib, median PFS was 11 mos and median OS was 21.6 mos from the start of second line tivozanib. **Conclusions:** This long term analysis of PFS and OS underscores the positive impact of tivozanib treatment after sorafenib failure in mRCC. Lack of access to second line therapies in pts in the tivozanib arm due to geographical reasons most likely affected trial results. Clinical trial information: NCT01030783, NCT01076010, NCT01369433.

4558 Poster Session (Board #232), Mon, 1:15 PM-4:45 PM

Characteristics of metastatic renal cell carcinoma (mRCC) patients treated with delayed targeted therapy: Results from the International mRCC Consortium (IMDC). *First Author: Haoran Li, Tom Baker Cancer Center, Calgary, AB, Canada*

Background: A small proportion of patients with mRCC may not require immediate targeted therapy (TT). Their clinicopathological features and prognoses are not well characterized. **Methods:** A retrospective analysis was conducted in mRCC patients who did not start TT until at least 1 year after diagnosis of metastatic disease (delayed TT). Patients treated with traditional immunotherapy were excluded. For comparison, patients that received immediate TT within 1 month of metastatic diagnosis were used (immediate TT). **Results:** 467/3202 (14.6%) mRCC patients had delayed TT. The majority of patients (96.6%) in delayed group had prior nephrectomy. Compared to patients who received immediate TT (n = 800), patients with delayed TT were more likely to have clear cell histology (87.8% vs. 82.7%, $p = 0.02$), lower grade primary lesions (low/int grade: 38.3% vs. 31.2%, $p = 0.03$), less likely to have sarcomatoid features (7.1% vs. 13.1%, $p = 0.002$), greater percentage of normal LDH (74.8% vs. 67.1%, $p = 0.02$) and less hyponatremia (11.9% vs. 19.3%, $p < 0.01$). However, slightly more brain and bone metastases at baseline were seen in the delayed TT vs immediate TT groups (8.7% vs. 5.7%, $p = 0.046$ and 38.3% vs. 31.4%, $p = 0.02$, respectively) and it is unknown if these patients were delayed due to metastatectomy or radiotherapy. IMDC risk factors were more favorable in delayed TT group, with less anemia (43.2% vs. 65.0%, $p < 0.001$), hypercalcemia (6.9% vs. 11.7%, $p < 0.01$), neutrophilia (11.3% vs. 22.0%, $p < 0.001$), thrombophilia (8.6% vs. 18.4%, $p < 0.001$), KPS < 80 (20.9% vs. 26.6%, $p = 0.03$). The response rate of TT was similar between two groups (27.0% vs. 27.0%, $p = 1.0$). The median PFS was 9.3 months in delayed TT patients vs 5.6 months in immediate group ($p < 0.001$), and the median OS was 26.6 months in delayed group vs 17.2 months in immediate group ($p < 0.001$). The differences in survival are due to patient selection. **Conclusions:** Patients with fewer adverse IMDC criteria were more likely to receive delayed systemic treatment. 14.6% of patients who start targeted therapy do so over a year from diagnosis of mRCC. Further studies are warranted to determine who can benefit most from delayed TT.

4559 Poster Session (Board #233), Mon, 1:15 PM-4:45 PM

A phase I study of buparlisib (BKM120) with bevacizumab (BEV) in patients (pts) with metastatic renal cell carcinoma (mRCC) progressing on prior vascular endothelial growth factor (VEGF) therapies. *First Author: Rana R. McKay, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: BKM120 is a pan-PI3K inhibitor with demonstrated activity in advanced solid tumors. The primary aim of this study was to determine the maximum tolerated dose (MTD) and dose limiting toxicities (DLTs) of BKM120 + BEV. Secondary objectives included safety, efficacy, and biomarker discovery. **Methods:** This was a 3+3 dose escalation study of BKM120 (60-100 mg/day (d)) + BEV (10 mg/kg every 2 weeks). After the MTD was defined, 14 pts were accrued to the expansion cohort. **Results:** A total of 32 pts were accrued (5 treated at 60 mg/d, 19 at 80 mg/d (2 remain on therapy), 6 at 100 mg/d, and 2 never received therapy). The majority had clear cell histology (88%) and 50% had ≥2 prior lines of systemic therapy. The MTD of BKM120 was 80 mg/d. With the exception of 1 case of cognitive disturbance deemed related to both agents, all DLTs (Table 1) were attributed to BKM120. 28 pts discontinued therapy: 16 due to progression, 7 dueto toxicity, 1 due to death, and 4 due to other reasons. Toxicity leading to therapy discontinuation included rash/pruritis, transaminitis, elevated lipase/amylase, suicidal ideation, and cognitive disturbances. Of the 30 pts who received at least 1 dose, 13% had a partial response (PR) (95% CI 4%, 31%), 50% had stable disease (SD), and 20% had progressive disease (PD). Of the 19 pts treated at the MTD, 11% had a PR (95% CI 1%, 33%), 53% had SD, and 16% had PD. The median time-to-treatment failure (TTF), progression-free survival (heavy censoring) and overall survival were 4 (95% CI 2, 9), 9 (95% CI 2, 9), and 18 (95% CI 4, not reached) months (mos) for the total cohort and 4 (95% CI 2, 9), 6 (95% CI 2, 9), and 13 (95% CI 5, not reached) mos for pts treated at the MTD, respectively. Of the 9 pts evaluated, 2 had activating PI3K mutations. One achieved a PR (TTF 13 mos) and the other achieved SD with 16% tumor shrinkage (TTF 9 mos). **Conclusions:** BKM120 at 80 mg/d + BEV was a tolerable regimen with preliminary activity in VEGF-refractory mRCC. Clinical trial information: NCT01283048.

Summary of DLTs.

Case	DLT	Grade	BKM Dose
11	Anxiety	3	100 mg
	Depression	3	
	Suicidal ideation	3	
12	Anorexia	3	100 mg
	Weight loss	3	
15	Cognitive disturbance	2*	80 mg

*≥1 CTCAE grade level increase defined as DLT.

4560 Poster Session (Board #234), Mon, 1:15 PM-4:45 PM

Prognostic value of genomic signatures in metastatic Clear Cell Renal Cell Carcinoma (mRCC) using The Cancer Genome Atlas (TCGA) data. *First Author: Guillermo de Velasco, Dana- Farber Cancer Institute, Boston, MA*

Background: Gene-expression signatures for prognosis have been reported in localized RCC. The aim of this study was to validate two different signatures; ClearCode34, a 34-gene signature model (Brooks et al. *Eur Urol.*, 2014) and an 8-gene signature model (Choudhury et al. *Eur Urol.*, 2015) in a population of mRCC. **Methods:** mRCC patients from five institutions who were part of TCGA KIRC were identified and clinical data were retrieved. Normalized RNAseq gene expression data were downloaded from the public TCGA portal. mRCC patients were dichotomized to good and poor prognostic risk groups using the 2 models. Cox proportional hazard regression was used to investigate an association between molecular subtype and overall survival (OS) from first-line therapy. **Results:** Overall, 56 patients were included in the analysis**.** Median age was 62 years. The proportions of patients in IMDC prognostic risk groups were 14%, 66%, and 20% for good, intermediate, and poor risk respectively. Fifty two (92.8%) patients received VEGF-targeted therapy. Median follow-up from initiation of first-line therapy was 25.2 months. Applying the ClearCode34, median survival for the ccA (n = 18) and ccB (n = 38) subtypes were 27.6 and 22.3 months (HR: 2.33; 95% CI, 1.02 to 5.31; P = 0.03), respectively. On multivariable analyses and adjusting for IMDC groups, ccB remained independly associated with a worse OS (p = 0.044). On the other hand, the 8-gene signature molecular subtypes did not predict survival in this cohort (HR 1.76; 95% CI, 0.8 to 3.85, P = 0.15). **Conclusions:** ClearCode34, but not the 8-gene molecular signature model, is prognostic in patients with mRCC. These data need to be externally and prospectively validated.

4561 Poster Session (Board #235), Mon, 1:15 PM-4:45 PM

Metastatic chromophobe renal cell carcinoma treated with target therapies: A Renal Cross Chanel Group (RCCG) study. *First Author: Emeline Colomba, Institut Gustave Roussy, Villejuif, France*

Background: Metastatic Chromophobe renal cell carcinoma (mChRCC) is a rare entity with no specific targeted therapy recommended. We aim to assess the outcome of targeted therapy (TT) in a large cohort of mChRCC patients (pts). **Methods:** RCCG collected data from 27 centers in France, UK and Italy. Patients' characteristics, treatments, best response and outcomes were collected. Time to treatment failure (TTF) for first-line treatment was calculated from the initiation of first-line treatment (t0) until failure (progression disease, toxicity, death). Overall survival (OS [95%CI]) was calculated from t0 until death. Survival outcomes were described using Kaplan-Meier method with 95% confidence interval. **Results:** Overall, 91 mChRCC pts were collected. Among these, 63 were treated with TT with a median follow-up of 3 years (range: 0.1-14). Median age at diagnosis was 58 years with a majority of men (62%, n = 39). Most pts had nephrectomy (92%, n = 58). International Metastatic RCC Database Consortium (IMDC) prognosis groups were good: 4% (n = 2), intermediate: 74% (n = 35), poor: 21% (n = 10), or unknown (ukn) = 16. Patients were treated either with anti-angiogenic (AA) (79%, n = 50), mTORi (17%, n = 11) or other (3%, n = 2) as first line. Most pts (84%) received sunitinib as AA. Best overall response with AA was CR+PR: 36% (n = 16), SD: 33% (n = 15), PD: 31% (n = 14), ukn = 5. Median TTF in first line in the entire population was 7 months [4-9]. Median TTF with AA was 8 months [5-10]. Median TTF was 7.9 [3.8-13.6], and 2.4 [0.7-8.0] months for intermediate and poor IMDC prognosis groups respectively. Second line treatment was administered in 30 pts (48%) and third line in 9 (14%) pts. Median OS was 23 [12-36], 30 [12-46] and 9 [2-NR] months for overall, AA and mTORi, respectively. Median OS was NR [11.6-NR], 22 [9.8-35.9] and 9 [1.1-35.1] months for good, intermediate and poor IMDC prognosis group respectively. **Conclusions:** We report the largest cohort of patients with mChRCC treated with targeted therapy. TTF and OS with VEGF/VEGFR inhibitors are similar to outcomes in patients with clear cell RCC. Integration of newly characterized biological insights in ChRCC will be the next step to improve outcomes of patients with mChRCC.

4562 Poster Session (Board #236), Mon, 1:15 PM-4:45 PM

Clinical effect of TKI dose-escalation after disease progression in patients with metastatic renal cell carcinoma. *First Author: Moshe Chaim Ornstein, Cleveland Clinic Fdntn, Cleveland, OH*

Background: Given the variability in drug levels with tyrosine kinase inhibitors (TKI) in patients (pts) with metastatic renal cell carcinoma (mRCC), escalation of dose at the time of progressive disease (PD) may have anti-tumor effect. **Methods:** Pts with mRCC who were treated at Cleveland Clinic with TKIs and were dose-escalated following PD per RECIST 1.1 were retrospectively reviewed. Patient and disease-related data were collected and summarized as frequency counts and percentages, or medians and ranges. The Kaplan-Meier method was used to summarize treatment duration on escalated doses. **Results:** Nineteen patients were identified. The majority of patients (84%) were male; median age was 58 (range, 40-71). The most common histology was clear cell (79%), 78% of pts were intermediate risk by IMDC criteria, and all but one patient had prior nephrectomy. Axitinib was the most frequently escalated agent following disease progression (89%); starting at 5mg BID and generally escalating by 1-2mg BID as tolerated. Sunitinib was the dose-escalated TKI in the remaining 2 patients; starting at 50 mg on a 4/2 schedule and escalating to 62.5mg on a 2/1 schedule. Prior to PD/dose-escalation, best response was partial response (PR) in 7 (37%) pts, stable disease (SD) in 10 (53%), and PD in 2 (11%) pts with a median treatment duration of 6.7 months (range, 1.6-49.8). Of pts with evaluable tumor measurements during the escalation period (n = 15), 11 pts (73%) had a decrease in tumor burden. Median decrease in tumor burden after dose-escalation was 11% (range, 0-58%); 6 (40%) pts had decreases > 10%: 3 (20%) > 20%, and 1 (7%) > 30%. Most pts continue to be treated at escalated doses; median duration of escalated therapy is estimated to be 9.8 months (range 0.6+ to 21.1+ months). **Conclusions:** Dose-escalation of TKIs after PD in select mRCC can lead to reduction in tumor burden and extend the duration of therapy.

4563 Poster Session (Board #237), Mon, 1:15 PM-4:45 PM

Clinical impact of loss of H3K36me3 expression in patients with clear cell renal cell carcinoma. *First Author: Abhisek Swaika, Mayo Clinic, Jacksonville, FL*

Background: Mutations in chromatin modifying enzymes play a role in the pathogenesis of clear cell renal cell carcinoma (ccRCC). However the clinical impact of histone methylation regulated by chromatin modifying enzymes remains unknown. Herein we analyze the clinical impact of loss of histone H3 lysine 36 trimethylation (H3K36me3) in a large cohort of ccRCC tumors and associate its expression with renal cell cancer-specific survival (RCC-SS) and pathologic features. **Methods:** We utilized the Mayo Clinic Renal Registry and identified 1454 patients who underwent nephrectomy to treat clinically localized ccRCC between 1/3/1990 and 4/14/2009 and who also had available tissue samples. We used immunohistochemistry (IHC) to detect H3K36me3 expression, and a central pathologist blinded to the outcomes scored tumors as either positive or negative. Tumors with heterogeneous or equivocal staining were not included in this analysis. For associations with pathologic features we employed Mann-Whitney U tests, and for associations with relapse free survival (RFS) and ccRCC-SS we generated Cox proportional hazard regression models. **Results:** Of the total 1454 samples, 1205 (83%) were scored as either positive or negative for H3K36me3 with 978 (81%) positive and 227 (19%) negative samples. H3K36me3 negative tumors strongly associated with male gender, older age, larger tumor size, higher grade (3-4), and positive tumor necrosis ($p < 0.001$ for all). After adjusting for age, H3K36me3 negative patients had decreased RFS (HR 2.87, $p < 0.001$) and decreased RCC-SS (HR 3.10, $p < 0.001$). After adjusting for age and the Mayo Clinic-Stage, Size, Grade, and Necrosis (SSIGN) score, H3K36me3 negative tumors continued to have decreased RFS (HR 1.30, p = 0.041) and trended towards decreased RCC-SS (HR 1.31, p = 0.064). **Conclusions:** This is the largest study evaluating the clinical significance of H3K36me3 expression in patients with ccRCC. Loss of H3K36me3 is a marker of poor prognosis and an independent predictor of decreased RFS. Efforts to elucidate the mechanisms of how loss of H3K36me3 contributes to worse tumor biology are underway.

4564 Poster Session (Board #238), Mon, 1:15 PM-4:45 PM

Precision medicine approach in kidney cancer: A pan renal cell carcinoma (RCC) study across three cancer genome atlas (TCGA) datasets for clinically relevant target identification. *First Author: Bradley Murray, Broad Institute, Boston, MA*

Background: Comprehensive molecular evaluation of clear cell (ccRCC),papillary (pRCC) and chromophobe (ChRCC) tumors through TCGA has provided significant insights into the biology of RCC. Yet, the translation of these efforts in terms of clinical impact remains under developed. We aim to report clinically relevant molecular alterations events that can be identified by precision medicine screening approach across 3 RCC datasets. **Methods:** TCGA datasets for ccRCC, pRCC and ChRCC were analysed for focal mutations using a previously reported 121-gene panel relevant for genomics-driven therapy (TARGET) that may have therapeutic, prognostic and diagnostic implications for patients with cancer (Van Allen, *Nature Medicine* 2014), and for relevant copy number alterations (CNA) defined as focal amplification (Amp) or homozygote deletion. **Results:** Overall, 760 RCC including 420 ccRCC, 275 pRCC and 65 ChRCC were analysed. A total of 1,089 clinically relevant somatic mutations and 110 clinically relevant somatic CNA were identified. Tumor specific incidence of mutation and CNA are reported (Table). **Conclusions:** Overall, at least 78.7% of RCC tumors (598/760) present a genomic alteration considered potentially clinically relevant. Both ccRCC and pRCC exhibit a large number of small incidence events. This report provides a strong rational for including RCC in ongoing clinical trials of target identification and to assess the clinical relevance of these events.

4565 Poster Session (Board #239), Mon, 1:15 PM-4:45 PM

Extension of overall survival (OS) beyond objective responses (OR) in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with high dose interleukin-2 (HD IL-2). *First Author: David D. Stenehjem, Department of Pharmacotherapy, College of Pharmacy, University of Utah, Salt Lake City, UT*

Background: The aim of this study is to determine if achievement of stable disease as a best response to HD IL-2 may improve survival outcomes. Recent data suggest that immunotherapy may improve survival even in those pts who do not experience objective responses (CR+PR). **Methods:** All sequential mRCC pts treated with HD IL-2 at the University of Utah (1988-2013) and University of Michigan (1997-2013) were included. Best responses to HD IL-2 were correlated with survival outcomes using landmark analysis at 2 months—the median time to first disease assessment. **Results:** A total of 391 pts (75% male; median age 55 yrs, range 13-77) were included and belonged to the following risk categories: 80 (20%) good, 251 (64%) intermediate, and 60 (15%) poor. A CR was identified in 35 (9%), PR in 39 (10%), SD in 125 (32%), progressive disease (PD) in 164 (42%), and not evaluable for response (NE) in 28 (7%) pts. Median OS for the favorable, intermediate and poor risk groups were 53.8 ($p=0.0015$ vs intermediate), 26.4 ($p<0.0001$ vs poor), and 12.2 ($p<0.0001$ vs favorable) months, respectively. Table shows correlation of response to survival. **Conclusions:** Stable disease as best response to HD IL-2 was achieved in 32% of pts and survival outcomes were not statistically different in these pts from those achieving PR, however significantly greater than those with PD. Stable disease is an important response criterion for treatment with HD IL-2, and may be discussed with the pts.

Correlation of best responses with survival outcomes in mRCC pts treated with HD IL-2: Landmark analysis at 2 months.

	Median PFS, months	Median OS, months
Overall	6.9	49.2
CR vs PR	113.8 vs 11.8 (HR 0.18, CI 0.09-0.37)	156.7 vs 37.8 (HR 0.21, CI 0.09-0.47)
CR vs SD	113.8 vs 9.0 (HR 0.13, CI 0.06-0.23)	156.7 vs 38.4 (HR 0.13, CI 0.05-0.26)
SD vs PD	9.0 vs 3.9 (HR 0.19, CI 0.12-0.31)	38.4 vs 19.9 (HR 0.41, CI 0.24-0.72)
OR vs (SD and PD)	26.4 vs 4.9 (HR 0.26, CI 0.18-0.36)	101.2 vs 24.1 (HR 0.24, CI 0.15-0.37)
(CR, PR, SD) vs PD	10.4 vs 2.6 (HR 0.10, CI 0.07-0.14)	53.9 vs 12.2 (HR 0.23, CI 0.16-0.33)
PR vs SD	11.8 vs 9.0 (HR 0.69, CI 0.44-1.04)	37.8 vs 38.4 (HR 0.60, CI 0.34-1.01)

4566 Poster Session (Board #240), Mon, 1:15 PM-4:45 PM

Efficacy and safety of endothelial growth factor receptor (VEGFR)-tyrosine kinase inhibitors (TKI) after programmed cell death 1 (PD-1) inhibitor treatment in patients with metastatic clear cell renal cell carcinoma (mccRCC). *First Author: Rosa Nadal, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Emerging agents blocking the PD-1 pathway show activity and may transform the current treatment landscape of mccRCC. The aim of this study was to evaluate the efficacy and safety of VEGFR -TKI therapy after PD-1 treatment. **Methods:** Patients (pts) with mccRCC treated with PD-1 monotherapy or in combination - with either cytotoxic T-lymphocyte antigen 4(CTLA4) inhibitor (PD1/CTLA4) or TKI (PD-1/VEGFR-TKI) - who subsequently received VEGFR-TKI, were retrospectively reviewed. The efficacy end points were objective response rate (ORR) and progression-free survival (PFS) stratified by type of prior PD-1 regimen. Safety by type and PD-1 exposure was also evaluated. **Results:** 63 patients were included, 84% of pts had at least one VEGFR-targeted therapy prior to PD-1-based therapy. The ORR for VEGFR -TKI therapy (68%, 17%, 14% and 1% pts received axitinib, pazopanib, sunitinib and sorafenib, respectively) after any PD-1 combination was 27% (17/63 PR). An additional 26 (41%) pts achieved SD. The median PFS (mPFS) was 6.9 months (mo) (95%, CI: 3.7 to 10.1). In the analysis by type of prior PD-1 therapy, there was a trend toward a higher ORR in pts who had prior therapy with PD1 monotherapy or PD1/CTLA4 therapy 33% versus 14% for pts previously treated with PD-1/VEGFR-TKI therapy ($p = 0.094$). The mPFS was longer in those pre-treated with PD-1 monotherapy or PD-1/CTLA4 therapy: 8.3 mo (95%, CI: 4.0-12.7) compared to those who previously received PD-1/VEGFR-TKI combinations: 6.4 mo (95%, CI: 3.9-8.8); $p = 0.049$. The most common adverse events (AEs) (all grades/g3-4) were asthenia (69%/11%), hypertension (41%/2%) and diarrhea (30%/0%). One patient experienced grade-2 immune-related colitis during VEGFR-TKI therapy. **Conclusions:** The efficacy and safety of VEGFR-TKIs after PD-1 treatment was demonstrated in this retrospective study. The response rate was lower and the mPFS shorter in those pts who received prior PD-1 in combination with VEGFR-TKI. PD-1 exposure does not seem to influence the safety of subsequent VEGFR-TKI treatment compared to historical control and immune-related AEs were rare.

4567 Poster Session (Board #241), Mon, 1:15 PM-4:45 PM

The DART Study: Part 1 results from the dalantercept plus axitinib dose escalation and expansion cohorts in patients with advanced renal cell carcinoma (RCC). *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Activin receptor-like kinase 1 (ALK1) is a novel target in angiogenesis involved in blood vessel maturation and stabilization. Concurrent targeting of ALK1 and vascular endothelial growth factor (VEGF) signaling results in dual angiogenic blockade and augmented inhibition of tumor growth in RCC xenograft models. Dalantercept (Dal) is an ALK1 receptor-fusion protein that acts as a ligand trap and has demonstrated monotherapy activity with an acceptable safety profile in a completed Phase 1 study. **Methods:** Part 1 of this study evaluated the safety, tolerability, and preliminary activity of escalating dose levels of Dal plus standard dose axitinib in pts with advanced RCC. 3-6 pts each received 0.6, 0.9, or 1.2 mg/kg Dal SC Q3W and axitinib 5 mg PO BID. Key eligibility: predominantly clear cell RCC, 1 prior VEGFR TKI, ≤ 3 prior tx. **Results:** As of January 16, 2015, a total of 29 pts were enrolled. During dose escalation, 15 pts were enrolled in 3 cohorts ($n = 6, 4, 5$) at dose levels of 0.6, 0.9 and 1.2 mg/kg, respectively. There were no DLTs. The 1.2 mg/kg dose level was expanded to include 9 more pts and edema events including peripheral edema ($n = 8$), fluid overload ($n = 1$), and ascites ($n = 1$) were reported. The 0.9 mg/kg dose level was then expanded to include 5 more pts. This dose level was well tolerated (4 pts with grade 1 edema, 1 pt with pleural effusion and no ascites), and selected for Part 2. AEs ($> 30\%$) regardless of attribution included: fatigue, diarrhea, dysphonia, peripheral edema, nausea, decreased appetite, epistaxis, hypertension, arthralgia, creatinine rise, cough, and hand-foot rash. There were no grade 4/5 related adverse events. 28 pts were evaluable by RECIST v1.1. The ORR was 25% ($n = 7$). Disease control (PR+SD) at 6 months was 57% ($n = 16$). The preliminary median PFS is 8.3 months for all dose levels combined. The mPFS at the 0.9 mg/kg dose level has not been reached. **Conclusions:** The combination of dalantercept and axitinib is well tolerated and has shown encouraging activity in pts who have received prior VEGF, mTOR, and immune therapies. Part 2 of this study will randomize 130 pts to dalantercept + axitinib vs. placebo + axitinib and is actively accruing patients. Clinical trial information: NCT01727336.

4568 Poster Session (Board #242), Mon, 1:15 PM-4:45 PM

Impact of salvage surgery and radiotherapy on overall survival in patients with recurrent primary urethral cancer. *First Author: Georgios Gakis, Eberhard-Karls University Tuebingen, Tuebingen, Germany*

Background: To evaluate the impact of salvage therapy (ST) on overall survival (OS) in recurrent primary urethral cancer (PUC). **Methods:** A series of 154 patients (109 men, 45 women; median age: 66, IQR: 58-76) were diagnosed with PUC at ten referral centers between 1993 and 2012. Kaplan-Meier analysis with log-rank was used to estimate the impact of ST on OS. The median follow-up was 21 months (mean: 32 months; IQR: 4-48). **Results:** The modality of primary treatment was cystectomy+urethrectomy in 43 (27.9%), total/partial urethrectomy in 39/6 (25.3/3.9%), transurethral resection in 39 (25.3%), chemoradiotherapy (CRT), radiotherapy (RT), chemotherapy (CT) and other in 9 (5.8%), 4 (2.6%), 3 (1.9%) and 9 (5.8%) patients, respectively. Neoadjuvant CT/CRT and adjuvant CT were administered to 16/9 (10.4/5.8%) and 23 (14.9%) patients, respectively. The locations of recurrences were: urethral in 28 (18.2%), lymph nodes (LN) in 18 (11.7%), LN+distant in 12 (7.8%), LN+distant+urethral in 9 (5.8%), LN+urethral in 6 (3.9%), distant in 5 (3.3%), distant+urethral in 4 (2.6%) and no recurrence in 72 (46.8%). In the 82 patients with recurrences, the modality of ST was surgery in 32 (39.0%), RT in 8 (9.8%), surgery+RT in 5 (6.1%) and none in 37 (45.1%). The 3-year OS for patients free of any recurrence (I), with solitary and/or concomitant urethral recurrence (II) and non-urethral recurrence (III) were 86.7%, 74.5/% and 41.7% respectively ($p < 0.001$ for I vs. III, $p = 0.001$ for II vs. III, $p = 0.53$ for I vs. II). In patients with recurrences, those who underwent ST had similar 3-year OS (surgery: 84.9%, RT: 80%, surgery+RT: 80%) compared to patients with no recurrence (86.7%, $p = 0.79$), and exhibited superior 3-year OS compared to patients who did not undergo ST (27.6%; $p < 0.001$ compared to surgery; $p = 0.016$ to RT-based ST; $p = 0.53$ for surgery vs. RT-based ST). Receipt of perioperative CT/CRT ($N = 16$) did not impact on 3-year OS after ST (79.3%) compared to no CT/CRT ($N = 29$, 85.5%, $p = 0.95$). **Conclusions:** In this study, patients who underwent surgery or RT-based ST for recurrent PUC demonstrated improved OS compared to those who did not receive ST and exhibited similar survival to those who never developed recurrence after primary treatment.

4569 Poster Session (Board #243), Mon, 1:15 PM-4:45 PM

Multi-institutional validation of the predictive value of Ki-67 in patients with high-grade urothelial carcinoma of the upper urinary tract. *First Author: Laura-Maria Krabbe, University Hospital of Münster, Münster, Germany*

Background: To validate the independent predictive value of Ki-67 in patients with high-grade upper tract urothelial carcinoma (UTUC). **Methods:** 475 patients from the international UTUC collaboration who underwent extirpative surgery for high-grade UTUC were included in this study. Immunohistochemical staining for Ki-67 was performed on tissue microarray (TMA) formed from this patient cohort. Ki-67 expression was assessed in a semi-quantitative fashion and considered overexpressed at a cut-off of 20%. Multivariate analyses (MVA) were performed to assess independent predictors of oncological outcomes and Harrell's C indices (HCI) were calculated for predictive models. **Results:** Median age of the cohort was 69.7 years and 55.2% of patients were male. Ki-67 was overexpressed in 25.9% of patients. Ki-67 overexpression was significantly associated with ureteral tumor location, higher pT-stage, lymphovascular invasion, sessile tumor architecture, tumor necrosis, concomitant carcinoma in situ (CIS), and regional lymph node metastases. In Kaplan-Meier analyses, overexpressed Ki-67 was associated with worse recurrence-free (RFS) (HR 12.6, $p < 0.001$) and cancer-specific survival (CSS) (HR 15.8, $p < 0.001$). In MVA, Ki-67 was an independent predictor of RFS (HR 1.6, 95% CI 1.07-2.30, $p = 0.021$) and CSS (HR 1.9, 95% CI 1.29-2.90, $p = 0.001$). Ki-67 improved HCI from 0.66 to 0.70 ($p < 0.0001$) for both RFS and CSS in our preoperative model, and from 0.81 to 0.82 ($p = 0.0018$) for RFS and 0.81 to 0.83 ($p = 0.005$) for CSS in our post-operative model. **Conclusions:** Ki-67 was validated as an independent prognostic predictor of RFS and CSS in patients treated with extirpative surgery for high-grade UTUC in a large, multi-institutional cohort.

TPS4570 Poster Session (Board #244a), Mon, 1:15 PM-4:45 PM

Design of an open label, randomized, phase II study of paclitaxel and panitumumab compared to paclitaxel alone in patients with relapsed or refractory urothelial cancer. *First Author: Andrea Necchi, Istituto Nazionale Tumori of Milan, Milano, MI, Italy*

Background: The paradigm shift in the treatment of urothelial cancer (UC) is perceived by the oncology community as a long-standing medical need under multiple aspects. For patients (pts) with advanced disease and who have failed chemotherapy attempts, no FDA-approved agent is still available. One plausible target in UC is the Epidermal Growth Factor Receptor (EGFR). Strong expression of EGFR is found in 50% of advanced UC and it is associated with a more aggressive phenotype. Signals of activity of anti-EGFR agents combined with chemotherapy have been observed. **Methods:** Pts will receive paclitaxel (TXL) and will be randomly assigned 2:1 to also receive Panitumumab or not until disease progression, unacceptable toxicity, or withdrawal of consent. The doses of the study drugs will be as follows: panitumumab 6 mg/Kg IV every 14 days and TXL 80 mg/m2 IV on days 1, 8 and 15 of a 28 day cycle. Pts will undergo computed tomography (CT) and positron emission tomography (PET)/CT scan at baseline and q2 months. The primary endpoint will be progression-free survival (PFS). It is foreseen an accrual of 120 patients, 80 + 40 in the two arms, corresponding to 114 disease progressions or deaths. This is the number of events necessary to yield 90% power of a one-sided logrank test at the 5% significance level in case of an improvement in PFS from a median of 2.5 months (H_0) to a median of 4.5 months (H_1), corresponding to a 44% hazard rate reduction in the experimental arm compared to control. Computations were done taking into account an annual 10% drop out rate and the use of O'Brien-Fleming type efficacy and futility stopping rules at the interim analysis, to be performed when 51 (50%) of the expected number of events will be recorded. Eligibility will include diagnosis of metastatic UC and failure of 1 or 2 chemotherapy regimens. A relapse within 6 months of a perioperative chemotherapy will be counted as one line. Pharmacodynamic analyses are planned on pre- and post- tissue samples and will include molecular alterations of EGFR/RAS pathways. The trial is currently open to accrual (registered with EudraCT, number 2014-000857-35). Clinical trial information: 2014-000857-35.

TPS4571 Poster Session (Board #244b), Mon, 1:15 PM-4:45 PM

KEYNOTE-045: Randomized phase 3 trial of pembrolizumab (MK-3475) versus paclitaxel, docetaxel, or vinflunine for previously treated metastatic urothelial cancer. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Boston, MA*

Background: Paclitaxel, docetaxel, and vinflunine are commonly used as second-line therapy for advanced urothelial cancer, but median OS is only 7-9 months. The PD-1 pathway plays a key role in evading the tumor immune response. Pembrolizumab is a highly selective anti–PD-1 monoclonal antibody designed to block the interaction between PD-1 and its ligands PD-L1 and PD-L2. In KEYNOTE-012, pembrolizumab 10 mg/kg every 2 weeks (Q2W) provided a 24% ORR (RECIST v1.1, central review) and an acceptable safety profile in 33 pts with PD-L1–positive advanced urothelial cancer, 76% of whom received $\geq$ 1 prior therapy. **Methods:** In the international, open-label, phase 3 KEYNOTE-045 trial (ClinicalTrials.gov, NCT02256436), pts with confirmed metastatic or locally advanced/unresectable urothelial cancer (transitional cell or predominantly transitional cell histology) of the bladder, renal pelvis, ureter, or urethra that has recurred or progressed following platinum-based chemotherapy are randomized 1:1 to pembrolizumab 200 mg Q3W or investigator's choice of paclitaxel 175 mg/m^2 Q3W, docetaxel 75 mg/m^2 Q3W, or vinflunine 320 mg/m^2 Q3W. Key eligibility criteria include $\leq$ 2 prior chemotherapy regimens and measurable disease per RECIST v1.1. Randomization is stratified by ECOG PS (0/1 vs 2), liver metastases (presence vs absence), hemoglobin level ($<$ 10 vs $\geq$ 10 g/dL), and time from last chemotherapy dose ($<$ 3 vs $\geq$ 3 mo). All pts must provide a recently obtained biopsy sample for PD-L1 evaluation at a central laboratory. Pembrolizumab will be given for up to 24 mo or until disease progression, unacceptable toxicity, or investigator decision. Treatment may be continued beyond initial radiographic progression in select pts. Pts who achieve complete response may discontinue pembrolizumab. Response will be evaluated at wk 9 and every 12 wk thereafter. After discontinuation, pts will be followed for survival every 12 wk. Primary end points are OS and PFS assessed per RECIST v1.1 by independent central review. Secondary end points include ORR and duration of response. Enrollment began in Oct 2014 and will continue until approximately 470 pts are enrolled. Clinical trial information: NCT02256436.

TPS4572 Poster Session (Board #245a), Mon, 1:15 PM-4:45 PM

KEYNOTE-052: Phase 2 study of pembrolizumab (MK-3475) as first-line therapy for patients (pts) with unresectable or metastatic urothelial cancer ineligible for cisplatin-based therapy. *First Author: Dean F. Bajorin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Standard first-line therapy for advanced urothelial cancer is cisplatin-based chemotherapy. Pts who are ineligible for cisplatin therapy, mainly due to renal dysfunction and/or poor performance status, have limited treatment options. The programmed death receptor 1 (PD-1) pathway is used by tumors to suppress immune control. Pembrolizumab is a highly selective, IgG4 anti-PD-1 humanized monoclonal antibody designed to block the interaction between PD-1 and its ligands PD-L1 and PD-L2. In the phase 1 KEYNOTE-012 trial, pembrolizumab 10 mg/kg once every 2 weeks (Q2W) demonstrated an ORR of 24% (RECIST v1.1, central review) in 33 pts with PD-L1–positive advanced urothelial cancer, 76% of whom received $\geq$ 1 prior therapy. **Methods:** KEYNOTE-052 (ClinicalTrials.gov, NCT02335424) is an international, open-label, phase 2 trial of pembrolizumab 200 mg Q3W as first-line therapy for adults with unresectable or metastatic urothelial cancer of the renal pelvis, ureter, bladder, or urethra who are ineligible to receive cisplatin. Pts are considered cisplatin ineligible if they have $\geq$ 1 of the following: ECOG PS 2, creatinine clearance (calculated or measured) $<$ 60 but $\geq$ 30 mL/min, grade $\geq$ 2 (CTCAE v4) audiometric hearing loss or peripheral neuropathy, or NYHA class III heart failure. All pts must provide a recently obtained biopsy sample for PD-L1 evaluation at a central laboratory. Pembrolizumab will be given for up to 24 mo or until disease progression, unacceptable toxicity, or investigator decision; treatment may be discontinued following complete response. Select pts may continue pembrolizumab beyond initial evidence of radiographic progression. Response will be evaluated per RECIST v1.1 by independent central review at 9 wk and every 6 wk thereafter. Survival follow-up will occur every 3 mo. Primary end point is ORR in pts with PD-L1–dependent tumors. Secondary end points include ORR in all pts, PFS, OS, duration of response, and the association between PD-L1 positivity and ORR. Up to 350 pts will be enrolled. KEYNOTE-052 is currently enrolling pts. Clinical trial information: NCT02335424.

TPS4573 Poster Session (Board #245b), Mon, 1:15 PM-4:45 PM

A multicenter randomized phase II trial comparing nab-paclitaxel to paclitaxel in patients with advanced urothelial cancer progressing on or after a platinum containing regimen: NCIC Clinical Trials Group BL 12 (NCT02033993). *First Author: Srikala S. Sridhar, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Metastatic urothelial cancer remains an incurable disease, for which there is no standard second line treatment. A previous phase II study of nab-paclitaxel in this setting demonstrated activity and good tolerability. The current study is designed to characterize the activity of nab-paclitaxel compared to paclitaxel in the second line treatment setting for advanced urothelial cancer. **Methods:** This is an NCIC Clinical Trials Group (NCIC CTG) led intergroup trial with the Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP). The primary objective is to compare the progression free survival (PFS) between the two arms. Secondary objectives include: objective response rate, clinical benefit rate, time to response, response duration, toxicity, quality of life, and cost effectiveness. Correlative biological studies relating to tissue predictive and prognostic biomarkers and pharmacogenomics will be conducted. Clinicodemographic factors will be prospectively collected using a health and demographic questionnaire to further understand the relationships between biomarkers and clinical outcome measures. **Statistical Design**: Planned accrual is 199 patients over 3 years with followup of 4 months. Assuming median PFS of 4 months with paclitaxel, the target hazard ratio is 0.67 (PFS of 4 mo vs. 6 months, 1-sided, 5% significance with 80% power). Estimated sample size accounts for loss to followup or withdrawal of consent. **Conduct to Date:** Study activation: Mar 2014 (NCIC), Feb 2015 (ANZUP). As of February 2 2015, current accrual is 38. In November 2014 an independent DSMC recommended trial continuation. Supported by Celgene Corporation Clinical trial information: NCT02033993.

TPS4574 Poster Session (Board #246a), Mon, 1:15 PM-4:45 PM

Phase II randomised placebo controlled neoadjuvant chemotherapy study of nintedanib with gemcitabine and cisplatin in locally advanced muscle invasive bladder cancer. *First Author: Syed A. Hussain, University of Liverpool, Clatterbridge Cancer Centre, Liverpool, United Kingdom*

Background: The triple angiokinase inhibitor nintedanib (nin) has shown reduced proliferation and elevated apoptosis to a greater extent than chemotherapy alone in animal models. We aim to compare the effectiveness of nin vs placebo in combination with gemcitabine (gem) and cisplatin (cis) in muscle invasive bladder cancer (MIBC) patients prior to radical treatment. A safety sub-study will run in parallel with the main study to establish the maximum tolerated dose (MTD) of nin for patients with impaired glomerular filtration rate (GFR). **Methods:** The study opened in September 2014 and has recruited 4 patients to date (3 to main study, 1 to sub-study). 14 UK sites are planned. All patients must have localised muscle invasive carcinoma with no evidence of metastatic disease, ECOG performance status grade 0 – 1 and adequate haematological and hepatic function. Linked-in tissue collection and translational samples are built into the protocol. **Main Study** Patients will be stratified by centre and baseline GFR and randomised to receive 4 x 21 day cycles of gem 1000 mg/m2 and cis 70mg/m2 with 200mg BD nin or placebo. The primary outcome measure is cystoscopic and pathological complete response rate, with secondary outcome measures of progression free survival and toxicity. Overall survival is not assessed in order to facilitate seamless expansion into a phase III study. 120 patients (60 per arm) will provide 80% power to detect a 20% response difference, $p < 0.01$. Initially patients' GFR must be $>$ 60ml/min. After sub-study data analysis and determination of MTD in patients with GFR 40 – 60 ml/min, these patients may be included in the main study with split dose cis. **Sub-study** A 3+3 design is followed with an initial cohort of 3 patients with GFR 40 – 60 ml/min receiving 4 x 21 day cycles of gem 1000mg/m2 and split dose cis 35mg/m2 on day 1 and day 8 with 150mg BD nin. Nin dose-escalation/de-escalation for future cohorts of 3 – 6 patients will occur based on the no. of dose limiting toxicities, with a max. 12 patients recruited. The primary outcome measure is the MTD and safety of nin in combination with gem and split dose cis in patients with impaired renal function. Clinical trial information: 56349930.

TPS4575 Poster Session (Board #246b), Mon, 1:15 PM-4:45 PM

A phase 2 study of the histone deacetylase (HDAC) inhibitor mocetinostat in patients with urothelial carcinoma (UC) and inactivating alterations of acetyltransferase genes. *First Author: Noah M. Hahn, Johns Hopkins Kimmel Cancer Center, Baltimore, MD*

Background: Platinum-based chemotherapy is standard treatment for advanced UC, but no standard exists after first-line therapy. Mocetinostat (MGCD0103) is a spectrum selective inhibitor of HDAC 1, 2, 3 and 11. Site specific histone acetylation is regulated by the interaction of CREBBP and EP300 acetyltransferases with HDACs 1 and 2. Inactivating alterations of the genes *CREBBP* and/or *EP300* are associated with responsiveness to mocetinostat in preclinical cancer models and are reported in the tumors of ~28% of patients (pts) with UC (TCGA, *Nature*2014; 507:315), providing a clinical proof of principle opportunity for mocetinostat. **Methods:** This single-arm Phase 2 trial evaluates the efficacy of mocetinostat in pts with unresectable or metastatic UC and inactivating alterations of *CREBBP* and/or *EP300* as determined by next generation gene sequencing performed by qualified local labs or the FoundationOne platform. Eligible pts have received at least one prior platinum-based chemotherapy regimen and have measurable disease. The primary endpoint is Objective Response Rate (ORR) by RECIST 1.1. Secondary objectives evaluate safety, progression-free and overall survival, and pharmacokinetics. Exploratory objectives assess predictive biomarkers of response and mechanisms of acquired resistance through analysis of gene alterations in tumor and circulating tumor DNA. The study will enroll in 3 stages; among 15 pts, if at least 3 experience objective response or 6 are progression-free at 4-months, 18 pts will be added; if at least 9 objective responses are observed among these 33 pts, 67 pts will be added, for a total of 100 pts. Mocetinostat capsules are administered orally three times weekly, beginning with 70 mg per dose during the first cycle in pts in the first stage and then increasing to 90 mg per dose for the remainder of the study, as tolerability permits. The final sample size of 100 pts will provide 99% power to reject the null hypothesis that ORR rate is $\leq$ 15% (assuming a true ORR of 35%), using an exact test for single proportion (two-sided $\alpha = 5\%$). Status: Enrollment into the study opened in December 2014. Clinical trial information: NCT02236195.

TPS4576 Poster Session (Board #247a), Mon, 1:15 PM-4:45 PM

A phase I/II multi-center study of intravesical nanoparticle albumin-bound rapamycin (ABI-009) in the treatment of BCG refractory non-muscle invasive bladder cancer. *First Author: James M. McKiernan, Department of Urology, Columbia University Medical Center, New York, NY*

Background: Inactivation of p53 and PTEN mutations promotes progression in bladder cancer via deregulation of the mammalian target of rapamycin signaling pathway (mTOR). mTOR expression increases as a function of the disease stage as it progresses from superficial to invasive bladder cancer. Our group has proven the efficacy of intravesical rapamycin to treat bladder cancer in a mouse model. With the advent of the nanoparticle albumin bound (nab) version of rapamycin (ABI-009), this hydrophobic entity can now be tested intravesically. We sought to investigate the safety and efficacy in the management of Bacillus Calmette-Guerin (BCG) refractory non-muscle invasive urothelial carcinoma of the bladder (NMIBC). **Methods:** Funded via the NIH small business innovation research program (grants 1R42CA171552 and 3R42CA171552), this combined phase I/II study is currently enrolling patients with BCG refractory NMIBC at Columbia University and Vanderbilt University. BCG refractory is defined as disease recurrence after BCG therapy ($>$ 9 doses). This population was chosen given the dearth of effective, non-surgical second line options. Inclusion criteria include: histologically confirmed NMIBC including CIS and/or papillary lesions of high-grade Ta/T1, refractory to BCG; be eligible and refuse radical cystectomy; have all grossly visible disease fully resected. A maximum of 15 patients will be recruited in phase I with a dose-escalation scheme starting at 100 mg and escalating in the 3 remaining cohorts by 100 mg following a 3+3 rule. After the dose is determined, the phase 2 segment will enroll 29 patients. Success will be defined by a complete response in 20% of patients with negative biopsy 6 weeks post-treatment. This trial is enrolling with Cohorts 1 and 2 complete with no DLTs. Cohort 3 has 2 patients who received treatment and 1 receiving treatment with no DLTs thus far. In conclusion, ABI-009 will be the first-in-human molecularly guided mTOR pathway intravesical therapy to be studied for patients with BCG refractory NMIBC. Clinical trial information: NCT02009332.

TPS4577 Poster Session (Board #247b), Mon, 1:15 PM-4:45 PM

The Borealis-2 clinical trial: A randomized phase 2 study of OGX-427 (Apatorsen) plus docetaxel versus docetaxel alone in relapsed/refractory metastatic urothelial cancer. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: Heat shock protein 27 (Hsp27) is over-expressed in many cancers including bladder, lung, prostate, and breast. Increased Hsp27 has been associated with inhibition of chemotherapy-induced apoptosis, increased tumor cytoprotection, and development of treatment resistance. OGX-427 (apatorsen) is an antisense oligonucleotide designed to bind Hsp27 mRNA, inhibiting production of the Hsp27 protein. Inhibition of Hsp27 has been shown to increase apoptosis, inhibit tumor growth and metastasis, and sensitize tumor cells to chemotherapy in a variety of malignancies, including urothelial cancer. Results of preclinical and phase 1 studies suggest that addition of apatorsen to chemotherapy is well tolerated and may improve treatment efficacy. Borealis-2 is a randomized, multicenter, phase 2 study of apatorsen in combination with docetaxel (DOC) vs. DOC alone in locally advanced/metastatic bladder cancer patients who received at least one line of prior platinum-based therapy. The primary objective is to evaluate overall survival. Secondary objectives include comparisons of safety and tolerability, disease response, and serum levels of Hsp27 and other pathway-related proteins. Associations between clinical outcomes, levels of Hsp27 and other proteins, and circulating tumor cells will be evaluated. **Methods:** Patients (N = 200) are randomized in a 1:1 ratio following stratification (time from prior systemic chemotherapy; Bellmunt criteria). Up to 2 prior systemic therapies are allowed. Treatment-arm patients receive three loading doses of apatorsen (600 mg) followed by up to ten 21-day treatment cycles (apatorsen 600 mg on Days 1, 8, and 15 and DOC 75 mg/M^2 IV on Day 1). Control-arm patients receive DOC 75 mg/M^2 IV on Day 1 of each cycle. Treatment may continue until disease progression, unacceptable toxicity, completion of ten cycles, or patient withdrawal. Patients who discontinue DOC due to toxicity after $\geq$ 2 cycles and do not have disease progression may receive maintenance therapy with apatorsen. One interim futility analysis will be performed. The trial will not be stopped early based on efficacy. Clinical trial information: NCT01780545.

TPS4578 Poster Session (Board #248a), Mon, 1:15 PM-4:45 PM

CheckMate 214: A phase III, randomized, open-label study of nivolumab combined with ipilimumab versus sunitinib monotherapy in patients with previously untreated metastatic renal cell carcinoma. *First Author: Hans J. Hammers, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Therapeutic options have improved outcomes for patients (pts) with metastatic renal cell carcinoma (mRCC). Nivolumab, a fully human IgG4 programmed cell death-1 immune checkpoint inhibitor antibody, has shown clinical activity in RCC and in other tumor types. In CheckMate 016, a phase I study, nivolumab + ipilimumab demonstrated acceptable safety and encouraging antitumor activity in patients with mRCC (Hammers HJ, et al. *J Clin Oncol*. 2014;3215 suppl]:4504). This phase III study evaluates nivolumab + ipilimumab compared with sunitinib monotherapy for previously untreated mRCC (NCT02231749). **Methods:** Adults with advanced or metastatic clear-cell RCC with no prior systemic therapy are eligible. Pts with one prior adjuvant/neoadjuvant therapy (excluding VEGF targeted therapies) following RCC resection are eligible if recurrence occurred $\geq$ 6 months after the last dose. Other key inclusion criteria include: Karnofsky Performance Status $\geq$ 70%, measurable disease per RECIST v1.1, and available tumor tissue. Pts with a history of, or current, central nervous system metastases are ineligible. Prior treatment with systemic corticosteroids/immunosuppressants within 14 days before first dose of study drug, or with any agent targeting T cell co-stimulation or checkpoint pathways is not permitted. The study is expected to randomize ~1,070 pts stratified by International mRCC Database Consortium prognostic score (0 vs 1–2 vs 3–6) and region (US vs Canada/Europe vs rest of world). Pts will be randomized to either: i) nivolumab 3 mg/kg intravenously (IV) + ipilimumab 1 mg/kg IV every 3 weeks for four doses, followed by nivolumab monotherapy 3 mg/kg IV every 2 weeks or ii) sunitinib 50 mg orally once daily for 4 weeks followed by 2 weeks off. Treatment will be discontinued for unacceptable toxicity or withdrawal of consent. Pts may continue treatment beyond progression (RECIST v1.1) if investigator-assessed clinical benefit is achieved and treatment is well tolerated. The co-primary endpoints are progression-free survival and overall survival. Secondary endpoints include objective response rate and safety. Clinical trial information: NCT02231749.

TPS4579 Poster Session (Board #248b), Mon, 1:15 PM-4:45 PM

Randomized phase 2 study to assess the safety and efficacy of CRLX101 in combination with bevacizumab in patients (pts.) with metastatic renal cell carcinoma (RCC) versus standard of care (SOC). *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Up to 30% of pts. with RCC present with metastatic disease and 5-year survival among these pts. is less than 10%. VEGF-targeted and mTOR inhibiting drugs constitute SOC in this setting but anti-tumor effects are generally short-lived and there exists a pressing need for new therapeutic strategies. Among pts. with tumors progressing through multiple prior lines of therapy, the GOLD trial (Motzer et al., Lancet Oncology 2014) reported that sorafenib and the comparator agent dovitinib achieved PFS of approx. 4 mos. CRLX101 is a novel camptothecin (CPT)-containing nanoparticle drug conjugate that delivers sustained levels of active CPT into cancer cells while reducing systemic exposure and toxicity. In addition to its topo-1 effect, CRLX101 durably inhibits HIF-1α, a hypoxia-induced transcription factor implicated in tumor angiogenesis, metastasis, and resistance to VEGF inhibitors. Clear cell RCC (ccRCC) accounts for approx. 80% of RCC and is characterized by high levels of HIF-1α, providing an ideal clinical setting in which to evaluate potential synergy between CRLX101 and the VEGF inhibitor bevacizumab (BEV). Phase 2 data presented separately at this conference highlight notable signals of RCC activity for this combination with objective response rate (ORR) and median progression free survival (mPFS) exceeding 20% and 9 mos., respectively. **Methods:** This randomized clinical trial is being conducted at approx. 40 U.S. cancer centers and will enroll 110 pts. with advanced, unresectable metastatic RCC who have completed 2 or 3 prior regimens of therapy. The primary endpoint will compare PFS among 90 ccRCC pts. treated with concurrently administered CRLX101 + BEV vs. SOC (any approved agent per investigator choice not previously used in the same patient). Statistical power is set at 80% to detect an increase in mPFS from 3.5 mos. to 5.8 mos. (HR~0.6). Secondary/exploratory endpoints incl. OS, ORR, safety, PK, and plasma biomarkers of efficacy. Additionally, 20 pts. with non-ccRCC histology will be evaluated independently. Enrollment is ongoing and is expected to be complete by the end of 2015. Clinical trial information: NCT02187302.

TPS4580 **Poster Session (Board #249a), Mon, 1:15 PM-4:45 PM**

A multicenter, open-label, proof of concept phase 1b/2 study to evaluate the safety and efficacy of RX-0201 in combination with everolimus to treat subjects with advanced renal cell carcinoma. *First Author: Christine Peterson, Rexahn Pharmaceuticals, Rockville, MD*

Background: RX-0201 is a 20-mer oligonucleotide that is complementary to AKT-1 messenger ribonucleic acid (mRNA). The specificity of RX-0201-mediated effect on AKT-1 mRNA levels was examined in human renal cell carcinoma (von Hippel-Lindau protein-deficient renal cell carcinoma cell line) UMRC2 cells and resulted in a reduction of AKT-1 mRNA levels **Methods:** The current study is a proof of concept phase 1b/2, multicenter, open label study conducted in 2 stages. Stage 1 is an open-label, dose-escalation phase 1b study of RX-0201 administered in combination with everolimus. RX-0201 will be administered by a 24 hour continuous intravenous infusion for 14 days followed by 7 days of rest. It is expected that 250 mg/m2/day or a lower dose of RX-0201 will be identified as safe and well-tolerated when administered in combination with 10 mg of everolimus. The dose of RX-0201 identified in Stage 1 will be studied further in Stage 2 which is the randomized, open-label, 2-arm study of RX-0201 in combination with 10 mg of everolimus versus 10 mg of everolimus alone. Up to 8 cycles of study treatment will be permitted. Approximately 9 subjects are targeted to receive escalating doses of RX-0201 in combination with everolimus in Stage 1. The initial dose of RX-0201 is 125 mg/m2/day. In Stage 2 approximately 30 subjects are planned to be randomized in a 1:2 ratio (i.e., up to 10 subjects in the everolimus arm and up to 20 subjects in the everolimus/RX-0201 arm). Eligible subjects must have confirmed histologic or cytologic evidence of renal cancer with a clear cell component, measurable or evaluable disease as defined by RECIST, received at least 1 course of therapy with a VEGFR inhibitor and progressed within 6 months of planned first dose of on study treatment and received no more than 3 prior treatments of systemic renal cancer therapy. Radiological imaging for disease assessments will be according to RECIST ver. 1.1 Clinical trial information: NCT02089334.

TPS4581 **Poster Session (Board #249b), Mon, 1:15 PM-4:45 PM**

A randomized, open label, multicenter phase 2 study to evaluate the efficacy of sorafenib in patients (pts) with advanced Renal Cell Carcinoma (RCC) after a radical resection of the metastases. *First Author: Elena Verzoni, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: Complete response with targeted agents approved for metastatic renal cell carcinoma (mRCC) is rarely achieved. Retrospective findings seem to indicate that metastasectomy (Mtx) may improve survival in selected pts. The RESORT study was designed to evaluate whether Mtx followed by sorafenib may provide an additional clinical benefit. VEGF expression may represent a prognostic factor for survival **Methods:** Overall 132 mRCC pts undergoing complete Mtx will be randomized 1:1 (66 pts per arm) to receive either sorafenib or best supportive care (BSC) for 52 weeks or until disease recurrence. Prognostic factors including time from nephrectomy, site of disease and number of lesions will be used to stratify pts Key inclusion criteria: · Maximum 3 metastatic lesions. · Complete removal of all metastatic lesions. · Microscopic examination of margins showing no tumor cells (R0 resection) · No more than three months from Mtx Pts will be recruited from 16 Italian centers. The primary endpoint is recurrence-free survival (RFS), defined as the time from randomization to diagnosis of disease relapse or death. Secondary endpoints are Overall survival (OS) and safety. Circulating levels of vascular endothelial growth factor (VEGF) and fibroblast growth factor (FGF) will be evaluate from consenting pts (optional) at baseline, every 3 months, and at the end of treatment. Sorafenib will be administered at the dose of 400 mg orally once daily for 21 days and then increased to 400 mg twice daily if the patient has not experienced grade 2 skin toxicity or any other grade 3 toxicities. Imaging assessments will be performed every 12 weeks *Statistical plan* Kaplan-Meier methods will be used for survival analyses and the log-rank test to compare sorafenib arm and BSC arm according to the stratification factors. The hazard ratio (HR) will be determined at the 95% confidence interval (CI). The hypothesis is to increase the RFS time from 12 months (BSC arm) to 18 months (sorafenib arm), corresponding to a 50% improvement. With a study power of 80% and a 1-sided error of 0.15, the estimated number of events required is 86. Twenty-six out of 132 pts have been enrolled Clinical trial information: NCT01444807.

TPS4582 **Poster Session (Board #250a), Mon, 1:15 PM-4:45 PM**

Patient identification and eligibility insights in the synchronous metastatic RCC population: An update from the ongoing ADAPT* phase 3 study experience. *First Author: Robert A. Figlin, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: AGS-003 is an autologous immunotherapy designed to induce a T-cell response specific to a patient's tumor antigens. Sunitinib is a TKI and first-line therapy for mRCC that also reverses the immune suppression observed in these patients. In a single arm phase 2 study, AGS-003 plus sunitinib was safe and yielded a median overall survival (OS) of over 30 months in newly diagnosed mRCC patients. **Methods:** The ADAPT study is a randomized (2:1) international phase 3 study comparing standard targeted therapy plus AGS-003 to standard therapy alone. The primary objective is to compare the median OS between treatment arms. The study is enrolling adults with synchronous, metastatic, clear cell RCC who are good candidates for surgery and standard targeted therapy (initiating with, but not limited to, sunitinib), KPS $\geq$ 70%, life expectancy of at least 6 months, between 1-4 Heng risk factors, and adequate end organ function. Initial enrollment patterns were investigated in order to gain insight on the features of mRCC patients that are candidates for cytoreductive nephrectomy. More than 130 sites in North America and other select countries have been activated and $>$ 840 patients have been consented and tumor samples collected. Enrollment is expected to conclude in the 1st half of 2015. To date, approximately 50% of patients screened for tumor collection were ineligible to participate in the treatment phase of the ADAPT study after surgery, with about half of these being excluded because of non-clear cell histology. Other major reasons include ineligibility for sunitinib and lack of evaluable metastatic disease after nephrectomy. The DMC last reviewed the trial in December 2014 and suggested that the trial continue as planned. Clinical Trials registry number: NCT 1582672 * ADAPT: An International Phase 3 Randomized Trial of Autologous Dendritic Cell Immunotherapy (AGS 003) Plus Standard Treatment in Advanced Renal Cell Carcinoma (RCC) Clinical trial information: NCT1582672.

TPS4583 **Poster Session (Board #250b), Mon, 1:15 PM-4:45 PM**

The DART Study: A phase 2 randomized double-blind study of dalantercept plus axitinib versus placebo plus axitinib in advanced clear cell renal cell carcinoma (RCC). *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Activin receptor-like kinase 1 (ALK1) is a novel target in angiogenesis involved in blood vessel maturation and stabilization. Concurrent targeting of ALK1 and vascular endothelial growth factor (VEGF) signaling results in dual angiogenic blockade and augmented inhibition of tumor growth in RCC xenograft models. Dalantercept is an ALK1 receptor-fusion protein that acts as a ligand trap by binding to ligands, bone morphogenetic proteins (BMP) 9 and 10. Part 1 of this study evaluated the safety, tolerability, and preliminary activity of escalating dose levels of dalantercept (0.6, 0.9, and 1.2 mg/kg) plus standard doses of axitinib (5 mg PO BID) every 3 weeks in patients with advanced RCC who received at least one prior VEGFR TKI and no more than 3 prior tx. 29 pts were enrolled in Part 1 and the combination was associated with an acceptable safety profile and preliminary activity (25% RR, preliminary median PFS of 8.3 months for all dose levels combined). The mPFS for the 0.9mg/kg dose level has not been reached. AEs ($>$ 30%) regardless of attribution: fatigue, diarrhea, dysphonia, peripheral edema, nausea, decreased appetite, epistaxis, hypertension, arthralgia, creatinine rise, cough, and hand-foot rash. There were no grade 4/5 related adverse events. The 0.9 mg/kg dose level was selected for Part 2. **Methods:** Part 2 is a multi-center Phase 2 study and is actively accruing patients across approximately 50 sites in the US. In Part 2, 130 patients will be randomized 1:1 to dalantercept plus axitinib or placebo plus axitinib in a double-blinded fashion. Key eligibility: predominantly clear cell RCC; ECOG 0-1; 1 prior VEGFR TKI. 1 prior mTOR inhibitor and any number of prior immune therapies are also permitted. An independent DMC will evaluate safety data during the study. The primary endpoint is PFS. Secondary endpoints include: ORR by RECIST v1.1, OS, pharmacokinetic assessments, and pharmacodynamic evaluations of ALK1 pathway and other angiogenesis markers in serum and archived tumor specimens. Clinical trial information: NCT01727336.

TPS4584 Poster Session (Board #251a), Mon, 1:15 PM-4:45 PM

Phase II study of pazopanib and weekly paclitaxel in metastatic or locally advanced squamous penile carcinoma patients previously treated with cisplatin-based chemotherapy: PAZOPEN study. *First Author: Miguel Angel Climent, Fundación Instituto Valenciano de Oncología, Valencia, Spain*

Background: Metastatic or locally advanced squamous penile carcinoma (MLASPC) is an infrequent disease, with extremely bad prognosis. Platinum based chemotherapy is the most active treatment with a response rate (RR) of 30% and only 12 months of overall survival. New active agents are urgently needed. The combination of the antiangiogenic agent Pazopanib and paclitaxel have been tested in transitional carcinoma and melanoma with high number of responses and good tolerance profile. The aim of this study is to test the activity and safety of the combination in patients (pts) with MLASPC progressing to platinum based regimens. **Methods:** Phase II open label, single arm, multicentre study. Main inclusion criteria are: diagnosis of squamous penile carcinoma, ECOG 0-1, measurable disease by RECIST criteria, progressive disease after previous platinum based treatment, either in neoadyuvant, adyuvant or metastatic setting, adequate hepatic, renal and haematological function. Patients will receive treatment with pazopanib 800 mg p.o daily and paclitaxel 65 mg/m2/weekly D1, 8 and 15 every four weeks cycle. Main objective is RR (complete (CR) and partial response (PR) measured by RECIST criteria). Secondary objectives: Clinical benefit rate, (CR+ PR + SD), progression-free survival, response duration, overall survival, toxicity and tolerance profile. Whole exome sequencing will be performed to describe most frequent alterations in penile cancer. This is a two stage Simon optimal design for phase II trials. Considering an estimated 30% RR with P0 = 10%, (alpha error 5%, beta 20%), 10 patients will be included in first stage and if 2 or more responses are observed, then 19 additional patients will be included in second stage. If more than 5 responses are observed efficacy of treatment will be considered. The sample size, taking into account a 10% drop out rate will be 32 pts. Trial will be performed in 8 hospital centres of the SOGUG group. Study has been approved by ethic committees and health authorities. Funded by a grant from GlaxoSmithKline. NCT02279576. Clinical trial information: NCT02279576.

TPS4585 Poster Session (Board #251b), Mon, 1:15 PM-4:45 PM

ATR-101 phase 1 clinical study for adrenocortical carcinoma. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ATR-101 (Atterocor, Inc., Ann Arbor, MI, USA) is a selective inhibitor of ACAT1 (acyl coenzyme A:cholesterol acyltransferase) in clinical development for the treatment of adrenocortical carcinoma (ACC). ACAT1 catalyzes cholesterol ester formation from cholesterol and long-chain fatty acyl-CoA and, in the adrenals, is particularly important in creating a reservoir of substrate for steroid biosynthesis. ATR-101 selectively distributes to the adrenals, inhibits steroidogenesis and causes apoptosis of cells of the adrenal cortex, as well as in H295R ACC cells. ACC is an ultra-rare malignancy, occurring in about 2 per million population annually. ACC is frequently discovered in Stage 4 and the overall disease survival is approximately 17 months. Tumors often overproduce steroids normally produced in the adrenal cortex and cause therapy-resistant Cushing's syndrome. Current therapies are toxic, difficult to administer, and poorly effective. **Methods:** ATR-101-001 is a phase 1 study being conducted at four centers in the United States and one in Germany. It is a "3+3" design: 3 subjects with advanced ACC who have failed or declined existing therapies are enrolled at each dose level for 28 days. If no Dose Limiting Toxicity is observed, three additional subjects are enrolled at a higher dose. An expansion cohort of 20 subjects will be enrolled after the MTD has been determined. Subjects who appear to be deriving benefit may stay on ATR-101 indefinitely. ATR-101 is taken by mouth. The primary objective is to determine the safety and tolerability of ATR-101 in subjects with advanced ACC. Secondary objectives include efficacy by RECIST, measurement of production of steroid hormones and intermediates, determination of pharmacokinetics, the Maximum Tolerated Dose and the recommended phase 2 dose. The study is open to patients age 18 and over with advanced ACC. Patient's mitotane level must be 5 μg/ml or less; the QTcF 470 ms or less; and if present, CNS metastases must be treated and inactive. Full study information is available on ClinicalTrials.gov, Identifier NCT01898715. Clinical trial information: NCT01898715.

Impact of gemcitabine + cisplatin + ipilimumab on circulating immune cells in patients (pts) with metastatic urothelial cancer (mUC). *First Author: Matt D. Galsky, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Immune checkpoint blockade may play a role in the treatment of mUC. However, the role of CTLA4 blockade, the impact of chemotherapy on immune cell populations, and the optimal approach to combination regimens in pts with mUC remains poorly defined. An increase in tumor infiltrating and circulating CD4+ICOS+ cells after ipilimumab has been shown in pts with localized UC and correlated with improved outcomes in ipilimumab-treated melanoma pts (Carthon, Clin Can Res, 2010). **Methods:** Pts with mUC were enrolled on a phase 2 trial of chemotherapy + CTLA4 blockade. Patients received 2 cycles of gemcitabine + cisplatin (GC) followed by 4 cycles of GC + ipilimumab (GCI). Flow cytometry was performed on peripheral blood mononuclear cells at baseline, after GC, and after GCI to determine the impact of treatment on the frequency and phenotype of CD4+ and CD8+ T cells, regulatory T cells (CD4+CD25+CD127-CD45RA- Tregs), and myeloid-derived suppressor cells (CD13+CD14+CD11b+HLA-DR- MDSCs). Comparisons between time-points were made using Wilcoxon's rank test. **Results:** The trial has completed enrollment (n = 36) and flow cytometry data are available for the complete treatment sequence on 17 pts as of 2/2015 (Table). **Conclusions:** GC alone generally had no significant impact on the median % of circulating immune cell subsets though the increase in CD4+ICOS+ cells warrants confirmation. GCI resulted in an increase in CD4+ and CD8+ T cells, including the subset of CD4+ICOS+ cells, with a lesser increase in Tregs. The impact of individual changes in immune cell subsets on pt outcomes, and the role of GCI in mUC, will be further defined as efficacy data matures. Clinical trial information: NCT01524991.

Impact of treatment on immune cell subsets (median % (IQR)).

	Baseline (BL)	Post-GC	Post-GCI	p (GC v. BL)	p (GCI v. GC)
CD3+CD8+	4.9% (8.3%)	4.0% (5.0%)	6.8% (10.1%)	0.2	0.04
CD8+ICOS+	0.01% (0.4%)	0.05% (2.4%)	0.4% (3.7%)	0.2	0.9
CD8+PD1+	0.02% (0.3%)	0.02% (0.2%)	0.02% (0.2%)	0.7	0.7
CD3+CD4+	9.0% (7.4%)	5.0% (6.8%)	15.9% (11.2%)	0.7	0.001
CD4+ICOS+	0.2% (0.7%)	0.5% (5.4%)	3.1% (8.9%)	0.03	0.04
CD4+PD1+	0.1% (0.2%)	0.1% (0.3%)	0.4% (0.4%)	0.08	0.03
TReg	0.4% (0.6%)	0.4% (1.0%)	1.0% (0.9%)	0.5	0.04

The Prostate Cancer Working Group 3 (PCWG3) consensus for trials in castration-resistant prostate cancer (CRPC). *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The availability of new agents for men with CRPC, recognition of new disease phenotypes, and an evolving regulatory environment have created the need for new CRPC clinical trial guidelines to succeed PCWG2, published in 2008. **Methods:** Eight face-to-face meetings were convened over 3 years to create the PCWG3 guidelines, with subcommittees meeting more frequently. PCWG2 criteria were updated or revised based on new evidence from clinical trial data and validation studies of PCWG2 recommendations **Results:** PCWG3 distinguishes between prostate adeno- and non-adenocarcinomas; considers the sequence and number of prior systemic therapies in lieu of the pre- and post-taxane distinctions in PCWG2; encourages detailed reporting of disease subtypes based on distribution patterns; and defines endpoints for patients transitioning between non-metastatic and metastatic disease. For non-cytotoxic therapies, outcomes are focused on establishing proof-of-mechanism and determining the optimal biologic dose. The strength of association between patient-reported outcomes, radiographic progression-free survival, circulating tumor cell enumeration, and time to clinical events is emphasized rather than alterations in individual biomarkers. Similarly, PCWG3 underscores the distinction between first evidence of progression based on one disease manifestation in contrast to terminating treatment because the patient is no longer benefitting. We emphasize the importance of documenting progression in existing lesions as distinct from the development of new lesions. The revised guidelines highlight the importance of serial biologic profiling of the disease from biopsies and/or blood to understand treatment resistance and identify predictive biomarkers of sensitivity for use in prospective trials. **Conclusions:** PCWG3 updates the PCWG2 consensus criteria based on available new treatments and disease manifestations, and data validating biomarkers that were proposed in PCWG2. The revised criteria define the endpoints for the M0 to M1 transition. These recommendations will guide clinical trial design and conduct for therapeutics being tested in both M0 and M1 CRPC patient populations.

Docetaxel and/or zoledronic acid for hormone-naïve prostate cancer: First overall survival results from STAMPEDE (NCT00268476). *First Author: Nicholas David James, University of Warwick, Coventry, United Kingdom*

Background: STAMPEDE is a randomised controlled trial using a novel multi-arm multi-stage design. It recruits men (pts) with high-risk locally advanced or metastatic prostate cancer (PCa) starting long-term hormone therapy (HT) for the first time. The trial initially assessed adding 1 or 2 of 3 treatment approaches to standard of care (SOC). We report primary survival results for 3 research comparisons that recruited through all their intermediate analyses: docetaxel (D), zoledronic acid (ZA) & the combination (D+ZA). **Methods:** SOC was hormone therapy for > = 3yrs; RT was encouraged for N0M0 pts up to Nov-2011, then mandated; RT was optional for N+M0 pts. Stratified randomisation allocated pts 2:1:1:1 to SOC (control), SOC+D, SOC+ZA or SOC+D+ZA. 4mg ZA was given for six 3-weekly cycles then 4-weekly until 2yrs. D was given as 75mg/m^2 for six 3-weekly cycles with prednisolone 10mg daily. The primary outcome measure was survival (time from randomisation to death from any cause). Pairwise comparisons to control on survival for each research arm had 90% power at 2.5% 1-sided alpha for a hazard ratio of 0.75 requiring ~400 control arm deaths, accounting for 3 intermediate lack-of-benefit analyses on failure-free survival. Analyses used the Cox model of the logrank test, adjusted for stratification factors. **Results:** From Oct-2005 to Mar-2013, 2,962 pts were randomised to the 4 arms. The groups were balanced with median age 65yrs; 61% metastatic, 14% N+/XM0, 22% N0M0; 93% diagnosed within 6m of randomisation; median PSA 65ng/ml. Median follow-up was 42m. Grade 3-5 toxicity was reported for 31% SOC, 50% SOC+D, 32% SOC+ZA and 52% SOC+D+ZA.There were 405 deaths on the control arm (84% from PCa). The hazard ratio was 0.76 (95% CI 0.63, 0.91; p = 0.003) for SOC+D vs SOC; 0.93 (95% CI 0.79, 1.11; p = 0.437) for SOC+ZA vs SOC; and 0.81 (95% CI 0.68, 0.97; p = 0.020) for SOC+D+ZA vs SOC. Median survival was increased by 10m from 67m on SOC to 77m on SOC+D. Results in M0 and M1 disease will be shown. **Conclusions:** Survival data from STAMPEDE show a clinically and statistically significant improvement in survival from adding docetaxel but not from adding zoledronic acid in men starting long-term hormone therapy for the first time. Clinical trial information: NCT00268476.

A phase III protocol of androgen suppression (AS) and 3DCRT/IMRT versus AS and 3DCRT/IMRT followed by chemotherapy (CT) with docetaxel and prednisone for localized, high-risk prostate cancer (RTOG 0521). *First Author: Howard M. Sandler, Department of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles, CA*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

5003 **Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

Characterization of neuroendocrine prostate cancer (NEPC) in patients with metastatic castration resistant prostate cancer (mCRPC) resistant to abiraterone (Abi) or enzalutamide (Enz): Preliminary results from the SU2C/PCF/AACR West Coast Prostate Cancer Dream Team (WCDT). *First Author: Eric Jay Small, UC San Francisco, San Francisco, CA*

Background: Mechanisms of resistance to androgen signaling inhibitors such as Abi or Enz are poorly understood. An increasing % of these pts develop NEPC. Pathologic (path), clinical, and genomic characterization of pts with NEPC was undertaken in the context of the WCDT project, which seeks to identify genetic pathways underlying primary and acquired resistance to Abi and Enz. **Methods:** Eligible mCRPC pts underwent a metastasis (met) biopsy (bx) at one of 5 WCDT centers, using a standardized bx protocol, and were uniformly followed for clinical outcomes. Tissue was both frozen, and formalin fixed/paraffin embedded. Independent path review was undertaken by 3 pathologists. Frozen specimens underwent laser capture micro-dissection, RNA isolation, library preparation and RNA sequencing (seq). Machine learning was used to derive a NEPC expression signature. **Results:** 150 of 300 planned mCRPC pts have undergone bx. Path review has been undertaken in 101. Classic small cell cancer (SmCC) was identified in 12%, adenocarcinoma (adenoca) in 33%. An intermediate histology distinct from SmCC or adenoca was seen in 27%. The remaining 28% were mixed histologies or were not classifiable. Anatomic site of bx (node, bone, liver) did not appear to enrich for a particular histology. Median overall survival was: not reached at 22 mos of follow-up in pts with adenoca, 8.9 mos in pts with intermediate histology, and 6.6 mos in pts with SmCC (log rank p = 0.027). RNAseq data are available on 45 biopsies. A 50 gene signature with 97% accuracy for NEPC (defined as SmCC or intermediate histology) was developed. **Conclusions:** RNAseq and expression analysis can be accomplished in small bone and soft tissue mCRPC biopsies. A distinct histology, intermediate to SmCC and adeno, was observed in 27% of pts. The development of NEPC in mCRPC resistant to Abi or Enz is far more common than previously appreciated and appears to result in poor survival. A 50 gene NEPC expression signature was derived which provides insight into the biology and potential treatment of NEPC.

5004 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Defining a molecular subclass of treatment resistant prostate cancer. *First Author: Himisha Beltran, Weill Cornell Medical College, New York, NY*

Background: A subset of advanced prostate cancers can progress from an androgen receptor (AR)-driven state to AR independence, often associated with low or absent AR expression and extensive neuroendocrine differentiation. Once neuroendocrine prostate cancer (NEPC) develops, patients often demonstrate an aggressive clinical course and poor overall survival. Diagnosis is important but remains challenging as the clinical and pathologic features associated with AR independence and NEPC are poorly defined. **Methods:** We performed whole-exome sequencing of 124 metastatic tumors from 81 patients (35 with morphologic features of NEPC). Serial or synchronous samples were included to characterize heterogeneity and the transition from adenocarcinoma to NEPC. Computational analysis of clonality and allele-specific quantification were performed using CLONET. Quantitative mRNA assessments, including AR signaling genes and DNA methylation, were evaluated in the context of genomic changes. **Results:** The mutational landscape of NEPC and castration-resistant prostate cancer (CRPC) did not differ significantly by rate of non-synonymous mutations or copy number burden (average $>$ 40% of genome was aberrant), and polyploidy was frequently detected together with common allelic imbalances. Comparative analysis at the DNA and mRNA level identified decreased AR signaling in NEPC and a range of AR signaling in CRPC, enrichment of copy number losses (including RB1 and multiple genes on 16q) in NEPC, and focal high level AR amplification in CRPC in contrast to NEPC ($p = 0.0007$). DNA allele-specific analysis of multi-sample cases suggested diverse genomic state of key lesions including aberrations in MYCN and CDKN1B. **Conclusions:** This is largest study to date focused on the molecular landscape of the NEPC resistance phenotype. NEPC is characterized by a molecular profile defined by distinct genomic alterations and decreased AR signaling. A subgroup of CRPC demonstrates lower AR signaling and molecular overlap with NEPC. This study supports clonal evolution of prostate adenocarcinoma to NEPC, provides new insight into NEPC biology and disease heterogeneity, and may aid in the detection of AR independence and emergence of the NEPC subclass of treatment resistance.

5005 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Biological heterogeneity in localized high-risk prostate cancer (LHRPC) from a study of neoadjuvant abiraterone acetate plus leuprolide acetate (LHRHa) versus LHRHa. *First Author: Eleni Efstathiou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Biological heterogeneity may have important implications for development of novel therapeutic approaches for LHRPC. This study examined clinical and biological heterogeneity of response and resistance to abiraterone acetate with prednisone (AA)+LHRHa vs LHRHa. **Methods:** A preoperative study of 12 wks of AA+LHRHa vs LHRHa alone (randomized 2:1) in pts with LHRPC (clinical stage T1c/T2 with biopsy Gleason $\geq$ 8, or $\geq$ T2b with Gleason $\geq$ 7 and prostate-specific antigen [PSA] $>$ 10 ng/mL). The effect of treatment on pathologic stage, androgen metabolites, and tumor epithelial cellular density (TECD, % of epithelial component [cellularity] in total tumor volume) in the residual tumor, and the link between TECD and PSA response, were evaluated, as was the association of key immunohistochemical (IHC) markers (eg, androgen receptor splice variant [ARv7], glucocorticoid receptor [GR], chromogranin A [CHROM], phospho-Src [p-Src]) with clinical, pathologic, and cellular responses. The difference in TECD between arms was assessed using the Wilcoxon rank sum test, with tumor volume determined using the Chen method. Correlations were evaluated using the Spearman method. **Results:** Sixty-five pts were accrued. Pathologic downstaging ($\leq$ pT2) occurred in 24/44 (54.5%) pts given AA+LHRHa vs 8/21 (38.1%) given LHRHa, $p = 0.21$. Post-treatment PSA nadir was $\leq$ 0.2 ng/mL in 41/44 (93.2%) for AA+LHRHa vs 3/21 (14.3%) for LHRHa, $p < 0.0001$. Despite these high rates of undetectable PSA, high TECD heterogeneity was observed in the AA+LHRHa arm (ie, 34% had $>$ 50% cellularity). Still, TECD was lower for AA+LHRHa vs LHRHa (median, 35% [range 1-75%] vs 70% [range 50-85%], $p <$ 0.0001). Specific to AA+LHRHa, higher ARv7, GR, and CHROM expression by IHC was associated with worse pathologic response, and higher ARv7, GR, and p-Src expression and lower CYP17 expression were correlated with higher TECD. **Conclusions:** We observed significantly lower TECD for the AA+LHRHa arm vs LHRHa.Our findings conclusively demonstrate greater cytoreduction with AA+LHRHa in hormone-naïve LHRPC and early emergence of resistance within 3 months of treatment initiation despite PSA declines. Clinical trial information: NCT01088529.

5006 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Interest of short hormonotherapy (HT) associated with radiotherapy (RT) as salvage treatment for biological relapse (BR) after radical prostatectomy (RP): Results of the GETUG-AFU 16 phase III randomized trial—NCT00423475. *First Author: Christian Carrie, Department of Radiation Oncology, Centre Léon Bérard, Lyon, France*

Background: RT is the standard as salvage treatment after RP. The role of HT is not demonstrated to date. This trial assessed the efficacy of RT alone *vs* RT+HT on progression-free survival (PFS) (biological or/and clinical relapse) for patients with BR after RP. Secondary objectives were overall survival (OS), toxicity and quality of life. **Methods:** Patients (pts) were randomized (1:1; stratification on risk factors at RP and type of planned RT) to RT alone (66Gy on prostate bed +/- pelvic irradiation according to pN status and risk of initial node involvement) or RT+HT (goserelin, for 6 months). Assuming 5-year PFS of 45% for RT arm, the trial required 369 pts per arm to detect an improvement of 12% on PFS in RT+HT arm (90% power and 5% alpha risk). BR was evaluated according to Astro-consensus. **Results:** From Oct. 2006 to Mar. 2010, 743 pts (RT: 374; RT+HT: 369) were randomized. Baseline characteristics were well balanced between the arms, median age: 67 y, pT2ac: 54%, pT3ac: 46%, gleason $>$ 6: 76%, positive margins: 51%, seminal vesicles' involvement 13%. PSA doubling time at relapse was $>$ 6 months in 74%. With a median follow-up of 63.1 months, 216 events were notified (138 in RT *vs* 78 in RT+HT). The intent to treat analysis showed an improved 5-y PFS of 62.1% (CI95%: 57-67) vs 79.6% (IC95%: 75-84) for RT and RT+HT, respectively (log-rank: $p <$ 0.0001). The 5-y OS was 94.8% for RT *vs* 96.2% for RT+HT ($p = 0.18$). Cause of death was progressive disease in 2.1% pts on RT arm *vs* 0.8%. Acute toxicities occured more frequently in RT+HT arm (89% *vs* 79%). No difference was found in grade ^{3}3 acute toxicities (1.9% *vs* 2.2%) and late toxicities (18.8% *vs* 21.9%). No toxic death was observed. **Conclusions:** GETUG-AFU 16 is the first randomized trial comparing RT *vs* RT+ short HT as salvage treatment for BR after RP with undetectable post-op PSA. RT+HT significantly improve the 5-y PFS without increasing acute or late grade 3 toxicities. A longer follow up is required to quantify the impact on OS but RT+HT could be considered as the standard in this situation. Clinical trial information: NCT00423475.

5007 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

TROG 03.06 and VCOG PR 01-03: The "timing of androgen deprivation therapy in prostate cancer patients with a rising PSA (TOAD)" collaborative randomised phase III trial. *First Author: Gillian M. Duchesne, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Background: This randomized, prospective phase III trial investigated if immediate intervention with androgen deprivation therapy (ADT) (Arm B) improved overall survival compared to delayed ADT introduction (Arm A) in prostate cancer patients with PSA relapse after definitive therapy, or in asymptomatic men not suitable for curative therapy at diagnosis. **Methods:** Eligible patients were randomised 1:1, and stratified by planned intermittent or continuous (I or C) ADT; treatment centre; prior therapy (prostatectomy or radiation therapy); relapse-free interval $<$ or $\geq$ 2 years; and PSA doubling time of $<$ or $\geq$ 10 months. The primary endpoint was unadjusted overall survival by intention-to-treat. Secondary endpoints were cancer specific survival, time-to-clinical progression, time-to-castration resistance, cancer- and treatment-related complications, and quality of life. Sample size calculations for 80% power, α level of 5%, and a 2-sided statistical test required 750 patients to show a 10% improvement in survival. **Results:** From September 2004 to July 2012, 293 patients were randomised (A: 151, B:142) with a median follow-up of 5.0 years. There were 46 deaths, 30 for Arm A (delayed) and 16 for Arm B (immediate). Overall survival (OS) (log rank unadjusted) was significantly higher in Arm B than Arm A ($p = 0.047$), with 6-year survival rates of 86% and 79% respectively. The hazard ratio (HR) for death from all causes for Arm B relative to Arm A (Cox adjusted regression analysis) was 0.54, 95% confidence interval (CI) 0.27,1.06, $p = 0.07$. Death from prostate cancer was reduced in Arm B (HR 0.50 CI 0.17,1.51, $p = 0.22$), as was death from other causes (HR 0.57 CI 0.31,1.05, $p = 0.07$), both non-significantly. Overt local and distant disease progression were significantly reduced in Arm B (HR 0.51 CI 0.34,0.76, $p = 0.001$; HR 0.54 CI 0.32,0.90, $p = 0.018$). There was no difference in the time to castrate resistance. In Arm A 34% of patients started ADT within 2 years, while 49% started later than 4 years on trial or had not yet commenced therapy. **Conclusions:** Overall survival and time to clinical progression were significantly improved for immediate versus delayed ADT. Clinical trial information: 12606000301561.

5008 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Long-term consequences of intermittent and continuous androgen deprivation in older patients with metastatic prostate cancer. *First Author: Dawn L. Hershman, Columbia University Medical Center, New York, NY*

Background: Although intermittent androgen deprivation therapy (ADT) has not been associated with better overall survival in prostate cancer (PC), it has the potential for lower side effects and potential for better quality of life (QOL). The incidence of long-term side effects has not been reported. **Methods:** We analyzed a subset of patients from S9346, a randomized SWOG trial of intermittent vs. continuous ADT in patients with metastatic PC. To identify late-effects by treatment arm , we established an innovative linkage between patient trial data and corresponding Medicare claims. To incorporate time from beginning of observation through evidence of a late effect, and to account for potential competing risks of death, we analyzed claims to determine the cumulative incidence of late effects. Cox regression was used to examine time-to-late effects, adjusting for covariates. **Results:** In total, n = 1134 eligible U.S.-based patients with metastatic prostate cancer were randomized to continuous vs. intermittent ADT on S9346. A total of 636 (56%) of trial participants had ≥ 1 year of continuous Medicare parts A & B coverage and no HMO participation. The mean age was 71.5 years. The most common late effects recorded in claims in the cohort were hypercholesterolemia (31%) and osteoporosis (21%). the 10-year cumulative incidence of ischemic and thrombotic events were differed by arm; 23% for continuous therapy and 32% for intermittent therapy patients (Hazard Ratio = 0.68, p = .02). On the IAD arm, there was no difference in the mean percentage of time receiving therapy between those with and without ischemic or thrombotic events (47% vs 47%, p = 0.86). There were no statistically significant differences by arm in any other late effects. **Conclusions:** Despite beliefs that intermittent ADT could reduce long-term health-related effects compared to continuous ADT, we found that older men assigned to intermittent therapy had a slightly increased incidence of ischemic and thrombotic events and no apparent reduction in bone related, endocrine, or cognitive events

5009 Poster Discussion Session; Displayed in Poster Session (Board #1), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Phase III SYNERGY trial: Docetaxel +/- custirsen and overall survival in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and poor prognosis. *First Author: Kim N. Chi, BC Cancer Agency, Vancouver, BC, Canada*

Background: Clusterin is a chaperone protein associated with treatment resistance and upregulated by apoptotic stressors such as chemotherapy. Custirsen is a 2nd-generation antisense that inhibits clusterin production. The SYNERGY trial evaluated docetaxel +/- custirsen as 1st-line therapy in men with mCRPC (N = 1022). Following 509 deaths, median overall survival (OS) was 23.4 months (m) vs. 22.2 m for custirsen and control arms, respectively (hazard ratio [HR] 0.93; P = 0.42). To explore the hypothesis that clusterin inhibition may be more relevant in poor prognosis disease, we evaluated outcomes by prognostic sub-groups retrospectively. **Methods:** A prognostic scoring system was developed in the control arm using multiple variable modeling. The modeling included evaluation of interactions and used hierarchical step down. Results of the final model included the following main effects: liver mets, opioid use, Karnofsky < 90, PSA, LDH, alk phos, and hemoglobin. The median score dichotomized pts into good and poor prognosis. Outcomes included survival and PSA progression as defined by PCWG1 and PCWG2. **Results:** The analysis included 984 pts with complete data. Median survival for the poor and good prognosis groups in the control arm was 14.0 m and 30.4 m, respectively (HR = 3.66). The custirsen HR effect differed between poor and good prognosis groups (interaction P = 0.069). The HR estimate for custirsen survival benefit was 0.73 (95% CI: 0.0589 to 0.902) for poor prognosis and 1.02 (95% CI: 0.760 to 1.37) for good prognosis. The poor prognosis group was analyzed separately for treatment effect (n = 492). The median OS was 17.0 m in the custirsen arm vs. 14.0 m in the control arm (stratified HR = 0.72, 95%CI: 0.579 to 0.892, P = 0.0026). PSA progression in the poor prognosis group also favored custirsen with a HR of 0.73 (95% CI: 0.589 to 0.907) for PCWG1 and 0.808 (95% CI: 0.633 to 1.031) for PCWG2. **Conclusions:** CRPC pts with a poor prognosis appeared to benefit from custirsen when added to docetaxel as 1st-line therapy. This finding underscores the importance of enriching for a study population based on the mechanism of action for targeted agents. Clinical trial information: NCT01188187.

5010 Poster Discussion Session; Displayed in Poster Session (Board #2), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

A multi-institutional randomized phase II study (NCT01505868) of cabazitaxel (CAB) plus or minus carboplatin (CARB) in men with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Paul Gettys Corn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Standard chemotherapy for mCRPC consists of sequential taxane monotherapy. We examined the contribution of CARB to taxane therapy (Oh, Ann Oncol 2010;21) and the hypothesis that men meeting the previously defined "anaplastic" or aggressive variant prostate cancer (AVPCa) clinical criteria (Aparicio, Clin Can Res 2013;19) derive increased benefit from a platinum-taxane combination. **Methods**: Men with mCRPC were randomized 1:1 (with stratification for AVPCa criteria) to IV CAB (25 mg/m2) or CAB/CARB (25 mg/m2; AUC4) Q21 days with growth factor support until disease progression, unacceptable toxicity or for up to 10 cycles. Imaging occurred every 2 cycles. The primary endpoint was progression free survival (PFS). Secondary objectives included evaluation of safety, PSA response rates, influence of AVPCa criteria on response, and correlation of changes in bone specific alkaline phosphatase (BAP) with response. **Results:** Since March 2013 we accrued 149 of 160 men and 135 (78 with AVPCa) have received ≥ 1 cycle of therapy. Median follow up is 11.4 months (mo). Median PFS is 4.4 mo (95%CI 2.8-5.7) with CAB vs 6.7 mo (95% CI 5.2-8.2) with CAB/CARB (p = 0.01). In men meeting AVPCa criteria, mPFS is 3.8 mo (95% CI 2.8-5.9) with CAB vs 5.7 mo (95% CI 4.4 = 8.9) with CAB/CARB (p = 0.009). Reductions in PSA > 50%, PSA > 90% and BAP > 50% occurred in 44%, 20% and 25% of men with CAB vs 60%, 28% and 63% with CAB/CARB. In men with RECIST measurable disease, a partial response occurred in 14% (5/35) vs 52% (17/33) with CAB vs CAB/CARB. The most common Grade 3-4 adverse events in the CAB vs the CAB/CARB arms were fatigue (4% vs10%), anemia (2% vs 17%), neutropenia (4% vs 15 %) and thrombocytopenia (0% vs 8%). No men with CAB and 2% with CAB/CARB had febrile neutropenia. **Conclusions:** Adding CARB to CAB is safe and improves PFS and response rates in men with mCRPC. Men meeting AVPCa clinical criteria benefit most from the CAB/CARB combination. The performance of a molecular signature for the AVPCa (Abstract #150631) will be tested in assembled tissue samples. A confirmatory phase 3 study is warranted to establish combination chemotherapy in advanced prostate cancer. Clinical trial information: NCT01505868.

Efficacy analysis of a phase III study of androgen deprivation therapy (ADT) +/- docetaxel (D) for men with biochemical relapse (BCR) after prostatectomy. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The optimal treatment (tx) of men with castration sensitive prostate cancer (CSPC) who biochemically recur following a radical prostatectomy (RRP) is not known. Data from E3805 suggest that men with metastatic CSPC live longer if they receive D in addition to ADT relative to ADT alone. We tested this hypothesis in non-metastatic CSPC, via a phase III study (TAX3503). **Methods:** PC pts who underwent an RRP with BCR and a doubling time ≤ 9 months (mo) were eligible. PSA ≥ 1 ng/mL and testosterone ≥100 ng/dl were required. Randomization was 1:1 to receive leuprolide 22.5 mg q3 mo x 18 mo, bicalutamide 50 mg x 30 days, with D at 75 mg/m2 q3 weeks x 10 cycles (Arm A) or without D (Arm B). The primary endpoint was PFS defined as a detectable PSA or death. Pts with T recovery >50 ng/dl were evaluable. The intent to treat population (ITT) was also examined. A sample size of 412, to yield 370 evaluable pts, was calculated to detect a HR of 1.6 with 90% power. The trial was closed by the sponsor after the pts completed treatment; remaining pts were then followed to PFS via a registry for 18 mo's. A test to detect a difference in the hazard rates between arms was generated by the log rank statistic. **Results:** 413 pts were randomized. Median f/u time in the ITT population was 31.5 mo's (0.0-60.2). Data are summarized below in the Table. **Conclusions:** The clinical benefit of ADT + D relative to ADT alone in men with high-risk BCR after RRP appears to be marginal, although there is a statistical trend towards improved PFS. Data are limited by the biases intrinsic to post-protocol registries and by short duration of follow up, although tracking of pts continues. Clinical trial information: NCT01813370.

Effects of radium-223 dichloride (Ra-223) with docetaxel (D) vs D on prostate-specific antigen (PSA) and bone alkaline phosphatase (bALP) in patients (pts) with castration-resistant prostate cancer (CRPC) and bone metastases (mets): A phase 1/2a clinical trial. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ra-223 is an approved α-emitter that prolongs survival in CRPC with symptomatic bone mets. We presented data from a phase 1/2a study of safety and antitumor effects of Ra-223 + D vs D alone showing that Ra-223 + D is safe and well tolerated (ESMO 2014). Here we report the effect of Ra-223 + D vs D on bALP and PSA dynamics. **Methods:** D-eligible pts with progressing CRPC and $\geq$ 2 bone mets received (2:1) Ra-223 (50 kBq/kg q 6 wk $\times$ 5) + D (60 mg/m^2 q 3 wk $\times$ 10) or D (75 mg/m^2 q 3 wk with a step-down option to 60 mg/m^2). bALP and PSA were recorded q 3 wk during the first 6-wk cycle, then q 6 wk and q 3 wk, respectively, and analyzed at a central laboratory. Changes in both markers are described by the % of pts whose best responses were $\geq$ 30%, $>$ 50%, and $>$ 80% declines from baseline (3 wk post last D injection); pts with elevated baseline bALP ($\geq$ 21 μg/L) were included for bALP analysis. bALP to below upper limit of normal (ULN) was also recorded, regardless of % decline. **Results:** 46 pts (33 Ra-223 + D vs 13 D alone) were enrolled. As of January 2015, 24 (Ra-223 + D) vs 5 (D) pts had all planned injections. Median (range) baseline PSA was 99 μg/L (3-1000) for Ra-223 + D pts and 43 μg/L (4-1042) for D pts. The table shows maximal changes in PSA and bALP levels from baseline. No pt had a bALP increase. Pts continue in follow-up (to 12 mo after first injection) for safety and progression. **Conclusions:** Ra-223 + D appears to favorably impact post-treatment declines in PSA and bALP and to be particularly effective at normalizing bALP levels vs D alone. Clinical benefits of such changes in serum markers require validation in larger prospective studies. Clinical trial information: NCT01106352.

Association of SLCO transport genes with intraprostatic abiraterone (ABI) levels and pathologic outcomes in men with high-risk localized prostate cancer (PCa). *First Author: Elahe A. Mostaghel, Fred Hutchinson Cancer Rsrch Ctr, Seattle, WA*

Background: Germline variation in solute carrier organic anion (SLCO) transport genes influences cellular uptake of steroids and has been associated with PCa outcomes. We hypothesized that due to its steroidal structure, ABI may undergo SLCO-mediated transport, and that germline variation in SLCO genes may influence intracellular ABI levels and pathologic outcomes in men with PCa. **Methods:** We measured ABI levels in prostatectomy tissue from 58 men with localized PCa treated with 6 months of castration plus ABI prior to radical prostatectomy (RP). Buffy coat DNA was genotyped for13 SNPs (minimum allele frequency $>$ 0.07) in 6 SLCO genes using TaqMan SNP assays. Transcript expression of SLCO genes was evaluated by qRT-PCR in microdissected tumor samples from a subset of patients. **Results:** SNPs in SLCO1B3 (rs4149177, p = 0.07) and SLCO2B1 (rs12422149, p = 0.0004; rs949069, p = 0.008; rs1789693, p = 0.01) were associated with significant differences in mean tissue ABI levels at RP. Contingency analysis showed higher rates of minimal residual disease (MRD, defined as tumor volume $<$ 0.5cm3) in those with good risk (higher tissue ABI) alleles of SLCO1B3 (rs4149177: 50% (14/28) vs 24% (4/17); Fisher exact p = 0.11) and in those with good risk alleles of SLCO2B1 (rs1789693: 67% (10/15) vs 27% (8/30); p = 0.02). Although not associated with tissue ABI levels, SLCO2B1 (rs1077858) and SLCO2A1 (rs34550074) were also associated with differences in MRD (p = 0.06 and p = 0.05, respectively).Transcript expression of SLCO2B1 increased 16 fold from a mean of -19 dCT (vs RPL13A) in untreated PCa to -15 dCT in ABI treated tumor samples (p = 0.01). **Conclusions:** SLCO transport genes may be pharmacogenetic determinants of intracellular ABI levels and may serve as novel predictors of response to ABI treatment. Clinical trial information: NCT00924469.

EARLY CTC decline as a biomarker of response to treatment in castration-resistant prostate cancer (CRPC): Analysis of the COU-AA-301 and IMMC38 trials. *First Author: David Lorente, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Circulating tumor cell counts (CTC) are prognostic in CRPC. Baseline (BL) CTC $\geq$ 5 CTCs/7.5mL are associated with worse prognosis. A post-treatment 30% decline in CTC has been associated with improved survival (OS) (Olmos et al, 2009). We investigated the value of 30% declines in CTC after 4 and 12 weeks (wks) of treatment in the COU-AA-301 (abiraterone) and IMMC-38 (chemotherapy) trial datasets. This is the first time %CTC decline has been evaluated in phase III CRPC clinical trials. **Methods:** CTC of patients (pts) were determined (CellSearch). Pts with BL CTCs $\geq$5 and valid counts at Wk 4/Wk 12 (IMMC38) or Cycle 2/Cycle 4 Day 1 (COU-AA-301) were evaluated. CTC response was defined as a $\geq$30% decline in CTC relative to BL (30%CTCresp). Association of 30%CTCresp with OS was evaluated with Cox regression in uni- and multivariable (MV) analysis with ECOG, LDH, ALP, Alb, Hb, BL CTC and PSA as covariates (continuous). C-index was calculated to determine the performance of the MV model with and without 30%CTCresp as a covariate. **Results:** 439 pts (326 in COU-301 and 113 in IMMC38) were analyzed. Median BL CTC was 18.5 in COU-301 and 23 in IMMC38. OS in pts with 30%CTCresp at Wk 4 was significantly better in COU-AA-301 and IMMC-38 datasets (Table). BL CTC (continuous) and 30%CTCresp at Wk4 were independently associated with OS in MVA in both datasets. C-index of the MV model improved from 0.677 to 0.712 (COU-AA-301) and from 0.747 to 0.800 (IMMC-38) after including 30%CTCresp. Equivalent results were acquired when evaluating 30%CTCresp at Wk 12. **Conclusions:** BL CTC and 30% CTC falls are independently associated with OS in in CRPC pts treated with abiraterone and chemotherapy. Adding CTC response improved the performance of the MV model. A 30% decline in CTCs from BL as early as 4 wks post-treatment may be a valid biomarker of response to treatment in CRPC.

30% CTC decline at 4 weeks and survival.

	N(%)	OS (m)	HR (95%CI)	p-value
COU-AA-301	326	11.6 (10.3-13)		
30% CTC Decline	208 (64%)	14.4 (13.2-15.5)	-	
No 30% CTC Decline	118 (36%)	7.9 (6.8-9)	0.4 (0.3-0.6)	<0.001
IMMC-38	113	11.2 (9.7-12.6)		
30% CTC Decline	75 (66%)	12.3 (8.2-16.3)	-	
No 30% CTC Decline	38 (34%)	6.8 (4.4-9.2)	0.5 (0.3-0.8)	0.001

Genomic analysis of circulating cell-free DNA (cfDNA) to investigate mechanisms of primary and acquired resistance to enzalutamide (ENZ) in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Arun Azad, BC Cancer Agency, Vancouver, BC, Canada*

Background: ENZ is a potent androgen receptor (AR) antagonist that prolongs survival in mCRPC patients (pts). However, factors driving resistance to ENZ are incompletely understood. Genomic analysis of cfDNA is a promising, minimally invasive approach for interrogating mechanisms of therapeutic resistance in mCRPC. **Methods:** Baseline plasma samples were collected from 57 mCRPC pts commencing ENZ. In 37 pts, additional samples at 12-weeks +/- end-of-treatment were obtained. DNA was extracted and subjected to array Comparative Genomic Hybridization (aCGH) for chromosome copy number (CN) analysis and AR gene (exon 2-8) sequencing (MiSeq) for mutation analysis. Endpoints were i) PSA50 or PSA30 response rates (RR) (PSA decline $\geq$ 50% or 30% for $\geq$ 3 weeks); and ii) radiographic/clinical progression-free survival (PFS). **Results:** On aCGH, the most frequent CN changes in baseline samples (n = 57) were 8p loss (25%), 8q gain (35%), MYC gain (26%) and AR gain/amp (33%). Compared to pts with no AR gain/amp, pts with pre-treatment AR gain/amp had lower PSA50 (39% vs. 21%, P= 0.16; X^2) and PSA30 RR (44% vs. 25%, P= 0.059; X^2) and shorter median PFS (4.5 vs. 2.2 months, P= 0.002; log-rank). On multivariate analysis, pre-treatment AR gain/amp (HR 2.56 P= 0.01) was confirmed as an independent prognostic factor for PFS. In pts with 12-week +/- end-of-treatment samples, 14% (5/37) had a change in AR CN status from baseline with 3 pts converting from no AR gain to AR gain and 2 pts from AR gain to AR amp. Median PFS in these 5 pts was 2.8 months. AR gene sequencing was performed on a subset of 4 pts with 4 high-frequency mutations detected in 3 pts including H874Y (n = 2) and L702H (n = 2), the latter of which converts glucocorticoids to AR agonists. Notably, both L702H mutations were found in end-of-treatment samples from pts who progressed rapidly on ENZ (2.9 months PFS each). Neither of these pts was on glucocorticoids at progression, potentially implicating L702H in ENZ resistance. **Conclusions:** Our data indicate that AR gene aberrations may be key biomarkers of primary and acquired resistance to ENZ in mCRPC. Complete AR gene sequencing data will be presented.

Validation of a genomic classifier for prediction of metastasis following postoperative salvage radiation therapy. *First Author: Robert Den, The Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA*

Background: Management of patients with a postoperative rising prostate-specific antigen (PSA) level is complex. Additional local treatment such as salvage radiation therapy (SRT) may be sufficient for many patients but some may require concurrent systemic therapy in order to delay or prevent metastatic disease. As PSA recurrence on its own is a poor surrogate for metastatic disease we hypothesized that the Decipher genomic classifier (GC), a validated predictor of metastasis may be able to better distinguish those patients where additional local therapy is beneficial from those where SRT on its own is likely insufficient. **Methods:** Genomic classifier (GC) scores were calculated from 166 prostate cancer patients, who received SRT at the Veteran Affairs Medical Center Durham, Thomas Jefferson University and Mayo Clinic, between 1990 and 2010. SRT was defined as administration of RT with Pre-RT PSA levels > 0.2 ng/ml. GC and CAPRA-S scores were compared using survival c-index, competing-risks and Cox regression analysis for the prediction of metastasis. **Results:** Survival c-index for predicting metastasis 5 years post SRT was 0.87 (95% CI: 0.73-0.90) for GC and 0.62 (95% CI: 0.48-0.77) for CAPRA-S. The cumulative incidence of metastasis at 5 years post-SRT was 2.8%, 5.8%, and 33.5% for low, average, and high GC scores ($p < 0.0001$) and 17%, 2.3% and 15% for low, average and high CAPRA-S scores ($p = 0.19$). In univariable analysis only GC, extraprostatic extension and Pre-RT PSA were significant predictors of metastasis. In multivariable analyses with clinical risk factors or the CAPRA-S nomogram, GC was the only independent predictor of metastasis with a HR of 1.59 (1.17-2.16, $p = 0.0017$) for a 10% unit increase in risk score. **Conclusions:** In patients treated with postoperative SRT for PSA recurrence, GC is a powerful predictor of metastasis. Patients with low Decipher have excellent prognosis with SRT and may avoid concurrent hormone therapy. Patients with high Decipher risk are at highest risk for metastatic disease and SRT failure and may benefit from concurrent systemic therapy.

Progression of low- to high-grade prostate cancer: Molecular profiling of tissue obtained by serial targeted biopsy. *First Author: Ganesh S. Palapattu, The Univ of Michigan Hosp, Ann Arbor, MI*

Background: Progression of prostate cancer (PCa) from low- to high-grade is believed to be uncommon. Here, we combined serial targeted biopsy to resample specific PCa sites over time with molecular profiling to determine clonality of high grade cancer. **Methods:** Nine men in active surveillance for low-risk PCa (Gleason Score = 6; GS6) were subjects of this IRB-approved pilot employing the Artemis MR-US fusion biopsy system. Each PCa site was electronically tracked and 1 year later additional tissue obtained from the same intra-prostatic site. Five of 9 men were re-classified on follow-up biopsy to GS $\geq$ 7. ERG immunohistochemistry (IHC) and targeted multiplexed PCR based next generation sequencing (NGS) was performed at each time point. DNA was co-isolated from 6-7 x 4μm formalin fixed paraffin embedded (FFPE) sections/sample. NGS was performed using a custom Ion Torrent Ampliseq panel (containing 3,434 amplicons interrogating oncogenes and tumor suppressors) and the Ion Torrent Proton sequencer. Data was analyzed using validated in-house methods. **Results:** Across the 18 paired samples from 9 patients, 7 pairs (early/late) were evaluable for ERG IHC. In all 7 evaluable cases, PCa in paired specimens was uniformly ERG+ (4 pairs) or ERG- (3 pairs). NGS generated an average of 847x coverage/sample. Copy number analysis identified no high level gains or losses. 3 prioritized driving somatic mutations were identified across the cohort (SPOP F133L in Pt#4, BRCA2 K2524fs in Pt#7 and KMT2B Q2076X in Pt#1), each of which occurred only in the later sample in the pair. Of these 3 men on repeat biopsy, Pt#1 and #4 had GS7 and Pt#7 had GS6 disease. **Conclusions:** In this first of its kind study, our data suggest that i) GS $\geq$ 7 cancers may arise clonally from GS6 cancers through acquired genetic alterations, ii) targeted prostate biopsy allows repeat sampling of a clonal focus, and iii) comprehensive molecular profiling of minute FFPE samples is possible. Our work also supports prior observations that some GS6 cancers possess oncogenic mutations. These findings could have important implications for the management of low risk PCa.

Combination statin/metformin and prostate cancer specific mortality: A population-based study. *First Author: Grace L. Lu-Yao, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Obesity and metabolic syndromes (MetS) are associated with an increased risk of prostate cancer mortality. A recent pre-clinical study showed that combination statin /metformin (CSM) was more effective in inhibiting metastasis than standard chemotherapy (docetaxel) with less toxicity in an *in vivo* model. As clinical data on this topic are limited, this population-based study is to examine the association between treatment with CSM and prostate cancer specific mortality (PCSM) by obesity/MetS status. **Methods:** SEER-Medicare linked data were used to identify patients with high-risk prostate cancer (stage T3/T4 or PSA>20 or Gleason 8-10) in 2007 – 2009. Prescription drug use was identified from Medicare Part D Event files. Obesity/MetS conditions were identified by the presence of ICD-9 diagnosis codes 278.00, 278.01, or 277.7. Cox proportional hazards models were used to compare PCSM with covariates including demographic characteristics, prognostic factors, and cancer treatment(s) received. **Results:** This study cohort consisted of 22,110 high-risk prostate cancer patients, of which 1,365 died of prostate cancer by 12/31/2009. Use of CSM was associated with a 43% reduction in PCSM, more pronounced in men with obesity/MetS conditions (Table). The results were similar when we limited the analysis to patients with minimal comorbidity. **Conclusions:** To our knowledge, this is the largest clinical study to assess the potential effect of CSM on PCSM. CSM or statin use was associated with a large reduction in PCSM, particularly in patients with obesity/MetS conditions. The potential benefits of metformin use may be secondary to concomitant statin use in this population. Further studies are needed to confirm these results.

Statin/metformin rreatment and PCSM among high-risk prostate cancer patients.

Medication used	Obese or MetS HR (95% CI) +	Non-Obese & non-MetS HR (95% CI) +	Overall HR (95% CI) +
Statin + Metformin (N=1,356)	0.30 (0.07 – 1.27)	0.60 (0.39 – 0.93)	0.57 (0.38 – 0.88)
Statin alone (N=4,481)	0.09 (0.01 – 0.64)	0.64 (0.50 – 0.82)	0.60 (0.47 – 0.76)
Metformin alone (M=471)	---	0.98 (0.57 – 1.68)	0.92 (0.54 – 1.57)

+HR=Hazard Ratios compared to non-users (N= 15,802) and 95% confidence intervals (CI).

A phase III trial of short-term androgen deprivation therapy in intermediate-risk prostate cancer treated with radiotherapy. *First Author: Abdenour Nabid, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada*

Background: The place of short term androgen deprivation therapy (STADT) in combination with radiotherapy (RT) for patients with intermediate risk prostate cancer (IRPC) remains controversial. The purpose of this prospective, randomized trial was to compare outcomes between patients with IRPC treated with different doses of RT with or without STADT, (PCS III trial, Clinical Trials.gov, #NCT00223145). **Methods:** From December 2000 to September 2010, 600 patients with IRPC were randomized to 6 months of STADT and two levels of prostate RT doses of 70 (arm 1) or 76 Gy (arm 2) versus prostate dose-escalated RT alone at 76 Gy (arm 3). STADT consisted of bicalutamide and gosereline for six months. RT (2 Gy per fraction) started four months after the beginning of STADT. Biochemical failure and disease-free survival (DFS) were primary end-points, with overall survival (OS) as secondary endpoint. DFS and OS rates were estimated with Kaplan-Meier and compared with log rank test and Cox regression. **Results:** Patient's characteristics were well balanced among the 3 arms (median age 71 years, median PSA 10 ng/ml, median Gleason score 7 and clinical stage). At a median follow-up of 6.5 years, biochemical failure occurred in 96 (16%) patients (arms 1 to 3: 13.5%, 11%, 23.5%) with statistical difference between arm 1 and 3 ($p = 0.01$) and arm 2 and 3 ($p < 0.001$) but not between arm 1 and 2. A total of 130 (21.7%) patients died with only 7 deaths (1.2%) attributed to prostate cancer. The 5-/10-year DFS rates were 92.8%, 97.1% and 85.5%, and 78.4%, 78.3% and 65.9%, respectively. Significant differences in DFS between the treatment arms were observed at 5 and 10 years between arm 1 and 3 ($p = 0.015$, $p = 0.012$) and arm 2 and 3 ($p < 0.001$ at 5-/10-year) but not between arm 1 and 2 ($p = 0.052$, $p = 0.385$). The 5-/10-year OS rates were 90.9%, 93.6% and 90.8%, and 63.8%, 70.8% and 75%, respectively. There was no statistical difference in OS between arms at 5 and 10 years. **Conclusions:** In patients with IRPC, the use of STADT in association with RT, even at lower doses, leads to a superior biochemical control and DFS as compared to dose-escalated RT alone. These outcomes did not translate into an improved OS. Source of Funding: AstraZeneca Pharmaceuticals Grant. Clinical trial information: #NCT00223145.

***HSD3B1* and resistance to androgen deprivation therapy in prostate cancer.** *First Author: Jason W.D. Hearn, Cleveland Clinic, Cleveland, OH*

Background: The somatic mutation *HSD3B1*(1245A > C) has been mechanistically linked to castration-resistant prostate cancer by encoding a mutant enzyme that augments intratumoral dihydrotestosterone (DHT) synthesis. Given the *HSD3B1*(1245C) allele is also frequently found in the germline, we hypothesized men inheriting this variant allele would exhibit resistance to androgen deprivation therapy (ADT), as manifested by worse clinical outcomes. **Methods:** We used a large, prospectively maintained prostate cancer registry to identify men treated with ADT for biochemical failure in the post-prostatectomy setting who were without evidence of metastatic disease. We analyzed progression-free survival (PFS), distant metastasis-free survival (DMFS), and overall survival (OS) according to *HSD3B1* genotype using Kaplan-Meier methods. Cox proportional hazards regression was performed to evaluate potential gene-dosage effects, with homozygous wild-type men serving as the reference group. Demographic and treatment characteristics were compared to assess for possible confounders using Fisher's exact test and Kruskal-Wallis analysis of variance. Multivariable analysis (MVA) was performed to assess whether *HSD3B1* genotype independently predicted clinical outcomes. **Results:** Of 118 men genotyped, 37% were homozygous wild-type, 53% were heterozygous, and 10% were homozygous variant. Demographic and treatment characteristics did not differ across groups. Median PFS diminished as a function of the number of variant alleles inherited (6.6 years in homozygous wild-type men, 4.1 years in heterozygotes, and 2.5 years in homozygous variant men; P = 0.01). Median DMFS likewise decreased according to the number of variant alleles inherited (9.1 years vs. 6.8 years vs. 3.6 years, respectively; P = 0.01). Finally, OS similarly diminished (5-year and 10-year OS: 82% and 55% vs. 74% and 35% vs. 58% and 0%, respectively; P = 0.006). On MVA, the associations between *HSD3B1* genotype and metastasis (hazard ratio (HR) 2.76; P = 0.023) and death (HR 3.33; P = 0.016) were maintained. **Conclusions:** Inheritance of the variant *HSD3B1*(1245C) allele that enhances DHT synthesis may be a powerful predictor of resistance to ADT for prostate cancer.

5021 Poster Session (Board #13), Sat, 1:15 PM-4:45 PM

Association of the prostate cancer risk mutation G84E in HOXB13 with the subtype of ETS fusion negative adenocarcinoma with early age of diagnosis. *First Author: Thomas J. Schnoeller, University of Ulm, Medical School, Department of Urology, Ulm, Germany*

Background: *HOXB13* was discovered as the first prostate cancer (PrCa) specific high-risk susceptibility gene. The most prevalent *HOXB13* germline mutation in PrCa patients of European descent is *HOXB13*G84E, which likely originated in Northern Europe. Previous molecular examination of a set of G84E driven tumors suggested a distinct somatic phenotype, where oncogenic ETS gene fusions appear at unusually low frequencies as compared to the general prevalence of ETS fusions in PrCa (22 % vs approx. 50 %). **Methods:** We have analyzed 942 cases from three European ancestry populations for the coincidence of *HOXB13* G84E and the most common ETS fusion, *TMPRSS2-ERG*(T2E), in corresponding tumor samples. **Results:** While the prevalence of T2E fusions was similar among study sites (range: 56.5% - 60.7%), the frequency of G84E genotypes differed markedly between US (1.5%), German (3.6%) and Finnish samples (8.3%). Despite the expected frequency gradient among study populations, all subsamples showed a strong enrichment of G84E mutation carriers among T2E fusion negative cases as compared to fusion positive cases (center adjusted OR = 4.90; 95%CI = 2.19 - 11.0; p = 0.0001). Consistent with the previous study, the crude frequency of the T2E fusion in *HOXB13*G84E carriers was 23.5 % (range 16.7 % - 28.5 %). Examination of disease characteristics highlighted age at diagnosis, with fusion positive cases being diagnosed 1.75 (0.87 - 2.63) years earlier than negative cases (p < 0.0001). Age at diagnosis in G84E carriers did not differ significantly from non-carriers (p = 0.26). However, within the subtype of fusion negative carcinoma, which is usually associated with later ages at diagnosis, carriers of G84E were diagnosed on average 2.93 (0.49 - 5.37) years earlier (p = 0.02). No associations were seen for tumor stage, tumor grade or diagnostic PSA levels. **Conclusions:** This study demonstrated a tumor type specific association for *HOXB13* G84E mutation carriers having a higher frequency of T2E fusion negative PrCa. Although the T2E fusion negative subtype is known to be associated with later ages of diagnosis, *HOXB13* driven tumors within this subtype may represent an early onset subgroup.

5022 Poster Session (Board #14), Sat, 1:15 PM-4:45 PM

Project Data Sphere: A first look at prostate cancer including concomitant medication use, prognosis, and toxicity. *First Author: Anthony M. Joshua, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: PDS (www.projectdatasphere.org) enables patient-level analyses of control arms of cancer trials. We aimed to include the use of concomitant medications (CM) to (i) validate and improve established prognostic metastatic prostate cancer (mCRPC) models (ii) establish novel predictive factors of toxicity. **Methods:** Data was obtained for 2,747 control subjects with mCRPC from 7 Phase III clinical trials (1962 subjects were available for OS analyses from 5 studies). OS was estimated using the Kaplan-Meier method. Cox-proportional hazards models, stratified by trial, were used to estimate hazard ratios. **Results:** Of 23 medication classes examined patients taking proton pump inhibitors (HR: 1.17, p = 0.017) and Erythropoietin (HR: 1.45, p < .001) had worse OS. Patients taking fish oil (HR: 0.67, p = 0.025) and non-lipophilic statins (HR: 0.67, p = .0.017) had improved OS. Initially, metastatic site was significant for OS (predicted median: Node 24.61m, Bone 22.77 m, Lung 21.39 m, Liver 15.18 m; p < 0.001). After adjusting for metastatic site, these medication classes remained significant (HR 1.15, p = 0.017; HR 1.493, p < 0.01; HR 0.68, p = 0.03; HR 0.68, p = 0.0278 respectively). We then validated and combined 2 multi-variate prognostic models for OS (Templeton et al, Sonpavde et al) after inclusion of CM. Patients taking metformin (HR = 0.729, p = .008) and Cox2 inhibitors (HR = 0.708, p = .015) had improved OS whilst those taking low molecular weight heparin (HR = 1.352, p = .004) had worse OS. Thereafter, a simplified prognostic model based on albumin and LDH alone, equivalent in prognostication was established. For docetaxel trials from baseline, baseline neutrophil to lymphocyte ratio was the best predictor of any toxicity (OR 4.23, p = .004) after accounting for number of cycles, whilst the lymphocyte count had an inverse relationship with the occurence of any severe AE (OR 0.31, p = 0.03). The incidence of toxicity after cycle 1 was the best predictor of subsequent adverse events (OR 5.82, p < 0.01) **Conclusions**: Initial analyses of PDS data in mCRPC allowed for insights into prognostic models and predictors of docetaxel toxicity. Expansion of trials and quality of data will facilitate future analyses.

5023 Poster Session (Board #15), Sat, 1:15 PM-4:45 PM

PET imaging with ^{68}Gallium-labelled ligand of prostate-specific membrane antigen (^{68}Ga-HBED-PSMA) for staging of biochemical recurrent prostate cancer after radical prostatectomy. *First Author: Tobias Maurer, Department of Urology, Technical University of Munich, Klinikum rechts der Isar, Munich, Germany*

Background: Staging of recurrent prostate cancer (PCa) after radical prostatectomy (RP) remains challenging especially at low PSA values. Prostate-specific membrane antigen (PSMA) shows increased expression on most PCa and might therefore be useful for detection of PCa lesions. Aim of this retrospective analysis of consecutive pts was to evaluate the detection rate of PET hybrid imaging using the PSMA inhibitor Glu-NH-CO-NH-Lys-(Ahx)-[(68)Ga(HBED-CC)] (^{68}Ga-HBED-PSMA) in pts with biochemical recurrence (BCR) of PCa after RP. **Methods:** 332 consecutive pts with BCR of PCa after RP and a median PSA value of 1.7 ng/ml (range 0.2-63 ng/ml) were included in this analysis. After injection of 122±17 MBq ^{68}Ga-HBED-PSMA-PET/CT or PET/MR was performed in 256 pts and 76 pts, respectively. One nuclear medicine physician and one radiologist reviewed imaging in consensus. Detection rates according to PSA value were determined. **Results:** In total, detection rates for ^{68}Ga-HBED-PSMA-PET hybrid imaging were 96.0% (143/149) for PSA values ≥ 2ng/ml, 92.0% (80/87) for PSA values 1-2ng/ml, 72.3% (34/47) for PSA values 0.5-1ng/ml and 53.0% (26/49) for PSA values 0.2–0.5ng/ml, respectively. In 28.9% (96/332) of pts solely PSMA-PET detected suspicious lesions whereas 2.7% (9/332) of pts only showed positive findings in morphological imaging. Additional lesions were seen in 21.4% (71/332) of pts in PSMA-PET and in 6.3% (21/332) in CT or MRI. **Conclusions:** ^{68}Ga-HBED-PSMA-PET hybrid imaging shows higher detection rates in pts with recurrent PCa at low PSA values than reported for other PET-tracers like ^{18}F-FDG or choline derivatives. Thus, ^{68}Ga-HBED-PSMA-PET hybrid imaging has the potential to replace PET imaging with these tracers for staging of BCR of PCa after RP in the future.

5024 Poster Session (Board #16), Sat, 1:15 PM-4:45 PM

Statin use at the time of initiation of androgen deprivation therapy and time to progression in patients with hormone-sensitive prostate cancer. *First Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

Background: Statin use has been associated with improved prostate cancer outcomes such as decreased risk of recurrence after local therapy and a lower risk of prostate cancer mortality. DHEAS is a precursor of testosterone and a substrate for SLCO2B1, an organic anionic transporter. We previously demonstrated that genetic variants of *SLCO2B1* correlated with time to progression (TTP) on androgen deprivation therapy (ADT). Statins utilize SLCO2B1 to enter cells, thus, we hypothesized that statin use at ADT initiation might prolong TTP by competing with DHEAS uptake. **Methods:** To determine if statins interfere with DHEAS uptake, we performed in vitro studies using prostate cancer cell lines. Next, we queried our institutional clinical database for patients treated with ADT for biochemical or metastatic recurrence or *de novo* metastatic prostate cancer (ADT cohort). The association between statin use and TTP on ADT was estimated using multivariable Cox regression and adjusted for known prognostic factors. **Results:** In vitro, we demonstrated that statins block DHEAS uptake by competitively binding to SLCO2B1. In our ADT cohort of 926 patients treated between January 1996 and November 2013, 283 (31%) were taking a statin at ADT initiation. After a median follow-up of 5.8 years, 644 patients (70%) had progressed on ADT. Median TTP on ADT was 20.3 months (95% CI: 18,24). Men on statins had a longer median TTP on ADT compared to non-users (27.5 vs. 17.4 months, p = 0.0005). The association remained statistically significant after adjusting for pre-defined prognostic factors [adjusted HR = 0.83 (p = 0.039)]. The positive statin effect was observed for both patients with and without metastases. **Conclusions:** Statin use at ADT initiation was associated with a significantly longer TTP on ADT even after adjusting for known prognostic factors. Our in vitro findings that statins competitively reduce DHEAS uptake and thus, effectively decrease the available intratumoral androgen pool, afford a plausible mechanism to support the clinical observation of prolonged TTP in statin users.

5025 Poster Session (Board #17), Sat, 1:15 PM-4:45 PM

Phase II trial of the PI3 kinase inhibitor BKM120 with or without enzalutamide in men with metastatic castration resistant prostate cancer (mCRPC). *First Author: Andrew J. Armstrong, Duke Cancer Institute, Duke University, Durham, NC*

Background: PI3K pathway activation is common in mCRPC. BKM120 (buparlisib) is an oral, pan-class I PI3 kinase inhibitor. Preclinical data demonstrated a reciprocal feedback loop between PI3K and androgen receptor (AR) signaling; thus, we evaluated the efficacy of BKM120 in men with heavily pre-treated mCRPC including those progressing on enzalutamide (E). **Methods:** This was a 3 site phase 2 Dept of Defense Prostate Cancer Clinical Trials Consortium open-label trial of BKM120 100 mg once daily with ongoing ADT in men with mCRPC who had failed or were not candidates for docetaxel. Continuation of E was permitted in men progressing on E with subsequent addition of BKM120. The primary endpoint was the rate of composite of radiographic and clinical PFS at 6 months with a goal of 40% vs. a historic rate 25% using a two-stage design with interim futility analysis. **Results:** Thirty men were accrued: 63% post-docetaxel; median PSA was 70 ng/dl, 83% had > 4 prior therapies for CRPC; 43% men received concurrent E. The trial met criteria for futility, with a 6 month PFS rate of 10% (95% CI 2.5-23.6%). Median composite PFS was 1.9 months (95% CI: 1.8, 3.4) and 3.5 months (95% CI 1.2, 5.5) with concurrent E. Median OS was 11 months (95% CI 4.8, 14.4). E did not appear to increase the BKM120 side effect profile. The PSA decline proportion was 23%, but no patients achieved a > 50% decline, with median PSA change of +39%. No objective responses were observed. Related SAEs occurred in 3 men including respiratory infection and organ failure (1), urinary tract obstruction due to local progression (1), and severe confusion (1). One seizure was observed in a man who was found to have a new CNS metastasis during concurrent BKM120/E therapy. Grade 3 related AEs were seen in 47% of patients, with 10% stopping BKM120 due to toxicity. The most common related AEs included grade 1-2 weight loss, diarrhea, nausea, fatigue, anorexia, rash, hyperglycemia, and anxiety and mood disorders. **Conclusions:** BKM120 did not improve PFS over historic control data in men with mCRPC, either alone or when added to AR inhibition in men progressing on enzalutamide. These data suggest that PI3K inhibition is not sufficient to block mCRPC progression. Clinical trial information: NCT01385293.

5026 Poster Session (Board #18), Sat, 1:15 PM-4:45 PM

National prostate cancer screening rates following the 2012 United States Preventive Services Task Force recommendation discouraging prostate-specific antigen (PSA)-based screening. *First Author: Michael William Drazer, University of Chicago, Chicago, IL*

Background: The prostate cancer screening debate intensified following the 2012 United States Preventive Task Force (USPSTF) recommendation discouraging prostate specific antigen (PSA) testing-based screening. Previously published USPSTF recommendations did not appreciably reduce screening among groups at high risk for over-diagnosis and over-treatment. The effects of the 2012 guidelines on screening are unknown. **Methods:** We used the National Health Interview Survey (NHIS), a nationally representative survey, to estimate the proportion of men age 40 and older screened for prostate cancer in 2010 and 2013. We utilized an externally validated nine-year mortality index to analyze screening rates based on remaining life expectancy. We used logistic regression to compare screening rates from 2010 to 2013 and explored which subgroups had significant changes in PSA screening. **Results:** Screening significantly declined from 2010 to 2013 among all men over 50. Men ages 60-74 were most heavily tested, with 51.2% screened in 2010 and 43.6% in 2013 ($P < 0.01$). Screening significantly declined for men ages 50-59 ($P < 0.01$) and over 75 ($P = 0.03$) but not among 40-49 year olds ($P = 0.4$). A large percentage of men with a high predicted likelihood (> 52%) of 9 year mortality were screened for prostate cancer, including approximately 32.2% of men over 75. Interestingly, college-educated men had higher screening rates than less college educated men but also had a larger screening decline from 2010 (62.7%) to 2013 (50.2%). **Conclusions:** Prostate cancer screening significantly declined among men over 50 following the 2012 USPSTF guideline discouraging PSA-based screening. A large proportion of men continue to be screened despite a high risk (> 52%) of nine-year mortality, including 32.2% of men age 75 and older.

5027 Poster Session (Board #19), Sat, 1:15 PM-4:45 PM

The combination of DNA ploidy status and PTEN/6q15 deletions to provide strong and independent prognostic information in prostate cancer. *First Author: Maximilian Lennartz, Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Aberrant DNA ploidy has been long discussed as a potential prognostic feature in prostate cancer. **Methods:** In this project, we analyzed the clinical significance of DNA ploidy in combination with the most frequent chromosomal deletions (PTEN, 6q15) with known prognostic impact in a contemporary series of 3,845 prostate cancers. Ploidy status was assessed in 3,845 cancers by using flow cytometry for which the 6q15 and PTEN deletion status was available from earlier projects. **Results:** The DNA status was diploid in 67.8%, tetraploid in 25.6% and aneuploid in 6.8% of tumors. Abnormal DNA content was significantly linked to high Gleason grade, advanced tumor stage, and positive nodal status ($p < 0.0001$ each). Deletions were seen for PTEN in 17.8% and for 6q15 in 20.3% of cases. Both deletions were significantly linked to high Gleason grade and advanced stage ($p < 0.0001$ each). Comparison with outcome data revealed, that the risk of PSA recurrence increased markedly from diploid to tetraploid tumors ($p < 0.0001$) and again from tetraploid to aneuploid cases. However, many patients with unfavorable tumor phenotype (39.9% of tumors with a Gleason grade of $\geq 4+4 = 8$) or with PSA recurrence (55.2%) had a diploid DNA status. The fraction of unfavorable tumors with a normal DNA status decreased to 21.1% of Gleason $\geq 4+4 = 8$ cancers and 29.0% of cancers with PSA recurrence, if DNA abnormality was defined as non-diploid and/or at least one of the two deletions. The significance of combining both deletions and ploidy was further demonstrated in a combined recurrence analysis. Here, presence of deletions markedly increased the risk of PSA recurrence in diploid ($p < 0.0001$), tetraploid ($p < 0.0001$), and aneuploid cancers ($p = 0.0049$). Moreover, multiple models of multivariate analyses including preoperatively and postoperatively available parameters identified the "combined DNA status" as a strong independent predictor of poor patient outcome. **Conclusions:** It is concluded, that a combinatorial DNA content analysis involving general (ploidy) and specific events (deletions) have the potential for clinical utility in prostate cancer.

5028 Poster Session (Board #20), Sat, 1:15 PM-4:45 PM

Phase 1b study of ARN-509 with abiraterone acetate (AA) and prednisone (P) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Edwin M. Posadas, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: ARN-509 and AA target the androgenreceptor (AR) axis via different mechanisms and may have complementary activity in mCRPC. ARN-509, a potent and selective AR antagonist, inhibits AR nuclear translocation and DNA binding without significant AR agonist properties (Clegg. *Cancer Res.* 2012). AA is a prodrug of abiraterone, a CYP17 specific inhibitor that blocks androgen synthesis. No overlapping toxicities are expected for the combination. This phase 1b study evaluates potential PK drug-drug interaction, antitumor activity, and safety of ARN-509 in combination with AA + P (NCT02123758). **Methods:** Pts with progressive mCRPC and ECOG PS $\leq$ 2 received AA (1000 mg/d) + P (5 mg BID) beginning on Cycle 1 Day 1 (C1D1) with the addition of ARN-509 (240 mg/d) on C1D8 in 28-day treatment cycles. Efficacy assessment was based on RECIST and PCWG2 criteria. **Results:** 29 pts started treatment on study. Median age was 70 years (range 49 - 83) and median PSA was 56.8 μg/L (range 4.1 - 2597.0 μg/L). Bone, nodal, and visceral disease were present in 25 (86%), 17 (61%), and 8 (29%) pts, respectively. 14 (48%) pts were previously treated with docetaxel, 12 (41%) with AA, 12 (41%) with enzalutamide (ENZ). 22 pts are currently on treatment and 7 discontinued for disease progression. Thus far, 41% of pts have had confirmed PSA declines $>$ 50%; 52% had any PSA decline. Confirmed PSA responses $>$ 50% included 3 pts who failed prior ENZ or AA therapy. Most common ($\geq$ 3 pts) drug-related adverse events (AEs) were grade 1-2 and included fatigue (n = 8), dysgeusia (n = 5), vomiting (n = 4), anorexia (n = 4), abdominal pain (n = 3), diarrhea (n = 3), nausea (n = 3). Grade 3 drug-related AEs (hyponatremia [n = 1], fatigue [n = 1], increased ALT [n = 1], and urinary tract infection [n = 1]) were managed by drug interruption and supportive measures. **Conclusions:** Interim data indicate that ARN-509 in combination with AA + P is well tolerated in pts with mCRPC. Further study of the efficacy and safety of ARN-509 and AA + P for mCRPC is warranted. Clinical trial information: NCT02123758.

5029 Poster Session (Board #21), Sat, 1:15 PM-4:45 PM

STEAP1 as a predictive biomarker for antibody-drug conjugate (ADC) activity in metastatic castration resistant prostate cancer (mCRPC). *First Author: Daniel Costin Danila, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: STEAP1 is overexpressed in mCRPC and is an ADC target. STEAP1 expression in tissue assayed by IHC, protein and mRNA expression levels in circulating tumor cells (CTC) and by ^{89}Zr-labeled anti-STEAP1 antibody uptake by iPET. **Methods:** Patients (pts) with progressive mCRPC received doses of the ADC ranging from 0.3 to 2.8 mg/kg once every three weeks. Antitumor activity was assessed by PSA declines, time on study and changes in CTC number (CellSearch). STEAP1 expression in tumor tissue by a validated IHC assay was used as reference biomarker on a scale of 0 (not detected) to 3+ (highest expression). Protein and mRNA expression in CTCs was explored by FACS and RT-PCR, and standardized uptake values (SUV) of ^{89}Zr-labeled anti-STEAP1 antibody by iPET. **Results:** At doses of $\geq$ 2 mg/kg, a $\geq$ 50% PSA decline was observed in 22% (10/45, 11-37%), and CTC conversions from unfavorable ($>$ 5 cells) to favorable (4 or fewer/7.5 ml of blood) in 55% (11/20, 32-77%) of cases. CTC showed a readily detectable STEAP1 +ve signal in EpCAM +ve events by FACS in 48% (14/29, 30-67%), confirmed by RT-PCR, along with AR (androgen receptor) and KLK3 expression. STEAP1 +ve events were EpCAM +ve in a range from 0-74%. ADC activity by IHC and CTC is shown in Table. For STEAP1 iPET imaged pts, PSA decline by $\geq$ 50% was noted in 4/14 (29%, 8-58%) pts. Time on treatment correlated with bone metastasis SUVmax (r = 0.63). All 8 PET-guided biopsies were confirmed STEAP1 IHC 2+/3+. **Conclusions:** The best evidence for STEAP1 ADC activity by PSA declines, time on study, and CTC conversion was seen in high expression tumors. Pts with IHC 2+/3+ tumors are being prospectively selected in an expansion study where predictive biomarkers are studied as companion diagnostics.

STEAP1 IHC score and treatment response.

IHC Score	Pts Observed/ Total (%, 95% CI)	PSA decline by $\geq$ 50%	$>$ 6 months on treatment	CTC conversion from U to F
1+	5/45 (11%, 4-24%)	1/5 (20%, 1-72%)	0/5 (0%, 0-52%)	1/3 (33%, 1-91%)
2+	27/45 (60%, 44-74%)	4/27 (15%, 4-34%)	6/27 (22%, 9-43%)	7/14 (50%, 23-77%)
3+	13/45 (29%, 16-44%)	5/13 (39%, 14-68%)	6/13 (46%, 19-75%)	3/3 (100%, 29-100%)

5030 Poster Session (Board #22), Sat, 1:15 PM-4:45 PM

Immune responses and clinical outcomes in STAND, a randomized phase 2 study evaluating optimal sequencing of sipuleucel-T (sip-T) and androgen deprivation therapy (ADT) in biochemically-recurrent prostate cancer (BRPC) after local therapy failure. *First Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: STAND (NCT01431391) assessed optimal sequencing of sip-T and ADT in men with BRPC at high risk of metastases after local therapy (i.e. prostate specific antigen doubling time [PSADT] $<$ 12 mo). **Methods:** Men (n = 68) were randomized to sip-T then ADT (2 wks post infusion 3; Arm 1) or ADT (3 mo lead-in) then sip-T (Arm 2). Cellular and humoral immune responses, and clinical outcomes were analyzed. PSA recurrence was defined as $\geq$ 2 serial rises in PSA and an absolute PSA value of $\geq$ 0.2 ng/mL (prior radical prostatectomy) or $\geq$ 2.0 ng/mL (prior radiotherapy alone). PSADT post-ADT was analyzed. Time to next anticancer intervention (TTACI) was measured from first ADT to the day of the next systemic therapy. Rate of metastases at 24 mo was also investigated. **Results:** All men received 3 sip-T doses, and 96% received 12 mo ADT. Cellular and humoral responses to PA2024 increased following treatment vs baseline (BL) and were sustained at all post-sip-T timepoints through 24 mo ($p < 0.05$). PA2024-specific T cell proliferation responses were higher in Arm 1 vs Arm 2 ($p<0.001$). The number of PA2024 antibody (Ab) responders (post-BL Ab titer $\geq$ 25,600) was similar between arms. Sip-T-mediated antigen spread was observed in both arms vs BL and maintained through 24 mo ($p < 0.001$). No significant differences between arms were observed in clinical outcomes: median time to PSA recurrence (21.8 vs 22.6 mo, HR: 0.70, 95% CI: 0.39–1.28; p = 0.357), PSADT (2.54 vs 2.58 mo, p = 0.944), metastases at 24 mo (6/31 vs 3/26, p = 0.419), or TTACI (medians not reached, p = 0.199). However, across the entire cohort, PA2024 Ab responses correlated with longer time to PSA recurrence (p = 0.007). Adverse events occurring in >20% were hot flashes, fatigue, headache, and chills. **Conclusions:** In men with non-metastatic BRPC, sip-T + 12 mo ADT induced a robust immune response that persisted for 24 mo. Data suggest a greater anti-PA2024 T cell proliferative response in Arm 1 (sip-T then ADT). Induction of a PA2024 Ab response may correlate with longer time to PSA progression. Clinical trial information: NCT01431391.

5031 Poster Session (Board #23), Sat, 1:15 PM-4:45 PM

Baseline analysis of circulating tumor cell (CTC) enumeration and androgen receptor (AR) localization in men with metastatic castration-resistant prostate cancer (mCRPC) in TAXYNERGY. *First Author: Scott T. Tagawa, Weill Medical College of Cornell University, New York, NY*

Background: Microtubule-targeted therapy with taxanes is the only chemo with survival benefit in advanced PC. Emerging molecular evidence suggests sensitivity/resistance to taxanes may relate to the ability of microtubules to inhibit AR nuclear trafficking. CTCs represent a real-time biomarker for molecular testing including taxane-induced microtubule stabilization and AR nuclear localization. **Methods:** TAXYNERGY is an international, multicenter phase 2 trial in progressive, chemo-naïve mCRPC men randomized (2:1) to docetaxel or cabazitaxel. Pre-treatment CTCs were enriched from 1 ml blood via a prostate-specific microfluidic device, enumerated, and analyzed by multiplex confocal microscopy for AR cellular localization. Nuclear AR % was calculated by integrating fluorescence intensity in the total cell and nuclear area. Bivariate correlations and multiple regressions examined associations between baseline characteristics and % nuclear AR or CTC count. **Results:** 63 men were randomized (median age 70 [range 53–84], median PSA 89 [2.4–1558], 24 [38%] previously received a CYP17 inhibitor and/or enzalutamide, 17 [27%] had visceral metastases). Of 59 with evaluable samples, CTCs were detected in 52 (88%), median 10 CTCs/mL of blood [0–542]. 638 CTCs were analyzed for AR localization with a mean 61.2% [30–85] nuclear AR per subject. Higher baseline LDH, pain assessments, and ECOG performance status were associated with higher CTC counts; LDH (p = 0.013) and analgesic scores (p = 0.036) remained significant on multivariate analysis. Visceral metastases were associated with a lower fraction of nuclear AR, remaining significant on multivariate analysis (p = 0.045). **Conclusions:** Nearly 90% of men with progressive chemo-naïve mCRPC have detectable CTCs available for molecular analysis using this platform, with higher CTC counts associated with adverse prognostic variables. Lower percent of nuclear AR was associated with visceral metastases, suggesting progressive visceral CRPC may be less AR-driven. The predictive value of these biomarkers for taxane response is being evaluated. Clinical trial information: NCT01718353.

5033 Poster Session (Board #25), Sat, 1:15 PM-4:45 PM

Performance of CCP assay in an updated series of biopsy samples obtained from commercial testing. *First Author: John W. Davis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The cell cycle progression (CCP) score is an RNA−based expression assay, which has improved the prediction of prostate cancer aggressiveness in nine separate retrospective cohorts. In this analysis, we characterized the patient population and CCP score performance in commercial testing. **Methods:** Formalin−fixed prostate biopsy samples from 4261 patients were submitted by 930 physicians to Myriad Genetic Laboratories for CCP test analysis. Patient clinicopathologic data was obtained from the test request form. The CCP score was calculated based on RNA expression of 31 cell cycle progression genes normalized to 15 housekeeping genes. Patients were sorted in to AUA risk categories and assigned a relative classification of cancer aggressiveness based on the CCP score. **Results:** Of the 4261 samples that contained sufficient carcinoma ($>$ 0.5mm linear extent), 4218 (99.0%) provided quality RNA for analysis. The CCP score distribution ranged from −2.9 to 3.4. Correlation with Gleason score was r = 0.35 and the correlation with PSA was r = 0.16. Based on the CCP score, 36.8% of men had a less aggressive cancer and 21.2% of patients had a more aggressive cancer than expected based on clinicopathologic prediction. **Conclusions:** The CCP test can improve risk stratification for men with prostate adenocarcinoma independent of other clinicopathologic variables. Fifty−eight percent of men tested in the commercial assay were assigned to a different risk category than predicted by their clinicopathologic features.

5034 Poster Session (Board #26), Sat, 1:15 PM-4:45 PM

Radium-223 in an international early access program (EAP): Effects of concomitant medication on overall survival in metastatic castration-resistant prostate cancer (mCRCP) patients. *First Author: Fred Saad, University of Montreal, Montreal, QC, Canada*

Background: The pivotal ALSYMPCA study reported improved overall survival (OS) in bone symptomatic mCRPC patients (pts) treated with radium-223 (Ra-223) vs placebo (median 14.9 vs 11.6 months [mos], HR = 0.70). Data from 696 EAP pts recruited from 14 countries (Europe, Canada, Israel) are presented. **Methods:** In this prospective phase IIIb study, mCRPC pts with symptomatic or asymptomatic bone metastases (no visceral disease) received Ra-223, 50 kBq/kg (iv injection) every 4 weeks for 6 cycles. Primary endpoints were safety and OS. The effects of concomitant medications, baseline (BL) pain, alkaline phosphatase (ALP) and ECOG PS on OS were assessed. **Results:** 696 pts were treated; 58% received all 6 Ra-223 injections. At BL: median age was 72 years; 88% of pts were ECOG PS 0–1; pain was reported as: no pain, mild-moderate, and severe in 21%, 52%, and 27% respectively. 60% of pts received prior therapy with docetaxel. For pts treated with concomitant therapy: 22% were with abiraterone; 20% with denosumab; 18% with bisphosphonates and 4% with enzalutamide. Grade 3/4 AEs were reported in 38% of pts; 21% discontinued Ra-223 due to AEs. At the time of analysis median OS was 16 mos [13–not estimated (NE)]. Median time to first SSE was 18 mos [17–NE]; 24% of pts had ≥ 50% confirmed ALP decrease from BL; 8% had $>$ 50% confirmed PSA decrease from BL. In post hoc analyses OS was statistically significantly longer in pts with BL: ALP $<$220 U/L vs ≥ 220 U/L; ECOG PS 0–1 vs ≥ 2; no pain vs mild-moderate vs severe; concomitant denosumab; concomitant abiraterone (Table). **Conclusions:** In Ra-223 treated pts, OS appeared to be better in those treated concomitantly with denosumab or abiraterone. Significantly longer OS was observed in pts with a good ECOG PS, no pain and low ALP. Clinical trial information: 2012-000075-16.

Characteristic	Pts, n	Median OS, mos (95% CI)	Log-rank p-value

5035 Poster Session (Board #27), Sat, 1:15 PM-4:45 PM

Circulating tumor cell (CTC) enumeration in men with metastatic castration-resistant prostate cancer (mCRPC) treated with enzalutamide post-chemotherapy (phase 3 AFFIRM study). *First Author: Martin Fleisher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CTC enumeration is a biomarker associated with clinical outcomes in patients (pts) with mCRPC. CTC count at baseline (BL) and post-treatment is prognostic for survival. Enzalutamide (ENZA) was approved for post-chemotherapy CRPC based on the overall survival (OS) benefit (AFFIRM trial). In this trial, CTC enumeration was embedded as a biomarker endpoint. **Methods**: AFFIRM was a phase 3 study (N = 1199; NCT00974311) randomizing men who received ≤ 2 docetaxel-based chemotherapy regimens to ENZA 160 mg/day or placebo (PBO) (2:1). CTC samples were collected at sites selected for logistics and investigator interest. Conversion rate was defined as a decline from ≥ 5 (unfavorable) to $<$ 5 (favorable) CTCs/7.5 mL of blood from BL to best post-BL result. **Results**: BL CTCs were obtained from 447 of 1199 pts at 89 of 156 study sites; BL demographics and disease history were similar to pts in whom samples were not collected. 382 pts had both BL and post-BL counts; OS, rPFS and select disease characteristics for pts with CTC data are shown in the table. Conversion from unfavorable to favorable CTC counts was observed in 61 of 127 pts (48%; 95% CI 39%-57%) treated with ENZA compared to 6 of 62 pts (9.7%; 95% CI 3.6%-20%) with PBO ($p < 0.0001$). Progression from favorable to unfavorable counts occurred in 18% of ENZA pts compared to 44% with PBO. **Conclusions:** Unfavourable baseline CTC counts were associated with higher PSA and greater disease burden. The higher rate of conversion from unfavorable to favorable and lower conversion from favorable to unfavorable for ENZA relative to placebo was consistent with observed OS benefit. Clinical trial information: NCT00974311.

5036 Poster Session (Board #28), Sat, 1:15 PM-4:45 PM

Enzalutamide (ENZA) in men with chemotherapy-Naïve metastatic castration-resistant prostate cancer (mCRPC): Final analysis of the phase 3 PREVAIL study. *First Author: Tomasz M. Beer, Oregon Health & Science University, OHSU Knight Cancer Institute, Portland, OR*

Background: PREVAIL (NCT01212991) was a phase 3 trial that investigated the impact of ENZA vs placebo (PBO) on overall survival (OS) and radiographic progression-free survival (rPFS) in asymptomatic or mildly symptomatic chemotherapy-naïve men with mCRPC. ENZA improved OS (hazard ratio [HR] 0.71; 95% confidence interval [CI] 0.60–0.84; $P < 0.0001$) and rPFS (HR 0.19; 95% CI 0.15–0.23; $P < 0.0001$) in a planned interim analysis after 540 deaths (Sep 16, 2013, data cutoff). On the basis of these results, ENZA was approved for chemotherapy-naïve mCRPC in the US and Europe. Final OS analysis was planned after at least 765 deaths. **Methods:** Patients (pts) were randomized 1:1 to ENZA 160 mg/day or PBO. OS and rPFS were coprimary endpoints and analyzed in the intent-to-treat population. Planned sample size was 1680 with at least 765 deaths to achieve 80% power to detect a target OS HR of 0.815, with a type I error rate of 0.049 and a single interim analysis. After the interim analysis, eligible PBO pts had the option to crossover to ENZA. All pts were followed in an open-label extension protocol. rPFS was determined by investigator review. The final OS and rPFS results reported here are from Jun 1, 2014, and Jan 15, 2014, data cutoff dates, respectively. **Results:** 1717 men were randomized (1715 treated) between Sep 2010 and Sep 2012. The final analysis at 784 deaths with a median follow-up of 31 months (mo) confirmed the OS benefits of ENZA with a 23% reduction in risk of death (HR 0.77; 95% CI 0.67–0.88; $P = 0.0002$) and a 4-mo improvement in median OS (35.3 mo [95% CI 32.2–NYR]) vs 31.3 mo [95% CI 28.8–34.2]). 42% of ENZA and 49% of PBO pts had died; 52% of ENZA and 81% of PBO pts (including 167 pts who crossed over to ENZA) received ≥ 1 subsequent life-extending prostate cancer therapy. A preliminary analysis of rPFS from the Jan 15, 2014, data cutoff showed a significant improvement with ENZA (HR 0.32; 95% CI 0.28–0.36; $P < 0.0001$). Median rPFS was 20.0 mo (95% CI 18.2–22.1) with ENZA vs 5.4 mo (95% CI 4.2–5.6) with PBO. **Conclusions:** With longer follow up time, ENZA continued to demonstrate a robust improvement in OS and rPFS in asymptomatic or mildly symptomatic chemotherapy-naïve mCRPC. Clinical trial information: NCT01212991.

5037 Poster Session (Board #29), Sat, 1:15 PM-4:45 PM

Phase 1 study with expansion cohorts of cabozantinib (C) + abiraterone (A) in metastatic castration resistant prostate cancer (mCRPC): Investigator-sponsored study. *First Author: Christopher Sweeney, Dana-Farber Cancer Institute, Boston, MA*

Background: A and C (multi-tyrosine kinase inhibitor including MET and VEGFRs) have complementary mechanisms of action and activity in CRPC. *In vivo* work with LAPC4-CR (castration and A resistant cell line) has shown the combination has enhanced activity. **Methods:** Phase 1, 3 + 3 trial with A fixed at 1,000 mg/day and prednisone 5mg BID and escalating daily doses of C (20mg, 40mg, 60mg) in pts with mCRPC was conducted. Cycles were 28 days. **Results:** 27 patients were enrolled with a median follow-up of 9.2 months (Range: 1.6-29.4 months). 11 pts had prior docetaxel therapy. No DLTs in the first 28 day cycle of dose escalation cohorts. The 60 mg C cohort had Gr 2 adverse events (AEs) of myalgias (2), fatigue (2) and DVT (1) in cycles 2 and 3 necessitating a dose reduction to 40 mg (no change to A). Due to a preferable tolerability profile, the 20mg and 40mg C cohorts were expanded to a total of 12 pts each. See Table for activity data. Gr 3 treatment related AEs: 5 pts at 20mg C [skin infection (1); diarrhea (1); anemia (1); transaminase (1); hypophosphatemia (1)]; 7 pts at 40mg C [hypertension (1); hypophosphatemia (2); transaminase (1); colitis (1); lipase incr. (1); thromboembolic (1)]. Dose reductions: 5 pts on 40mg C; none on 20mg C. 1 pt had A dose reduction [hypokalemia with Atrial Fib (1)]. The steady-state trough concentration PK data of A and C did not indicate a drug-drug interaction. **Conclusions:** C at either 20mg or 40 mg is tolerable when combined with standard dose A/pred. The long term tolerability and preliminary efficacy data support the investigation of this combination for further clinical development in mCRPC. Clinical trial information: NCT01574937.

5038 Poster Session (Board #30), Sat, 1:15 PM-4:45 PM

Acute toxicity and early quality of life after dose intensified salvage radiotherapy for biochemically recurrent prostate cancer after prostatectomy: First results of the randomized trial SAKK 09/10. *First Author: Pirus Ghadjar, Department of Radiation Oncology, Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Patients (pts) with biochemical recurrence after radical prostatectomy may benefit from dose intensified salvage radiotherapy (RT) of the prostate bed. We performed a randomized phase III trial assessing dose intensification. In this first report we report acute toxicity and early quality of life (QoL). **Methods:** Pts with biochemical recurrence but without evidence of macroscopic disease were enrolled in this randomized phase III trial. Pts were randomly assigned to either 64 Gy (32 daily fractions) or 70 Gy (35 daily fractions). Three-dimensional conformal RT (3D-CRT) or intensity-modulated RT (IMRT, or equivalent rotational techniques) were accepted techniques. The primary endpoint was freedom from biochemical recurrence. Secondary endpoints included acute toxicity according to the CTCAE v4.0 and QoL using the EORTC QLQ-C30 and PR25. **Results:** We enrolled 350 pts between 02/2011 and 04/2014. Three pts withdrew consent and three were not eligible, resulting in 344 pts in the safety population. Thirty (8.7%) and two (0.6%) pts had grade 2 and 3 genitourinary (GU) baseline symptoms. Acute grade 2 and 3 GU toxicity was observed in 22 (13.0%) and 1 (0.6%) with 64 Gy and 29 (16.6%) and 3 (1.7%) with 70 Gy, being not significantly different ($p = 0.2$). Baseline grade 2 gastrointestinal (GI) toxicity was observed in 1 (0.6%) patient. No baseline grade 3 GI toxicity was observed. Acute grade 2 and 3 GI toxicity was observed in 27 (16.0%) and 1 (0.6%) with 64 Gy and 27 (15.4%) and 4 (2.3%) with 70 Gy, again not significantly different ($p = 0.8$). Changes in QoL were marginal. However, pts receiving 70 Gy reported a more pronounced and clinically relevant worsening in urinary symptoms (mean difference between arms 3.6, $p = 0.02$). There was no significant difference between 3D-CRT and IMRT/rotational techniques. **Conclusions:** Dose-intensified salvage RT was associated with a low rate of grade 2 and 3 GU and GI toxicities. The impact of dose intensified salvage RT on QoL was marginal, with the exception of a worsening in urinary symptoms after 70 Gy. Clinical trial information: NCT01272050.

5039 Poster Session (Board #31), Sat, 1:15 PM-4:45 PM

Testosterone-guided schedule of androgen deprivation therapy (ADT) as an alternative to a fixed schedule in management of prostate cancer. *First Author: Saroj Niraula, CancerCare Manitoba and Univ of Manitoba, Winnipeg, MB, Canada*

Background: ADT with LHRH agonists that reduce testosterone production is effective initial therapy for treatment of men with advanced prostate cancer. LHRH agonists are usually administered indefinitely at a fixed interval despite their cost and serious toxicity. **Methods:** We recruited men with prostate cancer who had been on fixed-schedule injections of a LHRH agonist (most commonly given as 12 weekly injections) for at least one year and had castrate levels of serum testosterone (< 1.7 mmol/l). We measured their serum testosterone at 6-week intervals, and men resumed their injections only when their serum testosterone was ≥ 1.7mmol/l. We calculated median time to reinstitution of ADT by the Kaplan Meier method and used Cox regression analyses to identify factors predicting delay in reinstitution of treatment. Influence of this approach on quality of life (QoL) was measured by the Expanded Prostate Index Composite (EPIC). **Results:** From November 2009 to May 2014, a total of 82 men were enrolled. Median age at diagnosis was 68 years (range, 51-83 years). Median time to testosterone recovery after the last injection was 30.8 weeks (Inter-quartile range 17-65 weeks). Lower level of baseline testosterone (≤ 1 versus > 1 mmol/l) [Hazard Ratio (HR) 0.32; $p = 0.004$] and longer duration of disease (> 5 versus ≤ 5 years) [HR 0.38; $p = 0.03$] were independent predictors for prolonged time to testosterone recovery. Statistically significant improvement from baseline was noted in the hormonal domain of EPIC ($p = 0.002$) but not in overall score. Drug costs (LHRH agonist alone) dropped from a median of $4,550 to $1,900 per patient per year. **Conclusions:** Implementing a testosterone-guided approach to ADT results in a substantial reduction in exposure to, and symptoms from ADT. Drug cost is reduced by $> 60\%$ while still maintaining castrate levels of testosterone. Testosterone-guided approach to ADT can have major public health benefits. This approach should be discussed with men on ADT and be considered as the replacement of fixed schedule treatment by physicians and policy makers. Clinical trial information: NCT01007825.

5040 Poster Session (Board #32), Sat, 1:15 PM-4:45 PM

Immune response from STRIDE, a randomized, phase 2, open label study of sipuleucel-T (sip-T) with concurrent vs sequential enzalutamide (enz) administration in metastatic castration-resistant prostate cancer (mCRPC). *First Author: David I. Quinn, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: In mCRPC, data are limited regarding optimal combinatorial or sequential use of available treatments. P12-2 (STRIDE; NCT01981122) is an ongoing, randomized, open-label, phase 2 study evaluating concurrent vs sequential administration of the androgen receptor inhibitor, enz, with the autologous cellular immunotherapy, sip-T. **Methods:** Fifty-twopatients (pts) with asymptomatic or minimally symptomatic mCRPC were randomized 1:1 to receive 3 sip-T infusions with enz starting 2 wks before (n = 25, concurrent arm A) or 10 wks after (n = 27, sequential arm B) sip-T initiation. The primary endpoint is peripheral T cell proliferation response to PA2024, the sip-T immunizing antigen. Secondary endpoints include interferon (IFN)-γ ELISPOT and humoral immune responses to PA2024 and prostatic acid phosphatase (PAP), product release parameters (total nucleated cell count, $CD54^+$ cell counts, and antigen presenting cell activation [as measured by CD54 upregulation]), cytokine production, and adverse events (AEs). Results through wk 26 are described. **Results:** PA2024-specific T cell proliferative response was significantly elevated at all post-baseline time points ($p < 0.001$) and was sustained through wk 26, including a > 10-fold increase at wk 20 in both arms. This PA2024-specific response was observed in nearly all pts, 95.8% in arm A vs 92.6% in arm B. Both arms showed a significant and sustained increase in humoral responses to PA2024 and PAP as well as IFN-γ ELISPOT response to PA2024. Sip-T product parameters were similar between arms. Cytokines indicative of immune activation (such as IFN-γ, interleukin-2, and tumor necrosis factor-α) were also elevated in both arms. AEs were observed in 88% (arm A) and 100% (arm B) of pts. The incidence of grade ≥ 3 AEs was similar between arms. **Conclusions:** Most mCRPC pts receivingenz concurrently with or subsequent to sip-T demonstrated significant and sustained peripheral T cell and humoral immune responses through wk 26. These interim data suggest that both schedules were safe, and enz did not impair sip-T production or subsequent immune responses. Clinical trial information: NCT01981122.

5041 Poster Session (Board #33), Sat, 1:15 PM-4:45 PM

Relationship between abiraterone plasma concentration and PSA response in metastatic castration resistant prostate cancer patients. *First Author: Edith Carton, Medical Oncology, Paris Descartes University, Cochin - Port Royal Hospital, AP-HP, Paris, France*

Background: Abiraterone (ABI) is a standard treatment in metastatic castration-resistant prostate cancer (mCRPC). However, the large interindividual variability in ABI pharmacokinetics could contribute to the lack of PSA regression observed in some patients. We aimed to explore the pharmacokinetic/pharmacodynamic (PK/PD) relationship of ABI in progressive mCRPC patients (pts). **Methods:** We prospectively included mCRPC pts receiving ABI, pre-treated or not with docetaxel. ABI was administrated once daily at 1000 mg, in a fasted state, with 10 mg of prednisone. Trough ABI plasma concentration (C_{min}) was assayed using liquid chromatography at month 1, 2 and 3 after treatment initiation, and PSA level was measured at baseline and after 3 months (ms) of treatment. The individual average C_{min} during the first 3 ms of treatment was used for the statistical analysis. Pts who had a PSA decline of at least 50% after 3 ms were defined as responders, according to Prostate Cancer Working Group 2 (PCWG2). All pts gave their informed consent. **Results:** From December 2012 to October 2014, 57 pts were included. Forty-one pts (76%) were docetaxel-naïve. ABI C_{min} was available in 48 pts. The median average ABI C_{min} was 11.2 ng/mL (IQR 7.2 - 16.2 ng/mL). No intraindividual variability in ABI C_{min} was identified (CV = 23.5%, p = 0.79). The interindividual variability in ABI C_{min} was large (CV = 70%), but was not influenced by age, body mass index, albumin level, hepatic or renal function. Among 45 pts available for PK/PD assessment, 29 pts (64%, IC95% [50-78]) were responders at 3 ms. The average plasma ABI C_{min} was significantly higher in the responder group (median 13.1 [IC 95% 10.6 - 15.6] vs 8.5 [5.6-15.7] ng/mL, $p < 0.01$, respectively). Pts were classified into two groups based on ABI plasma C_{min}: low (quartile 1 [Q1]) and high (Q2-Q4). In 11 pts exhibiting average ABI C_{min} below 8.5ng/mL (Q1), 18% were responders. In contrast, 80% of pts in Q2-Q4 were responders (Fisher test, $p < 0.001$). **Conclusions:** In addition to molecular profiling, plasma monitoring of ABI C_{min} could help optimizing its efficacy. We propose 8.5 ng/mL as the threshold ABI C_{min} to explore the benefit of PK-guided dosing strategy in clinical practice.

5042 Poster Session (Board #34), Sat, 1:15 PM-4:45 PM

Genomic analysis of circulating tumor cells (CTCs) from men with metastatic castration resistant prostate cancer (mCRPC) in the context of enzalutamide therapy. *First Author: Jing Li, Duke University Medical Center, Chapel Hill, NC*

Background: Predictive biomarkers are essential to maximize benefit and minimize harms and costs in mCRPC. Goal of this study was to determine the feasibility of genomic analysis of DNA copy number changes and whole exome sequencing (WES) of CTCs from men with mCRPC receiving enzalutamide. **Methods:** We collected CTCs from men with mCRPC in the context of enzalutamide therapy. CTCs were isolated through red cell lysis, CD45 depletion, and flow sorting on EpCAM/CD45 expression. Whole genomic amplification, aCGH, and WES were performed. In aCGH, each sample hybridized with its own leukocytes. A copy number log ratio greater than 0.2 or less than -0.2 with at least 10 consecutive probes represents gain or loss. In WES, single nucleotide variant (SNV) or insertion/deletion (INDEL) was called if the site was covered by more than 10 reads. **Results:** We successfully profiled the genomic copy number of CTCs from 4 men with CRPC. We compiled copy gains and losses observed by aCGH in these 4 patients. Genomic copy gains in AR, EZH2, SPOP, CCND1, BRD4, MYC, FOXA1, ABL1, ABL2 and other genes were observed; while common losses of the locus including CHD1 FGFR2, PHLLP, NCOR1, NCOR2 were seen. During sequential analysis during enzalutamide resistant visceral progression, loss of AR amplification and gain of N-MYC was observed, consistent with evolution toward a neuroendocrine AR-independent clone. We successfully sequenced the whole exome from CTCs and leukocytes from a patient who progressed through enzalutamide therapy. We discovered many somatically acquired mutations in CTCs exome, including 138 SNVs and 47 INDELs in CTCs including NCOA1, MAX, NOD1,USP10, MLL, MMP8, which have been previously implicated in prostate cancer. **Conclusions:** Genomic analysis of whole genome DNA copy number changes and whole exome sequencing from CTCs of men with mCRPC are feasible and identified previously validated and novel complex genomic lesions. Our results suggest the potential of CTC genomic analysis to help identify and longitudinally track predictive biomarkers and novel targets of systemic therapy efficacy and resistance in men with mCRPC and form the basis for larger validation trials.

5043 Poster Session (Board #35), Sat, 1:15 PM-4:45 PM

Nine-year follow-up for a study of diffusion-weighted MRI in a prospective active surveillance cohort for prostate cancer. *First Author: Daniel Robert Henderson, Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom*

Background: Active surveillance (AS) for untreated prostate cancer requires accurate selection of patients unlikely to need treatment in their lifetime. Most studies have selected patients on biopsy and PSA criteria alone, but show a significant number requiring treatment for disease progression. Lower tumour apparent diffusion coefficient (ADC) values, derived from diffusion-weighted MRI (dwMRI), are associated with higher risk disease. We hypothesised that ADC values could aid selection of patients for AS. Early results from this study were published in 2009; we now present findings with the benefit of long-term follow up. **Methods:** We analysed a subset of patients having pre-enrolment dwMRI in a prospective research study of AS. Inclusion criteria: untreated prostate cancer, T1/T2a/N0M0, Gleason $\leq 3+4$, PSA < 15. Protocol follow up was by biopsy at 18-24 months, then every 24 months, along with regular PSA. To avoid influencing treatment decisions, results of dwMRIs were not available to the AS study investigators. Baseline data including PSA, biopsy grade, and T stage, along with ADC value, were analysed with respect to the outcomes of: time to adverse histology (TAH; primary Gleason ≥ 4, $\geq 50\%$ positive cores) and time to deferred radical treatment (TRT). **Results:** Eighty six patients were included (90% Gleason 6; 86% cT1). Median follow up was 9.5 years. Forty six patients developed adverse histology, and 59 received deferred radical treatment (2 due to patient choice). In univariate analysis, ADC below the median was associated with shorter TAH and TRT with hazard ratios of 2.13 (CI: 1.17-3.89; $p < 0.014$) and 2.54 (CI: 1.49-4.32; $p < 0.001$), respectively. Median TRT in patients with ADC above the median was 9.3 years (CI: 7.0-11.6) but 2.4 years (CI: 1.5-6.0) for those below the median. For TRT, addition of ADC to a multivariate model of baseline variables resulted in a significant improvement in model fit (HR: 1.33, CI: 1.14-1.54, $p < 0.0001$). ROC analysis for TRT: AUC 0.80 (CI: 0.70-0.88). **Conclusions:** Long-term follow up for this study provides strong evidence that ADC is a useful marker when selecting patients for AS. Routine dwMRI is now included in our ongoing prospective AS study.

5044 Poster Session (Board #36), Sat, 1:15 PM-4:45 PM

Computer automated bone scan index (BSI) as an analytically validated imaging biomarker to quantitate change in bone scan of patients with metastatic prostate cancer. *First Author: Aseem Anand, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A consistent imaging biomarker to standardize the evaluation of change in bone scan is an unmet need for patients (pts) with bone metastasis. BSI is quantitative interpretation of bone scan in pts with metastatic prostate cancer (mPCa). Here we have performed analytical and clinical studies to evaluate the change in computer automated BSI as a consistent imaging biomarker in pts with mPCa. **Methods:** Analytical studies with bone scan simulation using XCAT phantoms and SIMIND-MC program were performed to evaluate the consistency of automated BSI. Specifically, to assess linearity and accuracy, bone scan of 50 phantoms were simulated with tumor burden ranging from low to high disease confluence – from 0.10 to 13.0 BSI. To assess precision, another set of 50 phantoms were divided into 5 subgroups, each containing simulated bone scans of 10 phantoms at 0.5, 1.0, 3.0, 5.0 and 10.0 BSI, respectively. Additionally, to evaluate the clinical utility of automated BSI, two follow-up bone scans of 145 pts with progressing mPCa, irrespective of therapy regiment, were analyzed for change in BSI. The primary objective was to evaluate the association of change in BSI against overall survival (OS). The computer automated BSI was calculated using the software EXINI bone^{BSI}. Cox regression and Kaplan Meier analysis were used to evaluate association between BSI and OS. **Results:** Pearson correlation to evaluate linearity and accuracy of BSI, in the given range from 0.10 to 13.0, was observed to be 0.995 (N = 50, 95% CI 0.99 – 0.99, $p < 0.0001$). The mean coefficient of variation indicating precision of BSI at each of the pre-defined tumor burden was observed to be less than 20%. Change in BSI of 145 pts was significantly associated with OS (HR 1.1, $p < 0.0001$). The median OS for 110 (66%) pts who had a rise in BSI (> 0.10) was 31 weeks, 35 (34%) pts who had a decline or no change in BSI reached a median 72 weeks (HR 1.9, p 0.0002). **Conclusions:** Computer automated BSI is a consistent biomarker which can standardize the quantitative analysis of change in bone metastasis of pts with mPCa. The clinical utility of automated BSI, in multivariate biomarker panel, will be validated in subsequent studies.

5045 Poster Session (Board #37), Sat, 1:15 PM-4:45 PM

Identification of germline mutations in men with early onset prostate cancer. *First Author: Patrick Pilie, University of Michigan, Ann Arbor, MI*

Background: Prostate cancer (PCa) is generally considered a disease of older men, however, approximately 10% of new diagnoses occur in young men (< 56 years) and some of these cases are clinically aggressive. Epidemiological evidence suggests that early age of cancer onset is associated with increased genetic susceptibility. **Methods:** For this pilot study, we employed a gene panel approach to identify germline mutations in cancer-associated genes among men diagnosed with early-onset (EO) PCa. Fifty-five men with PCa diagnosed before age 56 were selected from the University of Michigan (UM) Prostate Cancer Genetics Project, a large family-based study of familial and EO PCa. Each of the men also had at least one of the following characteristics: 1) family history of breast and/or ovarian cancer, 2) multiple primary cancers in addition to PCa, and/or 3) clinically aggressive PCa defined as death from disease before age 66 and/or diagnosis of metastatic disease before age 56. All patients provided written consent and this project was approved by the UM IRBMED. Germline DNA from the 55 men was sequenced using the GeneRead Human Comprehensive Cancer Panel (Qiagen) which includes 124 genes previously associated with a variety of cancers. Potentially deleterious variants were confirmed via Sanger sequencing and then tested in all family members with DNA available to assess co-segregation with PCa status. **Results:** Over 2500 germline variants were identified, including 349 missense, 4 nonsense, and 6 frameshift variants. Seven of the ten protein truncating variants were confirmed. The 7 true positives included nonsense variants in *MSH2, ATM, and KRAS*, as well as frameshift variants in *FGFR3, TET2, and BRCA2*. **Conclusions:** Overall, 7 of 55 (~13%) high selected EO PCa cases harbored protein-truncating variants in one of the genes examined. Although deleterious mutations in *BRCA2* and *MSH2* have previously been associated with PCa risk, the other genes have been less well-studied for their role in PCa susceptibility. Further studies of this unique patient population will likely uncover additional novel variants and genes linked with PCa risk which may provide new insights into the development of the disease and ultimately suggest new therapeutic targets.

5046 Poster Session (Board #38), Sat, 1:15 PM-4:45 PM

Influence of prostate cancer disease state and therapeutic selection on peripheral whole-blood RNA signature. *First Author: Bobby Chi-Hung Liaw, Division of Hematology and Medical Oncology, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Prostate cancer is a heterogeneous disease with differences in tumor stromal interactions contributing to variability in treatment response and outcome. Gene expression of peripheral blood cells is altered by interactions with neoplastic tissue. We previously developed a peripheral whole blood six-gene signature prognostic for survival in mCRPC. Here we evaluate how different clinical disease states and treatment with different therapeutic agents impact this signature. **Methods:** Whole blood was collected in PAXgene Blood RNA tubes in two cohorts of prostate cancer patients, one at Mount Sinai (n = 135), the other in Munich (n = 59), in the context of prospective clinical studies. Whole blood RNA was extracted and the six target genes were amplified using qPCR. Scores were derived using normalized cycle threshold (ΔCT) values of the six genes, according to the model: 2 x ABL2 + SEMA4D + ITGAL – C1QA – TIMP1 – CDKN1A. Patients were categorized by disease state in the Mount Sinai cohort, and by treatment received in the Munich cohort, for data analysis. **Results:** CRPC is the only disease state with a mean six-gene score (18.06) above the high-risk cutoff (17.9), and is significantly higher than localized or hormone sensitive advanced disease (16.07, 16.52, respectively; p = 0.0002). Among patients with localized disease, there was no significant difference in the mean six-gene scores for patients with low-, intermediate-, and high-risk disease (16.07, 15.33, 16.66, respectively; p = 0.27). In CRPC patients treated with docetaxel, there are significant changes to the six-gene score over the course of treatment (p = 0.002), with a notable percentage decrease (-6.2%) at the 2-8 week timepoint that is not observed in patients treated with abiraterone or enzalutamide. **Conclusions:** Gene expression profiling of whole blood is influenced by the clinical state of prostate cancer as seen by differences to the six-gene score from localized to castrate resistant disease. Cytotoxic chemotherapy appears to modulate the six-gene score, something not seen with AR-directed therapies. Further investigation will be needed to understand the significance of these changes.

5047 Poster Session (Board #40), Sat, 1:15 PM-4:45 PM

Prognostic index model (PIM) for overall survival (OS) in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) without prior chemotherapy treated with abiraterone acetate (AA). *First Author: Charles J. Ryan, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: Models that predict prognosis may aid in treatment planning for mCRPC. We previously presented a PIM for radiographic progression-free survival from the phase 3 COU-AA-302 trial in mCRPC pts without prior chemotherapy (ECC 2013, #P370). In the final analysis of COU-AA-302, AA + prednisone (P) significantly prolonged median OS vs P (34.7 mo vs 30.3 mo; HR: 0.81; 95% CI 0.70 - 0.93; p = 0.0033). Using the final analysis dataset from COU-AA-302, we developed a PIM for OS in mCRPC pts in the AA + P arm. **Methods:** The complete set of baseline data was available from 493/546 pts (90%), and formed the basis for the modeling. Accepted values for lower (LLN) and upper (ULN) limits of normal were used to dichotomize laboratory factors; other factors were dichotomized for ease of interpretation. Factors were assessed for association with OS through a univariate Cox model and used in a multivariate Cox model with a stepwise procedure. Internal validation of the predictive performance of the final model was assessed by a bootstrap resampling procedure. Model discriminatory power was estimated by the C-index. **Results:** Four factors associated with poor prognosis were included in the final model: Brief Pain Inventory 2 - 3 (HR: 1.71, p < 0.0001), lactate dehydrogenase > ULN (234 IU/L) (HR: 2.03, p < 0.0001), alkaline phosphatase > ULN (131 IU/L) (HR: 1.60, p = 0.0004), and ≥ 10 bone metastases (HR: 1.92, p < 0.0001). Pts were categorized into good (n = 296), intermediate (n = 117), and poor (n = 131) risk groups based on number of risk factors. Median OS was calculated for each group (Table). The C-index was 0.67 ± 0.016. **Conclusions:** We identified 4 readily available clinical and laboratory factors to generate a PIM for OS in mCRPC, and categorized pts into 3 distinct risk groups. If validated in an independent dataset, this PIM may be useful for estimating OS in mCRPC and designing risk-adapted treatment strategies. Clinical trial information: NCT00887198.

Number of risk factors	Median OS, months (95% CI)	HR (95% CI)[a]
0 or 1 (good) n = 296	53.6 (47.6 - not estimable)	—
2 (intermediate) n = 117	38.4 (33.7 - 45.8)	2.04 (1.57 - 2.66)
3-5 (poor) n = 131	26.6 (24.5 - 28.5)	3.77 (2.94 - 4.84)

5048 Poster Session (Board #41), Sat, 1:15 PM-4:45 PM

Association of single nucleotide polymorphisms (SNPs) in *ESR1* and *PRMT8* and response to treatment with abiraterone acetate (AA) in men with metastatic castration refractory prostate cancer (mCRPC). *First Author: Neeraj Agarwal, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Germline variations in genes involved in androgen biosynthesis and metabolic pathways may predict response to AA in men with mCRPC, serve as prognostic and predictive biomarkers, and guide towards more individualized therapy. **Methods:** 785 single nucleotide polymorphisms (SNPs) from the Illumina OmniExpress genotyping platform within the boundaries of 60 genes reported to be involved in the androgen metabolic pathway were investigated for association with time to treatment failure (TTF) in 49 Caucasian men with mCRPC undergoing treatment with AA. Cox proportional hazard analysis was employed using Gleason score as a covariate and assessing each SNP under an additive genetic model in which the number of minor alleles contributes increasing risk (or protection). **Results:** Five SNPs in *ESR1* (estradiol-binding domain of the estrogen receptor gene), and 5 SNPs in *PRMT8* (protein arginine methyl transferase 8 gene) were associated with TTF on AA therapy (p < .005) while controlling for Gleason Score (Table). **Conclusions:** SNPs in *ESR1* and *PRMT8* significantly associated with TTF on AA therapy, and may serve as predictive markers to treatment with AA. Further validation is being performed in a larger cohort of men with mCRPC.

5049 Poster Session (Board #42), Sat, 1:15 PM-4:45 PM

TERRAIN. *First Author: Simon Chowdhury, Medical Oncology Department, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom*

Background: Enzalutamide (ENZA), an androgen receptor inhibitor, improves survival and radiographic progression-free survival (rPFS) in patients (pts) with mCRPC. TERRAIN (NCT01288911) compared ENZA to bicalutamide (BIC), which is frequently added to androgen deprivation therapy upon progression in pts with mCRPC. **Methods:** Pts with mCRPC were randomized 1:1 to ENZA 160 mg/day or BIC 50 mg/day. Primary endpoint was progression-free survival (PFS), defined as time to centrally confirmed radiographic progression, skeletal-related event, initiation of new anti-neoplastic or death (any cause), whichever occurred first. Radiographic progression was also assessed by investigators. Circulating tumor cell (CTC) counts were evaluated at baseline and on treatment. Favorable conversion was defined as decline from ≥5 to <5 CTCs/7.5 mL of blood from baseline. **Results:** 375 pts were enrolled. The median time on ENZA treatment was 11.7 months and 5.8 months on BIC. PFS (primary endpoint) and rPFS outcomes are shown (Table). Among pts with measurable soft tissue disease, objective tumor response rates were 54% (38/70) with ENZA and 11% (8/71) with BIC. Favorable conversion rates at week 25 were 67% (29/43) with ENZA and 43% (16/37) with BIC. Serious adverse events (AEs) were reported for 31% of ENZA vs 23% of BIC pts. The most common (≥10%) AEs reported more frequently with ENZA than BIC were fatigue, back pain, hot flush, hypertension, diarrhea, weight decrease and pain in extremity. Grade 3 or higher cardiac AEs were observed in 5.5% of ENZA vs 2.1% of BIC pts. **Conclusions:** In TERRAIN, pts treated with ENZA had prolonged PFS and rPFS, a higher objective tumor response rate, and superior week 25 CTC results when compared to pts treated with BIC. ENZA demonstrated safety broadly consistent with its known safety profile in men with mCRPC. Clinical trial information: NCT01288911.

5050 Poster Session (Board #43), Sat, 1:15 PM-4:45 PM

LBH589 (LBH) and bicalutamide (Bic) in castration-resistant prostate cancer (CRPC) patients (pts) progressing on second line anti-androgen (AA): NYU-08479/PCCTC. *First Author: Anna C. Ferrari, The Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: Retrospective studies of CRPC pts resistant to 2nd-line AA indicate that progression develops within ~4 months (mo) of a 3rd-line AA treatment (tx). The histone-deacetylase inhibitor LBH decreases expression of androgen receptor (AR) mRNA, splice variants, protein and its targets in CRPC models. Combined with Bic, LBH induces a synergistic anti-proliferative response in Bic-resistant cells. Thus, by epigenetic modulation of AR alterations and restoration of AA sensitivity, LBH may delay AA-resistant CRPC progression. **Methods:** AA-resistant CRPC pts were randomized 1:1 to 3-week (wk) cycles of Bic 50 mg daily and LBH 40 mg (arm A) or 20 mg (arm B) tri-weekly 2 wks/cy. *Endpoints (EPs)*: *Primary* (1°), radiographic progression (rP)-free survival (rPFS) at 6 & 9 mo with activity declared if *>15%* by Fisher Exact Test; *Secondary* (2°), PSA response, safety and tolerability. Pts receiving ≥ 2 tx cycles evaluated for 1°EP; all pts evaluated for 2°EP. **Results:** 52 pts (28/24, arms A/B) treated. Median (range): age 69 (48-84) years, PSA 14 ng/mL (2-543), previous AA tx, 2 (1-4); 50 pts had mets (mCRPC), 33 each bone/LN. *Arm A*: Tx cycles before stop (cycles,pts): < 2, 7; 2-7, 12 (+1 ongoing); 8-12 (≥ 6 mo), 8, of which 5 completed 13-25 cycles (> 9 mo).13/28 (46%) pts had LBH dose reduction to 30-25 mg. rPFS was 40% (8/20 pts) at 6 mo (p = 0.006), 25% (5/20 pts) at 9 mo (p = 0.35); 5 pts (25%) had rP. PSA declines were: > 30%, 6 pts; > 50%,1 pt. Toxicities: Grade(G) G4 thrombocytopenia 8; G3 fatigue 2, diarrhea 2; G2 diarrhea 9, fatigue 5. *Arm B:* Tx cycles before stop (cycles, pts): < 2, 4; 2-7, 16; 8-12, 4; > 12, 2. Only 1/24 reduced LBH to15 mg. rPFS was 20% (4/20 pts) at 6 mo,10% (2/20pts) at 9 mo (p > 0.3); rP occurred in 7/20 pts (35%). PSA declines were: > 30%, 2 pts; > 50%,1 pt. Toxicities**:** G4 thrombocytopenia 1, Kaposi's 1, G3 fatigue 1, diarrhea 1; G2 diarrhea1, fatigue 6. **Conclusions:** The proportion of mCRPC pts resistant to 2nd-line AA that achieved rPFS at 6 mo was significant after tx with Bic combined with LBH 40 mg and frequent dose reductions to 30-25 mg for tolerance. LBH 20 mg was not effective. Studies combining LBH with new 2nd-line AA are planned to prevent/delay resistance. Clinical trial information: NCT00878436.

5051 Poster Session (Board #44), Sat, 1:15 PM-4:45 PM

Phase 1-2 study of progesterone receptor (PR) inhibition with extended-release (ER) onapristone (ONA) in patients (pts) with castration-resistant prostate cancer (CRPC): PK, safety and PR testing results from the dose escalation cohort. *First Author: Anuradha Jayaram, The Institute of Cancer Research & The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: An urgent need exists for new therapies after progression (PD) onabiraterone (AA) and enzalutamide (ENZ). PR expression increases with castration resistance [Bonkhoff 2001]. ONA, a type-I PR antagonist, has clinical activity in other PR^{pos} cancers. An ER ONA tablet was developed to achieve continuous exposure, and an IHC companion diagnostic to detect activated PR. **Methods:** This open-label, phase 1-2 study with dose selection/expansion includes pts with: advanced CRPC, prior PD on AA or ENZ and ≤ 2 chemotherapies. Tumors are biopsied at baseline and on treatment to determine PR status. 1° endpoint for dose escalation is to define recommended phase 2 dose (RP2D). 2° endpoints include safety and PK. In stage 1a pts were randomized to 10/20 mg ONA BID. Stage 1b is currently open to enrollment (30/40/50 mg BID cohorts; 6 pts/cohort, 8 recruited to date). At the RP2D, 36 pts will be treated to confirm safety and activity. We present results of stage 1a (n = 10) and a separate biomarker validation cohort (n = 45). **Results:** Stage 1a is complete. There were no DLTs or significant LFT abnormalities at 10/20 mg BID. One pt had related G3/4 AEs: G3 nausea/anorexia. Most common related AEs were fatigue (n = 4) and anorexia (n = 3). 4 SAEs were reported, none considered related to ONA. There were no treatment discontinuations for AEs. Mean C_{max}/AUC/$t_{1/2}$ at 10 and 20 mg were 253 ng/mL, 5311 ng*h /mL, 5.98 hours and 384 ng/mL, 10240 ng*h /mL, 4.92 hours, respectively. 3 pts had paired biopsies: 1/3 pts had strong PR expression (> 50%) pre-treatment and no PR expression after 19 days of ONA. In the biomarker cohort, we tested pt-matched therapy-naïve (TN) and CRPC specimens and identified PR (> 1% cells) in 15 pts (33%: 5 CRPC and 10 TN). No TN but 4/45 CRPC (9%) biopsies had strong PR expression (> 50% cells). **Conclusions:** CRPC expresses PR. The IHC diagnostic method will be used for selective enrichment. The 1st stage of the study concluded with no DLTs, permitting escalation. Randomization now includes the 3 higher doses. PK appears dose proportional. Clinical trial information: NCT02049190.

5052 Poster Session (Board #45), Sat, 1:15 PM-4:45 PM

Disease burden and outcome in metastatic hormone sensitive prostate cancer (mHSPC). *First Author: Laurence Albiges, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients (Pts) with higher burden of mHSPC have shorter OS but there is no uniform definition of high (H) vs low (L) volume of disease (VD). **Methods:** Pts with mHSPC with known VD were analyzed [2 trials of ADT vs ADT + Docetaxel (D) and the Dana-Farber Cancer Institute Gelb center database of pts treated with ADT]. OS (95% CI) was calculated from randomisation for GETUG and E3805, and from initiation of ADT at the Gelb center, until death or censored at last follow-up. E3805 HVD defined as visceral metastases and/or 4 or more bone metastases (BM) with at least 1 beyond the pelvis/vertebrae. **Results:** 1,528 of 1,603 pts had data available to accurately categorize HVD/LVD. A gradient in outcome is noted for increasing BM burden. OS variability is seen in the 4-9 BM group and OS across the 3 cohorts. The E3805 composite definition consistently dichotomized the 5 groups (HR for HVD/LVD ≥ 2 for risk of death). **Conclusions:** A composite definition of HVD consistently dichotomized the 5 groups. Variability between cohorts may be due to different pts characteristics and CRPC therapy.

5053 Poster Session (Board #46), Sat, 1:15 PM-4:45 PM

IMAAGEN trial update: Effect of abiraterone acetate and low dose prednisone on PSA and radiographic disease progression in patients with non-metastatic castration-resistant prostate cancer. *First Author: Charles J. Ryan, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: Abiraterone acetate (AA) 1000mg, in combination with prednisone (P), 10mg daily is indicated for the treatment of patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). IMAAGEN is a phase II, multi-center study with a primary endpoint that evaluated the ability of AA plus 5 mg of prednisone (AA+5) to decrease PSA levels in pts with nmCRPC and a rising PSA; primary results have been reported earlier[1]. Herein we report updated results on secondary endpoints and safety from the IMAAGEN study (Nov 3, 2014 database cut-off date). **Methods:** All enrolled pts had high risk non-metastatic castration resistant prostate cancer (nmCRPC): PSA value $\geq$ 10ng/mL or PSA doubling time $\leq$ 10 months at screening. Pts received AA+5 daily; each treatment cycle = 28 days. Reported endpoints include time to PSA progression, time to radiographic progressive disease, and safety. **Results:** At the time of the data cutoff, 62 (47.3%) of the 131 patients enrolled in IMAAGEN remained on treatment in the study. The median duration of exposure was 17.9 months (range 0.1 – 40.7 months). Median time to PSA progression was 28.7 months (95% CI 21.2, NE). There were 21 confirmed radiographic progression events. The median time to radiographic progressive disease was not reached. 95.4% of pts had an adverse event (AE) (54.9% had a Grade 3 or higher) and 38.2% had a serious AE (SAE) with 35.9% having an SAE of Grade 3 or higher. 13.0% of pts had AEs resulting in discontinuation of study treatment. Four pts had AEs resulting in death (coronary artery disease, myocardial infarction, acute respiratory failure, and pneumonia). **Conclusions:** Treatment of high risk nmCRPC patients with AA+5 resulted in a median time to PSA progression of 28.7 months. The median time to radiographic disease progression was not reached. The safety profile of AA+5 reported in this IMAAGEN trial update is consistent with the safety profile from previously reported studies of abiraterone acetate 1000mg in combination with either 5mg or 10mg prednisone. [1]ASCO 2014 IMAAGEN primary endpoint poster presentation Clinical trial information: NCT 01314118.

5054 Poster Session (Board #47), Sat, 1:15 PM-4:45 PM

Tumor-directed PET imaging of metastases in metastatic castration-resistant prostate cancer (mCRPC) using Zr-89 labeled antiprostate-specific membrane antigen (PSMA) antibody J591. *First Author: Jarett L. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There is no standard imaging (SI) modality that specifically and accurately images prostate cancer (PC) metastases, hampering prognostication and response assessment. J591 is a humanized antibody that targets the external domain of PSMA. We have previously reported on the feasibility, PK and biodistribution of ^{89}Zr-J591 in 10 patients (pts) (Pandit-Taskar et al, Eur J Nuc Med Img 2014). We now report on the targeting/accuracy in 50 pts with mCRPC. **Methods:** Following standard CT/MRI, bone scan (BS), and FDG PET imaging, 5 mCi of ^{89}Zr-J591 was administered IV. ^{89}Zr-J591 was imaged 6-8 days after injection. Positive (pos) scan findings were confirmed, where possible, with biopsies (bxs) in the following preference: concordant ^{89}Zr-J591 and FDG pos, ^{89}Zr-J591 and FDG mismatch, and a mismatch between SI and any PET. **Results:** Imaging: A total of 703 lesions in 50 pts were identified using all imaging modalities. *Bone*:538 total bone lesions were detected. 491(91%) lesions were present on J591 of which 99 were only evident by J591. BS identified 339 (63%), CT 301 (56%), and FDG 207 (38%). *Soft Tissue:* 165 total soft tissue lesions were detected. 90 (55%) were seen on J591 of which 17 were only evident by J591. CT identified 124 (75%) and FDG 88 (53%). Pathology:46 bx's were evaluable (21 bone, 25 soft tissue) in 34 pts. Of the unique J591 lesions bx'd, 5/7 were pos for PC. *Bone*: We bx'd 19 J591 pos lesions and 2 J591 neg sites. Overall, path concordance with J591 was: 89% true pos, 100% true neg, 11% false pos, and 0% false neg. *Soft tissue*: We bx'd 16 J591 pos lesions and 9 J591 neg sites. Of these, we found 88% true pos, 11% true neg, 13% false pos, and 89% false neg. **Conclusions:** J591 PET identifies additional disease in bone not seen using other imaging modalities. These lesions are highly likely to correspond to disease by bx. The data also continues to affirm that J591 appears to be superior at identifying bony disease than soft tissue lesions. Clinical trial information: NCT01543659.

5055 Poster Session (Board #49), Sat, 1:15 PM-4:45 PM

Molecular characterization of clinically defined aggressive variant prostate cancer (AVPCa) in prospectively collected tissues and corresponding patient derived xenografts (PDX). *First Author: Ana Aparicio, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: AVPCa shares clinical features with small cell carcinoma (SCC) such as resistance to androgen signaling inhibition and frequent visceral metastases. A prospective clinical trial of platinum doublets (NCT00514540; Aparicio, Clin Can Res 2013;19) gave confidence that clinically defined AVPCa also shares chemotherapy sensitivity with SCC, irrespective of morphology. Here we screen for links between the clinical phenotype and molecular profile of AVPCa and corresponding PDX. **Methods:** 59 PC samples from 40 men (10 with SCC) registered to NCT00514540, and 8 PDX from 6 of them, were stained for RB, p53, AR, NKX3-1, ASCL1, AURKA, UBE2C and Ki67. We examined relationships between markers. We subjected DNA from 36 of the PC samples and all PDX to OncoScan to determine copy number alterations (CNA). We compared findings to reported TCGA data. We examined associated and downstream molecular events in the PDX. **Results:** The 40 men with tissues available for study were similar to remaining NCT00514540 patients except for higher ECOG PS and LDH values. 67% stained negative for RB and 32% for AR. Nuclear (N)-AR showed strong positive correlations with RB, NKX3-1, N-AURKA, as did p53 with N-UBE2C and Ki67 with UBE2C. Most common CNA across morphologies were 8q24 amplification, PTEN loss (largely gene-specific) and RB1 loss (often regional). Clustering segregated samples by CNA rate and associated with Tp53 mutational status but not histology. CNA in RB1, PTEN and MYC carried the highest weight in linear discriminant analyses distinguishing AVPCa from TCGA samples. Seven of 8 PDX bore Tp53 mutations. 2 of 3 RB-positive PDX had high levels of hyperphosphorylated RB. Only AR-negative PDX expressed pro-neural transcription factors, albeit heterogeneously. **Conclusions:** Clinically defined AVPCa of varied morphologies share molecular profile with SCC and are characterized by combined alterations in RB, p53 and/or PTEN. Analysis of corresponding PDX contributed biological insight. The ability of this signature to distinguish AVPCa is being evaluated in an independent prospective clinical trial (Abstract #152334).

5056 Poster Session (Board #50), Sat, 1:15 PM-4:45 PM

A molecular and clinico-pathological model for predicting abiraterone acetate/prednisone (AA/P) efficacy in metastatic castrate resistant prostate cancer (mCRPC). *First Author: Manish Kohli, Mayo Clinic, Rochester, MN, Rochester, MN*

Background: There are no known markers for predicting AA/P efficacy in chemo-naïve mCRPC stage. We explored a model for predicting the 12-week efficacy outcome after initiation of AA/P in a prospective clinical trial (NCT# 01953640). **Methods:** mCRPC patients initiating AA/P underwent biopsy of metastases at baseline (pre AA/P) and at week 12. Somatic whole exome DNA sequencing; gene expression for AR full length (ARFL) and splice variants (ARVs) was performed of baseline metastases. Composite progression on AA/P at week 12, (primary endpoint) was evaluated with PSA, RECIST, bone scan and symptoms (based on PCWG2 criteria). Candidate molecular factors (RNA expression of ARFL, ARV3, ARV7, ARV9, ARV23, ARV45, Chromogranin-A (CGA)) were explored in a multivariate Cox Proportional Hazard Regression (CPHR) model. Additionally, PSA/testosterone levels, Gleason Score (GS:2-6;7;8-10) at initial diagnosis; time from starting hormone therapy to mCRPC stage (years), serum CGA levels were also included. A final CPHR model fitted only those factors which exceeded an entry threshold in univariate analysis or were considered clinically relevant. **Results:** Between 6/2013 and 11/2014, 56/70 patients enrolled had disease assessed at the 12-week time point. The CPHR model includes 56 patients with complete sequencing and 12 week clinical outcomes. The median follow up for the cohort was 170 days (41-502 days). Progression at 12-weeks was observed in 23/56 patients. The final CPHR model included baseline expression of ARV45 (HR = 13.107, p-value = 0.017); CGA levels (HR = 0.998, p-value = 0.004); time from hormone therapy to mCRPC stage (HR = 0.782, p-value = 0.008); GS at initial diagnosis (HR = 0.004, p-value $<$ 0.001 for GS group 7 and HR = 0.008 p-value $<$ 0.001 for GS group 8-10) and ARFL, ARV3, ARV7, ARV9, ARV23. A C-statistic for the model was observed at 0.76 with an adjusted R^2 of 0.47 (likelihood ratio p-value $<$ 0.001). **Conclusions:** Clinical prediction rules are needed for developing precision medicine in mCRPC. An initial attempt to incorporate molecular and clinico-pathological factors appears feasible. Evaluation for model stability remains ongoing. Clinical trial information: NCT# 01953640.

5057 Poster Session (Board #51), Sat, 1:15 PM-4:45 PM

Validation of correlation of RECIST changes with survival in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Gregory Russell Pond, Ontario Clinical Oncology Group (OCOG), Hamilton, ON, Canada*

Background: In patients (pts) with mCRPC receiving chemotherapy, measurable disease response by World Health Organization criteria is prognostic for overall survival (OS). We now explored the association of changes in measurable disease by Response Evaluation Criteria in Solid Tumors (RECIST) with OS. **Methods:** Data from the control arm (n = 612) of the VENICE trial receiving docetaxel, prednisone and placebo (DPP) were available. Data on baseline clinical variables and outcomes were obtained. Cox proportional hazards regression was used to evaluate the prognostic ability of RECIST changes adjusting for known factors for OS using a 90-day landmark analysis. The association was validated using 388 patients in the DPP arm of the MAINSAIL trial who had RECIST measurements prior to day 90 and survival beyond day 90. **Results:** 363 pts in VENICE had measurable lesions, of whom 296 were evaluable for landmark analysis. 28 (9.5%) had progressive disease (PD) prior to day 90, while 58 (19.6%) had unconfirmed partial response (PR). In a multivariable analysis, the hazard ratio (HR) for OS for pts with PR was 0.64 (95% CI 0.42 – 0.99, $P = 0.045$) compared to those without PR, and 1.78 (95% CI 1.07 – 2.95, $P = 0.026$) for those with PD compared to those without PD. PD remained significant (HR = 1.85, 95% CI 1.10-3.12, $P = 0.020$) after adjusting for PSA changes, but PR was not ($P = 0.14$). The association of PR (HR 0.51, 95% CI = 0.22-1.18, p = 0.12) and PD (HR = 3.51, 95% CI 1.92-6.43, $p < 0.001$) with OS was externally validated in 388 pts in MAINSAIL who had measurable disease. After adjusting for PSA changes, PD was associated with poor OS (HR = 2.36, 95% CI 1.11-5.04, p = 0.026), but PR was not (p = 0.15). **Conclusions:** In men with mCRPC receiving first-line docetaxel-based therapy, RECIST changes within 90 days are associated with OS. Given the frequent detection of measurable disease with current imaging and the unclear association of PSA and bone scan changes with outcomes in the setting of new agents, the accrual of patients with measurable tumors in phase II trials to assess RECIST changes may provide a more objective signal of efficacy of new agents.

5058 Poster Session (Board #52), Sat, 1:15 PM-4:45 PM

Development of an imaging approach to detect splice variants of androgen receptor in prostate cancer. *First Author: Yusuke Imamura, Genome Sciences Centre, BC Cancer Agency, Vancouver, BC, Canada*

Background: Resistance to therapies that target androgen receptor (AR) ligand-binding domain (LBD) in prostate cancer patients may be due to expression of constitutively active AR splice variants that lack LBD. EPI small molecules bind to activation function-1 (AF-1) in the AR amino-terminal domain (NTD). Development of a radiolabeled analogue, ^{123}I-EPI, may be useful for imaging prostate cancer using single-photon emission computed tomography (SPECT). Currently AR is imaged with positron emission tomography with 16β-[^{18}F]-fluoro-5α dihydrotestosterone (^{18}F-FDHT) that binds to AR LBD. ^{18}F-FDHT cannot detect AR splice variants lacking LBD. Our approach would employ sequential imaging with ^{18}F-FDHT to detect solely full-length (fl)-AR and ^{123}I-EPI to detect NTD of both fl-AR and variant AR. Discordant distribution or level of uptake between ^{18}F-FDHT and ^{123}I-EPI may reveal expression of AR splice variants lacking LBD. **Methods:** Specific activity against AR by I-EPI was confirmed in cells using reporter gene constructs for AR and related steroid hormone receptors. Binding experiments were done using ^{123}I-EPI with recombinant AF-1 and fl-AR proteins, as well as to endogenous fl-AR and variant AR in cells. Evaluation of ^{123}I-EPI in whole-body distribution included dosimetry in xenografts by small animal SPECT imaging; and temporal evaluation of ^{123}I-EPI uptake and clearance by quantifying ^{123}I in harvested organs. **Results:** In cell-based assays, I-EPI was specific for AR and blocked the activity of an AR-driven reporter, while having no effect on transcriptional activities of other steroid hormone receptors. ^{123}I-EPI covalently binds specifically to AR in living cells and to recombinant fl-AR and AR AF-1. Whole body SPECT imaging showed preferential uptake in LNCaP95 human prostate cancer xenografts that express AR while negligible uptake was observed in PC3 xenografts that lack functional AR. **Conclusions:** An AR NTD-targeted molecular imaging probe such as ^{123}I-EPI may be useful to select patients for subsequent antiandrogen therapies, monitor treatment response, and provide insight into the role of all AR species in resistance mechanisms.

5059 Poster Session (Board #53), Sat, 1:15 PM-4:45 PM

Tissue-based genomics to augment post-prostatectomy risk stratification in a natural history cohort. *First Author: Ashley Ross, The Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Genomics has provided insight into the underpinnings of lethal prostate cancer and led to the development and clinical use of RNA expression based gene signatures. We performed genome wide expression profiling on tissue from a large natural history cohort of at risk men undergoing radical prostatectomy (RP). **Methods:** In an IRB approved study, we utilized a case-cohort design to identify 356 intermediate and high risk men who underwent RP and had no further treatment until the time of metastasis. RP specimens were regraded by 2005 ISUP criteria and index lesions were sampled. RNA was prepared, labelled and hybridized to Human Exon 1.0 ST microarrays from which expression signatures were analyzed. The study followed REMARK guidelines for prospective blinded evaluation and analysis of prognostic biomarkers. **Results:** Microarray quality RNA was obtained from 260 men (99 of whom metastasized) with a median follow up of 9 years (IQR 6-12). 34 gene signatures were evaluated, including 3 based on commercially available assays (genomic classifier [GC, Decipher], microarray derived [md]-CCP, and md-GPS). GC provided the highest c-index to predict metastasis free survival at 10 years post-RP (0.76). Cumulative incidence of metastasis among men with low (< 0.45), intermediate (0.45-0.6) and high (> 0.6) GC scores was 12, 31 and 47% respectively at 5 years post-RP ($p < 0.001$). GC was independently prognostic of metastasis on multivariable analysis. Stratification by GC was most notable among nomogram predicted intermediate risk men. For instance, among men with CAPRA-S score of 3-5, 10% with low GC scores would develop metastasis compared to 27% among those with high scores. Addition of expression signatures from other CLIA certified tests (md-CCP or md-GPS) or from the next best performing expression signature (md-Penney, c-index 0.74) did not improve the performance of the GC. **Conclusions:** Genomic expression signatures stratify metastatic outcomes and provide additional prognostic information in a natural history cohort of men undergoing RP. Of 34 expression signatures analyzed, GC had optimal performance and captured prognostic information provided via analysis of other signatures.

5060 Poster Session (Board #54), Sat, 1:15 PM-4:45 PM

Evaluation of the contribution of individual gene groups to a 17-gene prognostic prostate cancer signature. *First Author: Dejan Knezevic, Genomic Health, Inc., Redwood City, CA*

Background: A 17-gene biopsy-based RT-PCR assay (Onco*type* DX® Prostate Assay) has been validated as a predictor of adverse pathology and biochemical recurrence (BCR) in clinically very low to intermediate-risk prostate cancer patients. The assay measures expression of 12 cancer and 5 reference genes that are combined to calculate a Genomic Prostate Score (GPS; scaled 0-100), providing a biologic measure of tumor aggressiveness. The cancer genes represent four biological pathways: androgen signaling, stromal response, cellular organization and proliferation. We examined the effects of variation in quantitative expression of individual gene groups on GPS results and prediction of clinical risk. **Methods:** The first 3,500 tumor specimens processed in the Genomic Health Inc.'s reference laboratory were included. Expression of individual genes was measured and the expression of the four gene groups and GPS calculated. For each gene group, GPS of patients with the lowest 5% expression levels were contrasted with GPS of patients with highest 5% expression levels. **Results:** Percentages of NCCN very low, low and intermediate patients were 28%, 37%, 30%; median age was 65. Mean and median GPS were 24.6 and 23 (range 0-90). Individual gene groups exhibited wide expression ranges (e.g. proliferation-16-fold difference (FD) vs. cellular organization > 8000 FD). Large differences in expression of each gene group were reflected in GPS values and, based on a prior clinical validation study, translate into large differences in BCR risk (Table). **Conclusions:** Each of the four gene groups show large variations in expression, meaningfully affect the GPS, and contribute to the prediction of PCa aggressiveness.

Gene groups	Median GPS for lowest 5% of expression (1st, 3rd quartiles)	Predicted 5-year BCR Risk for median GPS for lowest 5% of expression [95% CI]	Median GPS for highest 5% of expression (1st, 3rd quartiles)	Predicted 5-year BCR Risk for median GPS for highest 5% of expression [95% CI]
Stromal	12 (8, 19)	6% [3%, 10%]	43 (34, 53)	26% [20%, 33%]
Cell Organization	37 (27, 46)	20% [15%, 25%]	21 (15, 27)	9% [6%, 13%]
Androgen	50 (44, 58)	36% [27%, 46%]	9 (5, 13)	5% [3%, 9%]
Proliferation	16 (11, 22)	7% [4%, 11%]	35 (26, 43)	18% [14%, 23%]

5061 Poster Session (Board #55), Sat, 1:15 PM-4:45 PM

Effects of preoperative abiraterone acetate (AA) plus enzalutamide (E) and leuprolide acetate (LHRHa) versus AA and LHRHa in localized high-risk prostate cancer (LHRPC). *First Author: Eleni Efstathiou, Alexandra General Hospital of Athens, Oncology Department, Department of Clinical Therapeutics, University of Athens, Athens, Greece*

Background: High degree of heterogeneity in cytoreduction has been observed in LHRPC following AA+LHRHa and LHRHa (Taplin et al, *J Clin Oncol* 2014;32:3705; Efstathiou et al, *J Clin Oncol*2012:30 (suppl; abs 4556). Rationale exists for AA+E combination and promising efficacy is reported in mCRPC. This study aims to determine effects of AA+E vs AA and modulation of androgen signaling in LHRPC. **Methods:** Single-institution preoperative study of 24 wks of 1 g AA + 160 mg E + 5 mg prednisone (P) QD + LHRHa (Arm A) vs AA/P+LHRHa (Arm B) (randomized 2:1) in LHRPC pts (clinical stage T1c/T2; biopsy Gleason score ≥ 8, or ≥ T2b with Gleason ≥ 7 and PSA > 10 ng/mL). Safety and treatment effect on pathology stage, androgen metabolites, cellular density (% epithelial component of tumor volume), and link between molecular markers (by IHC) with clinical, pathology, and cellular response were assessed. **Results:** Study accrued 66 pts; 39 completed 24 wks therapy and had robot-assisted laparoscopic prostatectomy. Preliminary observations in evaluable pts: no perioperative ≥ Gr 3 adverse events (AEs); on-treatment Gr 3 AEs: liver function test elevation (7 Arm A, 2 Arm B), hypertension (5 Arm A, 1 Arm B), hypokalemia (1 Arm A), cognitive disturbance (1 Arm A), pulmonary embolism (1 Arm A), fatigue (1 Arm A). Fatigue Gr 1/2 in 38/55 evaluable pts (29/38 [76%] Arm A and 9/17 [53%] Arm B). Preoperative PSA was ≤ 0.1 ng/mL in 23/26 (89%) Arm A pts vs 10/11 (91%) Arm B pts; (p = ns). To date pathologic downstaging (≤ ypT2N0) occurred in 11/27 (41%) in Arm A vs 7/12 (58%) in Arm B (p = ns); pCR (2 Arm A, 1 Arm B). Tumors segregated by low (≤ 30%) (range 0-30%, median 5%) vs high (≥ 45%) (range 45-80%, median 55%) cellular density; low density in 63% Arm A and 77% Arm B. Preoperative testosterone was undetectable in 33/39; when detectable (range 1-10 pg/mL). Tumors with pathology stage ≤ ypT2N0 had higher AR-N terminal expression (85% vs 58% and AR-C/AR-N ratio; p = 0.008). **Conclusions:** Tumor cytoreduction is dichotomised despite universal serum PSA decline at 6 ms preoperative treatment. Planned Comprehensive molecular characterization of androgen biosynthesis will inform marker-driven LHRPC treatment strategy. Clinical trial information: NCT01946165.

5062 Poster Session (Board #56), Sat, 1:15 PM-4:45 PM

Genomic characterization of primary and metastatic prostate cancer (PC) using a targeted next-generation sequencing assay. *First Author: Wassim Abida, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Genomic alterations in PC have been described across the disease continuum, creating opportunities for selective clinical trial enrollment of patients (pts) with high-risk or metastatic disease based on their tumor profile. MSK-IMPACT is an exon capture-based sequencing assay performed in a CLIA-certified laboratory that targets 341 cancer-associated genes, many of which are potential drug targets. We assessed mutations and copy number alterations (CNAs) in primary and metastatic samples from untreated, hormone-treated and castration resistant pts. **Methods:** Pts with localized and metastatic PC were enrolled on an IRB-approved protocol for tumor genomic profiling. Fixed tumor and matched germline samples were subjected to DNA sequencing analysis using MSK-IMPACT for the identification of somatic mutations and CNAs. **Results:** 135 tumor samples from 124 pts were successfully sequenced, including 83 primary and 52 metastatic tumors. Metastatic sites include LN (22), bone (12), liver (6), lung (2) and other soft tissue (10). 5 tumors were pathologically classified as neuroendocrine. Common alterations in the metastatic tumors include *TP53* deletion/mutation (44%), *AR* amplification/mutation (38%), *PTEN* deletion/mutation (29%), *RB1* deletion/mutation (17%), *BRCA2* deletion/mutation (13%), *FOXA1* mutation (12%) and *SPOP* mutation (8%). Common alterations in the primary tumors (67% with Gleason > 7) include *TP53* mutation (20%), *SPOP* mutation (11%) and *PTEN* deletion/mutation (10%). Among metastatic samples, tumors from pts with castration resistant disease have higher CNA burden when compared to tumors from untreated or castration-sensitive pts (0.30 vs. 0.19 fraction genome altered, p < 0.05, unpaired *t*-test) as well as higher rates of *AR* amplification/mutation (50% vs. 7%, p < 0.01, Fisher's exact test). **Conclusions:** Genomic profiling of primary and metastatic prostate tumors is feasible with the targeted MSK-IMPACT assay and recapitulates findings from broader whole exome-based studies. This will facilitate genomic biomarker development and the rational selection of single-agent or combination therapy trials for pts with high-risk and metastatic disease.

5063 Poster Session (Board #57), Sat, 1:15 PM-4:45 PM

Ra-223 experience in pretreated patients: EAP setting. *First Author: A. Oliver Sartor, Tulane Cancer Center, New Orleans, LA*

Background: The early-access program aimed to monitor acute and long-term Ra-223 safety. Herein the number of Ra-223 cycles was examined in relation to prior therapy with abiraterone (abi) and/or enzalutamide (enza). These agents were not approved at the time of the ALSYMPCA trial, the basis for Ra-223 approval. **Methods:** Symptomatic bone metastatic CRPC patients (pts) and no visceral mets were enrolled in the US if they were ineligible for (or refused) docetaxel (Doc), or had prior Doc. Ra-223 at 50 kBq/kg IV q 4weeks was planned for 6 cycles concomitant with "standard of care". We assessed the baseline characteristics and number of cycles administered in pts naïve to, with prior use of either/or, and abi + enza. **Results:** Of 184 pts; 39 had prior abi + enza; 65 had abi or enza; 47 were naive. Notable differences in baseline demographics were seen in the prior abi + enza group with higher baseline median values for PSA, alk phos, and a higher % of pts with prior Doc (85%). The abi + enza pre-treated group had a lower median number of cycles (4; ALSYMPCA 6) and a significantly lower percentage of pts (36%; P=0.0115) completed > 4 cycles. Naïve pts had the lowest % of prior DOC (28%), the highest median number of cycles (n=6) and the highest percentage (62%) of pts completing > 4 cycles. 57%, 43%, and 31% of pts had 6 cycles in the naïve, either/or, and abi + enza group, respectively. The number of pts receiving all 6 cycles in the naïve compared with prior abi + enza group was significant (P=0.0134). **Conclusions:** A trend was observed, pts with less prior treatment completed more cycles of Ra-223 treatment. Using Ra-223 later in the current sequencing paradigm may limit the number of pts able to receive 6 cycles of treatment, as recommended in the Ra-223 label. Clinical trial information: NCT01516762.

Interim performance of a non-DRE urine exosome gene signature to predict Gleason ≥7 prostate cancer on initial prostate needle biopsy from patients enrolled in a prospective observational trial. *First Author: Michael J. Donovan, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: PSA and DRE are used for biopsy decisions; however, limited sensitivity and specificity have resulted in the over-diagnosis and treatment of low risk prostate cancer (PCa). Non-invasive screening tools that add predictive value for identifying high-grade, Gleason score (GS) ≥ 7, should impact the current paradigm. We sought to evaluate performance of a gene signature that differentiated GS7+ from GS6 + benign disease by evaluating patients with first-time biopsy results and gray zone PSA (4-10ng/mL) from an ongoing prospective clinical trial. **Methods:** 499 sequentially obtained first-catch non-DRE urine specimens (standard cups) from 15 urology practices were collected from patients presenting for biopsy. Exosomes were isolated and RNA extraction performed. RT-qPCR RNA copy numbers of ERG and PCA3, normalized to SPDEF, were measured to generate a three-gene signature, defined to yield a score discriminating GS7+ vs. GS6 and benign lesions, evaluating NPV, Sensitivity and Specificity relative to standard of care. **Results:** Urine samples from 205 men of 499 total (PSA 4-10 ng/mL, first biopsy, < 50 mL donation volume; median age 64 years, median PSA 5.46 ng/mL, 80% negative DRE, 74% no family history, 68% Caucasian), were evaluated. With 50% and 33% prevalence of positive biopsy for any cancer or GS7+ disease, respectively, a dichotomous gene signature + standard of care demonstrated good clinical performance in predicting biopsy result. For GS7+, with a 90% fixed sensitivity, the NPV and PPV were 92% and 48%, respectively compared to 79% and 35% for the prostate cancer prevention trial risk calculator (PCPTRC). A continuous score alone had an AUC of 0.74 for discriminating GS7+ from GS6 and benign disease and the results were significantly better than PCPTRC, AUC 0.64(p = 0.026). **Conclusions:** We confirmed a novel, non-invasive urine exosome gene signature demonstrated independent, negative predictive value for the diagnosis of GS7+ from first biopsy patients with 'gray zone' PSA. Its use in the biopsy decision process should result in fewer prostate biopsies pending completion of the prospective trial.

5065 Poster Session (Board #59), Sat, 1:15 PM-4:45 PM

Contemporary national trends of prostate cancer screening among privately insured patients in the United States. *First Author: Simon P. Kim, Yale University, New Haven, CT*

Background: Little is known about the degree to which prostate cancer (PC) screening with prostate-specific antigen (PSA) testing has changed in the face of recent clinical research data and the Grade D against screening from the U.S. Preventive Services Task Force. We used a large private health insurance database to determine the national trends of PSA screening and to investigate which patient characteristics are associated with PSA testing. **Methods:** Using Optum Labs Data Warehouse, a large private health insurance claims database, we identified males age 40-80 years who underwent PC screening from 2008 to 2013. The primary outcome was use of PSA testing among a privately insured population-based cohort. Demographic covariates included age, census region, race, education level and household income range. The Charlson/Deyo comorbidity index was calculated to assess comorbidity burden. Rates were calculated based on member-years and reported per 1,000 member-years. **Results:** Among 11.6 million eligible enrollees, we identified 2.9 million (25%) men who underwent PSA screening from 2008 to 2013 ($>$ 800,000 screened per year). The majority of the screened population were white males, age 50-59 years residing in the Southern census region. The rate of men undergoing PSA screening remained stable from 190.4 per 1,000 member-years in 2008 to 196.4 in 2013 ($p = 0.66$). Among enrollees aged 50 to 74 years old, PSA screening rates were relatively stable. However, enrollees who were $>$ 75 years old had a marked decrease in PSA screening from 201.5 to 124.1 per 1,000 member-years from 2008 to 2013 ($p = 0.04$). PSA screening rates did not vary by racial groups or geographic region over time. **Conclusions:** In this large population-based cohort of privately insured men, we found little effect of new data and change in clinical practice guidelines on the overall rate of PSA screening. However, older men ($>$ 75) showed a significant reduction in screening over time.

5066 Poster Session (Board #60), Sat, 1:15 PM-4:45 PM

Safety and efficacy of everolimus (E), bevacizumab (B), and docetaxel (D) for castration resistant prostate cancer (CRPC). *First Author: Mitchell E. Gross, University of Southern California, Beverly Hills, CA*

Safety and efficacy of Everolimus (E), bevacizumab (B), and docetaxel (D) for castration resistant prostate cancer (CRPC) Background: Based on studies suggesting co-targeting mTOR and angiogenic pathways potentiates chemotherapy, we studied combining mTOR (E, formerly RAD001) and VEGF (B) inhibition with D in CRPC. **Methods:** Eligible patients (pts) had progressive, metastatic, chemo-naive CRPC. D+B was given IV day 1 with E PO daily on a 21 d cycle at level 1 (D 75 mg/m^2, E 2.5 mg), level 2 (D 75 mg/m^2, E 5 mg), or level 3 (D 65 mg/m^2, E 5 mg). B 15 mg/kg was given at all levels. B/E without D (B/E-D) was allowed after $\geq$ 6 cycles. Prophylactic growth factor support was allowed only after cycle 1, if required The primary endpoint was response, defined as maximal confirmed PSA decline and RECIST criteria. **Results:** Dose level 1 was identified as the recommended phase 2 dose (Gross et al, 2009) thus 37 of 43 patients received level 1 dosing. Median age was 65 (50-79) years, PSA 76.6 (0-1847) ng/mL, alkaline phosphatase 114 (37-768) U/L, hemoglobin 12.5 (0.0-15.7) g/dl. Metastatic sites included: bone 38 (88%), lymph nodes 19 (44%), and viscera in 8 (19%) pts. Median cycles delivered was 10 (3-21) which included B/E-D maintenance in 24 pts for 3 (1-10) cycles. Maximal PSA decline $\geq$ 30% and $\geq$ 50% was achieved in 33 (79%) and 31 (74%) of pts. RECIST responses were assessable in 25 pts with best response complete or partial in 20 (80%) of pts. Hematologic toxicities were the most common treatment related grade $\geq$ 3 adverse events including: febrile neutropenia 12 (28%), lymphopenia 12 (28%), leukocytes 10 (23%), neutrophils 9 (21%), and hemoglobin 2 (5%). Non-hematologic grade $\geq$ 3 AEs included: hypertension 8 (19%), fatigue 3 (7%), pneumonia 3 (7%), and mucositis 4 (5%). There was 1 treatment related death due to neutropenic fever and pneumonia on a pt treated at dose level 3 despite dose modifications and prophylactic growth factor support. **Conclusions:** The combination of E/B/D demonstrates significant clinical activity against mCRPC which must be balanced against hematologic and other toxicities. Correlative biomarker studies are ongoing to better define patient subsets which may be more likely to benefit from this therapy. Clinical trial information: NCT00574769.

5067 Poster Session (Board #61), Sat, 1:15 PM-4:45 PM

Detecting predictive androgen receptor modifications in circulating prostate cancer cells. *First Author: Julie Steinestel, Clinic of Urology, University Hospital Muenster, Münster, Germany*

Background: Molecular modifications of the androgen receptor (AR) can cause resistance to androgen deprivation therapy (ADT) and chemotherapy in prostate cancer patients. When resistance to therapy ensues, lack of representative tumor samples hinders therapy adjustments according to emerging AR-modifications and some patients may thus receive ineffective therapy. **Methods:** We devised a single-tube assay to detect the two most common AR-modifications (AR-V7 splice variants and *AR*point mutations) in circulating tumor cells (CTC) using immunomagnetic CTC isolation followed by quantitative real-time PCR and DNA pyrosequencing. We prospectively investigated 47 prostate cancer patients with PSA progression and molecularly uninformed therapy switch. Comparison of newly administered therapy and CTC-AR-status allowed effect size estimation. **Results:** Nineteen (51%) of 37 patients with detectable CTCs carried AR-modifications. Specifically, 17 patients carried the AR-V7 splice variant, one harbored a p.T878A point mutation and one harbored both AR-V7 and a p.H875Y mutation. We found a positive predictive value for response and non-response to therapy by AR status in CTCs of ~94%. We estimated the overall benefit from molecularly informed therapy switch by subtracting the molecularly uninformed (31%) and the AR-status unmatched (6%) response rates from the AR-status matched response rate (72%). Thus, for prospective clinical trial planning our data suggest an estimated effect size of ~33%. **Conclusions:** In summary, the ability to detect key resistance-mediating AR modifications in CTCs has the potential to considerably improve prostate cancer treatment.

5068 Poster Session (Board #62), Sat, 1:15 PM-4:45 PM

Androgen receptor (AR) amplification in patients (pts) with metastatic castration resistant prostate cancer (mCRPC) resistant to abiraterone (Abi) and enzalutamide (Enz): Preliminary results from the SU2C/PCF/AACR West Coast Prostate Cancer Dream Team (WCDT). *First Author: Rahul Raj Aggarwal, UC San Francisco, San Francisco, CA*

Background: Mechanisms of resistance to Abi or Enz in mCRPC pts are poorly understood. AR amplification (AR amp) is observed in Abi/Enz naive mCRPC pts, but its role in mCRPC pts who develop resistance to Abi/Enz is not known. As part of the WCDT project, which aims to identify genetic pathways underlying resistance to Abi and Enz, AR amp status was assessed in metastatic tumor biopsies from mCRPC pts. **Methods:** Eligible mCRPC pts underwent biopsy (bx) at one of 5 WCDT sites, using a uniform bx and clinical follow-up protocol. Formalin fixed, paraffin-embedded tissue underwent pathologic review and fluorescence in situ hybridization (FISH) for assessment of AR amp in a CLIA laboratory. AR amp by FISH was corroborated with array comparative genomic hybridization (aCGH) in select cases. **Results:** 150 mCRPC pts have undergone bx to date. To date, 92 have been evaluated by FISH for AR amp, including 36 from bone, 35 from lymph nodes, 16 from liver, and 5 from other soft tissues. Overall, 64% of mCRPC tumors were AR amplified by FISH and were corroborated by aCGH in 16/21 cases (76%). AR amp was seen in similar proportions in liver, bone, or nodal bx, and was present in $>$ 50% of tumors with small cell histology. AR amp was observed in 16/19 pts (84%) naïve to both Abi + Enz compared to 17/36 pts (47%) who were resistant to Abi ($p = 0.008$). 4/6 (67%) of Enz resistant tumor biopsies were AR amplified. In pts that received Abi or Enz post-bx, the PSA response rate (PCWG2 criteria) was 9/17 (53%) in AR amp and 5/12 (42%) in AR non-amplified tumors respectively. **Conclusions:** AR amplification status can be assessed by FISH from mCRPC biopsies. AR amplification was common in Abi/Enz-naïve tumors including those with small cell histology. AR amp was less frequent in pts with Abi resistance, suggesting that Abi may select for non-AR amplified cells. Sequential (paired) biopsies from the same pts are being evaluated to test this hypothesis. Preliminary data suggest higher rates of AR amp in pts who are resistant to Enz. The predictive utility of AR amp status and AR splice variants is currently being evaluated.

TPS5069 **Poster Session (Board #63a), Sat, 1:15 PM-4:45 PM**

Androgen receptor modulation optimized for response: Splice variant (ARMOR3-SV)–Randomized, open-label, multicenter, controlled study of galeterone vs enzalutamide in men with metastatic castration-resistant prostate cancer (mCRPC) expressing AR-V7 splice variant. *First Author: Mary-Ellen Taplin, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: mCRPC patients with tumors expressing the androgen receptor (AR) splice variant-7 (AR-V7), a constitutively-active truncated form of the AR lacking the ligand-binding domain, have been shown to have worse clinical outcomes after AR-targeting drugs than those without detectable AR-V7. Galeterone, a small molecule drug, disrupts AR signaling via selective inhibition of CYP17 lyase, AR blockade, and enhanced degradation of the AR protein. In preclinical models, galeterone showed activity against the full-length AR and AR alterations including AR-V7 and AR^{v567es} splice variants, and against activating AR mutations (eg, AR-T878A, AR-F876L). Given the encouraging results in patients with AR C-terminal loss in the galeterone Phase 2 ARMOR2 trial, further research is warranted in this patient subset. **Methods:** ARMOR3-SV is a Phase 3, randomized, open-label, multicenter study of galeterone vs enzalutamide in men with mCRPC expressing AR-V7 mRNA in circulating tumor cells (CTCs). Among other inclusion criteria, eligible patients must continue medical castration or have had surgical castration, and must not have received prior chemotherapy, abiraterone, or enzalutamide. Eligible patients will be prescreened and subsequently enrolled only if AR-V7 is detected in CTCs using a CLIA-certified, analytically-validated assay. A total of 148 patients will be randomized (1:1) to receive once-daily oral galeterone 2550 mg or enzalutamide 160 mg. The primary endpoint is radiographic progression-free survival determined by independent blinded, central radiologic review. Secondary endpoints include time to cytotoxic therapy or next anticancer intervention and overall survival. Other endpoints include time to first skeletal related event, decline in PSA, time to PSA progression, and best objective response rate (in men with measureable soft tissue disease [RECIST1.1]). Safety and pharmacokinetics of galeterone will also be assessed. CTCs will be enumerated and characterized molecularly in an exploratory fashion.

TPS5070 **Poster Session (Board #63b), Sat, 1:15 PM-4:45 PM**

Autologous dendritic cell vaccination (DCVAC/PCa) added to docetaxel chemotherapy in a double-blind, randomized phase III trial (VIABLE) in men with advanced (mCRPC) prostate cancer. *First Author: Nicholas J. Vogelzang, Carolina Urologic Research Center, The US Oncology Network, Myrtle Beach, SC*

Background: Prostate cancer (PCa) is the second most common cancer, and the fifth leading cause of cancer related death among men worldwide. Immunotherapy designed to induce tumor cell specific immune responses capable of destroying tumor cells has emerged as a promising treatment modality in solid malignant tumors. Clinical and preclinical trials have shown that docetaxel chemotherapy can be combined with vaccine without impairing the immune response. **Methods:** VIABLE is a randomized, double-blind, placebo-controlled, parallel-group, international phase III study to evaluate the efficacy and safety of DCVAC/PCa (active cellular immunotherapy based on dendritic cells) versus placebo in patients with mCRPC eligible for first-line docetaxel chemotherapy. The study was initiated in May 2014 and plans to enroll almost 1200 patients at approximately 300 sites globally. Eligible patients are required to present with metastatic castrate-resistant PCa defined by both presence and progression of the disease, maintenance of a castrate state with serum testosterone level less than 50 ng/dl, ECOG score 0-2, and adequate hematologic, hepatic and renal functions. All patients will receive standard of care docetaxel plus prednisone, and will be randomized 2:1 to DCVAC/PCa or placebo. Patients will be stratified by region (US vs other), previous therapy (enzalutamide and/or abiraterone) and ECOG score (0, 1 vs 2). The primary endpoint is overall survival (OS). Secondary objectives include assessments of safety, radiographic progression free survival, time to PSA progression, time to the first occurrence of skeletal related events (SRE), and quality of life (QoL) assessments based on the FACT-P questionnaire. Clinical trial information: Registration number NCT02111577, EudraCT number 2012-002814-38. Clinical trial information: NCT02111577.

TPS5071 **Poster Session (Board #64a), Sat, 1:15 PM-4:45 PM**

A phase 3 randomized, placebo-controlled double-blind study of ARN-509 plus abiraterone acetate (AA) in chemotherapy-naïve metastatic castration-resistant prostate cancer (mCRPC). *First Author: Dana E. Rathkopf, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: ARN-509, a potent and selective androgen receptor (AR) antagonist, inhibits AR nuclear translocation and DNA binding (Clegg, *Cancer Res.* 2012). AA directly inhibits androgen biosynthesis and has been approved for the treatment of mCRPC. Although ARN-509 and abiraterone both target the AR, each works through a different mechanism: the former blocks ligand binding, the latter inhibits ligand synthesis. Importantly, lack of sensitivity to one AR-targeted therapy does not necessarily imply resistance to another (Rathkopf, AACR 2014). Inhibiting the AR through multiple mechanisms simultaneously may be more effective than single pathway inhibition and has the potential to have a significant impact on the mCRPC field. This phase 3 trial will compare radiographic progression-free survival (rPFS) in pts with chemotherapy-naïve mCRPC treated with ARN-509 in combination with AA + prednisone/prednisolone (P) vs placebo + AA + P. **Methods:** This multicenter, double-blind, placebo-controlled trial is enrolling men with mCRPC with progressive disease and an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0 or 1. Pts will be stratified by presence or absence of visceral metastases, ECOG PS, and region (European Union, North America, and rest of world) and randomized (1:1) to ARN-509 (240 mg QD) + AA (1000 mg po QD) + P (5 mg po BID) or placebo + AA + P. The primary end point is rPFS using RECIST 1.1 or PCWG2 criteria. Secondary end points are overall survival, time to long-term opioid use, time to initiation of cytotoxic chemotherapy, and time to pain progression. Population pharmacokinetics of AA and biomarker analyses will be performed. The study uses a group sequential design, including 2 interim analyses. The stratified log rank test will be used for the time-to-event analysis. An independent data monitoring committee will review safety and efficacy data. Approximately 960 pts will be randomized over 2 years in 225 sites in 18 countries. (ClinicalTrials.gov Identifier: NCT02257736) Clinical trial information: NCT02257736.

TPS5072 **Poster Session (Board #64b), Sat, 1:15 PM-4:45 PM**

A phase 1/2 open-label study of safety and antitumor activity of EPI-506, a novel AR N-terminal domain inhibitor, in men with metastatic castration-resistant prostate cancer (mCRPC) with progression after enzalutamide or abiraterone. *First Author: Robert B. Montgomery, University of Washington Oncology, Seattle, WA*

Background: EPI-506 is a first-in-class, highly specific small molecule inhibitor of the androgen receptor (AR) N-terminal domain (NTD). *In vitro* and in *vivo* studies have shown activity against full length AR and constitutively active AR splice variants, including AR-V7 (associated with resistance to abiraterone and enzalutamide). EPI-506 is expected to be effective in mCRPC driven by both canonical and aberrant AR signaling by targeting the NTD common to full length and splice variant AR. Initial clinical development of EPI-506 will target mCRPC with progression after prior enzalutamide and abiraterone. **Methods:** This open-label, single-arm, phase 1/2 study will evaluate the benefit of 12 week once-daily dosing with EPI-506, after establishing the safety, pharmacokinetics (PK), and optimal dose of EPI-506 in single- and multiple-dose escalations. The study will involve ~20 investigational sites in the US and Canada, and is expected to launch in Q2 2015. The planned enrollment is 150 patients. Inclusion criteria include mCRPC with progression after one or more lines of hormonal therapy or chemotherapy, and progression on enzalutamide or abiraterone. Exclusion criteria include hematologic, hepatic or renal insufficiency. The phase 2 portion of the study will evaluate activity in 3 patient populations: post-enzalutamide mCRPC, post-abiraterone mCRPC, and enzalutamide/abiraterone naïve mCRPC. Primary endpoints include PSA response at week 12, defined as a $\geq$ 50% PSA decrease from baseline. Secondary endpoints include: PK, objective RECIST response, time to PSA progression, radiographic progression-free survival, and safety/tolerability. Exploratory endpoints include evaluation of AR splice variants and AR mutations from CTC-based and ctDNA-based methodologies, as well as molecular characterization of optional tissue biopsies. This trial will be the first to evaluate the novel NTD inhibitor EPI-506 in men with enzalutamide- and/or abiraterone-failure mCRPC, and is the first agent with the potential to inhibit both canonical and variant-mediated AR signaling.

TPS5073 **Poster Session (Board #65a), Sat, 1:15 PM-4:45 PM**

Phase II multicenter study to analyze the predictive value of fusion gene TMPRSS2-ETS assessed both in tumor and blood sample, as a marker of response to enzalutamide in patients with metastatic castration resistant prostate cancer (CRPC) pre-chemotherapy: PREMIERE-SOGUG Trial. *First Author: Enrique Grande, Hospital Universitario Ramon y Cajal, Medical Oncology Department, Madrid, Spain*

Background: Enzalutamide (E) is a newly authorized drug for metastatic CRPC. E inhibits binding of androgens to androgen receptors, nuclear translocation of activated receptors and DNA transcription. E decreases the growth of prostate cancer cells and can induce cancer cell death and tumour regression. The presence of TMPRSS2-ETS fusion gene rearrangement correlates with the effectiveness of abiraterone (Danila DC, et al 2011). This molecular alteration may also influence E clinical outcome. The aim of this study is to determine whether the efficacy and safety of E when administered to mCRPC before chemotherapy, is influenced by the presence or not of TMPRSS2-ETS fusion gene rearrangement both in primary tumor and circulating blood. **Methods:** This is a phase II open-label study conducted in chemotherapy naïve mCRPC patients older than 18 years, ECOG 0-1, testosterone $<$ 50 ng/dL and adequate, hematologic, hepatic, and renal function, that progressed to previous castration treatment documented by PSA (PCWG2), radiographic progression (modified RECIST 1.1) or bone scan progression. Patients will receive E treatment (160 mg/d) until clinical and/or radiographic disease progression. Primary objective is to assess the predictive value of the expression of TMPRSS2-ETS gene fusion in primary tumor tissue and circulating tumor cells correlated with progression free survival. Secondary objectives include assessing relationship between the presence of TMPRSS2-ETS fusion gene rearrangements with time to PSA response, overall soft tissue response rate, time to beginning of cytotoxic chemotherapy, safety of E treatment and circulating tumor cells (CTC) conversion rate. In this study is planned to include 98 patients. Sample size has been calculated using a Cox proportional hazards regression model with alpha 0.05, power 80% and 20% drop out rate. Patients will be included in 17 sites in Spain and it is expected to start in February 2015. Clinical trial information: NCT02288936.

TPS5074 **Poster Session (Board #65b), Sat, 1:15 PM-4:45 PM**

A randomized phase II study of androgen deprivation therapy with or without PD0332991 in RB-positive metastatic hormone-sensitive prostate cancer. *First Author: Phillip Lee Palmbos, University of Michigain Health System, Ypsilanti, MI*

Background: Androgens drive proliferation of prostate cancer cells via upregulation of cyclin D which complexes with the CDK4/6 kinases, resulting in phosphorylation of Rb and G1/S progression. Perturbations in this pathway (loss of Rb, upregulation of cyclin D) are felt to promote castration-resistance. PD0332991 (palbociclib) is a novel specific inhibitor of CDK4 and 6. Preclinically PD0332991 inhibited proliferation and promoted G1 arrest in an RB and Cyclin D-dependent manner. 80-90% of early metastatic hormone-sensitive prostate cancers are estimated to retain wild-type RB expression. Addition of PD0332991 to hormonal therapy in ER+ breast tumors demonstrated statistically significant improvements in progression-free survival. Hypothesis: Addition of PD0332991 to initial ADT in patients with newly metastatic RB-positive prostate cancer will significantly increase the efficacy of ADT. **Methods:** A multicenter randomized phase II study of PD0332991 was initiated (NCT02059213) in which patients (n = 60) with new metastatic hormone sensitive prostate cancer and RB intact tumors based on metastatic biopsy are stratified by disease extent and randomized (1:2) to ADT or ADT plus PD0332991. Primary endpoint is PSA response ($<$ 4 ng/mL) after 7 months of therapy. With 20 patients randomized to ADT and 40 randomized to ADT plus PD0332991 there will be a 64.2% power to detect a 20% difference in proportions with a one-sided type I error of 0.10 using the mid p-value method of the Fisher's exact test. Secondary endpoints: safety and tolerability of ADT + PD0332991, rate of undetectable PSA ($<$ 0.2ng/mL), biochemical and clinical progression-free survival, overall PSA and radiographic response rates, assessment of biomarkers which predict therapy response (circulating DNA and tumor cells, tumor protein and transcriptome analysis) and to establish a repository of metastatic hormone sensitive prostate tumor samples. Support: Movember-PCF Challenge Award, Pfizer. Clinical trial information: NCT02059213.

TPS5075 **Poster Session (Board #66a), Sat, 1:15 PM-4:45 PM**

A prospective, multicenter, randomized phase II trial of best systemic therapy (BST) or BST plus definitive treatment (Surgery or Radiation) of the primary tumor in metastatic prostate cancer. *First Author: Brian Francis Chapin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment for metastatic (M1) prostate cancer (PC) is centered on the use of systemic therapy. Evidence suggests that definitive treatment of the primary tumor (DTPT) may improve outcomes of men with advanced disease. In addition to prevention of symptomatic local progression there is evidence that local therapy may alter disease biology. Thus, DTPT may delay local and distant progression, prolong time to castration resistant PC (CRPC) and fatal metastatic burden. We sought to test the hypothesis that DTPT added to BST will delay time to CRPC in men presenting with M1 PC. **Methods**: After completing 6 months of BST (any standard therapy for M1 PC) 120 men will be randomized 1:1 to continue BST +/- DTPT. Patients are stratified by PSA nadir at randomization ($\leq$ 4 and $>$ 4) and by treatment center. Type of DTPT is based on patient preference and physician recommendations. Patients are evaluated every 3 months with a history and physical exam and serum PSA. Progressive disease is defined per the PCWG2. A Bayesian design with interim monitoring will be implemented. After a minimum of 60 patients have been randomized, if at any time, the probability of one arm (A) is better than the other arm (B) is greater than 97.5%, the trial will be stopped early and A will be selected as superior. Patients will be followed for a minimum 24 months before a final analysis is conducted. **Eligibility**: Prostate adenocarcinoma with documented evidence of M1 disease per AJCC v6. Patients must have castrate sensitive disease at randomization and have not received BST for $>$ 6 months prior to randomization. Exclusions include small cell carcinoma, brain metastases or CRPC within 6 months of initiating BST. **Enrollment:** 35 patients are enrolled to date and 20 have been randomized. 8 patients developed CRPC prior to the 6 month time point. The protocol is scheduled to open at 3 additional sites by spring 2015. **Correlative Studies:** Characterization of the prostate tumor and tumor microenvironment (stromal and immunologic components) and associated changes on magnetic resonance imaging will be used to identify a biomarker panel to predict benefit from DTPT. Clinical trial information: NCT01751438.

TPS5076 **Poster Session (Board #66b), Sat, 1:15 PM-4:45 PM**

Randomized phase-2 study of sipuleucel-T with or without radium-223 in men with asymptomatic/minimally symptomatic bone-metastatic castrate-resistant prostate cancer (CRPC). *First Author: Jong Chul Park, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Sipuleucel-T is an autologous cellular immunotherapy indicated for men with asymptomatic/minimally symptomatic metastatic CRPC. Recent analysis of immune responses in men treated with sipuleucel-T showed that antigen-specific immune responses to sipuleucel-T may be associated with survival, confirming the immune-based mechanism of action and suggesting the possibility that producing a stronger immune response may translate into the better clinical outcomes. Radiopharmaceutical agents have been shown to enhance immune modulation through a variety of mechanisms including enhanced display of tumor-associated antigens. Based on the immunomodulatory effects of radiopharmaceutical drugs, we hypothesized that combined use of radium-223 and sipuleucel-T may enhance the sipuleucel-T-induced immune response and improve clinical outcomes. **Methods:** This is a randomized phase 2 study comparing antigen-specific immune responses of sipuleucel-T used alone versus sipuleucel-T plus radium-223 in CRPC patients with bone metastases but no visceral involvement. Patients will be randomly assigned (1:1) to receive sipuleucel-T plus radium-223 (Arm 1) or sipuleucel-T alone (Arm 2); men in Arm 2 will receive 3 infusions of sipuleucel-T alone, while men in Arm 1 will receive 6 infusions of radium-223 plus 3 infusions of sipuleucel-T starting after the second radium-223 dose. The primary study objective is to determine whether addition of radium-223 to sipuleucel-T enhances immune response, as measured by peripheral PA2024-specific T-cell proliferation using a tritiated thymidine incorporation assay at 6 wks after the first sipuleucel-T infusion. With 15 men per arm, there is 80% power to detect a 3.6-fold increase in mean proliferation response between the two arms. PSA responses and radiographic responses (in men with measurable disease) will also be assessed. Incidence and severity of AEs will be graded according to CTCAE v4.0. Various immune parameters, both humoral and cellular, will be analyzed at multiple time points during the treatment period, and an exploratory assessment of antigen spread will also be performed.

TPS5077 **Poster Session (Board #67a), Sat, 1:15 PM-4:45 PM**

Randomised phase 3 trial of enzalutamide in first line androgen deprivation therapy for metastatic prostate cancer: the ANZUP ENZAMET Trial (ANZUP 1304). *First Author: Ian D. Davis, Monash University Eastern Health Clinical School, Box Hill, Australia*

Background: Androgen deprivation therapy (ADT) with a luteinising hormone releasing hormone analogue (LHRHA) or surgical castration, either alone or combined with conventional non-steroidal anti-androgen (NSAA), is widely used as initial treatment for hormone-naive, metastatic prostate cancer (PC). Meta-analysis of RCTs showed a 3% absolute improvement in 5 year survival with the addition of NSAA to ADT. Residual, low level androgen receptor (AR) signalling or agonist activity from conventional NSAA may provide a stimulatory signal to hormone-sensitive PC cells. We hypothesize that early use of enzalutamide, a more potent and effective androgen receptor blocker, will reduce residual AR signalling, and improve survival. The aim is to determine the effectiveness of ADT + enzalutamide versus ADT + conventional NSAA, as 1st line endocrine therapy for M1 PC. **Methods:** DESIGN Open label, randomised, stratified, 2-arm, intergroup, phase 3 trial including ANZ, Canada, UK and USA. ELIGIBILITY Metastatic PC starting 1stline ADT. STRATIFICATION Volume of disease, anti-resorptive therapy, comorbidities, early docetaxel use, study site. ENDPOINTS Overall survival (primary), PSA progression free survival (PFS), clinical PFS, health related quality of life, adverse events, cost-effectiveness. SAMPLE SIZE 1100 participants recruited over 2 years + 3.5 years minimum f/up for 80% power to detect a 25% reduction in the hazard of death assuming an OS rate at 3 years of 65% in control group. TREATMENT LHRHA or surgical castration plus either enzalutamide 160mg daily orally, or conventional oral NSAA until disease progression or prohibitive toxicity. ASSESSMENTS Baseline, days 29 and 85 then 12 weekly until clinical progression; imaging prior to randomisation and on progression (PSA and clinical). Tertiary correlative objectives include identification of prognostic/predictive biomarkers from archival tumour tissue and fasting bloods collected at baseline, week 24 and progression (PSA and clinical). Email: enzamet@ctc.usyd.edu.au Website: http://www.anzup.org.au/ Clinical trial information: ACTRN12614000110684.

TPS5078 **Poster Session (Board #67b), Sat, 1:15 PM-4:45 PM**

Randomised phase 3 trial of enzalutamide in androgen deprivation therapy with radiation therapy for high risk, clinically localised prostate cancer: The ANZUP ENZARAD Trial (ANZUP 1303). *First Author: Scott G. Williams, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Background: Adjuvant androgen deprivation therapy (ADT) including a luteinising hormone releasing hormone analogue (LHRHA) is standard of care given before, during, and after radiotherapy for localised prostate cancer (PC) at high risk of recurrence. Enzalutamide is a new, second generation androgen receptor (AR) inhibitor that is more potent and binds with a higher affinity to the AR than conventional non-steroidal anti-androgens (NSAA), and improves survival in metastatic, castration-resistant PC. We hypothesise that the incorporation of enzalutamide in adjuvant ADT, given before, during, and after radiation therapy for localised PC at high risk of recurrence will further improve outcomes.The aim is to determine the effectiveness of enzalutamide as part of adjuvant ADT with a LHRHA in men planned for radiotherapy for localised PC at high risk of recurrence **Methods:** DESIGN Open label, randomised, stratified, 2-arm, phase 3 intergroup trial. ELIGIBILITY Localised PC, high risk of recurrence, suitable for EBRT with curative intent. STRATIFICATION Gleason 8-10, T3-4, PSA $>$ 20, study site ENDPOINTS Overall survival (primary), cause-specific survival, PSA progression free survival (PFS), clinical PFS, health related quality of life, adverse events, cost-effectiveness. SAMPLE SIZE 800 participants accrued over 2 yrs + 5.5 years minimum f/up for 80% power to detect a 33% reduction in the hazard of death assuming a 5-year survival rate of 76% amongst controls. TREATMENT LHRHA for 24 months and EBRT (78Gy/39F) starting after week 16 plus either enzalutamide 160mg daily during months 1-24, or conventional NSAA during months 1-6. ASSESSMENTS Baseline, weeks 4, 12, 16, 20 and 24, then 3-4 monthly until year 5, 6-monthly until year 7, then annually. Imaging at baseline and then as clinically indicated. Tertiary correlative objectives include the identification of prognostic and predictive biomarkers from archival tumour tissue, and from fasting bloods collected at baseline, 24 weeks, 5 years, and first evidence of progression. Email: enzarad@ctc.usyd.edu.au Website: http://www.anzup.org.au/ Clinical trial information: ACTRN12614000126617.

TPS5079 **Poster Session (Board #68a), Sat, 1:15 PM-4:45 PM**

A randomized phase II study comparing bipolar androgen therapy vs. enzalutamide in asymptomatic men with castration resistant metastatic prostate cancer: The TRANSFORMER trial. *First Author: Benjamin A. Teply, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Prostate cancer can progress despite androgen deprivation therapy through overexpression of the androgen receptor (AR) and expression of AR splice variants. Almost paradoxically, testosterone given to cancer cells in this state can cause growth inhibition. The AR is normally degraded during progression through the cell cycle, but androgen-bound AR is stabilized, thus arresting the cell cycle and inducing DNA strand breaks through interaction with topoisomerase-IIb. Clinically, supraphysiologic testosterone given to men with castration-resistant prostate cancer was found to be safe in a pilot clinical trial, producing responses and re-sensitizing patients to subsequent anti-androgen therapy. In this context, we designed a randomized phase II study comparing bipolar androgen therapy (BAT) to enzalutamide for patients who have experienced progression on abiraterone. **Methods:** In this multi-center randomized study, funded by a grant from the Department of Defense, eligible patients have asymptomatic metastatic castration-resistant prostate cancer that has radiographically or biochemically progressed after treatment with abiraterone. Patients are enzalutamide-naïve and have not received docetaxel for castration-resistant disease. Patients randomized to BAT will continue on androgen deprivation therapy and receive monthly intramuscular testosterone at the FDA-approved dose of 400mg. This dose produces initial supraphysiologic testosterone levels with return to castrate levels after one month. Patients randomized to enzalutamide will receive 160mg daily. Crossover is encouraged. The primary endpoint is radiographic progression-free survival (rPFS). The trial is powered to detect a 50% improvement in median rPFS in the BAT arm compared to the enzalutamide arm (expected to be ~6 months), with planned accrual of 90 patients in each arm. The arms will be stratified for time to progression on abiraterone. Secondary endpoints include PSA response rates, safety, and quality of life. Correlative studies include the effect of BAT on AR variant expression. Enrollment opened in February 2015. Clinical trial information: NCT02286921.

TPS5080 **Poster Session (Board #68b), Sat, 1:15 PM-4:45 PM**

ARAMIS trial: Efficacy and safety phase 3 trial of ODM-201 in men with high-risk non-metastatic castration-resistant prostate cancer (nmCRPC). *First Author: Karim Fizazi, Department of Cancer Medicine, Institut Gustave Roussy, University of Paris Sud, Villejuif, France*

Background: There is no standard treatment for nmCRPC besides continuing androgen deprivation therapy (ADT). Preventing metastatic disease in nmCRPC is a major unmet need. Patients with nmCRPC who have shorter PSA doubling time (PSADT) are at high risk for metastatic disease or death (Smith et al. J Clin Oncol. 2013;31:3800-6). ODM-201, a novel second-generation oral androgen receptor inhibitor, has shown an excellent safety profile and promising anticancer activity in progressive CRPC (Fizazi et al. Lancet Oncol. 2014;15:975-85). The ARAMIS trial aims to evaluate the efficacy and safety of ODM-201 in high-risk nmCRPC. **Methods:** This international, randomized, double-blind, placebo-controlled phase 3 trial (NCT02200614) involves over 300 sites in more than 30 countries. 1500 patients on ADT will be randomized 2:1 to ODM-201 600 mg or placebo twice daily. Patients will be stratified by PSADT and baseline use of bone-targeting agent. Eligibility criteria include nmCRPC, PSADT $\leq$ 10 months, and screening PSA $\geq$ 2 ng/mL. The primary endpoint is metastasis-free survival based on central independent review of bone scan and CT/MRI every 16 weeks; progression of regional disease is not considered metastasis. Secondary endpoints are OS, time to first symptomatic skeletal event (SSE), initiation of first cytotoxic chemotherapy for prostate cancer, pain progression, and first opioid use. Additional endpoints are PFS, time to first prostate cancer–related invasive procedure, initiation of subsequent antineoplastic therapy, PSA progression, change in ECOG status, and changes in health-related QoL. Endpoints will be analyzed using a stratified log-rank test, accounting for stratification. The trial has 90% power to detect a target hazard ratio of 0.75 based on a 2-sided log-rank test at an overall significance level of 0.05. Kaplan-Meier estimates will be produced for both treatment groups. The ARAMIS trial is open and recruiting, with the first patient randomized in October 2014. Clinical trial information: NCT02200614.

TPS5081 **Poster Session (Board #69a), Sat, 1:15 PM-4:45 PM**

Prospect: A randomized double-blind phase 3 efficacy study of PROSTVAC-VF immunotherapy in men with asymptomatic/minimally symptomatic metastatic castration-resistant prostate cancer. *First Author: James L. Gulley, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: PROSTVAC, a targeted active immunotherapy, is being studied in men with asymptomatic to minimally symptomatic mCRPC in PROSPECT, a global double-blind, randomized phase 3 study. PROSTVAC is a prime-boost regimen consisting of subcutaneous administrations of poxvirus-based PROSTVAC-Prime (a modified vaccinia vector) and PROSTVAC–Boost (a modified fowlpox vector) that encode prostate specific antigen (PSA) as the target antigen with three T-cell co-stimulatory molecules (B7.1, ICAM-1, and LFA-3) also known as TRICOM. A statistically significant overall survival (OS) benefit of 8.5 months (P= 0.0061) with a hazard ratio of 0.56 (95% CI, 0.37 to 0.85), and a favorable risk-benefit profile were reported in a randomized, phase 2 study in mCRPC (Kantoff et. al. 2010 J Clin Onc 28:1099-1105). **Methods:** In PROSPECT, 1200 subjects have been randomized in a double-blind fashion to three arms: PROSTVAC, PROSTVAC plus GM-CSF, or Placebo at a 1:1:1 ratio. The 5 month treatment regimen comprises one PROSTVAC-Prime injection followed by 6 PROSTVAC-Boost injections. Enrolled subjects have asymptomatic/minimally symptomatic mCRPC and are chemotherapy-naïve. Subjects with rapidly progressing disease and visceral metastases are excluded. The primary endpoint is OS and pre-specified interim analyses are integrated in the statistical plan. Secondary efficacy endpoints include the proportion of event-free subjects at 6 months (radiographic progression, pain progression, chemotherapy initiation, or death) compared to placebo. Exploratory endpoints are planned, including immune responses. An immune monitoring program would inform future immunotherapy studies and potential identification of biomarkers. The trial is fully enrolled. ClinicalTrials.gov registry number: NCT01322490. Clinical trial information: NCT01322490.

TPS5082 **Poster Session (Board #69b), Sat, 1:15 PM-4:45 PM**

ERA 223: A phase 3 trial of radium-223 dichloride (Ra-223) in combination with abiraterone acetate (abiraterone) and prednisone in the treatment of asymptomatic or mildly symptomatic chemotherapy-naïve patients (pts) with bone predominant metastatic castration-resistant prostate cancer (mCRPC). *First Author: Matthew Raymond Smith, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Ra-223, a first-in-class alpha-emitting radiopharmaceutical targeting bone metastases, reduced risk of death by 30% and delayed time to first symptomatic skeletal event (SSE) versus placebo (15.6 vs 9.8 mo; HR = 0.66) in phase 3 ALSYMPCA (Parker et al. *NEJM* 2013, Sartor et al. *Lancet Oncol* 2014). Ra-223 favorable safety profile and lack of significant toxicity support combining it with other agents. Abiraterone improved radiologic progression-free survival (rPFS) and overall survival (OS) (Ryan et al. *NEJM* 2012) in chemotherapy-naïve men with mCRPC; it has no overlapping toxicity with Ra-223. This study investigates efficacy and safety of Ra-223 + abiraterone versus abiraterone alone in chemotherapy-naïve pts with mCRPC to bone. **Methods:** This phase 3, double-blind, placebo-controlled, multinational trial (ERA 223, NCT02043678) will randomize ~ 800 pts with asymptomatic or mildly symptomatic chemotherapy-naïve, bone-predominant mCRPC 1:1 to receive abiraterone (oral 1000 mg daily) and prednisone (oral 5 mg twice daily) + Ra-223 (50 kBq/kg IV) q 4 wk for 6 cycles or matching placebo until an SSE or death. Stratification is by geographic region, concurrent use of denosumab or bisphosphonates, and total alkaline phosphatase. The primary end point is SSE-free survival. Secondary end points include OS; time to opiate use for cancer pain, pain progression, and cytotoxic chemotherapy; rPFS; and acute and long-term safety. Pts are assessed at each treatment visit for efficacy, safety, and health-related quality of life, and every 3 months for progression and long-term safety. Pts who complete all study treatment and have no SSE enter active follow-up. Long-term follow-up begins after pts experience an SSE and ends 7 years after the last Ra-223 dose or at death, loss to follow-up, or withdrawal. SSE-free survival will be analyzed using a stratified log-rank test, accounting for stratification. Kaplan-Meier estimates will be produced for both treatment groups. As of January 15, 2015, 118 pts were screened. Clinical trial information: NCT02043678.

TPS5083 **Poster Session (Board #70a), Sat, 1:15 PM-4:45 PM**

The PRESIDE trial: A randomized, double-blind, placebo-controlled phase III efficacy and safety study of continued enzalutamide plus docetaxel after disease progression on enzalutamide alone in patients with metastatic castration-resistant prostate cancer. *First Author: Simon Chowdhury, Guy's King's and St Thomas Hospitals, London, United Kingdom*

Background: Enzalutamide (ENZA) is an oral androgen receptor inhibitor approved in the US for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC) (US PI, 2014) and in the EU for the treatment of asymptomatic/mildly symptomatic men with mCRPC after failure of androgen deprivation therapy in whom chemotherapy is not yet clinically indicated, or those whose disease has progressed on or after doxetaxel (DTX) therapy (EU SmPC, 2014). The PRESIDE study (NCT02288247) will evaluate the efficacy and safety of continued ENZA treatment vs placebo (PBO) when starting docetaxel plus prednisolone (PRED) after disease progression on first-line ENZA in chemotherapy-naïve mCRPC patients. **Methods:** PRESIDE will consist of an open-label treatment period with ENZA (period 1), followed by a randomized double-blind treatment with continued ENZA or PBO in addition to DTX plus PRED (period 2). Eligibility criteria include confirmed prostate adenocarcinoma, metastatic disease, prostate-specific antigen (PSA) progression on androgen deprivation or surgical castration, Eastern Cooperative Oncology Group performance status 0–1, testosterone $\leq$ 50 ng/dL, and minimally symptomatic patients (Brief Pain Inventory Short Form, question 3, $<$ 4 in the absence of opiate analgesia). In period 1, all patients will receive open-label ENZA 160 mg/day until radiographic progression and/or PSA progression with rapid PSA doubling time. In period 2, patients with confirmed disease progression on ENZA alone will be randomized to continue ENZA 160 mg/day or receive PBO. All patients will also receive therapy with DTX 75 mg/m^2 every 3 weeks plus PRED 10 mg/day. The primary end point is radiographic progression-free survival. Secondary end points include PSA and pain progression, PSA and radiographic response, opiate use for cancer-related pain, skeletal related events and quality of life. Planned enrolment is 650 patients in 90 sites across Europe for period 1, with $\geq$ 137 patients in each randomized arm for period 2. Recruitment commenced in December 2014. Clinical trial information: NCT02288247.

TPS5084 **Poster Session (Board #70b), Sat, 1:15 PM-4:45 PM**

The role of highly selective androgen receptor (AR) targeted therapy in men with biochemically relapsed hormone sensitive prostate cancer. *First Author: Rahul Raj Aggarwal, UC San Francisco, San Francisco, CA*

Background: Androgen deprivation therapy (ADT) is frequently applied in men with a rising PSA after surgery and/or radiation, often on an intermittent basis (Crook et al. NEJM 2012). Yet, progression to castration-resistant prostate cancer (CRPC) is a near universal event and many ultimately succumb from their disease, especially those with a short PSA doubling time (PSADT) (Freedland et al. JAMA 2005). Furthermore, ADT is associated with an adverse impact on quality of life (QOL), decreased bone density (BMD), and insulin resistance (Keating et al. JCO 2006). Potent AR antagonists have proven beneficial in metastatic CRPC but their role in castration-sensitive disease is unknown. We hypothesize that compared to standard ADT with luteinizing hormone releasing hormone (LHRH) agonist monotherapy: (1) potent AR antagonist monotherapy may have less detrimental impact on QOL and metabolic effects yet preserved efficacy, and (2) LHRH agonist + potent AR blockade may lead to more durable PSA suppression thereby allowing longer treatment-free intervals and hence improved QOL within an intermittent treatment framework. **Methods:** In the ongoing, open-label, phase 2 study (NCT01790126), patients are randomized 1:1:1 to receive ARN-509 monotherapy (240 mg/day), ARN-509 + LHRH agonist, or LHRH agonist monotherapy. Patients are treated for 12 months, then observed until the time of PSA progression. Eligibility criteria include prior definitive local therapy, rising PSA with PSADT $\leq$ 12 months, minimum PSA $>$ 1 if prior surgery (nadir + 2 if radiation alone), serum testosterone (T) $>$ 150 ng/dL, no prior ADT for biochemical relapse, and no metastases. The primary study endpoint is the percent change from baseline to 12 months in QOL as measured by FACT-P. Secondary endpoints include PSA nadir on treatment and PSA progression-free survival, median time to T recovery, and percent change from baseline in bone density, fasting insulin/glucose/lipids, and serum T and estradiol levels. Correlative studies include analysis of AR mutations in circulating tumor DNA and association with clinical outcomes. Thus far, 34 out of 90 planned patients have been accrued across five investigational sites. Clinical trial information: NCT01790126.

5500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A randomized phase II study of paclitaxel/carboplatin/bevacizumab, paclitaxel/carboplatin/temsirolimus and ixabepilone/carboplatin/bevacizumab as initial therapy for measurable stage III or IVA, stage IVB or recurrent endometrial cancer, GOG-86P. *First Author: Carol Aghajanian, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Paclitaxel (PC) is a standard initial therapy for advanced endometrial cancer (EC). We evaluated efficacy and tolerability of incorporating three novel agents into initial therapy. **Methods:** Patients (pts) had received no prior chemotherapy. Randomization (1:1:1) was stratified by measurable disease, recurrent disease, prior pelvic RT. Primary endpoint was progression-free survival (PFS). GOG 209 was used as historical control. **Results:** At least 70% received 6 cycles of C (70-83%) or P (74-82%); 68% received 6 cycles of I. Pts on arm 1 received a median of 12 cycles (0 - 78) of Bev compared with 9 cycles (0-53) on arm 3. A median of 8 cycles (0-62) of Tem was given on arm 2. Hypertension (G 3/4) was more common in the Bev arms (16%) than in the Tem arm (3%), $p = 0.001$. Pneumonitis ($p = 0.004$) and oral mucositis ($p < 0.001$), were more common in the Tem arm. PFS, compared using a log-rank test on data grouped by time intervals, was not significantly increased in any experimental arm ($p > 0.039$) when each arm was compared to historical control. HR (92% CI) for arms 1, 2 and 3 was 0.81 (0.63-1.02), 1.22 (0.96-1.55) and 0.87 (0.68-1.11), respectively. Overall survival (OS) censoring at 36 months, a secondary endpoint, was statistically significantly ($p < 0.039$) increased in arm 1 relative to control but was not significantly increased in arms 2 or 3 (HR (92% CI) arms 1, 2 and 3 was 0.71 (0.55-0.91), 0.99 (0.78-1.26) and 0.97 (0.77-1.23)). **Conclusions:** PFS is not significantly increased in any Arm. OS is significantly increased in the PC + Bev arm. Clinical trial information: NCT00977574.

5501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Adjuvant chemotherapy and radiation therapy (RT) versus RT alone for women with high-risk endometrial cancer: Toxicity and quality-of-life results of the randomized PORTEC-3 trial. *First Author: Carien L. Creutzberg, Leiden University Medical Center, Leiden, Netherlands*

Background: PORTEC-3 is an intergroup trial investigating survival improvement with adjuvant chemotherapy given during and after pelvic RT (CTRT) versus RT alone (RT) for women with high-risk endometrial cancer (HR-EC). Primary endpoints are overall and failure free survival, secondary endpoints toxicity and health-related quality of life (HRQL). Accrual was completed Dec 2013. Toxicity and 2-year HRQL results are presented. **Methods:** 686 women with HR-EC were allocated to RT (48.6 Gy in 1.8 Gy fractions) or CTRT (2 cycles of cisplatin 50 mg/m^2 during RT, followed by 4 cycles of carboplatin AUC5 and paclitaxel 175 mg/m^2). Adverse events (AE) were graded using CTCAEv3.0. HRQL was evaluated using EORTC QLQ-C30 and symptom scales from CX 24 and OV28 at baseline, after RT and at 6-12 month follow up (FU) intervals. **Results:** 674 patients met eligibility criteria, and 572 (85%) were evaluable for HRQL. Median FU was 30 months. Rates of AE were significantly higher for CTRT vs RT. During RT, grade ≥ 2 AE were found in 79 vs 44%, and grade ≥ 3 in 36 vs 13% of patients, both $p < 0.001$. During FU, any grade ≥ 3 AE were reported in 67% (CTRT) vs 32% (RT), especially hematologic (32 vs 8%), neurologic (10 vs 2%) and GI AE (14 vs 5%, all $p < 0.001$). AE decreased over time; at 1 yr differences for CTRT vs RT were only significant for grade ≥ 2 neurologic (12 vs 1%, $p < 0.001$) and musculoskeletal AE (3 vs 0%, $p = 0.015$). Rates of any grade ≥ 2 and ≥ 3 AE were 47 vs 39% ($p=0.06$) and 12 vs 8% (ns). At 2 years, grade ≥ 2 neurologic AE persisted (10 vs 2%, $p<0.001$) without differences in grade ≥ 3 AE. QLQC30 functioning scores were lower and HRQL symptom scores were higher for CTRT vs RT after RT and at 6 months, improving with time. At 1 and 2 years, small (mean 5-6 points) but significant differences in physical, role, emotional and social functioning remained. Most striking differences at 2 years were tingling/numbness (24 vs 7%, $p < 0.001$) and weakness arm/legs (14 vs 9%, $p < 0.001$). **Conclusions:** CTRT for high-risk endometrial cancer causes significantly higher AE and symptom ratings and reduced HRQL during and after treatment as compared with RT, but with recovery over time, without differences in grade ≥ 3 AE at 2 years. Clinical trial information: NCT00411138.

5502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Randomized phase II trial of carboplatin-paclitaxel (CP) compared to carboplatin-paclitaxel-bevacizumab (CP-B) in advanced (stage III-IV) or recurrent endometrial cancer: The MITO END-2 trial. *First Author: Domenica Lorusso, MITO and Fondazione IRCCS National Cancer Institute, Milan, Italy*

Background: The prognosis of advanced or recurrent endometrial cancer (AEC) is dismal. The antiangiogenic drug Bevacizumab (B) has reported activity in AEC with response rates ranging from 13 to 22% and 6-month disease control up to 40%. The This randomized phase II trial was designed to compare CP vs CP-B in the treatment of AEC in terms of progression free survival (PFS).(EUDRACT Number 003301-16) **Methods:** Eligible pts had advanced (stage III-IV) or recurrent (progression $>$ 6 months after completion of previous platinum chemotherapy) endometrial cancer, and ≤ 1 prior CT lines. All patients had measurable or evaluable disease and both type 1 and 2 endometrial cancers were eligible. Pts were randomized 1:1 to receive CP standard dose for 6-8 cycles with or without Bevacizumab 15 mg/kg in combination and maintenance until progression or unacceptable toxicity. **Results:** From January 2012 to October 2014, 108 pts were randomized (CP: 54 pts; CPB 54 pts). Overall, 2 out of 3 of pts presented with recurrent disease; almost 60% of cases had endometrioid histology, and 55% were G3. PS was $<$ or 1 in 83% and 15% of case, respectively. Vascular comorbidity was documented in 57% of pts. There was no difference in clinico-pathological features according to arm allocation. As on March 2015, median duration of follow up was 13 months; outcome data are summarized in the table. As far as toxicity, Grade 3 cardiac toxicity was documented in 4 cases in arm B versus no cases in arm A. 13 serious adverse events (SAE) were documented in 8 patients: 3 DVTs, 3 retinal artery thrombosis, 2 intracardiac thrombus, 1 silent myocardial infarction, and 1 cerebrovascular accident. **Conclusions**: The addition of B to CP significantly increased PFS in recurrent endometrial cancer. Cardiovascular toxicity should be carefully evaluated in a population with pre-existing cardiovascular risk factors. Clinical trial information: EUDRACT Number 003301-16.

5503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Impact of trebananib plus weekly paclitaxel on overall survival (OS) in patients (pts) with recurrent ovarian cancer and ascites: Results from the phase III TRINOVA-1 study. *First Author: Bradley J. Monk, Department of Obstetrics and Gynecology, University of Arizona Cancer Center Creighton University School of Medicine at Dignity Health St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Background: Trebananib is an antiangiogenic peptibody that inhibits angiopoietin 1 and 2 binding to the Tie2 receptor. TRINOVA-1 showed significantly longer progression-free survival (PFS) in the trebananib arm (Monk et al, *Lancet Oncol* 2014;15:799). We evaluated OS, including clinically important subgroups, and postprogression PFS (PFS2). **Methods:** 919 women with recurrent epithelial ovarian cancer (platinum-free interval $<$ 12 mo) were randomized to paclitaxel (P) 80 mg/m^2 IV QW (3 wks on/1 wk off) plus either blinded trebananib 15 mg/kg IV QW (T+P) or placebo (P alone). Treatment continued until progression, toxicity or consent withdrawal. PFS was the primary, intent to treat (ITT) OS a key secondary endpoint. Exploratory PFS2 analysis followed the EMA guidance (EMA/CHMP/27994/2008/Rev.1; 13 Dec 2012). **Results:** After median follow-up of 17.7 mo and 628 OS events, median OS (ITT) was 19.3 mo with T+P vs 18.3 mo with P alone (HR = 0.95, 95% CI, 0.81–1.11; $p = 0.55$). Prespecified subgroup analysis of OS also evaluated 295 (32%) pts with ascites at baseline. Characteristics did not differ between pts with and without ascites, and pts with ascites randomized to T+P vs P alone. There was a difference in median OS of 2.2 mo between pts with ascites receiving T+P vs P alone (14.5 vs 12.3 mo; HR = 0.72, 95% CI 0.55–0.93; $p = 0.011$). After on-study progression, 684 (74%) pts received a median of 2 (range, 1–8) additional lines of therapy. Median PFS2 in the T+P arm increased by 1.6 mo (12.5 vs 10.9 mo with P alone; HR = 0.85, 95% CI 0.74–0.98; $p = 0.024$). Analysis of time to second subsequent therapy confirmed the PFS2 result (median 13.4 vs 11.7 mo with P alone; HR = 0.83, 95% CI, 0.72–0.96; $p = 0.012$). The incidence of grade ≥ 3 adverse events (AEs) was 60% for T+P vs 56% for P alone. T+P was associated with more AE-related treatment discontinuations (22% vs 8%) and localized edema events (any grade, 59% vs 27%). **Conclusions:** Despite multiple additional lines of therapy, OS was longer with T+P among pts with ascites but not in the ITT population (no decrement). The initially reported PFS benefit was sustained through next subsequent anticancer therapy, translating into longer PFS2. Clinical trial information: NCT01204749.

5504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Efficacy and safety of chemotherapy (CT) ± pertuzumab (P) for platinum-resistant ovarian cancer (PROC): AGO-OVAR 2.20/ENGOT-ov14/PENELOPE double-blind placebo-controlled randomized phase III trial. *First Author: Christian Kurzeder, AGO and Kliniken Essen Mitte, Essen, Germany*

Background: Adding P to gemcitabine (GEM) for PROC improved progression-free survival (PFS) in a subset of patients (pts) with low tumor HER3 mRNA expression [Makhija 2010]. **Methods:** Eligible pts had recurrent PROC (progression [PD] during/within 6 mo of completing ≥ 4 platinum cycles) with centrally tested low tumor HER3 mRNA expression (concentration ratio ≤ 2.81 by qRT-PCR on cobas z480) and ≤ 2 prior CT lines. Investigators (INVs) chose CT (topotecan [TOP], paclitaxel [PAC] or GEM); recruitment was capped to ensure similarly sized CT cohorts. Pts were stratified by chosen CT, prior anti-angiogenic therapy and platinum-free interval (< 3 vs 3–6 mo) and randomized 1:1 to CT with either placebo or P 840→420 mg q3w until PD/unacceptable toxicity. The primary objective was to determine if independent review committee (IRC)-assessed PFS was superior with P + CT vs placebo + CT. The prespecified primary PFS analysis after 109 blinded IRC-assessed PFS events in 154 planned pts provided 95% power to detect a PFS hazard ratio (HR) of 0.50 (median 1.4→2.8 mo) with 2-sided log-rank $\alpha = 0.05$. Other endpoints include overall survival, INV-assessed PFS, objective response rate, safety and translational research. **Results:** From Oct 2013 to Sep 2014, 156 pts were randomized. Adding P to CT improved PFS (median 4.3 mo vs 2.6 mo for placebo + CT); however, significance was not achieved for the primary endpoint analysis. Subgroup analyses by CT showed inconsistent results. No new safety signals were seen. **Conclusion:** Although the primary objective was not met, subgroup analyses showed trends favoring P in the GEM and PAC cohorts, potentially explaining the significant findings in one of the sensitivity analyses. These results merit further exploration of P in ovarian cancer. Clinical trial information: NCT01684878.

PFS analysis	No. of events/pts	Stratified HR (95% CI)
Primary	126/156	0.74 (0.50–1.11); p = 0.14
Sensitivity		
IRC in first 109 PFS events	109/156	0.61 (0.39–0.94)
IRC backdating PD due to missing tumor assessment	126/156	0.82 (0.55–1.21)
CT subgroup, primary		
GEM	45/53	0.63 (0.34–1.14)
PAC	41/54	0.56 (0.29–1.09)
TOP*	40/49	1.19 (0.63–2.25)

*Recruitment to TOP was slowest.

5505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Retrospective analysis of candidate predictive tumor biomarkers (BMs) for efficacy in the GOG-0218 trial evaluating front-line carboplatin–paclitaxel (CP) ± bevacizumab (BEV) for epithelial ovarian cancer (EOC). *First Author: Michael J. Birrer, Massachusetts General Hospital/Dana Farber Cancer Center, Boston, MA*

Background: In EOC, the double-blind placebo (PLA)-controlled randomized phase 3 GOG-0218 trial showed significantly improved progression-free survival (PFS) (but not overall survival [OS]) with BEV added to front-line CP and continued alone. Plasma BM correlative analyses identified no predictive BMs for efficacy. Tumor BM evaluation was an exploratory objective. **Methods:** Patients (pts) with stage III (incompletely resected) or IV OC were randomized to receive 6 cycles of CP with: PLA (CPP); BEV 15 mg/kg q3w → PLA (CPB15); or BEV for 15 mo (CPB15+). Five tumor BMs (CD31, tVEGF-A, VEGFR-2, NRP-1, MET) with a biologic rationale for evaluation were assessed by immunohistochemistry (IHC). The BM-evaluable population (BEP; all pts with an evaluable BM sample and ≥ 1 post-baseline efficacy assessment) was analyzed using 1st, 2nd and 3rd quartile (Q) expression levels for each BM as the cutoff for high vs low BM subgroups. Correlations between tumor BM levels and PFS and OS were analyzed. **Results:** The BEP, comprising 1455 (78%) of 1873 pts in the ITT population, had very similar baseline characteristics and efficacy to the ITT population. No prognostic or predictive association was seen for VEGFR-2, NRP-1 or MET. However, when comparing CPB15+ vs CPP (control), higher microvascular density (MVD) measured by CD31 IHC showed prognostic (not shown) and potential predictive value for PFS (> Q3 MVD HR 0.38 [95% CI 0.25–0.58]; ≤ Q3 MVD HR = 0.68 [95% CI 0.54–0.86]; interaction p = 0.018) and OS (> Q3 MVD HR 0.57 [95% CI 0.39–0.83]; ≤ Q3 MVD HR 1.03 [95% CI 0.83–1.27]; interaction p = 0.0069). tVEGF-A showed potential predictive value for OS (and PFS) for CPB15+ vs CPP with a Q3 cutoff (> Q3 tVEGF-A OS HR 0.62 [95% CI 0.43–0.91]; ≤ Q3 tVEGF-A OS HR 1.01 [95% CI 0.82–1.25]; interaction p = 0.023). **Conclusions:** These retrospective tumor BM analyses suggest a positive correlation between expression levels of molecular (tVEGF-A) and cellular (endothelial cell) targets of anti-VEGF and magnitude of PFS and OS improvement from BEV in EOC. The predictive value of these candidate efficacy BMs requires validation in other relevant datasets. Clinical trial information: NCT00262847.

5506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

An international, biomarker-directed, randomized, phase II trial of AZD1775 plus paclitaxel and carboplatin (P/C) for the treatment of women with platinum-sensitive, *TP53*-mutant ovarian cancer. *First Author: Amit M. Oza, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Data suggest synthetic lethality when *TP53*-deficient cells are exposed to genotoxic drugs plus the Wee1 inhibitor AZD1775 (MK-1775). AZD1775 plus C was well tolerated in patients (pts) with advanced solid tumors (NCT00648648). This current two-part study (NCT01357161) evaluated the efficacy of AZD1775 plus P/C compared with P/C alone in women with *TP53*-mutant OC. **Methods:** After confirming a dose of AZD1775 (225 mg bid; capsules) in 15 pts in part 1, pts in part 2 received AZD1775 or placebo bid for 2.5 days plus P (175 mg/m^2; IV) and C (AUC5; IV) on day 1 per 21-day treatment cycle, until progression or the completion of six cycles. Primary objectives: PFS (enhanced [volumetric] RECIST v1.1, criterion for superiority = $P < 0.1$), safety and tolerability (CTCAE v4.0). Secondary objectives: PFS (RECIST v1.1), ORR (enhanced RECIST v1.1, CA-125 levels) and OS. **Results:** 121 pts with confirmed *TP53* mutations were randomized, 59 and 62 to AZD1775/P/C and P/C, respectively. PFS by independent central review (~57% maturity) was greater with AZD1775/P/C compared with P/C alone (enhanced RECIST: HR 0.63, 80% CI 0.45, 0.89, 95% CI 0.38, 1.06, $P = 0.080$, median 34.14 vs 31.86 weeks; RECIST: HR 0.55, 80% CI 0.39, 0.79, 95% CI 0.32, 0.95, $P = 0.030$, median 42.86 vs 34.86 weeks). ORRs were 81.4% vs 75.8% (difference 5.6%, 95% CI for difference –9.4, 20.2, $P = 0.459$) with AZD1775/P/C vs P/C, respectively. Best response rates based on CA-125 criteria were 81.35% vs 74.19% with AZD1775/P/C vs P/C, respectively. OS data are immature. Most common adverse events (AEs) were nausea (78.0% vs 60.0% for AZD1775/P/C vs P/C, respectively), diarrhea (74.6% vs 36.7%), alopecia (54.2% vs 66.7%) and fatigue (54.2% vs 55.0%). 85 pts had grade ≥ 3 AEs (78.0% vs 65.0% for AZD1775/P/C vs P/C, respectively), 36 pts had serious AEs (40.7% vs 20.0%) and 25 pts had AEs resulting in discontinuation (20.3% vs 21.7%). **Conclusions:** AZD1775/P/C was associated with a significant increase in PFS when compared with P/C alone, met the preset primary and secondary PFS efficacy bar for clinical importance, and showed acceptable tolerability in women with *TP53*-mutant OC. Clinical trial information: NCT01357161.

5507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A phase I study of continuous veliparib in combination with IV carboplatin/paclitaxel or IV/IP paclitaxel/cisplatin and bevacizumab in newly diagnosed patients with previously untreated epithelial ovarian, fallopian tube, or primary peritoneal cancer: An NRG Oncology/Gynecologic Oncology Group study. *First Author: Katherine M. Bell-McGuinn, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Veliparib, a poly-(ADP-ribose)-polymerase inhibitor, increases anti-tumor activity when combined with platinum chemotherapy and has monotherapeutic activity in *BRCA1* or *BRCA2* deficient tumors. This study was done to determine the recommended phase II dose (RP2D) of continuous veliparib in combination with initial treatment for epithelial ovarian, fallopian tube, or primary peritoneal cancer. **Methods:** Eligible patients had newly diagnosed, untreated, stage II-IV epithelial ovarian, fallopian tube, or primary peritoneal carcinoma or carcinosarcoma. Three regimens (six 21 day cycles) were evaluated: 1, IV q3week carboplatin (AUC 6) and paclitaxel (175mg/m^2); 2, IV q3week carboplatin (AUC 6) and weekly paclitaxel (80mg/m^2); and 3, IV paclitaxel (135mg/m^2, day 1), IP cisplatin (75mg/m^2, day 1 or 2) and IP paclitaxel (60mg/m^2, day 8). Bevacizumab 15mg/kg started in cycle 2 and continued as monotherapy for cycles 7-22. Veliparib continuous oral BID dosing in cycles 1-6 started at 30mg. A 3+3 dose escalation design evaluated dose-limiting toxicities (DLTs) in cycles 1 and 2. Once <2/6 patients experienced a DLT, that dose level was expanded to evaluate feasibility over 4 cycles. **Results:** We enrolled 189 patients; 32 were not evaluable. DLTs at ≥RP2D levels were as seen in the table. **Conclusions:** The RP2D for all regimens is veliparib 150mg BID. Clinical trial information: NCT00989651.

Veliparib dose (mg BID)	No. Evaluable Patients	No. Patients with DLTs	DLT (grade)[no. patients]
Regimen 1

5508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Results of ARIEL2: A Phase 2 trial to prospectively identify ovarian cancer patients likely to respond to rucaparib using tumor genetic analysis. *First Author: Iain A. McNeish, Institute of Cancer Sciences, University of Glasgow, Glasgow, Scotland*

Background: At least 50% of high-grade serous ovarian cancers (OC) may have homologous recombination deficiency (HRD). Germline *BRCA1* and *BRCA2* mutations (*gBRCA*^{mut}) account for ~1/3. Identification of *BRCA*^{wt} HRD tumors likely to respond to a PARP inhibitor remains challenging. ARIEL2 prospectively tested a novel next generation sequencing-based HRD assay and algorithm to predict rucaparib sensitivity by assessing tumor *BRCA* status and genome-wide loss of heterozygosity (LOH). **Methods:** ARIEL2 enrolled pts with platinum-sensitive, recurrent, high-grade serous or endometrioid OC. The primary objective was to evaluate clinical activity of 600 mg BID rucaparib in 3 pre-defined HRD subgroups: tumor BRCA^{mut}, BRCA^{wt}/LOH^{high} and BRCA^{wt}/LOH^{low}. Known *gBRCA*^{mut} pt enrollment was limited. Tumor HRD status was assessed in pre-treatment biopsies and archival tumor. Response was assessed by RECIST and GCIG CA-125 criteria. **Results:** In 206 treated pts: median age=64 [range 31-86]; 64% ECOG=0; 96% high-grade serous; 46% with ≥2 prior regimens. Treatment-related AEs in ≥15% of pts were GI symptoms (nausea, dysgeusia, ↓ appetite, vomiting, constipation, diarrhea), fatigue, ↓ Hgb, and transient ALT/AST elevations with no other evidence of liver dysfunction. Efficacy data for 135 pts indicate RECIST + CA125 ORRs of 69%, 39%, and 11% in BRCA^{mut}, BRCA^{wt}/LOH^{high}, and BRCA^{wt}/LOH^{low} pts, respectively (Table 1, p<0.0001, Cochran-Armitage trend test). Responses occurred in both *gBRCA*^{mut} (14/19, 74%) and somatic *BRCA*^{mut} (10/16, 63%) tumors. Only 15/161 (9%) BRCA^{wt} tumors had a loss-of-function mutation or homozygous deletion in a HR gene; 4/15 (27%) alterations were in *RAD51C*. All 4 tumors were LOH^{high}and responded to rucaparib, suggesting a potential HRD mechanism. Importantly, matched archival and screening tumor analysis revealed an increase in genomic LOH over time in a subset of tumors. **Conclusions:** ARIEL2 data indicate a tumor HRD assay and algorithm combining *BRCA* analysis and genomic LOH identifies OC pts likely to respond to rucaparib. Clinical trial information: NCT01891344.

Response by HRD status.

HRD Subgroup	# of Pts	RECIST, %	RECIST & CA-125, %
BRCA^{mut}	35	66	69
BRCA^{wt}/LOH^{high}	56	32	39
BRCA^{wt}/LOH^{low}	44	11	11

5509 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Avelumab (MSB0010718C), an anti-PD-L1 antibody, in patients with previously treated, recurrent or refractory ovarian cancer: A phase Ib, open-label expansion trial. *First Author: Mary L. Disis, University of Washington School of Medicine, Seattle, WA*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab (proposed INN) (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. Here we present results from a cohort of patients (pts) with recurrent or refractory ovarian cancer in an ongoing phase Ib study (NCT01772004). **Methods:** Pts with ECOG PS 0-1 received avelumab at 10 mg/kg Q2W. Best overall response (BOR) and progression-free survival (PFS) were assessed according to RECIST 1.1. Adverse events (AEs) were evaluated by CTCAE v4.0. A prespecified analysis of 23 pts with follow-up of ≥ 2 months showed confirmed and unconfirmed partial responses (PRs), leading to cohort expansion to 75 pts. **Results:** Seventy-five pts were enrolled from November 2013 to November 2014 (median age 62 [range 38-84]; ECOG PS 0 [41%] or 1 [59%]; median of four prior lines of therapy). As of January 2015, median duration of treatment with avelumab was 10 weeks (range 2-54 weeks), and 27 pts remained on treatment. Efficacy data from the 23 pts followed-up for ≥ 2 months (range 2–8 months) demonstrated 4 pts (17.4%, [95% CI, 5.0%, 38.8%]) achieved an unconfirmed BOR of PR,11 (47.8%) had stable disease, and 2 pts had >30% tumor shrinkage after progression was reported. Median PFS was 11.9 weeks (95% CI, 5.9, not reached), and the PFS rate at 24 weeks was 33.3% (95% CI, 11.5, 57.2). Drug-related treatment-emergent AEs (TEAEs; all grades) were reported in 18 pts (78.3%), and 2 pts (8.7%) experienced grade ≥ 3 drug-related TEAEs (increased lipase [1] and elevated creatine kinase and autoimmune myositis that led to discontinuation [1]). No drug-related serious TEAEs occurred. The most commonly reported drug-related TEAEs (> 10%) were fatigue, nausea, and diarrhea. **Conclusions:** These data represent the largest reported dataset of pts with recurrent ovarian cancer treated with anti-PD-L1 therapy. Avelumab demonstrated an acceptable safety profile and is clinically active in this heavily pretreated ovarian cancer pt population. Clinical trial information: NCT01772004.

5510 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Antitumor activity and safety of pembrolizumab in patients (pts) with PD-L1 positive advanced ovarian cancer: Interim results from a phase Ib study. *First Author: Andrea Varga, Gustave Roussy Institute, Villejuif, France*

Background: Pembrolizumab is a potent, highly selective humanized monoclonal antibody against PD-1 designed to block interaction with PD-L1 and PD-L2 and remove the inhibition of T-cell activation against cancer. PD-L1 was found to be overexpressed in ovarian cancer and can contribute to malignancy. We assessed the safety and efficacy of pembrolizumab in pts with PD-L1^{+}advanced ovarian cancer. **Methods:** KEYNOTE-028 (NCT02054806) is a nonrandomized, multicohort phase Ib trial of pembrolizumab in pts with PD-L1^{+} advanced solid tumors. Key eligibility criteria for the ovarian cancer cohort included advanced ovarian epithelial, fallopian tube, or primary peritoneal carcinoma; failure of prior therapy; PD-L1 expression in ≥ 1% of cells in tumor nests or PD-L1^{+} bands in stroma as determined by a prototype IHC assay at a central laboratory; and ECOG PS 0-1. Pembrolizumab 10 mg/kg was given every 2 weeks for up to 2 years or until confirmed progression or unacceptable toxicity. Primary end points: safety, tolerability, and preliminary efficacy. Response assessed per RECIST v1.1 by investigators every 8 weeks for the first 6 months and every 12 weeks thereafter. **Results:** 26 pts were enrolled. Mean (SD) age was 58.1 (7.5); 57.7% were white. 84.6% received prior therapies for recurrent/metastatic disease (38.5% received ≥ 5 therapies), and 50% received prior adjuvant therapies. One pt achieved complete response and 2 pts experienced partial response; 6 pts had stable disease. Of the 3 patients who responded, all remain in response with duration of response ≥ 24 weeks at the time of analysis. The best overall (confirmed) response was 11.5% (95% CI, 2.4-30.2). 6/26 (23.1%) had evidence of tumor reduction; 3 had a tumor reduction of at least 30%. All pts experienced ≥ 1 adverse event (AE) (regardless of treatment); most common were fatigue (42.3%), anemia (30.8%), and decreased appetite (30.8%). Drug-related AEs occurred in 69.2% of pts (grade ≥ 3, 1/26 pts). Currently, 6 pts remain on pembrolizumab treatment. **Conclusions:** PD-1 blockade with pembrolizumab is well tolerated and has antitumor activity in pts with advanced ovarian cancer. This preliminary signal for clinical efficacy will be further investigated. Clinical trial information: NCT02054806.

5511 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Association of *POLE*-mutated and MSI endometrial cancers with an elevated number of tumor-infiltrating and peritumoral lymphocytes and higher expression of PD-L1. *First Author: Brooke E. Howitt, Brigham and Women's Hospital, Boston, MA*

Background: TCGA identified two groups of endometrial cancers with high mutation frequency: an ultramutated group of tumors which harbored mutations in polymerase e (POLE) and a hypermutated group with microsatellite instability (MSI). We hypothesized that these hypermutated tumors may harbor more neoantigens and thus stimulate a stronger immune response compared to tumors with low mutation frequency. In this regard, we evaluated whether hypermutated tumors are associated with an elevated number of tumor-infiltrating lymphocytes (TILs) and peritumoral lymphocytes and higher expression of the immune modulatory molecule PD-L1. **Methods:** We evaluated 4 *POLE*-mutated (determined via Sanger sequencing of mutational hotspots), 28 MSI-tumors and 32 microsatellite stable (MSS) endometrioid endometrial tumors. MSI status was determined using immunohistochemistry (IHC). IHC was performed for CD3, CD4, CD8, CD20, PD-1 and PD-L1 using standard protocols. For evaluation of TILs, a photomicrograph (40X) of the area of maximum CD3+ intraepithelial lymphocytes was obtained with corresponding photomicrographs for the additional stains. For peritumoral lymphocytes, a semi-quantitative scoring method was utilized. **Results:** *POLE*-mutated and MSI tumors exhibited significantly elevated CD3+ ($p = 0.001$), CD4+ ($p = 0.078$) and CD8+ ($p < 0.001$) TILs compared to MSS tumors. CD20+ TILs were not statistically significantly different between MSI/POLE tumors and MSS tumors. Expression of PD-1 ($p < 0.001$) and PD-L1 ($p = 0.022$) was higher in TILs of POLE and MSI tumors compared to MSS tumors. Furthermore, POLE and MSI tumors harbored more peritumoral T-lymphocytes ($p < 0.001$) and higher expression of PD-1 ($p = 0.001$) and PD-L1 ($p < 0.001$) compared to MSS tumors. There were no significant differences in TILs, peritumoral lymphocytes and PD-1/PD-L1 expression between *POLE*-mutated and MSI tumors. **Conclusions:** *POLE*-mutated and MSI endometrial cancers are associated with an elevated number of TILs and peritumoral lymphocytes, and higher expression of PD-1 and PD-L1. These data support trials of immune-checkpoint inhibitors in hypermutated endometrial cancers.

5512 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Tumor infiltrating and peritumoral T cells and expression of PD-L1 in BRCA1/2-mutated high grade serous ovarian cancers. *First Author: Kyle Strickland, Brigham and Women's Hospital, Boston, MA*

Background: Previous studies have shown that the presence of CD3+ and CD8+ tumor-infiltrating lymphocytes (TILs) and a high CD8+/CD4+ ratio are associated with favorable overall survival in ovarian cancer. Given that BRCA1/2 mutated ovarian cancers are also known to be associated with improved survival, we assessed whether the presence of CD3+, CD8+ and CD4+ TILs is enriched in these tumors compared to non-BRCA1/2 mutated ovarian cancers. Furthermore, we assessed the expression of PD-1 and PD-L1 in these tumors. **Methods:** In this pilot study, we evaluated 34 high grade serous ovarian cancers with germline BRCA1 (n = 28) and BRCA2 (n = 6) mutations and 18 tumors without germline or somatic mutations in BRCA1, BRCA2 or other homologous recombination (HR) genes. Immunohistochemistry (IHC) was performed for CD3, CD4, CD8, CD20, PD-1 and PD-L1 using standard protocols. For evaluation of TILs, a photomicrograph (40X) of the area of maximum CD3+ intraepithelial lymphocytes was obtained with corresponding photomicrographs for the additional stains. For peritumoral lymphocytes, a semi-quantitative scoring method was utilized. **Results:** The number ofCD3+ TILs was not significantly different between BRCA1/2-mutated and non-BRCA1/2-mutated ovarian cancers (p = 0.23). However, BRCA1/2-mutated tumors were associated with a strong trend for increased CD8+ TILs (p = 0.06) while demonstrating significantly less CD4+ TILs (p = 0.05) compared to non-BRCA1/2-mutated tumors. Overall, there was a significantly higher CD8+/CD4+ ratio in BRCA1/2-mutated tumors (p = 0.02). Furthermore, peritumoral CD3+ T-cells were significantly increased in BRCA1/2-mutated (p = 0.03) compared to non-BRCA1/2-mutated ovarian cancers. We did not detect statistically significant differences in the intensity or distribution of PD-1 and PD-L1 expression between BRCA1 and non-BRCA1/2-mutated tumors. **Conclusions:** In this pilot study, BRCA1/2-mutated tumors were associated with significantly higher CD8+/CD4+ ratio of TILs and significantly higher peritumoral T cells. These findings support an additional mechanism for the improved survival of patients with BRCA1/2-mutated ovarian cancers.

5513 Poster Discussion Session; Displayed in Poster Session (Board #71), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

A phase II open-label, multicenter study of single-agent rucaparib in the treatment of patients with relapsed ovarian cancer and a deleterious BRCA mutation. *First Author: Ronnie Shapira-Frommer, Sheba Medical Center, Ramat Gan, Israel*

Background: Rucaparib is a potent oral PARP inhibitor that has shown robust activity in patients (pts) with homologous recombination deficient (HRD) tumors, with the highest response rates observed in ovarian and breast cancer pts harboring deleterious germline BRCA mutations (gBRCA^{mut}). This phase II study (NCT 01891344) evaluated the efficacy and safety of rucaparib in pts with relapsed gBRCA^{mut} high-grade epithelial ovarian, fallopian tube, or primary peritoneal cancer (EOC/FTC/PPC). **Methods:** Women with gBRCA-^{mut} EOC/FTC/PPC who received 2-4 prior chemotherapy (chemo) regimens and had a progression-free interval (PFI) $\geq$ 6 months after their last platinum dose were enrolled. ECOG PS 0-1 and adequate organ function were required. Pts received oral rucaparib 600 mg BID in 21 day cycles until disease progression. The primary endpoint was objective response rate (ORR) by RECIST 1.1. **Results:** 35 pts have been enrolled. Median age was 55 years (range 44-84). The median number of prior chemo regimens was 2 (range 2– 4). Fifteen pts (43%) had received $\geq$ 3 prior chemo regimens. RECIST/CA-125 ORR was 81% (21/26); RECIST ORR was 65% (17/26). RECIST ORR was 88% (7/8) and 56% (10/18), respectively, in pts with PFI 6-12 mo or $>$ 12 mos. In pts with $\geq$ 3 prior chemo regimens, 58% (7/12) achieved a RECIST response. The median duration of response and PFS have not been reached. The most common treatment-related AEs (generally grade 1/2) were nausea (55%), anemia (41%), ALT/AST elevations (41%), fatigue (41%), and asthenia (35%). The ALT/AST elevations are transient with no other evidence of liver dysfunction. No pts discontinued treatment due to an AE. No secondary malignancies have been observed. **Conclusions:** Rucaparib demonstrated robust activity in heavily pretreated EOC/FTC/PPC pts with gBRCA^{mut} tumors with 81% of pts achieving RECIST/CA-125 responses. Rucaparib was well tolerated and AEs did not result in any treatment discontinuations. The ongoing pivotal program in EOC/FTC/PPC pts is evaluating rucaparib in treatment (ARIEL2, NCT01891344) and maintenance (ARIEL3, NCT01968213) settings. Clinical trial information: NCT01891344.

5514 Poster Discussion Session; Displayed in Poster Session (Board #72), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Phase I/Ib study of the PARP inhibitor (PARPi) olaparib (O) with carboplatin (C) in heavily pretreated high-grade serous ovarian cancer (HGSOC) at low genetic risk (NCT01445418). *First Author: Victoria L. Chiou, Natl Cancer Inst, Bethesda, MD*

Background: O is a FDA-approved PARPi for advanced ovarian cancer with germline BRCA mutation (gBRCAm). O and C each have shown single agent activity in HGSOC. We hypothesize that addition of O to C to stress DNA repair machinery is tolerable and of clinical benefit in HGSOC pts without gBRCAm. **Methods**: 3x3 dose escalation examined O capsules (400 mg q12h, d 1-7) with C AUC 3, 4, or 5 on d1 or 2 every 21d over 3 dose levels. No more than 8 O + C cycles were given, followed by daily O maintenance. Safety was assessed every cycle. Response was assessed every 2 cycles. PBMCs were collected at baseline, d3, and post-cycle 1 for PAR incorporation. Tumor biopsies were performed in a 15 patient (pt) expansion cohort at maximum tolerated dose (MTD) pre-and post-cycle 1 for proteomics and apoptosis endpoints. **Results**: 30 women (median age 65 [49-71]) were treated over 3 dose levels of O + C AUC3 (3 pts), AUC4 (MTD, 21 pts), and AUC5 (6 pts). 24 pts had negative gBRCAm testing and 6 had BRCAPRO score $<$ 10% with negative family history. The median number of prior therapies was 7 (2-12). All pts received prior platinum (time from last platinum: median 17 mo [7-154]), with 11 platinum-sensitive and 19 platinum-resistant disease. Gr 3/4 AEs included neutropenia (23%), thrombocytopenia (20%), and anemia (13%). DLTs were gr 3 neutropenia/thrombocytopenia and gr 3 infection on AUC 5. 2 pts required C dose reduction and early discontinuation due to delayed marrow recovery. Of 28 evaluable pts, 5 PR (18%; median 4 [3-18] mo), and 10 SD $\geq$ 4 mo (36%; median 8 [4-11] mo) were observed, yielding a disease control rate of 54%. RR and median PFS were 36 % (4/11 pts) and 3.5 (1.5-10) mo in platinum-sensitive disease and 6% (1/17 pts) and 4 (1.5-18) mo in platinum-resistant disease. There was no significant difference in tissue apoptotic index pre-and post-cycle 1. PAR incorporation and proteomics results will be presented. **Conclusions**: Recommended phase 2 dose is O 400 mg capsules q12h d1-7 with C AUC4 on 21d cycles in heavily pretreated recurrent HGSOC pts without gBRCAm. Interactive marrow suppression was observed. Identification of biomarkers of response to O + C is needed in recurrent HGSOC without gBRCAm. Clinical trial information: NCT01445418.

Results of a phase I pharmacokinetic study of intraperitoneal bortezomib (B) and carboplatin (C) in patients with persistent or recurrent ovarian cancer (OC): An NRG/Gynecologic Oncology Group study. *First Author: Don S. Dizon, Massachusetts General Hospital, Boston, MA*

Background: Intraperitoneal therapy (IP) has been shown to improve survival outcomes for women with optimally cytoreduced, newly diagnosed, advanced OC, but whether IP has a role for recurrent OC is unknown. Preclinicial data show IP administration of the proteasome inhibitor bortezomib (B) prior to IP carboplatin (C) increased cellular platinum accumulation and results in synergistic cytotoxicity. Hence, we conducted this phase I trial of an IP regimen consisting of B+C in women with recurrent or persistent disease. **Methods:** We enrolled 33 pts with recurrent or persistent OC, GOG PS $\leq$ 2, with $\leq$ 4 prior regimens. After DLT at DL1 (B 0.5 mg/m^2]/C AUC 5), the protocol was amended to fixed C AUC4 with dose escalation of B: DL-1 (0.5); 1a (0.9); 2a (1.3), 3a (1.7), 4a (2.1), 5a (2.5). Treatment was delivered every 21 days for six cycles. Pharmacokinetics (PK) of B (by LC-MS/MS) and C (ultrafilterable, by AAS) were studied in cycle 1. **Results:** Of enrolled pts, 32/33 were evaluable for safety. Two patients experienced DLT at DL1 (G3 abdominal pain, G4 thrombocytopenia and G3 lung infection). At C AUC4, we escalated BTZ to DL5a without DLT. Grade 3/4 related toxicities included fatigue, abdominal pain, nausea, vomiting, and diarrhea; however, all were relatively infrequent. The overall response rate in patients with measurable disease (n = 21) was 19% (1 CR, 3PR). At DL5a (n = 5), the ORR was 20% (0CR, 1PR). PK revealed IP and peripheral blood plasma B C_{max} and AUC increased linearly with dose. The B IP to peripheral geometric mean ratios (range) were (N = 26): C_{max} 304 (317-2840), and AUC 139 (15-1867) and appeared independent of dose. Ultrafilterable platinum IP to peripheral geometric mean ratios (range) were (N = 9): C_{max} 49 (18-101) and AUC 17 (6-54). **Conclusions:** IP administration of B+C was feasible and showed promising activity in this phase I trial of heavily pre-treated women with OC. PK analysis showed a favorable exposure ratio of the peritoneal cavity relative to peripheral blood plasma. Further evaluation of this novel IP combination should be conducted. Clinical trial information: NCT01074411.

A phase Ib dose-escalation study of binimetinib (MEK162) in combination with weekly paclitaxel in patients with platinum-resistant epithelial ovarian, fallopian tube or primary peritoneal cancer. *First Author: Rachel N. Grisham, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Ovarian cancer is associated with key genetic alterations, including those that lead to activation of the RAS/RAF/MEK/ERK pathway. Binimetinib (BINI) is a potent, selective, allosteric inhibitor of MEK1/2. This study determined the recommended phase II dose (RP2D) of BINI administered on 2 dosing schedules in combination with weekly paclitaxel (PAC) and assessed the safety, pharmacokinetics (PK) and preliminary antitumor activity in female patients (pts) with platinum-resistant epithelial ovarian, fallopian tube or primary peritoneal cancer. **Methods:** BINI was administered orally either on a continuous (CONT) schedule at 30 mg twice daily (BID; dose level 1 [DL1]) or 45 mg BID (DL2), or on an intermittent (INTERM) schedule on Days (D) 1-5 weekly for 3 of every 4 weeks (q3/4w) at 45 mg BID, in combination with PAC 80 mg/m^2 IV on D1 weekly q3/4w. **Results:** Thirty-four pts were enrolled and treated, with 22 pts on the CONT schedule (14 at DL1; 8 at DL2) and 12 pts on the INTERM schedule. The median age was 63 years (range 42-77), baseline ECOG PS was 0 or 1 (97%), median number of prior systemic therapies was 4 (range 1-14) and the majority of tumors were high-grade serous (HGS; 74%) or low-grade serous (LGS; 18%). On the CONT schedule, dose-limiting toxicities (DLTs) of fatigue, nausea, neutropenia, rash and stomatitis were observed; the RP2D was declared as BINI 30 mg BID CONT with weekly PAC. On the INTERM schedule, a DLT of asthenia was observed; the RP2D was confirmed as BINI 45 mg BID INTERM with weekly PAC. The most common Grade 3/4 AEs included anemia (18%), vomiting (12%), and fatigue, nausea, neutropenia, pulmonary embolism, small intestinal obstruction and stomatitis (9% each). When administered in combination, no clinically relevant differences in BINI or PAC exposures were observed. Of the 29 pts with measurable disease, the response rate was 17% with 1 complete response (LGS) and 4 partial responses (1 LGS, 3 HGS). **Conclusions:** In this pt population, the combination of BINI on both the CONT and INTERM schedules with weekly PAC had an acceptable safety and PK profile at the RP2Ds. Responses were observed in HGS and LGS pts. Clinical trial information: NCT01649336.

Randomized phase III study comparing paclical-carboplatin with paclitaxel-carboplatin in patients with recurrent platinum-sensitive epithelial ovarian cancer. *First Author: Ignace Vergote, University Hospital Leuven, Leuven, Belgium*

Background: Paclical (Pcal), a CremophorEL-free formulation of paclitaxel (Oasmia Pharmaceutical AB) was compared with Paclitaxel (Pxel). Pcal can be administered without anti-allergic premedication as an iv infusion over 1 hour. **Methods:** Primary objective: To show non-inferiority between Pcal and Pxel in PFS using CT scans (RECIST) in platin-sensitive recurrent ovarian, fallopian tube or peritoneal carcinoma. To obtain 379 events of progression 850 were estimated to be accrued (non-inferiority HR = 1.2; α = 0.25 (one-sided); β = 0.8). Patients were randomized to Pcal 250 mg/m^2 iv 1 hr or Pxel 175 mg/m^2 iv 3 hrs, both followed by Carboplatin, AUC 5-6, q 3 wks. Stratification factors: CA 125 value ($<$ 250 U/L or $\geq$ 250 U/L) and relapse (1st or 2nd). CT scans were done before treatment, after 3 and 6 cycles and at the time of clinical symptoms or CA125 progression. A subset of 243 patients had CTs done every 3rd month until progression. Main inclusion criteria: response to prior platin containing treatment, $>$ 6 months platin-free interval (PFI), and CA 125 $>$ 2 x UNL. Patients with a history of severe allergy to study drugs were excluded. **Results:** 789 patients were 1:1 randomized in the period 2009 to 2012 in 81 centers. Inclusion was stopped when 437 patients showed progression. Main baseline characteristics were similar (PFI 6-12 months: 40% vs 43 %, $>$ 12 months 58% vs 57%; second line: 76% vs 76% for Pcal and Pxel, respectively). Non-inferiority of PFS for Pcal (10.3 months) compared to Pxel (10.1 months) was observed (HR:0.86 CI:0.72-1.03 p = 0.0938). In the subgroup of patients with CTs performed every 3rd month during follow-up the PFS was 12.2 versus 10.2 months, respectively (HR:0.76 CI:0.56-1.03 p = 0.0798). Response according to RECIST: 67% vs 65%; according to GCIG CA125 criteria: 86% vs 85%, respectively. AEs were noted in 90% in the Pcal group and 87% in the Pxel group. All grade peripheral neuropathy were 29% vs 32% and myalgia 11% vs 13%, respectively (NS). Severe allergic reactions were seen in 2% vs 1%. **Conclusions:** Pcal-treatment is as effective and safe as Pxel, without standard use of premedication and a shorter infusion time. Clinical trial information: NCT00989131.

Preliminary single agent activity of IMGN853, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), in platinum-resistant epithelial ovarian cancer (EOC) patients (pts): Phase I trial. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: IMGN853 (mirvetuximab soravtansine) is a FRα-targeting ADC that comprises a FRα-binding antibody conjugated with the potent maytansinoid, DM4. **Methods:** This phase I trial evaluates the safety, pharmacokinetics, pharmacodynamics and anti-tumor activity of IMGN853 in pts with FRα-positive solid tumors. A recommended phase II dose (RP2D) of 6.0 mg/kg, administered once every three weeks using adjusted ideal body weight was established in the dose-finding phase. Preliminary evidence of antitumor activity is being investigated at the RP2D in disease-specific cohorts of pts with platinum-resistant EOC and relapsed/refractory endometrial carcinoma. Here we report preliminary clinical activity (partial PR or complete CR response, CA125 response, SD $\geq$ 6 cycles) at the RP2D in pts with platinum-resistant EOC. **Results:** To date, 14 platinum-resistant EOC pts have been treated at the RP2D: 2 in dose escalation; 12 in the expansion cohort. All pts were heavily pretreated (mean: 4.5; range 2-12 prior treatments), all had prior taxane exposure, and all had progressed on their most recent regimen. All pts had FRα-positive tumor expression by IHC in archival tissue. Clinical benefit was observed in 5 /10 evaluable patients (4 have not reached 1st assessment): 4 PRs and 1 confirmed CA125 response, for an objective response rate (ORR) of 40% and clinical benefit rate (CBR) of 50%. In each pt with a PR, tumor regression had begun early on treatment (cycle 2 evaluation). Shrinkage of visceral metastases was seen: a PR pt had a 45% reduction in a 5 cm liver mass. One additional pt had an unconventional response: the disappearance of a non-target lesion with development of new lesions. The majority of adverse events (AEs) were CTCAE grade 1 or 2, with diarrhea, ocular events, cough, fatigue, decreased appetite, neuropathy and nausea reported in $>$ 20 % of pts. Nine of the 14 pts remain on study; enrollment continues. **Conclusions:** IMGN853 demonstrates promising preliminary clinical activity with an ORR of 40% and CBR of 50%, in heavily pretreated platinum-resistant ovarian cancer pts with a manageable AE profile. Clinical trial information: NCT01609556.

Autologous oxidized whole-tumor antigen vaccine in combination with angiogenesis blockade to elicit antitumor immune response in ovarian cancer. *First Author: Janos L. Tanyi, University of Pennsylvania, Philadelphia, PA*

Background: Personalized tumor lysate vaccines can encompass all putative antigens in tumors. **Methods:** A pilot clinical trial was conducted using an autologous oxidized whole tumor cell lysate dendritic cell (DC) based vaccine (vx) injected intranodally, alone or in combination with bevacizumab (Bev) with or without low-dose IV cyclophosphamide (Cy) and/or oral aspirin (ASA), in recurrent ovarian cancer patients (pts). Pts were treated every 3 weeks. Most of the pts were platinum-resistant and heavily pretreated. Adverse events (AEs) were graded by CTCAE v4.0 and clinical responses by RECIST v1.1. **Results:** To date, 35 pts (cohort 1 (vx only; n = 5), 2 (vx+bev; n = 10), 3 (vx+bev+Cy; n = 10) and 4 (vx+Bev+Cy+ASA; n = 10) have received over 392 vx doses. The treatment was well tolerated without serious AEs. Immune response to autologous antigen was seen mainly in cohorts 3 and 4, which received low-dose Cy. An increase in the frequency of T cells recognizing known tumor associated antigens (Her2, WT1, mesothelin, NY-ESO-1) was observed post-vx. Moreover, it is demonstrated for the first time that vaccination with whole tumor lysate-loaded DCs elicited a CD8 T cell response against mutated peptides derived from private non-synonymous somatic tumor mutations. Six pts achieved a partial response or were disease-free at end of treatment. The median progression-free survival (PFS) of cohort 1, 2, 3 and 4 were 4, 3.8, 11.1 and 10.1 mos, respectively. The median overall survival (OS) of cohorts 1 and 2 were 35.3 and 11.4 mos, while for cohorts 3 and 4 it has not been reached, with median potential follow up of 19 mos. A historic population (HP) of 16 pts from the same institution who received Bev+Cy (without vx) had PFS and OS of 4.1 and 26.4 mos respectively. Estimated PFS at 6 mos was 70% for cohorts 3 and 4 and 31% in the HP. The OS at 20 mos was 100% and 90% for cohorts 3 and 4, respectively and 61% for the historic cohort. **Conclusions:** Clinical benefit was demonstrated only in pts who exhibited an immune response against whole tumor lysate or autologous tumor. The use of oxidized whole tumor lysate DC vaccine is safe, effective in eliciting a broad antitumor immunity including private neoantigens. Clinical trial information: NCT01132014.

MITO (Multicentre Italian Trials in Ovarian cancer): CERV 2 trial—A randomized phase II study of carboplatin and paclitaxel +/- cetuximab, in advanced and/or recurrent cervical cancer. *First Author: Sandro Pignata, MITO and Istituto Nazionale Tumori di Napoli, Napoli, Italy*

Background: Carboplatin (C) plus paclitaxel (P) is among standard options for treatment of advanced or recurrent cervical cancer (ARCC) patients (pts). Cervical cancer cells often express Epidermal Growth Factor receptor (EGFR). Cetuximab (CET), an anti-EGFR monoclonal antibody, can be safely combined with CP. MITO-CERV 2 is a comparative randomized phase 2 study, testing the addition of CET to CP. **Methods:** ARCC pts, < 2 previous chemotherapy, ECOG PS$\leq$1, were randomized to CP (C AUC5 + P 175 mg/m^2, d1q21) for 6 cycles +/- CET (400 mg/m^2 one week before starting CP, then 250 mg/m^2 weekly) until disease progression or unacceptable toxicity. Primary endpoint was event-free survival (EFS), i.e. time from randomization to progression, death, definitive discontinuation of the whole treatment or loss to follow-up, whichever occurred first. With a 4.5 mos expected median EFS and a 6.4 mos auspicated EFS (HR 0.70), 0.20 one-tailed α and 80% power, 89 events were required for the final intent-to-treat analysis. **Results:** 108 pts were randomly assigned to CP (n = 53) or to CP-CET (n = 55). Median age was 50, 69% were PS0, 76% had recurrent disease, 91% had distant metastasis and 57% had received previous chemotherapy. A median number of 6 CP cycles was given in both arms. After a median follow-up of 23 mos (95% CI:20-26), 102 pts had an event, 97 progressed and 61 died. Median EFS was 4.7 and 6.0 mos (one-tail p = 0.43), median PFS was 5.2 and 7.6 mos (one-tail p = 0.20) and median OS was 17.7 and 17 mos (one-tail p = 0.27), with CP and CP-CET, respectively. One patient died for a stroke during standard treatment. There was no difference in the occurrence of severe side-effects, except grade 3-4 skin toxicity reported only with CP-CET (8 cases, 6 with acneiform rash, p = 0.004). Out of 86 patients eligible for RECIST, objective response rate was 43% and 38% with CP and CP-CET respectively (p = 0.63). **Conclusion**: The addition of CET to CP is not worthy of further investigation in unselected ARCC pts. Efforts are ongoing to retrospectively collect tumor samples for an exploratory biomarker analysis. ClinicalTrials.gov NCT00997009. Partially supported by Merck Serono. Clinical trial information: NCT00997009.

Effect of sentinel lymph-node biopsy alone on the morbidity of the surgical treatment of early cervical cancer: Results from the prospective randomized study Senticol2. *First Author: Patrice Mathevet, CHU Vaudois, Lausanne, Switzerland*

Background: Sentinel lymph node (SLN) biopsy is now part of the management of early cervical cancer. Feasibility and low false negative rate in case of bilateral detection have been demonstrated by several studies. However, patients' benefits have not been demonstrated after SLN biopsy only. **Methods:** A multicenter prospective randomized study comparing SLN biopsy alone (Arm A) versus SLN biopsy + pelvic lymph-node dissection (Arm B) in early cervical cancer, has been carried out in France. Patient's eligibility criteria were: 1) FIGO stage IA/IB1/IIA1 cervical cancer, 2) squamous or adenocarcinoma histology, 3) non pregnant patients aged $>$ 18. All patients underwent SLN identification with a combined method (technetium + Patent blue). Patients with negative SLN at per-operative assessment were randomized. The primary objective was to compare the surgical morbidity of the 2 arms. The planned sample size was 124 patients per arm for a type I error rate of 5% and a one sided test. The protocol has been funded by the French NCI and has been reviewed by an Ethical Committee. **Results:** 267 patients were included between March 2009 and July 2012, and 61 patients were not randomized due to: unilateral or no SLN detection, positive SLN at frozen sections and other reasons. Of the remaining 206 patients, 105 were in arm A and 101 in arm B. The analysis was performed in intention-to-treat. The median number of SLN was 3 per patient and 1 per side. No false negative case was identified in arm B. The surgical morbidity related to the lymph-node dissection was largely and significantly reduced in arm A: 33 cases (31.4%) vs 52 cases (51.5%) in arm B, (p = 0.0046, X2test) and major morbidity related to the lymph-node dissection was also reduced: 1 case in arm A vs 6 cases in arm B (p = 0.06). The rate of early post-operative neurological symptoms was significantly reduced in arm A (7.8% vs 20.6% in arm B, p = 0.01). **Conclusions:** SLN biopsy may improve the management of early cervical cancer, as it induced less surgical morbidity than full pelvic lymphadenectomy. This study leads to morbidity-sparing approaches in cervical cancer treatment incorporating SLN biopsy alone in negative SLN patients. Clinical trial information: NCT01639820.

CT perfusion as an early biomarker of treatment efficacy in advanced ovarian cancer: An ECOG-ACRIN and NRG GOG study. *First Author: Ting-Yim Lee, Lawson Health Research Institute, London, ON, Canada*

Background: GOG-0262 is an advanced stage ovarian cancer phase III trial comparing standard paclitaxel (q3 week)/carboplatin to dose-dense paclitaxel (weekly)/carboplatin with and without bevacizumab per physician choice. ACRIN 6695's primary objective was to determine whether CT perfusion (CTP) parameters are prognostic of progression-free survival (PFS) at 6 months (PFS-6) in a cohort of GOG-262 patients. **Methods:** FIGO stage III or IV patients with suboptimal surgical cytoreduction or undergoing neoadjuvant therapy were recruited and underwent CTP studies before (T0) and at 3- (T1) and 4-weeks (T2) after chemotherapy initiation. Target lesion blood flow (BF) and blood volume were derived with CTP software (GE Healthcare). The association of BF changes from baseline to T2, dichotomized at zero ($\Delta BF_{\pm}$), and the response rate (best confirmed response by RECIST criteria) and PFS-6 rate were assessed with Fisher's exact tests. Cox regression model was used to assess the association between $\Delta BF_{\pm}$ and time-to-progression (TTP) and overall survival (OS). **Results:** From August 2011 to July 2013, 120 patients were screened, yielding 76 evaluable (with both T0 and T2 CTP studies analyzable) patients from 19 centers. The median age and TTP of those 76 patients were 61 (range 25-87) years and 427 (95% CI: 372-505) days. Overall response and PFS-6 rates were 74% (56/76) and 96% (73/76), respectively. 11/76(14%) patients had increase in tumor BF from baseline to T2 (positive $\Delta BF_{\pm}$). Positive $\Delta BF_{\pm}$ were significantly associated with lower response rate (45% vs. 78%, p = 0.03) and shorter TTP (median TTP 335 vs. 457 days, HR 2.9, 95% CI: 1.3-6.4, p = 0.008); and a trend towards lower PFS-6 rate (82% vs. 98%, p = 0.053). The significant association between $\Delta BF_{\pm}$ and TTP remained after adjusting for age, baseline tumor volume, change in tumor volume or surgery status (adjuvant vs. neoadjuvant) individually ($p < 0.02$). $\Delta BF_{\pm}$ was not significantly associated with OS (p = 0.28). **Conclusions:** CTP parameters measured within 4 weeks of initiating therapy may provide early prognostic information for treatment response and TTP, and could be used to refine treatment interventions for advanced ovarian cancer in future clinical trials. Clinical trial information: NCT01167712.

The role of PET-CT in treatment decision making for women with locally advanced cervical cancer. *First Author: Lorraine Margaret Elit, McMaster University, Hamilton, ON, Canada*

Background: Women with locally advanced cervical cancer (LACC) are treated with concurrent chemotherapy and radiation therapy (CRT) with curative intent. Pre-treatment staging is important to define the extent of disease and guide therapy. Staging with ^{18}FDG PET-CT may detect more extensive disease compared to usual CT. Although promising, the existing data on PET-CT for this indication is based on small retrospective studies. OCOG conducted a randomized trial to address this question. Our objective was in patients with LACC, to determine the added value of staging with PET-CT over usual CT abdomen-pelvis in terms of the treatment received. **Methods:** Women with FIGO Stages IB-IVA carcinoma of the cervix who were candidates for CRT were randomized 2:1 to PET-CT or CT abdomen-pelvis. Stratification was by center, MRI, and Stage (1B1-2A and 2B – 4A). Treatment delivered was classified as standard pelvic CRT of curative intent; more extensive CRT of curative intent e.g. extended-field radiation (CRT-EF); or palliative treatment of non-curative intent (e.g. symptom management, radiation, chemotherapy or both). Treatment received was adjudicated by experts unaware of arm. **Results:** 171 women were randomized to PET-CT (113) or CT (58) between Apr 2010 and Jun 2014. The arms were well-balanced with a slightly higher rate of Stage 3B in the PET-CT arm (21%) compared to the CT (14%) arm. MR staging was performed in 68%. In the PET-CT arm, 59.8% of subjects had standard pelvic CRT, 34.8% had CRT-EF, and 5.4% had palliative/non-curative therapy. The corresponding data for CT arm was 73.2%, 21.4% and 5.4%. There was no difference detected in the rates of more extensive CRT of curative intent or palliative treatment between PET-CT (40.2%) versus CT (26.8%), OR 1.90, 95%CI 0.92, 3.92, p = 0.08). At a median FUP of 25.8 months, there have been 13 deaths (11.5%) in the PET-CT arm and 7 (12.0%) in the CT arm. **Conclusions:** We were unable to detect a difference in treatments received with the addition of PET-CT. Improvement in CT quality and use of MRI may explain the negative result. In an era of cost constraint, the additional benefit from PET appears to be limited in women with LACC. Clinical trial information: NCT00895349.

Utility of PET-CT to evaluate retroperitoneal lymph node metastasis in high risk endometrial cancer. *First Author: Mostafa Atri, University Health Network, Toronto, ON, Canada*

Background: To assess if PET-CT improves accuracy of CT to detect lymph node (LN) metastasis in high risk endometrial cancer. **Methods:** This was a prospective HIPAA compliant ACRIN/GOG multicenter trial. Patients underwent contrast enhanced PET-CT followed by pelvic and abdominal lymphadenectomy. Seven independent blinded readers reviewed PET-CT and CT only images in different sessions at least one month apart. Region correlation was performed between pathology and review results for abdomen (right and left para-aortic, right and left common iliac) and pelvis (right and left external iliac and right and left obturator) regions. Abdomen and pelvic regions were combined, respecting laterality, to calculate accuracy values at participant level. Reference standard was pathology of surgically removed LNs. Reader average sensitivities/specificities of PET-CT vs CT were compared with generalized linear mixed models. Reader average AUCs were compared with Obuchowski's method. Fleiss' kappa was used to assess reader agreement. **Results:** A total of 207 patients had PET/CT and pathology proof in the abdomen from 215 patients enrolled between January 2010 and June 2013.Twenty-three of 207 patients had metastasis to abdominal LNs. All 23 abdominal positive and 26 randomly selected abdominal negative patients were used for reader study. Reader study cases were from 36 to 81 years old (mean; 62.7±9.6). Cancer stages were: I = 30, II = 14, III = 5; sixteen endometrioid, 17 serous, 6 carcinosarcoma or MMT, 6 mixed epithelial carcinoma, and 4 others. Three were 5 grade 2, 20 grade 3, and 24 unknown. Mean sensitivities of PET-CT/CT alone in abdomen were 0.65 (CI:0.57,0.72)/0.50 (CI:0.43,0.58) (p = 0.01) and in pelvis 0.65 (CI:0.57,0.72)/0.48 (CI:0.41,0.56) (p = 0.004). Corresponding mean specificities were 0.88 (CI:0.83,0.92)/0.93 (CI: 0.89,0.96) (p = 0.11) and 0.93 (CI:0.86,0.96)/0.89 (CI:0.82,0.94) (p = 0.27). Mean AUCs were 0.78 (CI:0.66,0.89)/0.74 (CI:0.63,0.86) (p = 0.39) and 0.82 (CI:0.71,0.92)/0.73 (CI:0.63,0.84) (p = 0.02). Agreement for PET/CT was 0.81in both abdomen and pelvis. **Conclusions:** Addition of PET to diagnostic CT significantly increased diagnostic accuracy to detect LN metastasis in abdomen and pelvis. Clinical trial information: ACRIN6671GOG0233.

5525 Poster Session (Board #83), Sat, 1:15 PM-4:45 PM

Randomized phase III trial of carboplatin/paclitaxel alone (CP) or in combination with bevacizumab followed by bevacizumab (CPB) and secondary cytoreduction surgery in platinum-sensitive recurrent ovarian cancer: GOG0213, an NRG Oncology/GOG Study—Analysis of patient reported outcomes (PRO) on chemotherapy randomization. *First Author: Karen Basen-Engquist, The University of Texas MD Anderson Cancer Center, Houston, TX*

Purpose: GOG 213 is a bifactorial, phase III, randomized trial studying the efficacy and tolerability of the incorporation of B and secondary cytoreduction in women with platinum sensitive recurrent EOC. The primary endpoint was OS. Here we report intervention related PROs. **Methods:** PRO's were assessed using the ovarian Functional Assessment of Cancer Therapy-Trial Outcome Index (FACT-O TOI, QoL endpoint for chemotherapy objective), treatment side effects related to B (TSE-B), physical function (PF) subscale of the Rand SF-36 (QoL endpoint for surgical randomization), and treatment side-effects related to surgery (TSE-Surg). Assessment time points were baseline, prior to cycles 1, 3 and cycle 6, 6 mo. after cycle 1, and 12 mo. after cycle 1. QoL scores were compared using a linear mixed model adjusting for baseline score, age, and assignment to secondary surgery. Mixed effects mixed distribution model evaluated treatment differences in physical functioning on the RAND SF-36. **Results:** Patients randomized to CT (n = 298 (88%)) or CTB (n = 302 (90%)) were evaluable for QoL. Treatment compliance was 93% at baseline, 88% at cycle 3, 83% at cycle 6, 82% at 6 months and 78% at 12 months. More CTB patients completed PRO assessments (P = 0.037). FACT-O TOI scores at baseline were similar. Subscales of FACT-O showed no differences in TSE-Bev, except pre-cycle 3 physical well-being, which was negatively impacted by treatment (p = 0.028). CPB patients had significantly worse physical functioning (P = 0.0156): treatment difference of 3.4 points (95% CI: 0.05-6.7, p = 0.048) at cycle 3 and 6.8 points (95%CI: 3.0-10.6, p = 0.0004) at cycle 6. **Conclusion**: Treatment with CPB was not associated with a significant difference in health-related QoL measured by the FACT-O TOI. While receiving CPB, patients may experience lower physical functioning with recovery to baseline during maintenance B. Clinical trial information: NCT00565851.

5526 Poster Session (Board #84), Sat, 1:15 PM-4:45 PM

Clinical characteristics and survival outcomes in *BRCA1*-methylated epithelial ovarian cancer (Bmeth-OC): A pooled analysis of data for 1,278 patients across five studies. *First Author: Roshni Deepa Kalachand, Department of Medical Oncology, Beaumont Hospital, Dublin, Ireland*

Background: *BRCA1/2* mutations render ovarian cancers (OC) homologous recombination deficient (HRD) and thus sensitive to platinum and PARP inhibitors. Data on *BRCA1* promoter methylation in OC, another potential biomarker of HRD, are conflicting and limited. **Methods:** We searched PubMed and ASCO/ESMO abstracts for studies with survival outcomes in Bmeth-OC. Individual patient data were obtained from 5 studies. Associations between clinical characteristics and Bmeth-OC were determined using the Cochran-Mantel-Haenszel test. Progression-free (PFS) and overall survival (OS) differences between Bmeth-OC and non-Bmeth-OC (and between Bmeth-OC, *BRCA1/2*-mutated OC and *BRCA1/2*-wild type non-Bmeth-OC where data available) were estimated with Kaplan-Meier analysis, adjusting for cohort. **Results:** We obtained data for 164 patients (pts) with Bmeth-OC and 1114 pts with non-Bmeth-OC (Bmeth-OC frequency = 12.8%). Median age was 59 (range 26-93) and median follow-up was 31 months (range 0-203). 72.7% of OCs were high grade serous. 91.3% of pts received adjuvant platinum-based chemotherapy. Bmeth-OC was associated with high grade (85.4% vs 80.7% of non-BmethOC, p = 0.016) and younger age (< 59: 58.5% vs 47.1% of non-BmethOC, p = 0.012), but not stage, histology, cytoreduction or platinum sensitivity. There was no difference in median PFS (18.7 vs 19.1 months, p = 0.42) or OS (44.3 vs 46 months, p = 0.62) between Bmeth-OC and non-Bmeth-OC. *BRCA1/2* mutation status was assessed in 3 cohorts (639 pts). *BRCA2*-mutated OC had a better median PFS and OS compared to *BRCA1*-mutated OC, Bmeth-OC, and *BRCA1/2*-wild type non-Bmeth-OC (PFS: 26 vs 17.6, 15.6, 15.8 months, p = 0.025; OS: 74.3 vs 49.3, 41.9, 44mths, p = 0.003).On multivariate Cox analysis including clinical variables, *BRCA2* mutation but not *BRCA1* mutation/methylation had a significant effect on OS/PFS (p = 0.001, HR = 0.44 95%CI [0.27-0.70]/p = 0.001, HR = 0.5 95%CI [0.33-0.77]). **Conclusions:** *BRCA1* methylation occurs in OC in younger pts, but has no impact on survival. *BRCA2* mutation, in contrast to *BRCA1* mutation/methylation, is an independent prognostic factor for improved survival in OC.

5527 Poster Session (Board #85), Sat, 1:15 PM-4:45 PM

Efficacy and safety comparison between belotecan and topotecan in patients with recurrent or refractory ovarian cancer: A multi-center, randomized, open-labelled, parallel-group phase IIb trial. *First Author: Hee Seung Kim, Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, South Korea*

Background: Belotecan is a camptothecin derivative with anti-tumor properties. Previous studies suggested the feasibility of belotecan-based chemotherapy for patients with primary or recurrent ovarian cancer. Thus, we conducted a phase IIb trial to compare the efficacy and safety between belotecan and another derivative of camptothecin, topotecan, in patients with recurrent or refractory ovarian cancer. **Methods:** Patients with recurrent or refractory ovarian cancer were randomized to receive belotecan 0.5 mg/m^2 (B-arm) or topotecan 1.5 mg/m^2(T-arm) intravenously for 5 consecutive days every 3 weeks till 6 cycles or disease progression. The primary endpoint was overall response rate based on RECIST or GCIG criteria, and secondary endpoints were progression-free survival (PFS), overall survival (OS) and adverse events according to NCI-CTCAE version 4.0. **Results:** One hundred and forty one patients were randomized from January 2011 to June 2014. Among all patients, 140 were eligible in full analysis (FA) set where patients received at least one dose (B-arm, n = 71; T-arm, n = 69), and 130 were eligible in per protocol (PP) set where patients completed the study protocol (B-arm, n = 66; T-arm, n = 64). Clinico-pathologic characteristics were not different between the two arms. ORR was not different between B- and T-arms in FA and PP sets (29.6% vs. 26.1%, p = 0.645; 30.3% vs. 25%, p = 0.499). Median values of PFS in B- and T-arms were 26.4 vs. 17.3 months in FA (HR = 0.69; 95% CI 0.41-1.16) and PP sets (HR = 0.68; 95% CI 0.39-1.16) without significant difference. However, OS was improved in B- versus T-arm in FA set with marginal significance (median values, 37.1 vs. 21.3 months, log-rank p = 0.053; HR = 0.60; 95% CI 0.35-1.01), and PP set (median values, 37.1 vs. 24.9 months, log-rank p = 0.023; HR = 0.53; 95% CI 0.31-0.93). Grade 3 or 4 adverse events were not different between the two arms. **Conclusions:** Belotecan may have a similar response and toxicity rates to topotecan in patients with recurrent or refractory ovarian cancer. Moreover, belotecan may prolong OS when compared with topotecan in these patients. Clinical trial information: NCT01630018.

5528 Poster Session (Board #86), Sat, 1:15 PM-4:45 PM

Multicentre trial of carboplatin/paclitaxel versus oxaliplatin/capecitabine, each with/without bevacizumab, as first line chemotherapy for patients with mucinous epithelial ovarian cancer (mEOC). *First Author: Martin Eric Gore, Royal Marsden Hosp NHS Trust, London, United Kingdom*

Background: Advanced mEOC responds poorly to standard therapy. It comprises < 8% pts in ovarian cancer trials, so it is difficult to examine treatment effects in this subgroup. We conducted the first ever randomised trial specific for this rare subgroup (4 regimens). **Methods:** mEOC/GOG 241 is a multi-centre randomised phase II trial (UK, USA) in chemo- naive pts with advanced/recurrent disease. Six 21-day cycles of chemotherapy were given to each of 4 arms: (A) carboplatin (AUC 5/6) + paclitaxel (175mg/m^2); (B) oxaliplatin (130 mg/m^2) + capecitabine (850mg/m^2 bd; D1-14); (C) carboplatin/paclitaxel with bevacizumab (15mg/kg); (D) oxaliplatin/capecitabine with bevacizumab. Bevacizumab was given concurrently, then alone 3-weekly for 12 more cycles. 332 pts required to detect 5 month increase in median PFS for oxaliplatin/capecitabine (B+D), or adding bevacizumab (C+D). **Results:** Trial stopped early (2013) due to poor accrual (median follow up 23 months; 31 progressions/deaths). 50 pts recruited: n = 13, 13, 11, 13 in arms A-D. Median age 54 yrs; FIGO stage II (n = 15), III (n = 25), IV (n = 4), recurrent (n = 6); ECOG 0 (n = 34), 1 (n = 15), 2 (n = 1). 62, 85, 82, 69% in arms A-D completed 6 cycles of combination therapy, and 36, 46% completed 12 maintenance cycles of bevacizumab (arms C,D). 2,2,4,2 pts (arms A-D) had complete/partial response. Median PFS 10.1 (B+D) vs 15.4 (A+C) months; hazard ratio (HR) 1.08, 95% CI 0.53-2.19, p = 0.83. Median PFS 17.4 (C+D) vs 8.8 (A+B) months, HR 0.88 95% CI 0.43-1.79, p = 0.72. Grade 3-4 toxicities (most common: neutropenia, & hypertension for bevacizumab) were seen in 62, 62, 55, 92% pts in arms A-D (total 4 pts with grade 4). After specialist pathology review n = 36 so far, 19 were considered to not have primary mEOC (many metastatic disease). **Conclusions:** Setting up & conducting this international trial was challenging in this rare group; correctly assigning histological diagnosis was difficult. Bevacizumab may delay progression (ITT analyses), but without sufficient pts no conclusions can be made. Primary mEOC is rarer than previously thought so different approaches are needed to evaluate new therapies. Clinical trial information: NCT01081262.

5529 Poster Session (Board #87), Sat, 1:15 PM-4:45 PM

Efficacy and safety of olaparib monotherapy in a subgroup of patients with a germline *BRCA1/2* mutation and advanced ovarian cancer from a Phase II open-label study. *First Author: Susan M. Domchek, Basser Research Center for BRCA at the Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Olaparib (Lynparza), an oral PARP inhibitor, has demonstrated antitumor activity in patients (pts) with *BRCA*-mutated(m) ovarian cancer. Data from the overall cohort of pts in this Phase II study (NCT01078662) have been reported (Kaufman *et al. JCO* 2014). Presented here are data from a subgroup of pts with germline (g)*BRCA*m ovarian cancer, stratified by prior lines of chemotherapy (< 3 or ≥ 3) and platinum sensitivity. **Methods:** Pts were treated with olaparib 400 mg twice daily (bid; capsule formulation) monotherapy until disease progression according to RECIST v1.1. Objective response rate (ORR) and duration of response (DoR) were assessed for pts with measurable disease at baseline (n=167). Safety and tolerability were assessed for all pts (n = 193). **Results:** Of the pts with measurable disease at baseline, 30 and 137 had received < 3 and ≥ 3 prior lines of chemotherapy, respectively. Adverse events (AEs) most commonly causally related to olaparib were nausea (107/193 pts, 55%), fatigue (99 pts, 51%) and anemia (60 pts, 31%; grade ≥ 3 in 36/193 [19%]). Twenty pts (10%) had a serious AE causally related to olaparib. Two pts developed leukemia and one pt myelodysplastic syndrome; all three had been heavily pretreated. **Conclusions:** Olaparib 400 mg bid (capsule form) monotherapy demonstrated notable antitumor activity in g*BRCA*m pts with advanced ovarian cancer, including heavily pretreated, platinum-resistant pts. No new safety signals were identified. Clinical trial information: NCT01078662.

5530 Poster Session (Board #88), Sat, 1:15 PM-4:45 PM

A GINECO phase I study evaluating lenalidomide (Le) combined with pegylated liposomal doxorubicin (PLD) and carboplatin (C) in late (>6 months) recurrent ovarian cancer (LROC) patients (pts). *First Author: Frédéric Selle, Medical Oncology, Hôpital Tenon, Paris, France*

Background: Le is a thalidomide analogue with both immunomodulatory and anti-angiogenic properties. Le has shown efficacy and good tolerability as single agent for LROC pts (Selle F, et al. Ann Oncology 2014). **Methods:** LROC pts were enrolled in cohorts of 3 to 6 pts and treated with PLD 30 mg/m2 and C AUC 5 day (d)1 q4 weeks in combination with daily oral escalation dose of Le (15, 20 and 25 mg/d) according to different schedules (A: 21 consecutive days from d1; B: 21d from d2; C: 21d from d7; D: 14d from d2). Dose limiting toxicities (DLT) were defined as: treatment delay (> 14d), grade (Gr) 3 febrile neutropenia, Gr 4 neutropenia or Gr 4 thrombocytopenia lasting more than 7 d, bleeding with platelet transfusion and all other Gr ≥ 3 toxicity (except vomiting) occurring at cycle 1. Completion of the 6 planned cycles without inacceptable toxicity defined feasibility of the regimen. Secondary objectives were response, progression-free (PFS) and overall survival (OS) rates. **Results:** 22 pts were enrolled up to 01/2014 with a median age of 61.4 years (47-73). Pts characteristics were: serous (82%), previous lines (one 68%, two 32%), median platinum-free interval (PFI) 11.4 months and ECOG 0 (73%). Safety: all the 4 schedules were evaluated at a 15mg/d Le dose. With schedule A&B, 2DLT/3pts and 3DLT/4pts were observed. DLT was cycle delay > 14d for neutropenia (2pts) or neurotoxicity (1pt), Gr3 thrombosis (1pt) and Gr3 visual acuity decreased (1pt). With schedule C&D, 1DLT/9pts (Gr3 rash) occurred at cycle 1, only 1 pt completed the 6 planned cycles without dose reduction and 6 pts stopped early for toxicity (hematotoxicity for 5pts). Efficacy: complete and partial responses were observed in respectively 10% and 29% of pts. Median PFS and OS were 9.2 months (95% CI, 7.4-11) 28 months (95% CI, 18.9-37.1) respectively. **Conclusions:** Lenalidomide combined with PLD-C was not feasible at the dose and schedules evaluated, mainly due to cumulative hematologic toxicity. Clinical trial information: NCT01111903.

5531 Poster Session (Board #89), Sat, 1:15 PM-4:45 PM

Phase II randomized trial of neoadjuvant (NA) chemotherapy (CT) with or without bevacizumab (Bev) in advanced epithelial ovarian cancer (EOC) (GEICO 1205/NOVA TRIAL). *First Author: Yolanda García, Corporació Sanitaria Universitaria Parc Taulí, Universitat Autonoma de Barcelona, Barcelona, Spain*

Background: First-line carboplatin(C)-paclitaxel(P) and Bev has proved to be an active combination after primary debulking surgery and improved overall survival in suboptimal resected advanced EOC patients (pts). However, the role of Bev in the NA setting has not been well defined yet. **Methods:** We performed a phase II randomized open label multicentric study in 66 pts with high grade serous or endometroid EOC, FIGO stage III-IV, ECOG 0-2, considered unresectable in whom NA CT and interval debulking surgery (IDS) were planned. Main exclusion criteria were intestinal occlusion and contraindication for Bev therapy. Pts were randomized to four courses of triweekly C AUC 6 and P 175 mg/m2 iv alone or with at least 3 courses of bev 15 mg/kg i.v. every 3 w. in experimental arm. The primary endpoint was the complete macroscopic response rate at the time of IDS. Secondary objectives were safety, surgical feasibility, optimal surgery rate, RECIST 1.1 and GCIG response rate. Biomarker analysis were performed in pre and post biopsies. All pts received 3 additional courses of CT and Bev after IDS followed by maintenance Bev up to complete 15 month. **Results:** We report the preliminary data of 64 pts. Clinical pts characteristics were well balanced with median age 59.9 y.o and a 34.4% stage IV. No differences in the primary endpoint were found (1/32 Control Arm and 0/32 Bev Arm) but there was a higher rate of surgical feasibility in the Bev Arm (64 vs 88%). Optimal surgery rate also favored the Bev arm (77.7 vs 86.4%) and there wasn't any patient deemed unresectable at the time of surgery in the Bev arm (2 vs 0). None of these figures were statistically significant difference. There were lower rates of serious adverse events (grade 3-4) in bev arm (40.6 vs 18.8%, p = 0.055). Three Bev related adverse events of special interest were observed in 3 pts (1 G3 entero-vaginal fistulae, 1 surgical dehiscence, 1 deep venous thrombosis). **Conclusions:** Our preliminary data have shown that NA bev seems feasible and could improve the surgical outcomes in advanced EOC considered initially unresectable. Updated clinical and translational data will be provided. Clinical trial information: NCT01847677.

5532 Poster Session (Board #90), Sat, 1:15 PM-4:45 PM

Use of homologous recombination deficiency (HRD) score to enrich for niraparib sensitive high grade ovarian tumors. *First Author: Keith Matthew Wilcoxen, TESARO, Inc., Waltham, MA*

Background: The therapeutic potential of PARP inhibitors is predicted to extend beyond patients with germline BRCA mutations ($BRCA^{mut}$) to those with homologous recombination deficient (HRD) cancers. An HRD test is being applied to patient samples to identify BRCA mutated tumors, provide a categorical determination of tumor HRD, and determine an enrichment strategy for patients with tumors that are sensitive to niraparib treatment. **Methods:** Archival FFPE tumor tissue obtained from ovarian cancer patients enrolled in an ongoing Phase III clinical study (ENGOT-OV16/NOVA, NCT 01847274) and a living tumor bank was subjected to HRD testing. The final HRD score is a numeric output ranging from 0-100. A predefined cut-off score of 42 was utilized to determine HRD status of each tumor and classify it as HR deficient (HRD score $\geq$ 42) or non-deficient (HRD score $<$ 42). Classification of BRCA mutations from tissue was based on analysis criteria consistent with the laboratory's approved diagnostic BRCA testing. Niraparib efficacy was evaluated utilizing a living tumor bank of orthotopic patient-derived ovarian xenografts. Intraperitoneal tumorgrafts were monitored for tumor growth with twice-weekly transabdominal ultrasound imaging. **Results:** One hundred and six high grade serous ovarian tumors from a living tumor bank were evaluated for HRD, BRCA1/2 mutations, and BRCA1 promoter hypermethylation. Twenty six tumors (25%) were BRCA deficient (a deleterious BRCA1/2 mutation or BRCA1 hypermethylation with a concomitant loss of heterozygosity). All BRCA1/2 deficient tumors had an HRD score of 42 or greater, with the exception of one tumor. The in-vivo response to niraparib monotherapy has been evaluated in 20 unique tumor models across a range of HRD scores. All responding tumors had an HRD score of 42 or above, irrespective of BRCA deficiency. **Conclusions:** HRD testing of ovarian cancer was predictive of BRCA deficiency. Response to niraparibwas only observed in HRD positive (HRD+) tumors. Our data are supportive of the use of HRD testing to enrich for niraparib responders in high grade ovarian cancer.

5533 Poster Session (Board #91), Sat, 1:15 PM-4:45 PM

The influence of polypharmacy on grade III/IV toxicity, prior discontinuation of chemotherapy and survival in recurrent ovarian cancer patients: An individual participant data meta-analysis of the North-Eastern German Society of Gynecological Oncology (NOGGO) of 1,213 patients. *First Author: Hannah Woopen, Department of Gynecology, European Competence Center for Ovarian Cancer, Charité, University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: In ovarian cancer patients prevalence of comorbidity and quantities of prescribed comedications increase with age. We aimed to evaluate the influence of polypharmacy on grade III/IV toxicity, prior discontinuation of chemotherapy and survival. **Methods:** Synthesized raw data of three phase II/III studies ("Tower", "Topotecan phase III" and "Hector") of the North-Eastern German Society of Gynecological Oncology (NOGGO) including 1213 patients were analyzed using logistic regression and cox regression analyses. **Results:** In our analysis 349 patients (28.8%) were older than 65 years at initial diagnosis. Most patients were in an advanced stage at the time of diagnosis (1047 patients FIGO III/IV, 86.3%). Hematological grade III/IV toxicity was documented in 715 cases (58.9%), non-hematological grade III/IV toxicity occurred in 531 cases (43.8%). While 110 patients (9.1%) were naive to comedication, 530 patients (43.7%) were prescribed less than five co-drugs, 683 patients (56.3%) were treated with five or more co-drugs, and 267 (22.0%) were treated with ten or more co-drugs. Most frequent comedications were beta-blockers (211 cases, 17.4%), diuretics (163 patients, 13.4%) and ACE-inhibitors (133 patients, 11.0%). In the multiple regression models, an increasing amount of comedications was associated with overall ($p < 0.001$; OR 1.120), hematological ($p < 0.001$; OR 1.056) and non-hematological ($p < 0.001$; OR 1.134) toxicity. Prior discontinuation of therapy was not associated with the amount of comedications ($p = 0.196$). Increasing number of comedication was not associated with overall survival ($p = 0.068$). **Conclusions:** Our synthesized data analysis suggests that polypharmacy in ovarian cancer recurrence may be a clinically useful predictor of increased risk of grade III/IV toxicity during chemotherapy. Patients with increasing amount of comedication had no disadvantage regarding survival. Hence, polypharmacy should not be a criterion for exclusion of clinical studies in ovarian cancer.

5534 Poster Session (Board #92), Sat, 1:15 PM-4:45 PM

Characteristics of homologous recombination deficiency (HRD) in paired primary and recurrent high-grade serous ovarian cancer (HGSOC). *First Author: Jai Narendra Patel, Levine Cancer Institute, Charlotte, NC*

Background: Defects in the HRD pathway, particularly those involving *BRCA1/2*, have a major impact on the response to DNA damaging platinum-based therapy used in patients with HGSOC. The objective of this study was to assess characteristics of HRD in paired primary and recurrent HGSOC specimens. **Methods:** HRD scores were determined in paired primary and recurrent specimens of HGSOC from 25 patients treated with adjuvant carboplatin and paclitaxel. *BRCA1/2* mutation and *BRCA1* methylation (including loss of heterozygosity (LOH) status), and HRD scores were characterized using tumor DNA-based assays. **Results:** All 50 samples analyzed yielded *BRCA1/2* mutation and *BRCA1* methylation assay data and 7 failed HRD analyses, leaving 19 primary-recurrent pairs available for comparative analysis of HRD. *BRCA1/2* mutations (3/25, 12%) comprised only *BRCA1*, and LOH at *BRCA1* was observed in all mutated tumors. All 3 mutant pairs had high HRD scores (range 46-76, 1 missing value in the primary). No reversion of mutations was observed in recurrent samples. In 3 primary-recurrent pairs with methylation and LOH at the *BRCA1* locus, high HRD scores (range 55-72) were observed. A fourth pair was below the methylation threshold in the primary tumor but had high HRD scores in both primary and recurrent. Two primary-recurrent pairs had high HRD scores with intact *BRCA1/2*. HRD scores between primary and recurrent samples were highly correlated ($r^2 = 0.91$). Scores were somewhat more likely to be higher in the recurrent tumor than in the primary, but the difference was not significant (mean = 2.6, paired t-test p-value = 0.11). Comparison of the genomic profile in paired samples revealed that while a number of tumors acquired additional genomic rearrangements that were different between the primary and recurrent sample, this did not significantly impact the HRD score. **Conclusions:** All markers of HRD examined were maintained between the primary and recurrent specimen. High HRD scores were prevalent (42%) and primarily linked to *BRCA1* mutation and methylation. These data suggest that characterization of recurrent tumors may not yield alternative treatment strategies compared to analysis of the primary tumor.

5535 Poster Session (Board #93), Sat, 1:15 PM-4:45 PM

Role of HE4, CA125, and ultrasound in risk assessment in pelvic mass patients: Results from a prospective, multicentric study. *First Author: Elena Ioana Braicu, Charité – Universitätsmedizin Berlin, Department of Gynaecology, European Competence Center for Ovarian Cancer, Charité Campus Virchow Klinikum, Berlin, Germany*

Background: Ovarian cancer (OC) lacks of specific symptoms and biomarkers for early diagnosis. Advanced stages are associated with poor survival. CA125 and HE4 are overexpressed in OC. Their role in early diagnosis is controversial discussed. Ultrasound criteria (e.g. IOTA algorithms) seem to improve the sensitivity and specificity for risk assessment. **Methods:** In a prospective, multicentric study performed in 676 pelvic mass patients, transvaginal ultrasound together with blood sampling and biomarker analysis were performed. All patients had an ovarian (including paraovarian and tubal) mass and underwent a standardized ultrasound examination, according to IOTA criteria, prior to surgery. ROMA algorithm combining CA125, HE4 and menopausal status, was used to distinguish between benign and malignant disease. An online data base was provided for the prospective documentation of clinical parameters, ultrasound, surgical methods and histology. Patients were included at 7 clinics in Berlin. All samples were analyzed centralized at Labor Berlin. These results represent the analysis of the training cohort. **Results:** From the 676 patients, 57% were premenopausal, 13.3% were diagnosed with OC, 4.3% with borderline tumors, 0.2% Krukenberg tumors and 0.8% rare malignancies of the ovary. The area under the receiver operating characteristic curve (AUC) for the discrimination between benign and malignant tumors was for CA125 0.840 and 0.899, for HE4 0.860 and 0.885 and for ROMA 0.863 and 0.930 in pre-and postmenopausal patients, respectively. The IOTA LR2 model includes one clinical and five ultrasound predictors: age, presence of ascites, presence of papillations with detectable blood flow, maximum diameter of largest solid component, irregular cyst walls and presence of acoustic shadows. IOTA LR2 reached an AUC of 0.971 in premenopausal and of 0.748 in postmenopausal patients. **Conclusions:** HE4 performed slightly better than CA125 in risk assessment in premenopausal patients, nevertheless ultrasound criteria could best discriminate between benign and malignant disease in premenopausal patients. In postmenopausal patients, ROMA reached the best sensitivity and specificity.

5536 Poster Session (Board #94), Sat, 1:15 PM-4:45 PM

Is it time to change the primary endpoint in clinical trials in recurrent ovarian cancer (ROC)?: Symptom burden and outcomes in patients with platinum resistant/refractory (PRR) and potentially platinum sensitive ROC receiving ≥ 3 lines of chemotherapy (PPS ≥ 3)—The Gynecologic Cancer Intergroup (GCIG) Symptom Benefit Study (SBS). *First Author: Michael Friedlander, Prince of Wales Cancer Centre, Randwick, Australia*

Background: The primary endpoint for clinical trials in PRR/PPS ≥ 3 ROC is progression free survival (PFS) and symptom benefit is not typically measured or reported. The primary aim of GCIG SBS is to validate a patient-reported outcome measure (PROM), the MOST (Measure of Ovarian Symptoms and Treatment concerns), to assess symptom benefit from palliative chemotherapy (PC). The SBS recruited 949 patients; the secondary aims provide insights into symptom burden, patients' and clinician's expectations of treatment and outcomes in a "real world" setting. **Methods:** Patients with PRR/PPS ≥ 3ROC completed 4 PROMs before each cycle of chemotherapy. They reported expectation of symptom improvement. Clinicians documented the indications for PC, symptoms at baseline, adverse events and estimated the number of cycles patients would receive. **Results:** Palliation was the major indication for chemotherapy. The mean number of prior regimens was 2.6 (range 1-10). 60% of patients had PRR and 40% had PPS > 3 ROC. At baseline, most patients were symptomatic; 75% rated at least one symptom as moderate (³5 on a 0-10 scale) and 30% rated > 5 symptoms as moderate or worse. The symptoms included pain, fatigue, anorexia, abdominal distension, dyspnea, and constipation. Many had symptoms related to prior chemotherapy (e.g. neuropathy in 28%). Most patients had high expectations of symptom benefit from chemotherapy. 36% of patients received the predicted number of cycles. 25% of patients with PRR-ROC stopped treatment in < 8 weeks mainly due to progression/death. The median number of cycles and median PFS were 4 and 5.6m in PPS≥3ROC, and 3 and 3.7m in PRR ROC respectively. **Conclusions:** Patients with PRR/PPS ≥ 3ROC reported a number of significant baseline symptoms. They had high expectations of symptom improvement and this should be measured. The results underscore the importance of incorporating PROMs and including symptom benefit as primary endpoints in trials in patients with PRR/PPS ≥ 3 ROC. Clinical trial information: ACTRN12607000603415.

5537 Poster Session (Board #95), Sat, 1:15 PM-4:45 PM

First-in-human phase I/II dose-escalation study of IMAB027 in patients with recurrent advanced ovarian cancer (OVAR): Preliminary data of phase I part. *First Author: Ugur Sahin, TRON GGmbHI, Mainz, Germany*

Background: Ovarian cancer (OC) is a high medical need disease. Most patients (pts) relapse following initial therapy with limited therapeutic options. IMAB027 is the first-in-class monoclonal antibody (mAB) directed against claudin 6 (CLDN6), a cancer cell specific, embryonic tight junction protein and cancer stem cell marker. CLDN6 is expressed in > 55% of OCs and frequently in other cancer types. In preclinical models, IMAB027 executes potent anti-tumor activity via AB-dependent cellular cytotoxicity and complement-dependent cytotoxicity without mediating off-target toxicity. **Methods:** This first-in-human, open-label, dose escalation Phase I/II trial assesses the safety/tolerability (NCI-CTCAEv4.0), pharmacokinetics (PK) and clinical efficacy (RECIST 1.1) of IMAB027 in pts with advanced, recurrent CLDN6$^+$ OC. Here we report preliminary data on 12 pts enrolled in the Phase I part of the study as of August 15, 2014. Pts received 100, 300, 600, or 1000 mg/m^2 IMAB027 (n = 3/group) q3w IV until disease progression. **Results:** Pts had a median age of 64 (54–75) years, platinum-resistant disease and had received a median of 4 (3–9) lines of previous chemotherapies. All administered doses were safe and well tolerated, no DLT was observed and the MTD was not reached. 108 AEs have been recorded, all but 5 (4 grade [gr] 3, 1 gr 4) were gr 1–2 (82 and 21 AEs, respectively). 29 AEs were considered IMAB027 related (22 gr 1, 6 gr 2, 1 gr 3 as deemed by investigator). Five AEs (all in 1 pt) were classified as SAEs incl. one gr 2 hypersensitivity (study drug-related SUSAR). IMAB27-related SAEs were manageable and fully resolved. IMAB027 PK was well described with a 2-compartment model (mean AUC: 20,770–86,160 μg/mL×h; mean C_{max}: 151–611 μg/mL for 300–1000 mg/m^2). First signs of IMAB027 clinical activity were observed. **Conclusions:** This is the first clinical study to show effects of a therapy targeting CLDN6. Based on these preliminary Phase I data, IMAB027 may present a safe and well tolerated treatment option for women with recurrent, advanced OC. This warrants further clinical evaluation of IMAB027 in this patient population with a high medical unmet need. Clinical trial information: NCT02054351.

5538 Poster Session (Board #96), Sat, 1:15 PM-4:45 PM

Correlation of baseline clinical characteristics and laparoscopic extent of carcinomatosis of women with initially unresectable ovarian, tubal or peritoneal adenocarcinoma, in ANTHALYA study: A randomized, open-label, phase II study assessing the efficacy and the safety of bevacizumab in neoadjuvant. *First Author: Roman Rouzier, Insitut Curie, Paris, France*

Background: ANTHALYA study is a randomized non comparative clinical trial to evaluate the efficacy and safety of neoadjuvant chemotherapy associated with bevacizumab. It was a 2:1 randomization to receive carboplatin, paclitaxel with (experimental arm) or without (control arm) bevacizumab in the neoadjuvant setting. The extent of initial carcinomatosis is a major determinant of complete resection but is rarely well described. We report here the extent of carcinomatosis explored by laparoscopy of patients included in Anthalya and its correlation with baseline characteristics. **Methods:** Non-optimally resectable stage IIIC or IV ovarian cancer patients were eligible for this study. Disease extent was evaluated by a standardized form and the Fagotti score was calculated. Baseline clinical characteristics were compared to trials comparing primary debulking surgery and IDS. **Results:** This multicenter study was conducted in 15 centers: 205 patients have been screened and 95 patients were included. Median age was 63 years, ECOG performance status 0/1 was 92%, FIGO stage IIIc and IV was 70% and 30% respectively. Lesions assessed were larger than 5 cm in diameter in 63% of patients and larger than 10 cm in 28%. Median CA-125 was 1045 U/ml (over 500U/mL in 71% cases). Carcinomatosis explored by laparoscopy was present on diaphragmatic peritoneum and digestive tract in 96% patients and 89% patients, respectively. Fagotti score > = 8 was 46%. There were more stage IV patients with low Fagotti score than stage IIIC. There was a correlation between carcinomatosis extent and tumor size > 100mm. Baseline characteristics were balanced between arms and similar to previous neoadjuvant trials. **Conclusions:** ANTHALYA aims to determine the efficacy and safety of neoadjuvant bevacizumab. 46% of patients had high Fagotti score (> = 8). The evaluation of the carcinomatosis by laparoscopy present in 99% of patients confirms advanced disease tumor. ANTHALYA tumor and patient characteristics were similar to previous neoadjuvant trials. Clinical trial information: NCT01739218.

5539 Poster Session (Board #97), Sat, 1:15 PM-4:45 PM

Tumor biopsies in high grade ovarian cancer: Clinical utility and challenges for biomarker-directed therapy. *First Author: Michelle K. Wilson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Molecular profiling of tissue obtained with a biopsy aids detection of predictive and pharmacodynamic biomarkers to guide patient (pt) selection and treatment. This study assesses the safety and success rate of obtaining FFPE tissue for profiling in ARIEL2 - a large multi-center Phase II trial of rucaparib (oral PARP inhibitor) in high grade serous or endometrioid ovarian cancer (HGOC). **Methods:** Screening biopsy and archival tissue samples were required at study entry. Success was defined as the ability to obtain tissue with minimal pt risk and to complete Foundation Medicine's next generation sequencing-based comprehensive genomic profiling (NGS-based CGP), which requires tissue specimens with tumor nuclei ≥ 20% and volume ≥ 0.2 mm^3. Usability of tissue was assessed by biopsy site. **Results:** 201 pts were enrolled, with results available for 189 screening and 195 archival specimens. 8 pts had insufficient/inaccessible tissue at the time of biopsy. No serious biopsy-related adverse events were seen, with grade 1 pain in only 4 pts (2%). Omental/peritoneal disease was the most common site biopsied (table). Overall NGS-based CGP success rate was 83%. Greater success was seen with archival tissue (179; 92%) than screening biopsies (141; 75%). Unsuccessful profiling on biopsies was due to insufficient tumor nuclei in 36 pts (75%; med tumor nuclei 5%), inadequate volume in 10 (21%; med 0.08mm^3), and insufficient DNA yield in 2 (4%). Success was higher in nodal biopsies (84%) but lower in omental/peritoneal samples (63%). No pt tumors failed profiling on both screening biopsy and archival tissue. **Conclusions:** Research biopsies in HGOC are safe, feasible, and can be profiled with a NGS-based assay. Nodal biopsies had higher success rates compared to peritoneal/omental samples. Algorithms to guide biopsy site choice should be developed considering primary disease, radiologic appearance, and test in question. Clinical trial information: NCT01891344.

	Overall	Sufficient tumor nuclei and volume		Successful NGS-based CGP

5540 Poster Session (Board #98), Sat, 1:15 PM-4:45 PM

Molecular profiling of mucinous epithelial ovarian carcinomas (mEOC): Opportunities for clinical trials. *First Author: Michael Friedlander, Prince of Wales Cancer Centre, Randwick, Australia*

Background: mEOCs are an uncommon subset of epithelial ovarian cancers. Most patients have early stage disease at presentation and a good prognosis. However, patients with advanced stage disease at diagnosis are rare and can be difficult to distinguish from gastrointestinal metastases to the ovary. They have a poor prognosis and a low response to standard platinum /taxane chemotherapy. Rather than assigning chemotherapy according to the tissue of origin, selecting treatment based on the molecular characteristics of mEOC should be explored. Molecular profiling of mEOCs may help identify patients for clinical trials with targeted/novel therapies. **Methods:** 304 mEOCs referred to Caris Life Sciences (from 2009 - 2014) were evaluated. The diagnosis was based on reported pathology. Specific testing was performed per physician request and included a combination of sequencing (Sanger, NGS or pyrosequencing), protein expression (IHC), gene amplification (CISH or FISH), and/or RNA fragment analysis. **Results:** Alterations in the MAP Kinase pathway were common in mEOCs with the most frequent mutations observed in KRAS (49%). The mutation rate in BRAF was 3.5%. Alterations in the mTOR pathway occurred at a less frequent rate (PIK3CA 12% and PTEN 6%). PD-1 positivity was observed in 43% of tumor infiltrating lymphocytes and PD-L1 was positive in 14% of mEOCs. cMET overexpression was seen in 33% of cases, but no cMET amplification was seen. HER2 amplification (per ASCO-CAP guidelines) by FISH was observed in 11%. EGFR amplification occurred in 50% of cases and 57% had overexpression of EGFR by IHC.35% of mEOCs tested (37 of 105 cases) had P53 mutations. P53 mutated (n = 37) and wildtype (n = 68) mEOCs differed significantly in ER, PR and HER2 expression and BRAF, PIK3CA and PTEN mutation prevalence. **Conclusions:** Molecular profiling highlights the genomic heterogeneity and distinct molecular subsets in mEOCS and demonstrates the similarities with mucinous gastrointestinal cancers. There are a number of potential treatment targets and therapeutic options that could be investigated in phase 2 basket trials. Given the rarity of advanced stage mEOCs this will require international collaboration.

5541 Poster Session (Board #99), Sat, 1:15 PM-4:45 PM

Phase I study of intraperitoneal IL-12 plasmid formulated with PEG-PEI-cholesterol lipopolymer administered in combination with pegylated liposomal doxorubicin in recurrent or persistent epithelial ovarian, Fallopian tube, or primary peritoneal cancer patients: An NRG/GOG study. *First Author: Premal H. Thaker, Washington Univ School of Medicine, St. Louis, MO*

Background: EGEN-001 is an immunotherapeutic agent that comprises a human IL-12 plasmid that encodes for functional IL-12 and a synthetic DNA delivery system polyethyleneglycol-polyethyleneimine-cholesterol that facilitates plasmid delivery into cells. Ip injection of EGEN-001 is associated with increases in IL-12 levels and its downstream cytokines in the tumor environment without a significant increase in systemic circulation. The study's purpose was to assess safety and efficacy of escalating doses of EGEN-001 with pegylated liposomal doxorubicin (PLD) in recurrent or persistent epithelial ovarian, fallopian tube or primary peritoneal cancer (EOC) patients. **Methods:** Patient eligibility criteria: Females age ≥ 18 years with persistent or recurrent EOC. Patients were not required to have measurable disease and could have a biochemical recurrence; must have had one prior platinum-based chemotherapeutic regimen and up to two additional cytotoxic regimens; have adequate organ function. The trial was a standard 3 + 3 phase I dose escalation with patients receiving PLD every 28 days and EGEN-001 ip on days 1, 8, 15, and 22 of a 28 day cycle (table 1). Cycles were repeated every 28 days until disease progression. **Results:** Sixteen evaluable patients enrolled on trial from 9/2012-7/2012. No DLTs were found during cycle one of each dose level. The adverse side effects were 3 grade 3 anemia; 2 grade 3 abdominal pain; 7 grade 3 neutropenia and 2 grade 4 neutropenia. There were minimal side effects of fever, flu-like symptoms, and infusion or injection site reactions. A clinical benefit of 57.1% (PR = 21.4%; SD = 35.7%) was found in the 14 patients with measurable disease. The highest number of PRs were found at dose level 3 (28.6%) along with SD at 57.1%. The MTD was not achieved. Translational studies are ongoing. **Conclusions:** EGEN-001 in combination with PLD has clinical benefit in recurrent or persistent EOC and warrants further investigation with escalating doses of EGEN-001. Clinical trial information: NCT#01489371.

Dose Level	EGEN-001 (mg/m^2 ip)	PLD (mg/m^2 iv)
1	24	40
2	36	40
3	36	50

5542 Poster Session (Board #100), Sat, 1:15 PM-4:45 PM

A phase I/II trial of multiple dose VB-111 and weekly paclitaxel in recurrent platinum-resistant Müllerian cancer. *First Author: Richard T. Penson, Massachusetts General Hospital and Harvard Medical School, Braintree, MA*

Background: VB-111 is a gene therapy agent consisting of a non-replicating adenovirus vector (Ad-5) with a modified murine pre-proendothelin promoter leading to apoptosis of tumor vasculature by expressing a fas-chimera transgene in angiogenic endothelial cells. One hundred and sixty five patients have been treated so far with VB-111 across different cancer indications including Recurrent GBM, advanced well differentiated thyroid carcinoma with preliminary evidence of anti-tumor activity with no significant safety issues. Safety of VB-111 in combination with paclitaxel was evaluated for patients with recurrent Müllerian cancers in a phase I/II dose-escalation study. **Methods:** VB-111 was administered as a single intravenous infusion at escalating doses from $3x10^{12}$ (DL1&2) to $1x10^{13}$ viral particles (VPs) (DL3), followed by repeat doses every 2 months. Paclitaxel was given at 40 mg/m2 (DL1), and 80mg/m2 weekly (DL2-3), with a planned dose expansion at DL3. Assessments included safety, pharmacokinetics, pharmacodynamics, tumor response (CA125 and RECIST criteria) and progression free survival (PFS). **Results:** Fourteen patients at 2 US centers received up to 6 repeat doses of VB-111. Of these 10 received the higher dose ($1x10^{13}$ VPs). Patients were relatively older (Median age 65 (41-74)) with poor prognosis disease. No DLTs were observed. VB-111 was associated with flu-like symptoms and mild infusion reactions. CTCAE grade ≥ 3 toxicity included infection (1), proteinuria (1), GI (2), and thrombosis (2) including a fatal MI, anaphylaxis (1), neutropenia (2), hypophosphatemia (2). 57% (8 /14) of the patients had a CA125 response (defined as 50% reduction), 62% (8/13) had clinical benefit (RECIST stable disease) on study. Median progression free survival was 2.0 months (1.6 to 12.0). **Conclusions:** The expansion cohort was defined as VB-111 1x1013 VPs in combination with weekly paclitaxel 80 mg/m2. VB-111 was safe and well tolerated in combination with paclitaxel in ovarian cancer patients. Anticipated toxicities and clinical benefit were observed. Clinical trial information: NCT01711970.

5543 Poster Session (Board #101), Sat, 1:15 PM-4:45 PM

Urinary acetylated polyamines in ovarian cancer. *First Author: Johanna Unelma Maenpaa, School of Medicine, University of Tampere, Tampere, Finland*

Background: Diacetylated polyamines have been detected in the urine of patients with malignant tumors since 1960s but methodological problems have hindered research. We have recently developed a liquid chromatography tandem mass spectrometry (LC-MS/MS) method for a simultaneous analysis of 14 polyamines in free, mono- and diacetylated forms in human urine, without any derivatization. The present study was undertaken to explore urinary polyamine profiles in the differential diagnostics of ovarian tumors in postmenopausal women. **Methods:** Forty-five postmenopausal women presenting with an abnormal adnexal mass, and as controls, 21 women with genital prolapse scheduled for surgery, were included prospectively. A morning urine sample was obtained before surgery. The urinary concentrations of 14 polyamines were analyzed simultaneously with LC-MS/MS. Preoperative serum CA12-5 concentrations were also determined, and the risk of malignancy indexes (RMI) calculated in the research arm. The statistical analysis was performed by Wilcoxon rank sum test. **Results:** There were 22 benign and 23 malignant ovarian tumors (16 low malignant potential and 7 high grade tumors). Of the urinary polyamines, N1,N12-diacetylspermine (DiAcSpm) was the best one to make the distinction between the benign and malignant tumors. The urinary levels of DiAcSpm were similar in controls and in women with benign tumors. However, DiAcSpm was elevated in malignant vs. benign tumors ($p = 0.0002$), in high grade vs. low grade cancers ($p = 0.0003$), and in Stage III-IV vs. Stage I-II cancers ($p = 0.0007$), respectively. Also the difference between benign tumors and early-stage cancer (Stage I-II) was statistically significant ($p = 0.006$). DiAcSpm had similar specificity (Sp) (65%) and better sensitivity (Se) (91%) (AUC 0.82) as CA12-5 (Sp 65% /Se 68 %, with a CA12-5 cut-off value 35, respectively) (AUC 0.75) and as RMI (Sp 70%/Se 68% with a RMI cut-off value 200, respectively) (AUC 0.72). **Conclusions:** DiAcSpm was elevated in the urine of patients with ovarian cancer as compared to women with benign tumors and to women with genital prolapse. It seems to be able to detect even early-stage cancer, and its performance seems to be at least comparable to CA12-5 and RMI.

5544 Poster Session (Board #102), Sat, 1:15 PM-4:45 PM

A phase I trial and pharmacokinetic study of non-pegylated liposome-encapsulated doxorubicin citrate (NPLD) plus carboplatin in patients with recurrent gynecological and primary peritoneal tumors. *First Author: Andres Poveda, Instituto Valenciano de Oncologia, Valencia, Spain*

Background: Pegylated liposomal doxorubicin (PLD) plus carboplatin is one of the standard treatments for platinum-sensitive recurrent ovarian patients (pts). PLD shortage during 2012 and 2013 was determining in the need to search for an alternative doxorubicin combination with carboplatin. Non-pegylated Liposome-Encapsulated Doxorubicin Citrate (NPLD, Myocet) has been developed in the past decades with proved activity and limited skin-cardiac toxicity. **Methods:** This open multicentric dose-escalation phase I trial aimed to determine the maximum-tolerated dose (MTD) and the pharmacokinetic (PK) profile of Carboplatin+NPLD using a traditional 3+3 design. Main eligibility criteria: measurable or evaluable recurrent gynecological and primary peritoneal cancer (ca), ECOG: 0-2, normal organ function, no limited number of prior regimens, left ventricular ejection fraction (LVEF) $>$ 50%. Prior anthracycline therapy permitted only for previous responders. Dose Limiting Toxicity (DLT) was defined as G4 hematologic and/or G3 febrile neutropenia and/or ^{3} G3 non-hematologic toxicity (NCI-CTCAE v4.03). If more than one DLT occurred at a specific dose level the previous dose level was defined as the MTD. **Results:** 22/23 evaluable pts were treated with NPLD (40, 50, 60, 70 mg/m^2) and carboplatin (AUC 5) every 21 days. ECOG 0:14, 1: 8, 2:1. Median age: 57y (40-79). 9 pts had epithelial ovarian, 9 cervical, 5 endometrial ca. Number of prior regimens: 3 (1-7). Previous anthracycline: 7/22. *MTD was LEDC 60mg/m^2 + Carboplatin AUC 5.* DLT were: NPLD 40mg/m2: G3 febrile neutropenia, (1/6); 50mg/m2: G4 thrombocytopenia (1/6); 60 mg/m2: G4 thrombocytopenia (1/6); 70mg/m2: G4 thrombocytopenia (1/4), G3 febrile neutropenia, (1/4). Other non-hematologic G2 toxicities were (%): asthenia (16), infection (7) and anorexia (5). No cardiotoxicity was reported. 1PR and 17SD at 8 weeks were observed. PK data will be presented at the Meeting. **Conclusions:** The MTD for NPLD when combined with carboplatin AUC 5 is 60mg/m^2. The regimen is well tolerated, antitumor activity was observed. A phase-II study is ongoing. Clinical trial information: EudraCT: 2012-003173-25.

5545 Poster Session (Board #103), Sat, 1:15 PM-4:45 PM

Comparison of metachronous epithelial ovarian carcinomas. *First Author: David Arguello, Caris Life Sciences, Phoenix, AZ*

Background: Epithelial ovarian carcinoma (EOC) is a relatively common malignancy with high, initial response rates to standard chemotherapy but frequent relapses. Next-generation sequencing (NGS) is a promising technology with the potential to alter how this disease is managed. However, much remains unknown regarding its applicability in ovarian carcinomas. The purpose of this study is to compare metachronous epithelial ovarian carcinoma specimens arising from different sites in an attempt to better understand how to apply NGS in the management of this disease. **Methods:** A retrospective analysis of sequencing results for 83 metachronous (defined as specimens collected greater than 28 days apart) EOC specimens was performed. In most instances, comparisons involved two different metastatic sites (n = 50), while the rest involved a comparison of the primary and a subsequent metastatic specimen (n = 33). All specimens had up to 47 genes analyzed using the Illumina MiSeq NGS platform. Tumors were sequenced to a depth of 1500x, enabling the detection of mutations down to 10% variant frequency. **Results:** Metachronous paired specimens were collected from 43 to 2793 days apart (mean = 519). Mutations were detected in 23 different genes (48.9%, 23/47). A majority (56.6%, 47/83) shared just one mutation, with TP53 being the most common (59.0%, 49/83). Only twelve paired specimens had disagreement in gene results and all of these disagreed in only one gene. A change from wild type to mutated status was found in APC (I1307K, I1317K), BRAF (I463T), PIK3CA (E542K), PTPN11 (G503V), SMO (S342F), and TP53 (G245S, R248Q, R282W). Meanwhile, a reversion from mutated status to wild type was detected in APC (E1317Q, A1474T) and NOTCH1 (R1568K). Overall, 85.5% (71/83) of paired samples showed complete agreement. **Conclusions:** This metachronous paired analysis indicates that, at least utilizing this 47-gene panel, a majority of patients with EOC showed no change in their molecular profile, regardless of where the metastatic lesion was located. Utilizing NGS argues for a more comprehensive approach to EOC therapy, and to obtain the most therapeutic options in this disease. These findings, and their clinical impact, should be validated in further studies.

5546 Poster Session (Board #104), Sat, 1:15 PM-4:45 PM

What clinical factors influence advanced *BRCA1/2* mutant ovarian cancer patient (BMOC pt) outcomes to poly(ADP-ribose) polymerase inhibitor (PARPi) treatment? *First Author: Saeed Rafii, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: The PARPi olaparib (Ola) was recently granted FDA accelerated approval in advanced BMOC. Despite impressive clinical activity in BMOC, the impact of baseline pt factors remains unclear. We hypothesized that the platinum chemotherapy (Plt chemo) to PARPi interval (PTPI) can be used to refine the conventional prediction of response to PARPi based on the clinical categorization of pts into Plt sensitive (Plt-S) and Plt resistant (Plt-R). **Methods:** Retrospective study of pt with advanced BMOC treated in relapsed setting with $\geq$ 200 mg bid Ola between 4/2006 – 8/2013 in multiple centers. Pearson Chi^2, odds ratios (OR) and Fisher's exact probability tests were used for statistical analyses. **Results:** 108 advanced BMOC pts were assessed; median age 55y (range 38-79); 83 (77%) pts had high grade serous carcinoma. *BRCA1*:*BRCA2* mutations ratio 71:29. Median prior lines of chemo: 3 (range 1-10). 41 (38%) pts had prior breast cancer (BC). 64% had Plt-S disease and 36% had Plt-R disease prior to Ola. Median PTPI was 53 weeks (w) (range 4-244). Median PTPI was 68.7w for Plt-S pts versus (vs) 25.9w for Plt-R pts ($p < 0.0001$). RECIST complete or partial responses (CR/PR) were observed in 23/65 (35%) Plt-S pts vs 5/38 (13%) Plt-R pts ($p < 0.02$). Pts with $>$ 52w PTPI had higher CR/PR rates than those with $<$ 52w PTPI independent of their Plt status (37% vs 18%, respectively, $p = 0.053$). Pts who had only 1 prior line of chemo had higher CR/PR rates vs pts who had $>$ 1 prior line ($p < 0.005$). No differences in CR/PR rates were noted between pts with *BRCA*1 vs pts with *BRCA2* mutations, pts with prior BC vs pts without, or use of chemo for BC vs none. Median progression-free survival was 70w for pts with PR/CR vs 28w for pts without (log-rank, $p = 0.0004$). Median survival was 161w for pts with CR/PR and 64w for pts without (log-rank, $p = 0.0005$). **Conclusions:** These data suggest that prediction of response to PARPi in advanced BMOC based on conventional Plt-S/Plt-R categorization may be refined by PTPI. Treatment of Plt-R BMOC pts with a non-Plt agent prior to Ola in order to prolong PTPI may be an appropriate clinical strategy. These findings should be validated prospectively in a larger data set.

5547 Poster Session (Board #105), Sat, 1:15 PM-4:45 PM

Development and validation of a prognostic nomogram to predict overall survival (OS) in platinum-resistant ovarian cancer (PROC): An AURELIA substudy. *First Author: Chee Lee, ANZGOG, NHMRC Clinical Trials Centre, University of Sydney, Camperdown, Australia*

Background: PROC describes a heterogeneous group of patients (pts) with a variable but generally poor prognosis and low response to chemotherapy. Predicting OS in PROC would help stratify pts in trials and guide treatment decisions. We developed a nomogram to predict OS in PROC. **Methods:** Data from two randomized phase III trials evaluating chemotherapy for PROC – CARTAXHY [Lortholary Ann Oncol 2012] and AURELIA [Pujade-Lauraine JCO 2014] (chemotherapy-alone arm) – were combined to form the training cohort (N = 331) for nomogram development. Baseline variables significantly associated with OS were identified using Cox regression analysis. Pts were assigned scores based on the weighted sum of the relative importance of each variable in the multivariate model. The nomogram was then validated in the chemotherapy plus bevacizumab arm of the AURELIA trial (N = 166). Nomogram performance was assessed by calculating the c statistic. A classification based on the nomogram's score was generated to group pts according to prognosis. **Results:** Poor performance status, CA125 $\geq$ 100 U/mL, ascites, platinum-free interval $<$ 3 months, primary platinum resistance, and largest tumor $>$ 5cm were associated with shorter OS. The nomogram predicted OS with a c statistic of 0.69 (training) and 0.67 (validation). In the training cohort, the median OS in good (N = 93), intermediate (N = 162), and poor (N = 76) prognostic groups was 25.3, 15.6, and 6.9 months, respectively ($P < 0.0001$). In the validation cohort, median OS in good (N = 50), intermediate (N = 79), and poor (N = 37) prognostic groups was 26.7, 13.8, and 9.0 months, respectively ($P < 0.0001$). **Conclusions:** This nomogram combining six baseline factors accurately predicts OS in PROC pts treated with chemotherapy either alone or in combination with bevacizumab. It could help to select pts for treatment, counsel pts regarding prognosis, and stratify according to risk in trials. Clinical trial information: NCT00976911.

5548 Poster Session (Board #106), Sat, 1:15 PM-4:45 PM

Exploratory outcome analyses according to stage and residual disease in the ICON7 trial of front-line carboplatin/paclitaxel (CP) ± bevacizumab (BEV) for ovarian cancer (OC). *First Author: Antonio Gonzalez-Martin, GEICO and MD Anderson Cancer Center Spain, Madrid, Spain*

Background: In ICON7, progression-free survival (PFS) was significantly improved in patients (pts) receiving BEV with front-line CP and continued as a single agent [Perren 2011] but no overall survival (OS) difference was detected in the intent-to-treat (ITT) population. Front-line BEV-containing therapy is approved in Europe for pts with stage IIIB–IV OC. **Methods:** In ICON7, pts with advanced (stage IIB–IV) or high-risk early-stage (stage I–IIA and clear cell/grade 3) OC were randomized to receive 6 cycles of CP either alone or with BEV 7.5 mg/kg q3w followed by single-agent BEV for a further 12 cycles (total duration 12 months). The primary endpoint was PFS; OS was a secondary endpoint. A post hoc exploratory analysis of subgroups defined by stage and extent of residual disease at diagnosis within the label population was performed. **Results:** The PFS benefit from BEV observed in the ITT population was seen consistently in all subgroups explored. As in the ITT population, no OS difference was seen in any subgroup except the previously defined 'high-risk' subgroup. Safety results in subgroups were in line with the overall population. **Conclusions:** Adding BEV to CP improves PFS irrespective of stage/residual disease. In pts with stage III >1 cm/IV OC this translates into an OS benefit. No OS difference (benefit or detriment) was seen in other subgroups explored. Clinical trial information: NCT00483782.

5549 Poster Session (Board #107), Sat, 1:15 PM-4:45 PM

Single agent vanucizumab (RO5520985) for platinum (Pt)-resistant recurrent ovarian cancer (OC): Results from a single arm extension phase of the phase I FIH study. *First Author: Ana Oaknin, Vall d´Hebron University Hospital, Barcelona, Spain*

Background: Vanucizumab is a bi-specific human IgG1 antibody, simultaneously blocking the complementary roles of Ang-2 and VEGF-A induced tumor angiogenesis. Both, VEGF-A and Ang-2 inhibitors are known to be clinically active in ovarian cancer. Hence, co-targeting of both ligands in a bi-specific manner represents an encouraging approach to improve treatment outcomes. **Methods:** Eligiblepatients (pts) had platinum (Pt)- resistant/ refractory epithelial OC (measurable by RECIST 1.1). Pts with history of bowel obstruction, > 2 prior lines of systemic chemotherapy, or previous treatments with agents targeting Ang/Tie2 receptor axis were ineligible. Pts were treated with vanucizumab (RP2D) at 30 mg/kg IV Q2W until disease progression or unacceptable toxicity. Primary endpoint was objective response rate (ORR) per RECIST 1.1, with tumor re-assessments every 8 weeks (wks). **Results:** 41 pts (40 Pt- resistant/ 1 Pt- refractory) with median age of 60 years (range 30-77) were enrolled. 13 (32%) pts were pre-treated with bevacizumab (BEV). All pts had at least 1 tumor re-assessment. At this point in time, twelve (29%) pts achieved partial response (6 confirmed PR/6 unconfirmed PR) including two pre-treated with BEV. Interestingly, a delayed response was observed in 7/12 PRs, following 16 wks (6 pts) or 32 wks (1 pt) of treatment. 22 (54%) pts experienced disease stabilization and 7 (17%) pts progressed. The most frequent adverse events (AE) of any grade (G) were hypertension (53%), asthenia (39%), constipation (34%), abdominal pain (32%), peripheral (24%)/lymphedema (19%), vomiting (24%) and diarrhea (19%). Most common AEs ≥ G3 were hypertension (10/24%), pyelonephritis (3/7%), GI-perforation, peritonitis, intestinal obstruction, pulmonary embolism and dyspnea (2/5%). One AE of peritonitis had a fatal outcome 3 months after onset. **Conclusions:** In this study, vanucizumab Q2W had an acceptable safety profile while demonstrating encouraging anti-tumor activity in pts with Pt-resistant, recurrent OC that seems to exceed reported results for single VEGF-A inhibition in this setting. Clinical trial information: NCT01688206.

5550 Poster Session (Board #108), Sat, 1:15 PM-4:45 PM

Frequency, severity and timing of common adverse events (AEs) with maintenance olaparib in patients (pts) with platinum-sensitive relapsed serous ovarian cancer (PSR SOC). *First Author: Ursula Matulonis, Dana-Farber Cancer Inst, Boston, MA*

Background: Maintenance monotherapy with the PARP inhibitor olaparib prolongs progression-free survival in PSR SOC pts with no adverse impact on HRQoL. *BRCA*m pts derive greater benefit. Nausea, vomiting, fatigue and anemia are consistently the most common AEs in olaparib trials. **Methods:** In this randomized, double-blind Phase II trial (NCT00753545), pts received olaparib 400 mg twice daily (capsules; n=136) or placebo (n=128). AEs were graded by CTCAE v3.0; the timing and severity of AEs were analyzed. **Results:** Olaparib-treated pts most commonly reported early but transient grade (G)1/2 AEs of nausea, vomiting, fatigue and anemia that resolved with supportive treatment without olaparib regimen changes. G>2 AEs were uncommon and manageable with dose interruptions/reductions and supportive treatment. Anemia was the most common G>2 AE. Common AEs were generally reported later for placebo pts. AEs causing discontinuation were uncommon (olaparib, n=9; placebo, n=2). *BRCA*m pts had a similar AE profile. **Conclusions:** AEs commonly reported with olaparib are of mostly mild to moderate intensity, transient and manageable without olaparib discontinuation. Clinical trial information: NCT00753545.

5551 Poster Session (Board #109), Sat, 1:15 PM-4:45 PM

Bevacizumab (BEV) with or after chemotherapy (CT) for platinum-resistant recurrent ovarian cancer (PROC): Exploratory analyses of the AURELIA trial. *First Author: Aristotelis Bamias, HECOG, University of Athens, Medical School, Athens, Greece*

Background: In the open-label randomized phase III AURELIA trial, adding BEV to CT for PROC significantly improved progression-free survival (hazard ratio [HR] 0.48; p < 0.001) and response rate (27% vs 12%) vs CT alone, but not overall survival (OS). **Methods:** Eligible patients (pts) had measurable/assessable OC that had progressed < 6 mo after platinum CT. After CT selection, pts were randomized to CT ± BEV until progression (PD), unacceptable toxicity or consent withdrawal. Crossover to BEV at PD was optional in the CT arm but prohibited in the BEV–CT arm. Exploratory post hoc analyses assessed factors potentially affecting the decision to crossover to BEV, and efficacy and safety according to post-PD BEV. **Results:** 179 pts were randomized to BEV–CT and 182 to CT alone. 72 pts (40%) in the CT-alone arm crossed over to BEV after PD and 110 never had BEV. There were no significant differences in pt characteristics between these subgroups at baseline but at the time of PD, 51% vs 35%, respectively, had ECOG performance status (PS) 0 (p = 0.034). 3-month landmark analyses, excluding 28 pts who died or were lost to follow-up before this time, showed significantly longer OS in pts who received BEV either with CT (HR 0.72, 95% CI 0.54–0.97) or after PD (HR 0.69, 95% CI 0.48–0.99) vs those who never received BEV. These differences remained significant after adjusting for identified prognostic factors for OS (chosen CT, platinum-free interval, ECOG PS, baseline ascites, baseline CA-125). When analyzed from the time of PD, the OS HR vs never BEV was 0.84 (95% CI 0.62–1.14) for upfront (pre-PD) BEV–CT and 0.55 (95% CI 0.38–0.79) for BEV after PD. Tolerability was similar with pre- vs post-PD BEV. **Conclusions:** There appears to be no clear difference in OS between upfront vs post-PD BEV therapy. Pts who never received BEV had the worst OS. These analyses of a non-randomized phase of the study with no information on other post-PD therapies do not allow definitive conclusions about upfront vs post-PD BEV efficacy. Nevertheless, as 60% of pts randomized to CT alone never received BEV, upfront treatment with BEV–CT is important, as reserving BEV until after PD may deny some pts the opportunity to benefit from BEV. Clinical trial information: NCT00976911.

5552 Poster Session (Board #110), Sat, 1:15 PM-4:45 PM

Prognostic and predictive value of primary vs secondary platinum resistance for bevacizumab treatment in platinum-resistant ovarian cancer in the AURELIA trial. *First Author: Fabian Trillsch, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Progression-free survival (PFS) and patient-reported outcomes (PRO) were significantly improved with the addition of bevacizumab (BEV) to standard chemotherapy (CT) for platinum-resistant ovarian cancer (OC) in the randomized phase III AURELIA trial. We examined the relevance of primary (PPR) vs secondary platinum resistance (SPR) on treatment efficacy. **Methods:** Platinum resistance was categorized as PPR if progression was $<$ 6 months after completing first platinum therapy or SPR if not. We performed exploratory Cox and logistic regression analyses to correlate platinum resistance with PFS, overall survival (OS), and PRO from the time of randomization to CT $\pm$ BEV. **Results:** Of the 361 randomized patients (pts), 262 (73%) had PPR and 99 (27%) had SPR. Baseline characteristics were generally similar in the two subgroups, except that FIGO stage IV disease and ascites were more common in PPR pts. In the BEV+CT arm (n = 179), SPR was associated with more favorable PFS (median 10.2 vs 5.6 months [mo] in the PPR subgroup; $P < 0.001$) and OS (median 22.2 vs 13.7 mo, respectively; $P < 0.001$) but not PRO (22.0% vs 21.9% with $\geq$ 15% improvement in abdominal/gastrointestinal symptoms at week 8/9; P = 0.99). In two separate multivariate analyses, SPR remained an independent prognostic factor for better PFS (adjusted hazard ratio [HR] 0.41, 95% CI 0.25–0.67, $P < 0.001$) and OS (HR 0.49, 95% CI 0.30–0.80, P = 0.005) in the BEV+CT arm. In the CT-alone arm, the prognostic effect did not reach statistical significance for PFS or OS. The magnitude of benefit from adding BEV to CT appeared greater in the SPR than the PPR subgroup for PFS (SPR: HR 0.30, 95% CI 0.18–0.48, $P < 0.001$; PPR: HR 0.55, 95% CI 0.42–0.71, $P < 0.001$; interaction P = 0.07) with a similar direction of effect for OS (SPR: HR 0.62, 95% CI 0.37–1.02, P = 0.06; PPR: HR 0.94, 95% CI 0.71–1.24, P = 0.65; interaction P = 0.18). **Conclusions:** Median PFS and OS were more favorable in SPR than PPR pts treated with BEV+CT but BEV effect on PRO was similar. The PFS and OS benefit of BEV+CT over CT alone was more pronounced in the SPR than the PPR subgroup. PPR vs SPR should be a stratification factor in future trials of anti-angiogenic therapy for OC. Clinical trial information: NCT00976911.

5553 Poster Session (Board #111), Sat, 1:15 PM-4:45 PM

Single agent trabectedin in heavily pretreated patients with recurrent ovarian cancer (ROC). *First Author: Feriel Boumedien, Faculty of Medicine, Université de Montreal, Montreal, QC, Canada*

Background: Trabectedin is approved in Canada since 2010 in combination with liposomal doxorubicin for platinum-sensitive ROC in patients who are not expected to benefit, are ineligible or not willing to receive retreatment with platinum-based chemotherapy. In 2012, due to a shortage of liposomal doxorubicin, single agent trabectedin was proposed to patients with ROC. The aim of this study was to evaluate the efficacy and tolerability of trabectedin in this context. **Methods:** This retrospective IRB approved study included all patients who received trabectedin for ROC between January 1st 2012 and June 30th 2014 at the CHUM. This study was not funded.The primary outcome was progression free survival (PFS) based on CA-125 and clinical exam. We also evaluated overall survival (OS), response rate and toxicities (CTCAE v4.0). PFS and OS were estimated by Kaplan-Meier method. **Results:** A total of 25 evaluable patients with a median age of 59 years received trabectedin 1.3 mg/m^2 I.V. in 3 hours every 3 weeks in 3rd or 4th line (36%), 5th or 6th line (36%) and $\geq$ 7 lines (28%). Among the patients, 60% were platinum-sensitive and 40% platinum-resistant. The median number of cycles received was 5 (range 1-16 cycles) for a total of 130 cycles. Complete response (CR), partial response (PR), stable disease (SD) and progression occurred in 16%, 20%, 24% and 40% of patients respectively. The median PFS was 3.7 months (95% CI 1.9-5.6). In patients with a response (CR, PR, SD), the median PFS was 4.9 vs 0.8 months ($p < 0.001$). Death occurred in 15 patients (60%). The median OS was 16.2 months. The Cox model reported that response to treatment is the only variable influencing the PFS and the OS ($p < 0.001$), but not the platinum status or the number of previous lines received. Grade 3 or 4 toxicities include: neutropenia (8%), febrile neutropenia (4%) and muscle weakness (4%). Dose reduction was required in 4 patients for hepatic and hematologic toxicities. No death was attributable to toxicities. **Conclusions:** Our results demonstrate that trabectedin has an interesting efficacy as a single agent in heavily treated ROC patients. At a dose of 1.3 mg/m^2 every 3 weeks, trabectedin is well tolerated with few adverse events.

5554 Poster Session (Board #112), Sat, 1:15 PM-4:45 PM

Early stage ovarian cancer clinical behavior according to FIGO 2014 Staging changes with a focus on IC subtype: data from prospective GEICO registry. *First Author: Ignacio Romero, Instituto Valenciano de Oncología, Valencia, Spain*

Background: Early stage ovarian cancer (ESOC) represents 10-15% of all Ovarian Cancer (OC) cases and most frequent ESOC substage (IC) has undergone major changes in FIGO 2014 staging. **Methods:** A centralized prospective registry of ESOC (I-IIb) patients treated at GEICO (Spanish Group of Ovarian Cancer Research) centers was initiated on January 1998 and updated up to November 2014. We aim at prospectivley explore both the robustness of FIGO in ESOC and the role of ascites in terms of prognosis. We analyze FIGO 2014 stage IA-IB (1), IC1+IC2 (2), IC3 citology positive in washing (3) or in ascites (4) and IIA-B (5). **Results:** A total of 1,178 cases with a median age of 53 yrs. (16-97 yrs) have been included. Histology distribution according to Kurman (Int J Gynecol Pathol 2008) showed type I 65.5% and type II 34.5%, grade 1 23.6%, grade 2 21.4% and grade 3 45%. Distribution of ESOC stages, frequency and Relapse Free Survival (RFS) and Disease Specific Survival (DSS) are summarized in table 1; subclassification in IC stage was unavailable in 80 cases. With a median follow-up of 77 months [0-285 mo], 16.7% relapsed after a median of 27 months [2-221 mo] and 9.1% died after a median of 42 months [4-181 mo]. RFS at 5 and 10 years were 84%, 80% and and DSS 93.5% and 87.2% respectively. RFS was inversely associated with stage ($p<0.001$) (table 1). The presence of positive citology in ascites had worse outcome than in washings. Up to 81% received adjuvant chemotherapy. **Conclusions:** In this large prospective cohort of ESOC, FIGO 2014 staging system for ESOC is prognostic. We propose to further explore the bad prognosis of positive citology in ascites.

Group	FIGO 2014	N	%	RFS 5-yrs (%)	RFS 10-yrs (%)	DSS 5-yrs (%)	DSS 10 yrs (%)
1	IA-IB	428	36.3	96	94	98	97
2	IC1+IC2	398	33.7	93	88	97	96
3	IC3 positive citology in washing	68	5.7	80	74	88	83
4	IC3 positive citology in ascites	33	2.8%	72	72	86	75
5	IIA-IIB	171	14.5	69	63	87	80

5555 Poster Session (Board #113), Sat, 1:15 PM-4:45 PM

Epigenome and genome alterations in platinum resistant ovarian cancer. *First Author: Daniela Matei, Indiana Univ Simon Cancer Ctr, Indianapolis, IN*

Background: Epigenetic changes, particularly DNA methylation aberrations have been implicated in acquired resistance to platinum in ovarian cancer (OC). **Methods**: An ongoing phase I/II multi-institutional clinical trial uses the novel DNA methyl transferase inhibitor (DNMTI) SGI-110 to re-sensitize platinum resistant OC to carboplatin. Patients enrolled in this trial had recurrent, platinum resistant OC and multiple lines of prior therapy. Tumor biopsies were collected at baseline and after two cycles of SGI-110 administered daily for 5 days (30mg/m^2). The objectives of the study were to analyze and integrate global RNA expression and DNA methylation profiles of platinum resistant tumors and to measure genomic and epigenomic changes induced by the DNMTI. RNA and DNA were extracted from 48 and 57 baseline tumors and analyzed using next generation sequencing (RNA-seq) and Infinium HM450 BeadChip array, respectively. Differential gene expression and DNA methylation profiles were generated and used for Ingenuity Pathway Analysis (IPA) to identify significantly altered pathways in response to SGI-110. **Results**: Analysis of a limited number of paired samples before and after treatment (n = 8) revealed significant changes in global gene expression profiles induced by SGI-110, with 960 significantly altered genes representing immunopathway enrichment, including cytokine production in macrophages and T helper cells by IL-17A and IL-17F, granulocyte/agranulocyte adhesion and inflammation, IL-8 signaling, p38 MAPK signaling, cAMP-mediated signaling, and innate immunity. HM450 analysis showed a significantly greater number of hypermethylated genes in baseline tumors compared to primary OC samples in the Cancer Genome Atlas (TCGA) and demethylation (decreased beta-values relative to baseline) of a large number of loci (381 gene promoters) after SGI-110 treatment. IPA analysis of baseline tumor transcriptome and methylome demonstrated significant enrichment in pathways associated with cancer, stem cells, inflammation and the immune system. **Conclusions:** These data suggest that SGI-110 induces reactivation of immune responses in OC. Correlations between methylation changes and expression profiles are being explored. Clinical trial information: NCT01696032.

5556 Poster Session (Board #114), Sat, 1:15 PM-4:45 PM

Validation of a second-generation mia (MIA2G) for triage of adnexal masses. *First Author: Judith Wolf, Vermillion, Inc., Austin, TX*

Background: Many women with ovarian cancer receive non-guideline care. Failure to refer to a gynecologic oncologist is one likely cause. To improve specificity of Multivariate Index Assay (MIA) for ovarian cancer triage, we undertook the re-design and validation of a second-generation test (MIA2G). **Methods:** A panel of MIA-positive malignant and benign case- controls was used to evaluate candidate biomarkers to improve specificity. These, and the 5 MIA biomarkers were then further ranked and developed into the MIA2G using banked samples from a previously published prospective, multi-site FDA registration trial of MIA (N = 585). Upon verification, the algorithm was encoded into diagnostics-grade software to calculate MIA2G in subsequent validation studies. Clinical validity was established under a double-blinded protocol using banked samples from the OVA500 trial, a second prospective MIA multi-site pivotal trial. Samples were assayed at 3 external sites, results were generated at a commercial laboratory and submitted to an independent statistician for decoding and analysis. MIA2G was compared with physician assessment (PA) or MIA. Results were compared for sensitivity, specificity, positive and negative predictive value (PPV and NPV), positive and negative likelihood ratios, concordance and percent overall accuracy. **Results:** Three MIA markers (CA125-II, transferrin and Apo A-1) and 2 new biomarkers (FSH and HE4) were selected for inclusion in MIA2G. MIA2G results range from 0-10, with a single cut-off separating hi- and low- malignancy risk of ^{3}5.0. 493 of 519 OVA500 subjects were evaluable (276 pre and 217 post-menopausal). MIA2G specificity (69.1%) and PPV (40.4%) were significantly improved over MIA (53.6% and 31.4%, respectively). Sensitivity and NPV were not significantly different. Overall accuracy was significantly improved from 60.9% (MIA) to 73.2% (MIA2G). When MIA2G was combined with PA sensitivity was 93.5% and specificity was 64.8% **Conclusions:** The redesigned multivariate index assay, MIA2G, has significantly improved specificity, PPV and accuracy compared with MIA. These changes enable high-sensitivity detection of malignancy while reducing likelihood of over-referral.

5557 Poster Session (Board #115), Sat, 1:15 PM-4:45 PM

The PACOVAR-trial: A multicenter phase I trial of pazopanib (GW786034) and metronomic cyclophosphamide in patients with recurrent platinum-resistant ovarian cancer. *First Author: Michael Hans Robert Eichbaum, St. Marienkrankenhaus Frankfurt, Frankfurt, Germany*

Background: A combined therapy consisting of the investigational anti-VEGFR tyrosine kinase inhibitor pazopanib (GW786034, paz) and metronomic oral cyclophosphamide may offer a well-tolerable treatment option to patients with recurrent platinum-resistant epithelial ovarian cancer (EOC). **Methods:** This study was designed as a multicenter phase I trial evaluating the optimal dose for paz as well as activity and tolerability of a combination regimen consisting of paz and metronomic cyclophosphamide 50mg daily p.o. in monthly cycles. Patients with histologically proven recurrent platinum-resistant EOC were included. Dose escalation of paz followed a phase I design in three dose levels (DL) of 400mg, 600mg and 800mg daily p.o. , respectively. Toxicity and survival data were obtained. **Results:** 16 patients were treated within this trial, mean age was 66 years. In DL I and II one dose limiting toxicity (DLT) was seen in one patient out of six (AST-elevation, hypertonus). Within DL III, two patients out of four showed a DLT (AST-elevation), leading to a maximum tolerated dose (MTD) of 600mg paz daily. Median number of administered cycles was 6 (2-13), with three patients being treated for at least 13 months. Median progression-free survival (PFS) and overall survival (OS) were 6.7 months and 15.2 months, respectively. A total of 254 adverse events (AE) occurred. The most often documented AE were leukopenia in 14.6% of the cases, followed by elevation of ALT (10.2%) and elevation of AST (9.5%). Moreover, 27 AE were probably or very likely related to cyclophosphamide (10.6%) and 55 AE were probably or very likely related to paz (21.7%). A total of five serious adverse events (SAE) occurred in four patients. The events were hypertension as well as sepsis, vomiting, ileus and fatigue. Besides sepsis, which had a fatal outcome, all other SAE were recovered. **Conclusions:** Paz 600mg daily p.o. and metronomic cyclophosphamide 50mg daily p.o. is a feasible regimen for patients with platinum-resistant recurrent, pre-treated EOC. Further evaluation of this palliative regimen in phase II setting is warranted. Clinical trials information: NCT01238770. Clinical trial information: NCT01238770.

5558 Poster Session (Board #116), Sat, 1:15 PM-4:45 PM

Phase 1 study of IMGN853, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC) in patients (Pts) with epithelial ovarian cancer (EOC) and other FRA-positive solid tumors. *First Author: Hossein Borghaei, Fox Chase Cancer Center, Philadelphia, PA*

Background: IMGN853 (mirvetuximab soravtansine) is a FRα-targeting ADC comprising a FRα-binding antibody and potent maytansinoid, DM4. **Methods:** This Phase 1 trial is being conducted to determine safety, pharmacokinetics (PK), pharmacodynamics, maximum tolerated dose, recommended phase 2 dose (RP2D) and evidence of activity of IMGN853 in pts with EOC or other FRa-positive solid tumors. As previously reported, the occurrence of ocular adverse events (AEs) was associated with peak drug exposure and pt weight. Dosing by adjusted ideal body weight (AIBW) instead of total body weight (TBW) was implemented to decrease PK variability. Two dosing schedules are being evaluated; (A) once every 3 weeks and (B) Days 1, 8, and 15, every 4 weeks. **Results:** Fifty nine pts enrolled to dose escalation to date, 44 (30 TBW; 14 AIBW) pts in A, 16 (AIBW) in B. RP2D for A was determined to be 6.0 mg/kg, while dose finding in B continues. Exposure to IMGN853 increased with an increase in dose in a more than dose-proportional manner indicating non-linear PK. AIBW dosing enabled better control of drug exposure, with more pts treated within a clinically relevant therapeutic window. The majority of AEs have been CTCAE grade 1 or 2, generally similar across both schedules: included GI events, ocular events, cough, fatigue, and neuropathy in $>=$ 20% of patients. Nausea, vomiting and headache may be more common on schedule B. Diarrhea may be more common on schedule A. Preliminary evidence of clinical benefit (CB) (partial PR or complete CR response, CA125 response, SD $\geq$ 6 cycles) has been observed with both schedules during escalation. In A, CB was observed in 11/44 pts: 4 PRs; 2 confirmed CA125 responses; 5 SD, 2 for 10 cycles. In B, 5/15 evaluable pts had CB: 1 PR; 4 SD, 3 with confirmed CA125 response; six pts remain on study. Benefit was seen in epithelial and transitional cell ovarian cancer, endometrial cancer and NSCLC. **Conclusions:** With both schedules,IMGN853 demonstrates encouraging clinical activity in heavily pretreated patients during dose escalation with a manageable AE profile. A RP2D has been identified for schedule A, while schedule B continues dose finding. Clinical trial information: NCT01609556.

5559 Poster Session (Board #117), Sat, 1:15 PM-4:45 PM

A phase 1 study optimizing the dosing of olaparib tablet formulation combined with cediranib in recurrent ovarian cancer. *First Author: Joyce Liu, Dana Farber Cancer Inst, Newton, MA*

Background: PARP inhibitors and anti-angiogenics are clinically active in recurrent ovarian cancer (OvCa). Pre-clinical studies suggest these agents can synergize; a phase 2 study demonstrated that combination cediranib/capsule olaparib (C/O) increased progression-free survival (PFS) and response rate (RR) compared to olaparib alone. Olaparib clinical development will proceed using the tablet formulation; we therefore investigated the toxicities and recommended phase 2 dosing (RP2D) of C/O with olaparib tablets. **Methods:** Cediranib (C) once daily and olaparib (O) twice daily were administered orally in cohorts of 3 patients in a standard 3+3 Phase 1 design. Eligibility included pts with recurrent ovarian cancer. Pts had measurable disease by RECIST 1.1 or met GCIG CA125 criteria. No prior anti-angiogenics in the recurrent setting or prior PARP inhibitor were allowed. **Results:** 24 pts have been treated since May 2014 at 6 dose levels (C 20mg QD/O 200mg BID (3 pts); C 20mg QD/O 250mg BID (3); C 20mg QD/O 300mg BID (6); C 30mg QD/O 150mg BID (3); C 30mg QD/O 200mg BID (6); C 30mg QD/O 250mg BID). One DLT (gr 3 rotator cuff injury) occurred at the 30/200 dose level and two DLTs (1 $>$ 7d hold for proteinuria; 1 gr 4 HTN and gr 2 intracranial hemorrhage) at the 30/250 dose level. Other related gr 3/4 adverse events (AEs) included HTN (5), vomiting (1), fatigue (1), myalgia (1), and thromboembolic event (1). Most common AEs included nausea (79%), fatigue (75%), diarrhea (58%), vomiting (42%), and HTN (42%). The RP2D levels are C 30mg QD/O 200mg BID and C 20mg QD/O 300mg BID. Best response in 21 evaluable OvCa pts (13 plat-resistant; 8 plat-sensitive) include 2 CR, 4 PR, 14 SD, 1 PD, including 1 CR, 2 PR and 2 SD in 5 evaluable pts at the 30/200 and 1 CR and 4 SD in 5 pts at the 20/300 dosing levels. **Conclusions:** RP2D for combination C/O tablets is cediranib 30mg/olaparib 200mg BID or cediranib 20mg/olaparib 300mg BID. Observed toxicities are consistent with those seen with combination using olaparib capsules. Preliminary assessment of activity demonstrated a 29% unconfirmed response rate in OvCa pts using a regimen that is safe and tolerable. An expansion cohort will enroll at the cediranib 30mg/olaparib 200mg BID level. Clinical trial information: NCT01116648.

5560 Poster Session (Board #118), Sat, 1:15 PM-4:45 PM

Ovarian carcinosarcoma share similar molecular profile as ovarian serous carcinoma but not endometrial carcinosarcoma. *First Author: Haider Mahdi, Cleveland Clinic, Cleveland, OH*

Background: Ovarian carcinosarcomas (OCS) are rare and aggressive malignancies with limited treatment options. It is unclear if this uncommon type of cancer shares similar molecular changes as endometrial carcinosarcoma (ECS) or serous ovarian carcinoma (SOC). We compared the molecular profile of a cohort of OCS to that of SOC and ECS to explore the potential overlap in treatment paradigms. **Methods:** 110 OCS, 141 ECS and 1587 SOC were evaluated using a commercial multiplatform profiling service (CARIS Life Sciences, Phoenix, AZ). Specific testing performed included a combination of gene sequencing (Sanger, NGS), protein expression (IHC) and gene amplification (CISH or FISH). **Results:** TP53 was the most commonly mutated gene in all three malignancies with 76.4 % of OCS, 68.8 % of ECS and 69% of SOC. Alteration of PI3K/AKT/mTOR and MAPK pathways were noted to be similar in OCS and SOC but was less frequently altered than ECS including mutation in PIK3CA (7.6% and 2.3% vs. 22.2%, $p < 0.001$), FBXW7 (0% and 0.6% vs.12.1%, $p < 0.001$), PTEN (3.7% and 0.8% vs. 12%, $p < 0.001$) and KRAS (5.2% and 5.0% vs. 13.5%, $p < 0.001$). For homologous recombination pathway, SOC and ECS were more likely to have BRCA1 (20% and 18% vs. 9%) and BRCA 2 mutations (18% and 27% vs. 12%) than OCS. However, the differences were not statistically significant. No difference in alteration of RB, NOTCH, angiogenesis and FGFR pathways was noted among the three cohorts. Estrogen (14.6% and 25.1% vs. 53.1%, $p < 0.001$) and androgen receptors (18.8% and 12.2% vs. 32.4%, $p < 0.001$) were expressed less frequently in OCS and ECS than SOC respectively. On the other hand, expression of progesterone receptors was more frequent in in OCS and SOC than ECS (26.5% and 30.5% vs. 20.9%, $p < 0.001$). **Conclusions:** While ovarian carcinosarcoma and uterine carcinosarcoma are histologically similar, we reveal that OCS share molecular changes similar to that of SOC. Both OCS and SOC have significantly lower activity of PI3K/AKT/mTOR, MAPK pathways and higher progesterone receptors expression than ECS. Treatment with regimens that are active in ovarian serous could be considered when treating patients with ovarian carcinosarcoma.

5561 Poster Session (Board #119), Sat, 1:15 PM-4:45 PM

Derivation of a second generation multivariate index assay to improve specificity in pre-surgical evaluation of adnexal masses for risk of ovarian malignancy. *First Author: Zhen Zhang, Johns Hopkins Medicine, Baltimore, MD*

Background: The FDA cleared in vitro diagnostic multivariate index assay OVA1, with its intended utility to assist in referral of high risk patients to gynecologic oncologists, was by design to have a high sensitivity in assessing risk of malignancy in patients diagnosed with an adnexal mass prior to planned surgery. In this study, we developed and evaluated a second generation multivariate index assay (MIAG2) to improve specificity while maintaining a level of sensitivity similar to OVA1. **Methods:** CA 125 II, prealbumin, apolipoprotein A-1 (ApoA1), beta 2-microglobulin, transferrin (TRF), follicle-stimulating hormone (FSH), and Human epididymis protein 4 (HE4) were retrospectively analyzed on serum samples from a prospective multicenter study of patients with a documented pelvic mass planned for surgery. The samples were divided by block randomization into a training set (pre-/post-menopausal: 130/150; benign: 174, malignant: 106 including 35 stage I/II and 16 low malignant potential (LMP) cases) and a preliminary validation set (pre-/post-menopausal: 154/151; benign: 233, malignant: 72 including 19 stage I/II and 13 LMP cases). **Results:** Selected through extensive statistical resampling, the MIAG2 panel consists of CA 125 II, ApoA1, TRF, FSH, and HE4. Its algorithm uses two ensembles of classification models, for pre- and post-menopausal women respectively. However, with the help of FSH, the outputs of the models were integrated into a single-valued index with a cutoff of 5.0 arbitrary units for all patients. The specificity and sensitivity of the MIAG2 for the validation set were 60.1% (140/233) and 88.9% (64/72), respectively, compared to OVA1 which had a specificity of 47.2% (110/233) at a sensitivity of 95.8% (69/72). The improvement in specificity was statistically significant ($p < 0.001$). It is of interest to note that both the MIAG2 and OVA1 had a high sensitivity in detecting non-LMP ovarian cancer at 96.6% (57/59) and 100.0% (59/59), respectively. **Conclusions:** The MIAG2 significantly improved specificity over that of OVA1 while maintaining a comparably high sensitivity in pre-surgical assessment of adnexal masses for risk of malignancy.

5562 Poster Session (Board #120), Sat, 1:15 PM-4:45 PM

Early drug development in advanced gynecologic cancer based on genetic tumor profiling. *First Author: Ana C. Garrido-Castro, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: The broad spectrum of actionable molecular alterations (MA) detected with new techniques has increased interest in matched targeted therapies (MTT) after failure to standard treatment. **Methods:** Advanced gynecologic tumor (GYNT) patients (pts) were analyzed in our Molecular Prescreening Program for MA: mutations (mt) detected with Sequenom (Sq) or VHIO Card Amplicon Seq Panel (VCASP), Notch and PI3K amplifications (amp), PTEN loss (Hscore $\leq$ 50) and PDL1 expression. Pts were allocated to Phase I trials with MTT based on MA. Time to treatment failure (TTF) with MTT (TTF2) was compared to TTF with the previous unmatched therapy (TTF1). **Results:** From Jan 2012 to Dec 2014, 129 GYNT pts (mean age: 52.6 yrs; median no. previous treatments: 3 [0-7]) were screened for MA; 87 ovarian (OC; 23 type I, 64 type II), 27 endometrial (EC; 15 type I, 12 type II) and 15 cervical (CC) cancers. Of 69 pts with MA (53.5%), 33 received MTT (47.8%) including one OC pt treated with 2 consecutive MTT. MA were identified in 15 type I and 27 type II OC pts; mt in *PI3KCA* (9), *KRAS* (7), *BRAF* (2), *TP53* (8), amp in *Notch* (8) and *PI3K* (1), PTEN loss (18) and PDL1+ (3). In 12 type I and 9 type II EC, mt in *PIK3CA* (4), *KRAS* (8), *TP53* (2), *PTEN* (2), *FGFR1* (1), *ESR1* (1) and *ABL1* (1), PTEN loss (13) and PDL1+ (2) were found. *KRAS* (2), *PI3K/AKT*(2) mt and PDL1+ (2) were detected in CC. Two Sq wild-type pts tested with VCASP held TP53 mt. Of 16 *PIK3CA* MA pts, 6 were treated with α-specific PI3Ki, 1 with PI3K/mTORi and 3 with α-PI3Ki combined with IGFR1 or FGFRi. *KRAS* mt pts (17) were matched to MEKi-based combos: 7 MEK/PI3Ki, 2 MEK/AKTi and 1 MEK/IGFR1i. Multiple MA in a type I OC pt (*KRAS/BRAF* mt) were treated with PI3K/MEKi, a type I EC pt (*PIK3CA/KRAS* mt) with mTORi, and a type II EC pt (*TP53/FGFR1/ABL1* mt) with MET/FGFR/AXLi. Of 10 *TP53*mt, 1 PTEN loss pt received PI3Ki. Notch-i was offered to 5 of 8 amp OC and anti-PD1/PDL1 agents to 3 of 6 PDL1+ GYNT. Although no differences were found between TTF1 and TTF2 (17.8 vs 15.0 wks, $p = 0.156$), TTF2/TTF1 was > 1.2 in 11 of 34 MTT (32.4%). **Conclusions:** Albeit statistical significance was not reached, TTF improved in $> 30\%$ of pts meriting further evaluation of MTT in GYNT. More time is needed to elucidate the impact of genetic/proteomic tumor profiling in drug development of GYNT.

5563 Poster Session (Board #121), Sat, 1:15 PM-4:45 PM

Use of neoadjuvant chemotherapy in advanced ovarian cancer. *First Author: Larissa Meyer, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In 2010, a randomized trial demonstrated no difference in survival in advanced ovarian cancer patients treated with neoadjuvant chemotherapy (NAC) or primary debulking surgery (PDS). We examined the use and effectiveness of NAC in clinical practice over time. **Methods:** Prospective cohort study of women with stage IIIC/IV ovarian cancer treated at National Comprehensive Cancer Network (NCCN) institutions between 2003-2012. We examined the use ($N = 961$) and outcomes ($N = 414$) of NAC + interval debulking (IDS) +/- adjuvant chemotherapy versus PDS +/- adjuvant chemotherapy. Propensity score matching was used to balance observed confounders between groups in the outcomes analyses and trial participants excluded. Cox regression, logistic regression, and Fisher's exact test were used to examine overall survival, residual disease, and perioperative morbidity in the matched sample. **Results:** Use of NAC+IDS increased from 0-39% between 2003-2010, and rose to 53% (stage IIIC) and 58% (stage IV) in 2011-2012. Adoption of NAC+IDS varied by institution from 0%-29% (stage IIIC, $P < 0.001$) and 13%-48% (stage IV, $P = 0.04$). After propensity-score adjustment, NAC+IDS was associated with lower survival in stage IIIC disease, compared with PDS (median 31 vs. 50 months, hazard ratio [HR] 1.54, 95% confidence interval [CI] 1.05-2.24), and comparable survival in stage IV disease (median 43 vs. 32 months, HR 0.78, 95% CI 0.50-1.22). NAC+IDS was associated with higher odds of an R0 resection [odds ratio (OR): 2.26, 95% CI 1.28-3.98, stage IIIC; OR 4.03, 95% CI 1.73-9.38, Stage IV), and fewer ostomies (adjusted rates: 3% vs. 9%, $P = 0.11$, stage IIIC and 3% vs. 11%, $P = 0.06$, stage IV). Readmission rates were lower in NAC+IDS, compared with PDS (adjusted rates: 2% vs. 16% for stage IIIC and 2% vs 15% for stage IV, both $P < 0.001$). **Conclusions:** NAC+IDS use increased significantly at NCCN centers between 2003-2012. In this observational study, overall survival was comparable in patients with stage IV disease, and NAC+IDS was associated with lower ostomy rates and perioperative morbidity in stage IIIC and IV disease. NAC+IDS was associated with decreased survival in patients with stage IIIC disease, however additional selection bias may remain after propensity-score matching.

5564 Poster Session (Board #122), Sat, 1:15 PM-4:45 PM

Baseline predictors of early treatment failure in patients with platinum resistant/refractory (PRR) and potentially platinum sensitive (PPS ≥ 3) recurrent ovarian cancer (ROC) receiving ≥ 3 lines of chemotherapy: The Gynaecologic Cancer Intergroup (GCIG) Symptom Benefit Study (SBS). *First Author: Felicia T Roncolato, ANZGOG, NHMRC Clinical Trials Centre, University of Sydney, Camperdown, Australia*

Background: Women with PRR/PPS ≥ 3 ROC are a heterogeneous group with unpredictable response to palliative chemotherapy (PC). GCIG SBS recently completed recruitment of 949 patients treated with PC. Primary aim is to validate an instrument to measure symptom benefit; secondary aims include identifying factors that predict early progression. 25% of patients with PRR-ROC received < 8 weeks of PC. **Methods:** Physicians recorded baseline characteristics, symptoms (symptomatic ascites, cramping abdominal pain), site/extent of disease and prespecified lab values. Association between baseline characteristics and progression-free survival (PFS) was assessed using time-to-event methods. Median PFS was calculated according to clinically relevant categories and log-rank test applied to assess prognostic value. Cox regression was used to compute hazard ratios and 95% CI to assess the effect of variables on PFS. **Results:** Sufficient follow up for analysis of PFS was available in 791 patients. Median PFS and overall survival were 4.3 (95% CI: 3.9-4.9) and 12.9 months (95% CI: 11.4-14.0) respectively. In univariate analysis factors with statistically significant associations with PFS included: haemoglobin, PRR-ROC, ascites and abdominal cramps, nodal disease, thrombocytosis, CA125 > 1000, LDH > 600, ECOG status, and elevated c reactive protein. Non-significant factors included: visceral metastases, albumin < 25, lymphocytes < 0.5, tumour volume. Significant variables in multivariable analysis included: ECOG ≥ 2 (HR 1.61 95% CI 1.18-2.19 p = 0.003); nodal disease (HR 1.37 95%CI 1.13-1.67 p = 0.002); ascites (HR 1.54 95%CI 1.24-1.92 p = 0.0001); platinum resistant vs. sensitive (HR 1.39 95%CI 1.12-1.72 p = 0.002), CA125 > 1000 (HR 1.35 95%CI 1.09-1.67 p = 0.005); LDH > 600 (HR 1.88 95%CI 1.36-2.60 p = 0.0001). **Conclusions:** Several simple clinical variables help predict patients who progress rapidly and will be used to construct prognostic models to aid clinical decisions and trial stratification for clinical trials in PRR/PPS ≥ 3 ROC Clinical trial information: 12607000603415.

5565 Poster Session (Board #123), Sat, 1:15 PM-4:45 PM

Preliminary phase II results of selinexor, an oral selective inhibitor of nuclear export in patients with heavily pretreated gynecological cancers. *First Author: Ignace Vergote, University Hospital Leuven, Leuven, Belgium*

Background: Multiple tumour suppressor proteins (TSPs) are altered in ovarian (OC), endometrial (EC) & cervical (CC) cancers, including p53, BRCA1/2, CDKN2A & pRB. Selinexor, an oral first in class, inhibitor of XPO1 mediated nuclear export, results in nuclear retention and activation of multiple TSPs. Selinexor has anti-cancer activity in preclinical models of CC & platinum-resistant OC & in a phase I clinical study. This phase II trial explores the efficacy & tolerability of Selinexor in patients (pts) with advanced/metastatic incurable OC, EC & CC. **Methods:** Pts with ≥ 1 line of prior therapy were treated with single agent oral S using Simons two-stage design (NCT02025985). The primary endpoint is disease-control-rate (DCR = PR+SD ≥ 12weeks [wk]). Other endpoints are ORR, PFS, safety, & tolerability. Three treatment schedules (50 mg/m^2 twice-weekly (BIW); 35 mg/m^2 BIW; & 50 mg/m^2 QW in 4-wk cycles) are evaluated. The three cohorts (OC, EC & CC) are evaluated independently for response by RECIST 1.1 after 6 & 12 wks, then every 8 wks. **Results:** All three cohorts have passed efficacy response rates for Simon analysis & proceeded to stage two. 30 OC (Median age [MA] 63, ECOG 0/1: 16/14, median 5.5 (1–11) prior treatment regimens [PTR]), 15 EC (MA 69, ECOG 0/1: 8/7, median 2 (1–5) PTR) & 18 CC (MA 55.5, ECOG 0/1: 13/5, median 3 (1–8) PTR) heavily pre-treated pts have been enrolled. No Grade 4 toxicities have been seen. Grade 3 drug related adverse events (AEs) include: Nausea (13%), Thrombocytopenia (13%), Vomiting (11%), & Fatigue (10%). Commonly reported Grade 1/2 drug related AEs for all three cohorts include: Nausea (54%), Vomiting (5%), Fatigue (32%), & Anorexia (25%). Dose reductions occurred in 30 % of pts. DCR in evaluable pts: OC: 36%; EC: 64%; CC: 28%. ORR in evaluable pts: OC: 9%; EC: 18%; CC 7%. **Conclusions:** The initial phase 2 data demonstrate meaningful single-agent anti-tumor activity of Selinexor in all three heavily pretreated gynaecological malignancies. Some pts required dose reduction of Selinexor due to fatigue & anorexia. The most tolerable dosing regimen will be selected for phase III trials. The trial continues to enrol pts. Updated data will be presented. Clinical trial information: NCT02025985.

5566 Poster Session (Board #124), Sat, 1:15 PM-4:45 PM

Genomic characterization of long-term responders to olaparib. *First Author: Stephanie Lheureux, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: *BRCA1/2* mutations (*BRCA*m) predict benefit from olaparib (*vs* placebo) in platinum sensitive high grade serous ovarian cancer (HGSOC). However not all patients (pts) with *BRCA*m respond and others without *BRCA*m have very durable benefit from PARP inhibitors. This study characterised long (LT ≥ 2 years) and short-term (ST ≤ 3months) responders on olaparib maintenance. **Methods:** Clinical (previous chemo lines, stage, platinum free interval) and molecular variables from archival tumor were assessed from study D0810C000019 – olaparib/placebo after response to platinum in HGSOC. Germline *BRCA1/2* testing, Homologous Recombination Deficiency (HRD) score (positive ≥42) and *BRCA1* methylation were determined by Myriad Genetics. A comprehensive genomic profile with next generation sequencing was performed through Foundation Medicine. Fisher's exact test was used to test the association between presence and absence of any factor comparing ST *vs* LT. **Results:** Of pts who received olaparib maintenance, 32 had LT and 21 ST disease control. In the LT group, 21 pts had *BRCA*m (66%, *BRCA1* 9 pts, *BRCA2* 12 pts), positive HRD scores and deleterious *TP53* mutations. Variants of Unknown Significance were found in 2 LT pts (6%) with positive HRD scores and *TP53* mutations but negative for *BRCA1* methylation. In the overall study population, *BRCA1* methylation was not observed within LT pts: 27/37 LT pts (olaparib/placebo) had *BRCA1* methylation status available and none were methylated. 42/61 ST pts had methylation status available and 8 (19%) had *BRCA1* methylation. Complete response at the time of olaparib maintenance (p=0.026) and HRD deficiency status (p=0.026) were associated with LT on univariate analysis, and did not discriminate ST *vs* LT in the placebo group. LT group showed a trend for the presence of deleterious *TP53* mutation (p=0.051); *TP53* mutation status was available in 28/32 LT and 16/21 ST; deleterious mutations were detected in 27/28 LT *vs* 12/16 ST pts; in contrast with *TP53* wild-type found in 1/28 LT pt and 4/16 ST pts. **Conclusions:** Comparison of LT and ST responders provides a contrasting assessment of the intersection of disease biology on effect of olaparib and may allow identification of predictive patterns of durable benefit that need to be validated.

5567 Poster Session (Board #125), Sat, 1:15 PM-4:45 PM

Phase 2 studies of multiple peptides cocktail vaccine for treatment-resistant cervical and ovarian cancer. *First Author: Satoshi Takeuchi, Iwate Medical University, Morioka Iwate, Japan*

Background: We have conducted phase 2 studies of peptides vaccine (PV) immunotherapy for cervical (CC) and ovarian cancer (OC) using human leukocyte antigen (HLA)-restricted tumor specific epitope peptide and VEGF receptor1 (VEGFR1) and 2. Institutional review board had approved these studies. **Methods:** All patients (pts) with heavily treated and with HLA-A2402 or A0201 within PS2 were enrolled. Written-informed consent had obtained. Enrollment finished on October 20,2014. PV cocktail were as follows: FOXM1, MELK, HJURP,HIG2,VEGFR1 and VEGFR2 for OC, FOXM1, MELK, HJURP,URLC10 and HIG2 for CC. Each peptide (GMP grade) was mixed at a dose of 1mg with 1ml of adjuvant, MONTANIDE,ISA51. Vaccination schedule included 12 subcutaneous weekly injections. Thereafter, additional administrations (adms) were performed. CTL was analyzed by ELISpot assay. Clinical responses were evaluated every three months by RECIST v 1.1 and additional immune-responsive (ir-) RECIST **Results:** Twenty one pts of CC and 46 pts of OC were enrolled. PV was generally well tolerated with no major adverse events, and most of the patients developed specific CTL responses until 8 adms. Two patients showed complete response by RECIST. Median overall survival(mOS) of CC and OV was 15.4 months(m)and 8.8 m,respectively. No significant survival benefits were seen among HLA type and histology subtypes, but c-reactive protein levels (lower than 2.0 mg/dl) at base line in OC and dermatological hypersensitivity (DTH) during adms in CC and OC was strongly related their OS. Lower CRP group showed longer median OS (mOS = 19.0m vs. 3.0m, logrank p = 0.0016) in OC. As for DTH, negative versus positive patients, the mOS was 3.3 m vs. 21.2m, logrank p = 0.065, in CC, and it was 1.4 m vs. 17.7 m, logrank p < 0.0001, in OC. **Conclusions:** These findings suggest that this PV immunotherapy was safe and effective even for incurable patients and they would be applicable for maintenance therapy for cervical and ovarian cancer. Clinical trial information: UMIN000003860,3862,3902,3903.

5568 Poster Session (Board #126), Sat, 1:15 PM-4:45 PM

Propensity-score analysis of neoadjuvant chemotherapy vs. primary surgery in advanced ovarian cancer: Does surgical quality matter? *First Author: Hyo Sook Bae, National Cancer Center, Goyang, South Korea*

Background: Although there are many studies that compared the outcome of neoadjuvant chemotherapy (NAC) and primary surgery in advanced ovarian cancer, most of them showed some limitations such as selection bias and the quality control of surgical procedure. **Methods:** Data of 1124 patients with advanced epithelial ovarian cancer (stage III-IV) were reviewed retrospectively. To mitigate the possible biases from the retrospective nature of the study, we performed a propensity score analysis. Progression-free survival was assessed using a multivariate Cox-proportional hazards regression model with inverse probability weights to adjust for propensity score. **Results:** Among the 1124 patients, 198 patients (17.6%) underwent NAC. The factors associated with the use of NAC were old age, non-serous histology, poor histologic grade, stage IV and higher serum CA 125 levels (P-value 0.211, 0.050, < 0.001, < 0.001 and < 0.001, respectively). After a propensity score adjustment using those factors, the progression-free survival of the NAC group was not significantly different from that of the primary surgery group (HR 1.187, CI 0.932-1.512, *P*-value 0.164). Especially, no significant difference was observed between the two treatment strategies in the subgroup from the hospitals with higher surgical standards with the average rate of optimal cytoreduction was over 50% (HR 1.166, CI 0.885-1.536, *P*-value = 0.275). However, when we did not adjust the confounders, the outcome of primary surgery group was superior to that of NAC group (HR 1.24, CI 1.016-1.515, *P*-value 0.035). **Conclusions:** Progression-free survival of NAC group did not differ significantly from primary surgery in patients with advanced ovarian cancer. Even in the institutions providing a good standard of surgical care, we did not found any evidence suggesting that primary surgery is better than NAC in patients with advanced ovarian cancer.

5569 Poster Session (Board #127), Sat, 1:15 PM-4:45 PM

Feasibility and outcome of interval debulking surgery (IDS) after carboplatin-paclitaxel-bevacizumab (CPB): Results from a subgroup of patient from the MITO-16A-MANGO OV2A phase 4 trial. *First Author: Gennaro Daniele, National Cancer Institute Naples, Castel S Giorgio, Italy*

Background: Few data are available on the outcome of surgery after a bevacizumab-containing regimen. The MITO 16A- MANGO OV2A phase 4 trial evaluates the outcomes of first-line CPB in a clinical-practice-like setting. Here we present the results of the subgroup of patients undergoing IDS after neoadjuvant treatment or suboptimal primary surgery. **Methods:** 400patients aged $\geq$ 18 with untreated AOC, ECOG PS 0-2 were eligible to receive C (AUC 5 d1, q21) plus P (175mg/m^2 d1, q21) and B (15 mg/kg d1 q21) for 6 cycles followed by B maintenance until cycle 22nd within the MITO 16 trial. **Results:** With data available at Dec 31, 2014, 79/400 patients (20%) underwent IDS; bevacizumab was omitted before IDS in 5 patients. In the remaining 74 patients, median age was 61.2, 72% had FIGO IIIC disease, 23% FIGO IV and 5% FIGO IIIB. 60 patients (82.3%) had a suboptimal ($>$ 1cm) primary surgery, while in 14 cases a neoadjuvant therapy was given after a biopsy with no attempt of resection. The median number of cycles before IDS was 3 (Interquartile range, IQR: 3-4) and 3 (IQR: 2-3) for chemotherapy and bevacizumab respectively, with a median interval between the last bevacizumab and the IDS of 38 days (IQR: 34-47). The median duration of the IDS was 3.5 hours (IQR: 2.8-5) and discharge of the patients was after a median of 7.5 days (IQR: 6-10). The outcome of IDS is unknown for 3 patients; 10 patients (12.7%) were suboptimally debulked, while the residual disease was absent or $\leq$ 1 cm in 61 patients (82.4%). After IDS there was no major adverse events. Fever complicated 4% of the interventions and 4% of the patients required blood transfusion after surgery. Surgical wound infection and/or dehiscence, pelvic abscess, intestinal sub-occlusion and fistula were experienced by one patient each. **Conclusions:** In the MITO16A-MANGO OV2A phase 4 trial, combined chemotherapy and bevacizumab did not prevent IDS and the rate of perioperative complications was similar to what expected without bevacizumab. These data support the hypothesis that the opportunity to add bevacizumab to chemotherapy in first line treatment of ovarian cancer might not be denied to patients for whom IDS is planned. Clinical trial information: NCT01706120.

5570 Poster Session (Board #128), Sat, 1:15 PM-4:45 PM

Durable tumor remission in patients with platinum-resistant ovarian cancer receiving nivolumab. *First Author: Junzo Hamanishi, Kyoto University, Kyoto, Japan*

Background: Programmed death-1 (PD-1) is a co-inhibitory receptor expressed on activated T cells which regulates antitumor immunity. Nivolumab is a fully-humanized IgG4 that blocks the engagement of PD-1 by PD-1 ligands. We previously showed nivolumab can mediate tumor regression in a substantial proportion of patients with ovarian cancer in phase II trial (ASCO 2014, UMIN000005714), but the potential of durable anti-tumor response by nivolumab for these patients was unknown. **Methods:** Patients with platinum-resistant ovarian cancer (n=20) enrolled from 2011 to 2014 were treated with nivolumab (1mg/kg, n=10; 3mg/kg, n=10, each) intravenously every two weeks up to one year were followed how long anti-tumor response continued. **Results:** Among 20 patients in whom response could be evaluated, we followed two patients with complete response in 3mg/kg cohort and one patient with partial response of 1mg/kg cohort. At the time of data cut off, a partial responder had responses for 5 months, and two complete responders survived without disease progression for 17 and 14 months, each. The duration of response of these patients after treatment discontinuation was 6months and 3months, each. **Conclusions:** Anti-tumor responses were durable and continued after niolumab-treatment discontinuation. Now we explore the biomarker of these responders and next phase of clinical trials will further assess the significance of nivolumab on survival in patients with ovarian cancer. Clinical trial information: UMIN000005714.

5571 Poster Session (Board #129), Sat, 1:15 PM-4:45 PM

A phase 1b, open-label, non-randomized multicenter study of birinapant in combination with conatumumab in subjects with relapsed epithelial ovarian cancer, primary peritoneal cancer, or fallopian tube cancer. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: Treating patients (pts) with relapsed ovarian cancer remains challenging. Birinapant is a bivalent SMAC mimetic in clinical development for solid and hematological malignancies. *In vitro* there is synergy with birinapant and Amgen's DR-5 agonist antibody, conatumumab. Birinapant alone was not active in relapsed ovarian cancer, but the combination with conatumumab is thought promising. This study sought to determine the safety and tolerability of birinapant with conatumumab in relapsed ovarian cancer. **Methods**: Pts with relapsed epithelial ovarian, primary peritoneal or fallopian tube cancer were enrolled to 1 of 2 cohorts. Birinapant was dosed intravenously (IV) at 13 mg/m^2 2x weekly, 3 weeks of 4 (Days 1, 4, 8, 11, 15, and 18; Cohort 1); and 13 mg/m^{2}2x weekly, 4 weeks of 4 (Days 1, 4, 8, 11, 15, 18, 22 and 25; Cohort 2), with conatumumab at a fixed dose of 10 mg/kg IV, on Day 1 and Day 15 for each 28-day cycle. Assessments for dose limiting toxicities (DLTs), as well as safety, clinical response, pharmacokinetics (PK) and pharmacodynamics were performed. **Results**: To date 18 pts have been enrolled; 6 to Cohort 1 and 12 to Cohort 2. DLTs were seen in 1 pt in Cohort 1 (Grade 3 amylase and lipase elevation) and 1 pt in Cohort 2 (Grade 3 cranial nerve palsy). The most common ($\geq$ 3 pts) reported adverse events (AE) were fatigue; nausea; vomiting; abdominal pain; headache; hypomagnesemia; pruritis; chills; constipation; depression; diarrhea; dizziness; pyrexia; mucositis; urinary tract infection. The only serious adverse event seen in $>$ 1 pt was bowel obstruction (2 pts). An additional pt in Cohort 2 developed Grade 2 cranial nerve palsy. The PK of birinapant and conatumumab were unchanged from that reported previously for either agent. Pharmacodynamic evaluation is ongoing. Best response was PR seen in 1 pt; an additional 4 pts demonstrated best response of SD. Median time on study is 1.9 months (0.1-5.9 months). **Conclusions**: The combination of birinapant plus conatumumab in relapsed ovarian cancer is tolerable. Dose expansion (Cohort 3) is continuing at a dose of birinapant 11 mg/m^2 2x weekly, 3 weeks of 4. Clinical trial information: NCT01940172.

5572 Poster Session (Board #130), Sat, 1:15 PM-4:45 PM

Carboplatin hypersensitivity reactions (HSR) in carboplatin retreatment for recurrent ovarian cancer. *First Author: Roisin Eilish O'Cearbhaill, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: The reported risk of HSR during carboplatin retreatment is 18-44% and increases with repeated carboplatin exposure. We aimed to prospectively study the effect of an extended incremental infusion of carboplatin on the rate of HSR. **Methods:** Eligible patients (pts) with recurrent ovarian cancer were consented to an IRB-approved phase II randomized study from 01/2011-01/2015. Pts were randomly assigned 1:1 to standard 30-minute or an incremental 3-hour (1% in 1st hour, 9% in 2nd hour and 90% in 3rd hour) carboplatin infusion. Pts were stratified for concomitant taxane. Based on historical estimates the study was powered to detect a reduction in HSR from 20% to 5% with the extended infusion. All pts were prescribed premedication with montelukast 10 mg nocte x 3 days, dexamethasone 20 mg the night before and morning of, as well as famotidine 20 mg (or ranitidine) and diphenhydramine 50 mg (or hydroxyzine) prior to carboplatin. Pts were deemed evaluable for the study endpoint if they completed ≥ 5 cycles of carboplatin-based treatment or had carboplatin HSR. CTCAE criteria were used. **Results:** A total of 143 pts with recurrent ovarian cancer were enrolled. Median age was 62 years (35-82). 104 pts (52 in each arm) were evaluable for the study endpoint. Among these pts, 72 (69%), 27 (26%), 2 (1.9%) and 3 (2.9%) pts had 1, 2, 3 and 4 prior platinum-based regimens, respectively. 27 pts (26%) received carboplatin single agent and the remainder a platinum-doublet (46 liposomal doxorubicin, 24 gemcitabine, 7 paclitaxel). There were 15 HSR (14% of pts); 9 HSR in standard arm (9/52, 17%) and 6 HSR in the extended arm (6/52, 12%). There was 1 grade 3 HSR in the extended arm. No pt required hospitalization or epinephrine for HSR. The other 14 HSR were grade 1 or 2. HSR occurred on cycle #1 (1 pt); #2 (5 pts); #3 (4 pts); #4 (2 pts); #5 (2 pts) and #6 (1 pt). 2/9 HSR pts in standard arm were able to complete therapy with an extended infusion without further HSR. **Conclusions:** We did not demonstrate a statistically significant reduction in carboplatin HSR with use of an extended carboplatin infusion. However, the relatively low frequency of severe HSR in both arms suggests there may be a role for prophylactic premedication prior to carboplatin retreatment. Clinical trial information: NCT01248962.

5573 Poster Session (Board #131), Sat, 1:15 PM-4:45 PM

A phase Ib/II trial with expansion of patients at the MTD trial of olaparib plus weekly (metronomic) carboplatin and paclitaxel in relapsed ovarian cancer patients. *First Author: Saul E. Rivkin, Swedish Cancer Inst, Seattle, WA*

Background: We established the olaparib tablet maximum tolerated dose, dose limiting toxicities (DLT's) and response to therapy of carboplatin, paclitaxel and olaparib tablet given simultaneously, reported at ASCO 2014. This abstract will include data from both the phase 1b and the phase 2 expansion. **Methods:** A total of 54 subjects were evaluated in this trial, 14 in phase 1b and 40 in phase 2. Eligibility required measurable disease, adequate organ function and ECOG performance status of ≤ 2. Subjects had to have failed first line platinum containing chemotherapy. BRCA testing was conducted as available. Subjects received the metronomic therapy of paclitaxel 60mg/m2 IV and carboplatin AUC 2 IV weekly, 3 weeks out of 4, and olaparib tablets at the MTD of 150 mg bid administered orally for 3 consecutive days (D1-D3), every week for each cycle. Subjects were assessed for toxicity and response according to the protocol. Subjects that reached a confirmed complete remission were transitioned to olaparib tablets only, 300 mg bid, until disease progression. **Results:** Median age was 58 and median number of prior regimens was 4. There have been no deaths due to the study regimen. One patient had grade 4 neutropenia and an allergic reaction to carboplatin. The common grade 3 toxicities caused by this regimen were neutropenia, anemia and thrombocytopenia. Two subjects had mild GI toxicities. There was no evidence of cardiac, hepatic, or pulmonary toxicities in any of these subjects. 22.5% of subjects had a complete remission (CR), 30% had PR, 25% had SD and 22.5% had PD. Of the 9 CR's, 6 were gBRCA mutated. PFS median for gBRCA mutated subjects is 19 months vs 4 months for non-mutated gBRCA subjects. OS median for gBRCA mutated subjects is 24 months vs 16 months for gBRCA non-mutated subjects. All of the CR's are alive. **Conclusions:** Olaparib tablets can be safely administered simultaneously with a weekly regimen of carboplatin and paclitaxel in heavily pretreated ovarian cancer subjects. Olaparib appears to be highly effective in gBRCA mutated. This is the first successful combination of olaparib tablets with carboplatin and paclitaxel that has been well tolerated. Clinical trial information: NCT01650376.

5574 Poster Session (Board #132), Sat, 1:15 PM-4:45 PM

BL1 gene expression subtype to predict outcome in serous ovarian cancers. *First Author: Rob Seitz, Insight Genetics Inc, Nashville, TN*

Background: A new 2188-gene model classifies triple-negative breast cancer (TNBC) into six distinct subtypes: two basal-like, two mesenchymal-like, immunomodulatory and luminal androgen receptor subtypes. Among taxane-treated TNBC patients, significantly higher response rates were seen in patients with BL1 compared to BL2 tumors. Recently we showed that a "lean algorithm" of 101 genes could replicate this result in TNBC patients. As TNBC and serous ovarian cancer share many features, similar sub-classification of ovarian cancers may also be clinically important. **Methods:** A cohort of 592 patients with serous ovarian carcinoma (primarily platinum/taxane-treated) was analyzed. Patients were classified using both the original 2188-gene and 101-gene centroid models. Patients who had an insignificant or multiple statistically indistinguishable correlations with the subtype centroids were considered "unclassified." Three-year survival was examined using log-rank test and Cox proportional hazard regression analysis. **Results:** While both models had a higher percentage of unclassified patients in ovarian as compared to TNBC, the 101-gene model classified more patients (60%) than the 2188-gene model (34%). In the subset classified by both models, the models showed 95% agreement. Ovarian cancer patients with BL1 tumors had significantly better 3-year overall survival compared to all other subtypes (hazard ratios of 0.48 and 0.41, p = 0.02 and 0.01, 2188 and 101-gene models respectively). If age and stage—both independent predictors of survival—were included as covariates, only the 101-gene model defined BL1 subtype had a significant association with outcome (HR 0.47, p = 0.02). **Conclusions:** There was excellent agreement between the original 2188-gene TNBC classifier and a streamlined 101-gene classifier when applied to an ovarian cancer cohort. BL1-classified ovarian cancer patients had significantly better 3-year survival outcomes than patients with tumors of other subtypes; however, only the 101-gene classification of the BL1 subtype was independent of age and stage. Studies aimed at the refinement of gene expression-defined serous ovarian carcinoma subtypes that can guide therapeutic management will be presented.

5575 Poster Session (Board #133), Sat, 1:15 PM-4:45 PM

Genomic profile and immune infiltrate in paired ovarian cancer (OC) samples pre- and post-neoadjuvant chemotherapy (NC). *First Author: Alexandra Leary, Royal Marsden Hospital, London, United Kingdom*

Background: Most studies of OC have analysed tumors at diagnosis, little is known about the evolution of the genomic or immune landscape of OC with NC. Profiling after NC may be informative as the residual tumor may be enriched for resistant clones. **Aim**: Compare matched post- vs pre-NC tumors to describe changes in immune infiltrate, genomic stability (GS) and characterize the chemo-resistant sub-populations by identifying SCNAs selectively enriched post-NC. **Methods**: 27 frozen OC samples (13 paired pre/post-NC and 1 subsequent relapse) were subjected to aCGH. GS was evaluated by the % altered genome and the number of altered segments > 15Mbp (*N*). Changes in copy number alterations (CNA) were considered relevant if log(2)ratio difference in matched post- vs pre-NC samples > 0.5. FFPE samples (N = 66; 33 paired) were scored for % stromal tumor infiltrating lymphocytes (sTILs) on whole sections. **Results**: Cellularity of frozen samples was high (70-90%) and included 12 high grade serous OC (HGSOC) and 1 low grade SOC. At baseline, HGSOC were unstable with 10 showing *N*> 10 (range 14-48) and 31%-70% altered genome. LGSOC showed 2% altered genome. GS increased in 8/12 HGSOC resulting in < 2% altered genome post-NC for 3; GS decreased in 2/12 and did not change in 3. CNAs enriched in paired post-vs pre-NC included gains in genes involved in p53 signalling (*MDM4, TP53BP2),* EMT/senescence (*PKD1, ESRP1, RB1CC1*), or epigenetic modification (*CEBBP, SMARCB1, RBBP7*) and changes in DNA repair genes implicated in chemoresponsiveness (*PALB2*, *ERCC4, RAD54B* or *RAD21*). In addition potentially actionable targets were upregulated post NC (*AKT3*, *BRAF, RAS* family or *FGF6*). For the case with 3 samples, the profile at relapse was different from pre-NC but identical to the post-NC. sTILs increased with NC in 48% (16/33) of paired cases, and 6 tumors had ≥ 60% sTILs post-NC. An evaluation of changes in PDL1 with NC is ongoing and will be presented. **Conclusions**: The immune and genomic landscape of OC changes with NC. Surprisingly a proportion showed increasing TILS and GS. Comparative profiling of post- vs pre-NC tumors could be used to select therapies such as immune or targeted therapies to eradicate the residual lethal clones driving relapse.

5576 Poster Session (Board #134), Sat, 1:15 PM-4:45 PM

Homologous recombination (HR) deficiency, tumor *BRCA1/2* mutations (tmBRCA) and association with response and outcome following platinum monotherapy in high grade serous ovarian cancer (HGSOC). *First Author: Robert Brown, Imperial College London, London, United Kingdom*

Background: Response to DNA-damaging agents, including platinum, is associated with defects in BRCA1/2 and other HR pathway genes. The HRD score is a sum of three previously described metrics (Abkevich et al, Birkbak et al, Popova et al), and is significantly associated with both tmBRCA and response to DNA damaging agents. This study examined whether HR deficiency (HRD score ≥ 42 or tmBRCA positivity) was predictive of response or prognostic in a carboplatin monotherapy treated HGSOC cohort from the SCOTROC4 phase 3 trial (Bannerjee et al 2013). **Methods:** DNA from formalin-fixed archival tumor from 165 HGSOC patients treated with first-line single-agent carboplatin was analyzed for HRD scores and tmBRCA. Cox proportional hazards analysis was used to test CA125 response, HR deficiency, and tmBRCA for associations with progression free survival (PFS) and overall survival (OS). HR deficiency and tmBRCA were evaluated as predictors of CA125 complete response using logistic regression. **Results:** BRCA1/2 mutations were detected in 26/165 (16%) of primary HGSOC. HR deficiency was present for 53/151 (35%) tumors analyzed. Patients with CA125 complete response (n = 64) had significantly improved PFS (p = 6.6x10-7) and OS (p = 3.3x10-7) compared to no or partial CA125 response (n = 45). HR deficiency predicted CA125 complete response in all evaluable patients (p = 0.0033, n = 96) and in the *BRCA1/2* wild type subset (p = 0.034, n = 75). TmBRCA trended but was not significantly associated with CA125 response (p = 0.079, n = 107). HR deficiency and tmBRCA were associated with improved PFS (p = 0.00058; 0.012 respectively) and OS (p = 0.0040; 0.026 respectively) in an independent manner from known prognostic clinical factors. **Conclusions:** HR deficiency and tmBRCA were significantly associated with outcome in HGSOC patients treated with platinum monotherapy. HR deficiency was also significantly associated with complete CA125 response in the entire cohort, and importantly, in *BRCA1/2* wild type tumors. Pending validation evaluation of HR deficiency and tumor BRCA status should be considered in the development of platinum combination therapies.

5577 Poster Session (Board #135), Sat, 1:15 PM-4:45 PM

Delayed recurrences and survival after relapse in patients initially treated with intraperitoneal chemotherapy for advanced ovarian cancer: A Gynecologic Oncology Group study. *First Author: Daniel Stuart Kapp, Stanford Univ Medcl Ctr, Stanford, CA*

Background: Randomized trials have shown that intraperitoneal (IP) therapy is superior to intravenous (IV) chemotherapy in advanced ovarian cancer patients with long-term survival outcomes. We proposed to determine the contribution to improved survival in those treated with IP over IV therapy. **Methods:** Data from Gynecologic Oncology Group protocols 114 and 172 were retrospectively analyzed. Kaplan Meier estimates and Cox proportional hazards regression models were used for statistical analyses. **Results:** Of 876 women, the median age was 57 years (range: 49 to 66 years). All patients had stage III disease and 73% had serous, 10% endometrioid, 4% clear cell, 2% mucinous and 12% others. 64% had gross residual and the remaining 36% had no visible disease after surgery. After a median follow-up of 10.7 years, 27% (118/440) of IP vs. 22% (96/436) of IV patients remained free of disease (p = 0.098). Recurrences were delayed for the IP vs. IV patients at a median 24.4 (95%CI: 14.3–60.1 months) vs. 20 months (95%CI: 11.5–43.7 months; p = 0.002). The 10 year progression-free survival was 18% and 16% (p = 0.019), respectively. 201 patients remained on follow-up beyond 5 years with 111 from IP and 90 from IV therapy. We then evaluated the survival after recurrence and found that the median overall survival after relapse for IP vs. IV patients was 25.3 vs. 21.7 months, respectively (HR = 0.84; 95%CI: 0.71–0.99, p = 0.034). Factors associated with survival after recurrence included: younger age (HR = 1.01 95%CI: 1.00–1.02 p = 0.022), clear / mucinous histology (HR = 2.90 95% CI:2.08–4.04 p < 0.001), gross residual disease (HR = 1.25; 95%CI: 1.04–1.50; p < 0.001), and progression-free interval after primary treatment (HR = 0.72; 95%CI: 0.66–0.78 p < 0.001). **Conclusions:** The improvement in long-term survival in patients initially treated with intraperitoneal chemotherapy for advanced ovarian cancer is associated with both delayed recurrence after primary treatment and better survival after relapse. Our findings support the contention that the OS endpoint is attainable even in ovarian cancer patients with long post progression survivals.

5578 Poster Session (Board #136), Sat, 1:15 PM-4:45 PM

Part I of GANNET53: A multicenter phase I/II trial of the Hsp90 inhibitor ganetespib (G) combined with weekly paclitaxel (P) in women with high-grade serous, high-grade endometrioid, or undifferentiated, platinum-resistant epithelial ovarian, fallopian tube or primary peritoneal cancer. *First Author: Isabelle Ray-Coquard, GINECO and Centre Léon Bérard, Lyon, France*

Background: Stabilized mutant p53 protein (mutp53) is a novel target in epithelial ovarian cancer (EOC). Due to aberrant conformation, mutp53 proteins depend on folding support by the Hsp90 chaperone. Hsp90 blockade induces degradation of mutp53, resulting in tumor cell cytotoxicity and increased sensitivity to chemotherapeutics. Preclinical synergy of the Hsp90 inhibitor G combined with P provided the rationale for testing the combination in relapsed platinum resistant EOC patients (pts) in the GANNET53 trial (EUDRACT 2013-003868-31). **Methods:** Eligiblepts had platinum resistant EOC. Pts with > 4 prior chemotherapy and low grade carcinoma were not eligible. Weekly P (80 mg/m^2) and increasing doses of G (100, 150 mg/m^2) were given i.v. on days 1, 8, 15 in a 28 days cycle until disease progression or unacceptable toxicity. End points were safety and determination of phase II dose. Dose limiting toxicity (DLT) was defined as grade (gr) 4 toxicity (with exceptions) occurring in cycles 1 & 2. **Results:** Ten pts (median age 57 years; range 43-70) were enrolled. No DLT occurred in cohort 1 (4 pts treated with P + G 100 mg/m^2), nor in cohorts 2 and 3 (6 pts treated with P + G 150mg/m^2). The most common adverse events (AEs) related to G were transient gr 1/2 diarrhea (n = 9). The most frequent gr 1/2 AEs were diarrhea (n = 9), nausea (n = 5), anemia (n = 6), fatigue (n = 4), headache (n = 5), and QTc prolongation (n = 6). AEs ≥ gr 3 were anemia (n = 3), neutropenia (n = 2), and acute cardiac failure (n = 1). There was 1 death on study (after DLT period) due to digestive tract hemorrhage from duodenal ulcer. Two pts discontinued due to SAEs (digestive hemorrhage n = 1, cardiac failure n = 1), 4 due to progressive disease, one due to physicians decision. Three pts are still on study at time of abstract submission. **Conclusions:** The combination of ganetespib 150 mg/m^2 with paclitaxel 80 mg/m^2 once weekly for 3 out of 4 weeks was generally well tolerated with no DLTs, and therefore chosen for the planned randomized phase II trial. Clinical trial information: 2013-003868-31.

5579 Poster Session (Board #137), Sat, 1:15 PM-4:45 PM

The use of patient-derived xenograft models for prioritizing therapeutic targets. *First Author: Clare L. Scott, Walter and Eliza Hall Institute of Medical Research, Parkville, Australia*

Background: Treatment options for women with high-grade serous ovarian cancer (HGSC) remain limited. Defective DNA repair capability may underlie response to standard chemotherapy and to PARP inhibitor therapy[1,2]. Thus, molecular characterization of HGSC may indicate likely sensitivity or resistance to therapeutics. However, determining which potential targets actually drive tumor growth and should be prioritized for therapy is challenging. Pre-clinical HGSC cell lines have been shown to poorly reflect human disease[3] and rarely contain DNA repair gene mutations[4]. In contrast, patient-derived xenograft (PDX) models provide relevant, accurate and tractable models for pre-clinical testing, representative of patient outcome[5,6]. **Methods:** A patient derived xenograft (PDX) cohort was generated from consecutive, treatment-naïve human HGSC and stratified according to DNA repair capability including BROCA sequencing[7] and next generation sequencing by Foundation Medicine. *In vivo* response to standard chemotherapy with cisplatin was determined. Resistance to therapy was driven by re-treating relapsed PDX *in vivo*. Potentially "actionable" aberrations were targeted *in vivo* with relevant novel therapeutics. **Results:** To date, of 30 HGSC PDX studied, 11 contained defects in the DNA repair genes, *BRCA1* or *BRCA2* (9 had *BRCA1/2* mutations, 2 had *BRCA1* methylation) and another 3 PDX contained mutations in other DNA repair genes (FANCL, ATM, CHK2). All *BRCA1/2*-mutant PDX responded to platinum therapy. Dominant oncogenes (eg *CCNE1*, *LIN28B*, *MYCN* and *BCL2*) were overexpressed in platinum-refractory PDX. Potentially actionable targets were targeted *in vivo* with novel therapeutic strategies. **Conclusions:** As patient surrogates, PDX models represent a powerful tool for addressing individualized therapy. PDX are reliably generated from HGSC with DNA repair defects, not seen with cell lines. PDX with serial histologic, molecular, therapeutic annotation and clinical outcome data can be useful in assessing response to novel therapies. 5580 Poster Session (Board #138), Sat, 1:15 PM-4:45 PM

Phase II trial of weekly nab-paclitaxel with GM-CSF as an immune modulator in recurrent platinum resistant ovarian, fallopian tube, and primary peritoneal cancer: Clinical and immune responses. *First Author: John Ben Liao, University of Washington, Seattle, WA*

Background: Antitumor immune responses in ovarian cancer have been associated with prolonged survival. In addition to direct cytotoxic activity, chemotherapies can also possess immunomodulatory properties. Paclitaxel may enhance metastasis and drug resistance by signaling via the TLR4 pathway. GM-CSF has been shown to induce the generation of myeloid dendritic cells and enhance antigen presentation. We hypothesized that weekly nab-paclitaxel followed by GM-CSF may enhance overall anti-tumor immunity. **Methods:** Peripheral blood mononuclear cells (PBMC) were evaluated by flow cytometry for circulating monocytes, dendritic cells, natural killer cells, T-lymphocytes, and myeloid derived suppressor cells (MDSC). Elispot assays for interferon gamma were performed on PBMC to identify immunity against ovarian cancer antigens. **Results:** Twenty-one patients with recurrent platinum resistant ovarian, fallopian tube, or primary peritoneal cancer enrolled after receiving an average of 3 prior lines of chemotherapy. 52% had previously received bevacizumab. Median OS was 16.8 months. Mean time to progression was 5.5 months for those patients who achieved a CR and 4.5 months for those who did not. Overall response rate was 71% (29% CR, 43% PR). Interferon gamma Elispot responses at mean follow-up timepoints against insulin-like growth factor 1 receptor (IGF1R) correlated with time to progression ($r = 0.723$, $p = 0.0035$). The fold change achieved above baseline Elispot responses against IGF1R ($r = 0.827$, $p = 0.0003$) also correlated with time to progression. Levels of MDSC at time of study enrollment were associated with achieving a complete response to treatment ($p = 0.0544$). **Conclusions:** Our results show activity of this regimen and immune correlates for response have been identified. Rational combinations of immune modulators with cytotoxic chemotherapies should be investigated further for platinum resistant recurrent ovarian cancer with a focus on identifying immunologic synergies and those patients most likely to respond through immune biomarkers. Clinical trial information: NCT00466960.

5581 Poster Session (Board #139), Sat, 1:15 PM-4:45 PM

Modifiable risk factors for ovarian cancer: A multinational case-control study. *First Author: Mohammed Shaik, Michigan State University, East Lansing, MI*

Background: Prior ovarian cancer (OC) epidemiological studies have investigated the relationship of diet, exercise, and smoking. Evidence of these risk factors for ovarian cancer has been inconsistent. In this multinational case control study we evaluated those potential modifiable risk factors. **Methods:** Data were obtained from the Global Epidemiological Study, a multinational database to assess disease risk factors. A total of 1344 (OC = 672 and controls = 672) matched for age and race, were recruited from Poland, Vietnam, Western Europe and USA. Information regarding risk factors included different diets in number of servings (serv), exercise, and smoking. For categorical and continuous variables chi-square and t-test were used, respectively. Adjusted multivariable logistic regression analysis was used for odds ratios (OR) with 95% confidence intervals (CI) as estimates of the relative risk of OC. **Results:** Median age was 59 yrs and median BMI for cases and controls was 25.7 and 26, respectively. In the multivariate analysis, OC risk was significantly associated with a self-report of dairy [*OR = 1.91; 95% CI (1.4-2.4)*], whole grain *[OR = 0.64; 95% CI (0.51-0.87)*], fish [*OR = 2.7; 95% CI (2.04-3.56)*], exercise [*OR = 1.54; 95% CI (1.19-1.99)*] and tobacco smoking [*OR = 0.43; 95% CI (0.25-0.74)*], respectively. There was no association with fruits, vegetables, and meat consumption on OC risk (see table). **Conclusions:** Consumption of fish (any serv/wk), dairy (> 2 serv/day), whole grains (< 2 serv/day) and exercise (> 120 min/wk) were associated with a decreased risk of OC. Smoking > 40 pack-yr (pyr) showed an increased risk for OC. Further prospective studies are needed to validate our findings.

Modifiable risk factors in ovarian cancer.

Variables	Adjusted OR (CI)	p-value
Fish intake (No *vs.* Yes)	2.7 (2.04-3.56)	< 0.0001
Whole Grain (< 2/day serv *vs.* ≥ 2/day	0.64 (0.51- 0.87)	0.003
Dairy (< 2/day serv *vs.* ≥ 2/day)	1.91 (1.4-2.4)	< 0.0001
Vegetables (< 2/day serv *vs.* ≥ 2/day)	0.78 (0.6-1.02)	0.07
Fruits (< 2/day serv *vs.* ≥ 2/day)	1.16 (0.8-1.5)	0.24
Meat (< 3/wk serv *vs.* ≥ 3/wk)	1.2 (0.95-1.52)	0.10
BMI	1.001 (0.9-1.02)	0.92
Smoking (<40 pyr *vs.* ≥ 40 pyr)	0.43 (0.25-0.74)	0.002
Exercise (< 120 min/wk *vs.* ≥ 120 min/wk)	1.54 (1.19-1.99)	0.0008

5582 Poster Session (Board #140), Sat, 1:15 PM-4:45 PM

EP-100 + paclitaxel to overcome taxane resistance in patients with recurrent LHRH-receptor expressing ovarian cancer. *First Author: Alpa Manchandia Nick, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EP-100 (E) is a synthetic cytolytic peptide conjugated to Luteinizing Hormone Releasing Hormone (LHRH). It targets cells that overexpress LHRH receptors and kills by membrane disruption. Preclinical studies demonstrate synergy between E and paclitaxel (P). This randomized phase 2 trial explored the efficacy, safety and toxicity of E+P in women with advanced ovarian cancer. **Methods:** "Run-in" dose-escalation specified at least 1 patient would be treated with E per dose level. Patients were randomized 1:1 to receive weekly P (80 mg/m^2 IV) + biweekly E (30 mg/m^2 IV, E+P) vs. weekly P (80 mg/m^2 IV). Unlimited prior regimens were allowed. Central IHC for tumoral LHRH receptors was required. The 1^O endpoint was overall response rate (ORR) per RECIST 1.1. The 2^O endpoint was disease control rate (DCR = CR+PR+SD). For an improvement in ORR and DCR of at least 30% with E+P vs. P, a sample size of 20 patients/arm estimated CIs of 6-47% (P alone) vs. 27-73% (E+P). Patients progressing on P were allowed to receive E (30 mg/m^2 IV) plus continuation of P (80 mg/m^{2}IV). Time to progression (TTP) was assessed. **Results:** The "run-in" consisted of 6 patients and established RP2 dose of E+P: 30 mg/m^2 (E) IV biweekly and 80 mg/m^2 (P) IV weekly. 44 patients were enrolled in the phase 2 study. The ORR 34.8% (E+P: 95% CI: 16-57.3%) vs. 33.3% (P: 95% CI 14.6-57%). The DCR was 73.9% (E+P: 95% CI 51.6-89.8%) vs. 71.4% (P: 95% CI 47.8-88.7%). All 44 patients were assessable for safety; 43.5% (E+P) and 47.6% (P) had grade 3 or 4 events, primarily GI and related to underlying disease. The incidence of infusion-related reactions of all grades was greater with E+P (52%, n = 12) than with P (23.8%, n = 5). 10 patients progressed on P and received E+P. 50% had > 3 months of disease stabilization with TTP of 3-7 months, including 1 PR. 60% of these 5 patients had 3 times > TTP with E+P compared to their respective previous TTP after P alone. The addition of E did not complicate the AE profile of P and was well tolerated. **Conclusions:** EP-100 appears to sensitize paclitaxel-resistant ovarian tumors leading to further shrinkage of target and non-target lesions and prolongation of treatment response. A larger study comprising paclitaxel resistant patients is warranted. Clinical trial information: NCT0145848.

5583 Poster Session (Board #141), Sat, 1:15 PM-4:45 PM

Combination therapy with temsirolimus and trabectedin for recurrent clear cell carcinoma of the ovary: A phase II study with biomarker analysis. *First Author: Masashi Takano, National Defense Medical College, Tokorozawa, Japan*

Background: Recurrent clear cell carcinoma (RCCC) of the ovary showed exceedingly chemo-resistant phenotype, especially in the case with recurrent or refractory to previous therapy. A phase II trial to evaluate the effect of combination therapy with temsirolimus and trabectedin for patients with RCCC was performed. **Methods:** Eligible patients were as follows: (a) ECOG PS = 0~2 (b) histologically confirmed ovarian clear cell adenocarcinoma (c) diagnosed as platinum-resistant ovarian cancer (d) written informed consent. Patients with RCCC were treated with weekly regimen using two drugs: 15mg/m^2 of temsirolimus and 0.15mg/m^2 of trabectedin (3 weeks, one week rest). Treatment was continued until development of progressive disease (PD) or unmanageable adverse effects. There was no significant difference of serum level of VEGF according to the response evaluation. Biomarker analyses including serum VEGF and BNP were also conducted. **Results:** A total of 21 patients were analyzed in the present study. There were no cases that discontinued the therapy due to toxicities. Median age was 59 years (range: 30-69), and median number of previous chemotherapy was 3 (range: 1-6). All cases were assessable by RECIST and CTCAE. One patient (5%) had a complete response (CR), and two cases (10%) achieved a partial response (PR), and 6 patients (29%) had a stable disease (SD) beyond three months, resulting in clinical benefit rate (CBR; CR+PR+SD > 3month) of 43%. Median response duration in CBR case was 3.5 months (range: 3-40+). There were no cases that developed toxicities more than grade2. There was no significant difference of serum level of VEGF according to the response evaluation. **Conclusions:** Combination therapy with temsirolimus and trabectedin was a candidate for salvage therapy for patients with RCCC. These results warrant further study in such clinical settings with biomarker analyses.

5584 Poster Session (Board #142), Sat, 1:15 PM-4:45 PM

Omentin as a biomarker associated with improved overall survival in serous ovarian cancer. *First Author: Michaela Onstad, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Omentin is a protective adipokine secreted by the mesothelial cells of visceral adipose tissue. Its expression is inversely related to obesity and low levels have been found to be associated with disease states, such as diabetes and hypertension. Recently it has been found to have tumor suppressor activity in ovarian cancer, leading to decreased ovarian cancer cell proliferation, motility and invasion potential. We sought to explore whether omentin could be used as a biomarker to predict overall survival among patients with serous ovarian cancer. **Methods:** Serum samples were obtained from 148 women with serous ovarian cancer at the time of initial surgery. Circulating omentin levels were quantified using a commercially available ELISA kit. Clinical and demographic data were obtained from the electronic medical record. Overall survival was measured from the date of omentin collection to the date of last follow-up or death. A multivariate analysis of overall survival was performed to account for potential confounding variables. **Results:** Among women with serous ovarian cancer, a higher omentin level (per 100 units) is significantly associated with a decreased risk of death ($p = 0.0004$). Using a cutoff point of 350ng/mL, a Kaplan-Meier curve demonstrates a significantly improved survival for women with omentin $>$ 350ng/mL at the time of initial surgery ($p < 0.0001$). A multivariate analysis was performed to consider other risk factors that may contribute to risk of death, including stage and grade of cancer, optimal debulking, use of neoadjuvant chemotherapy, BMI, menopausal status, diabetes and metformin use. After adjusting for these factors, the relationship between omentin and overall survival remained statistically significant ($p < 0.0001$). **Conclusions:** Omentin levels $>$ 350ng/mL are predictive of improved overall survival among women with serous ovarian cancer, after adjusting for potential confounders. This may be reflective of the tumor suppressor activity of this adipokine, or may be due to the ability of ovarian cancer cells to down-regulate production of omentin. These findings warrant validation in another large ovarian cancer dataset.

5585 Poster Session (Board #143), Sat, 1:15 PM-4:45 PM

Utility of PET-CT vs CT alone to evaluate retroperitoneal lymph node metastasis in advanced cervical cancer. *First Author: Mostafa Atri, University Health Network, Toronto, ON, Canada*

Background: To assess if PET-CT improves accuracy of CT to detect lymph node (LN) metastasis in advanced cervical cancer. **Methods:** This was a prospective ACRIN/GOG multicenter trial. Patients underwent contrast enhanced PET-CT followed by extra-peritoneal or laparoscopic pelvic and abdominal lymphadenectomy. Seven independent blinded readers reviewed PET-CT and CT only images at least one month apart. Region correlation was performed between pathology and central review results for abdomen (right and left para-aortic, right and left common iliac) and pelvis (right and left external iliac and right and left obturator) regions. Abdomen and pelvic regions were combined, respecting laterality, to calculate accuracy values for these regions at participant level. Reference standard was pathology of resected LNs. Reader average sensitivities/specificities of PET-CT vs CT were compared with generalized linear mixed models. Reader average AUCs were compared with Obuchowski's method. Fleiss' kappa was used to assess reader agreement. **Results:** A total of 153 patients had PET/CT and pathology proof in the abdomen from 169 patients who were enrolled between September 2007 and December 2012. Forty-three of 153 patients had metastasis to abdominal LNs. Forty abdominal positive and 40 randomly selected abdominal negative patients were used for review based on sample size calculation. Reader study cases ranged from 24 to 74 years old (mean;48.9$\pm$10.6). Cancer stages were: IB = 25, II = 44, III = 11; sixty-nine squamous cell carcinomas, 6 adenocarcinoma and 5 others. Mean sensitivities of PET-CT/CT alone in abdomen were 0.50 (CI:0.44,0.56)/0.42 (CI:0.36,0.48) ($p = 0.052$) and in pelvis 0.83 (CI:0.78,0.87)/0.79 (CI:0.73,0.83) ($p = 0.15$). Corresponding specificities were 0.85 (CI:0.80,0.89)/0.89 (CI:0.84,0.92) ($p = 0.21$) and 0.63 (CI:0.54,0.70)/0.62 (CI:0.53,0.69) ($p = 0.83$). Mean AUCs were 0.70 (CI:0.61,0.79)/0.68 (CI:0.59,0.77) ($p = 0.43$) and 0.80 (CI:0.71,0.88)/0.76 (CI:0.67,0.85) ($p = 0.21$). Kappa for PET/CT was 0.65 in pelvis and 0.77 in abdomen. **Conclusions:** Addition of PET to diagnostic CT resulted in statistically borderline increase in sensitivity to detect LN metastasis in abdomen. Clinical trial information: ACRIN6671GOG0233.

5586 Poster Session (Board #144), Sat, 1:15 PM-4:45 PM

Identifying actionable mutations in uterine leiomyosarcoma. *First Author: Tara Soumerai, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Uterine leiomyosarcoma (uLMS) is a rare gynecologic malignancy affecting 2000 women annually in the United States. Little is known about the genomic basis of uLMS and there are no targeted therapies currently approved for this disease. We aimed to describe the genetic alterations present in a cohort of patients with uLMS in order to identify those that are potentially targetable by available or investigational agents. **Methods:** Thirty-one tumor samples were prospectively collected from 2/2014 to 1/2015; all had central pathology review at Memorial Sloan-Kettering. Patients were consented to an IRB-approved biospecimen protocol and samples were analyzed in a CLIA-compliant laboratory with the Memorial Sloan-Kettering Integrated Mutation Profiling for Actionable Cancer Targets (MSK-IMPACT). This NGS, bait-capture platform assesses for mutations, copy number variations, and fusions within 341 genes that are common drivers of oncogenic transformation. Variant calls were made against matched germline DNA. **Results:** All samples were successfully assessed by MSK-IMPACT. The most commonly identified genetic aberrations were deletions/truncating mutations of TP53 in 19 (61%) cases, RB1 in 15 (48%) cases, and ATRX in 10 (32%) cases. MED12 mutations were seen in 3 (10%) cases, 2 of which were hotspot mutations *G44A/C*. Genetic events activating the PI3K signaling pathway were identified in 9 (29%) cases, including PTEN deletions or truncating mutations, PIK3CA activating mutations, or deletions/mutations of PIK3R1 or PIK3CG. One case was hypermutated (epithelioid LMS) with 65 somatic mutations; this tumor was tested for mismatch repair gene deficiency and showed equivocal immunohistochemistry for MSH6. One case had a BRAF *V600E* mutation and this patient was enrolled on a clinical trial of a BRAF inhibitor. In total, three (10%) patients have been enrolled in clinical trials of targeted therapy matched to their mutational status. **Conclusions:** Among 31 patients with uLMS, 10 (32%) were found to have potentially actionable somatic tumor mutations. Genomic characterization of uLMS may offer insights into tumorigenesis and identify potential therapeutic targets in this rare and heterogeneous disease.

5587 Poster Session (Board #145), Sat, 1:15 PM-4:45 PM

Phase II study of concurrent chemoradiotherapy with weekly CDDP/PTX in patients with locally advanced uterine cervical cancer: JACCRO-GY-01 trial. *First Author: Munetaka Takekuma, Department of Gynecologic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: A multicenter phase II trial was conducted to assess the efficacy and toxicity of concurrent chemoradiotherapy (CCRT) with weekly CDDP/PTX in patients with locally advanced uterine cervical cancer. **Methods:** The patients with FIGO stages III-IVA uterine cervical cancer who had no para-aortic lymphadenopathy ($>$ 10 mm) assessed by CT were enrolled. Patients received definitive radiotherapy (RT) consisting of external beam whole pelvic RT and HDR-ICBT. The cumulative linear quadratic equivalent dose (EQD2) was 62-65 Gy prescribed at point A. Cisplatin 30 mg/m(2) and Paclitaxel 50 mg/m(2) weekly was administered concurrently with RT for 5 courses. **Results:** Of the 70 patients registered, 68 were eligible. The Compete response rate was 76.5% (95%CI, 66.4% to 86.6%). With a median follow-up of 27 months(range: 7.9-33.5), the 2-year progression-free survival rate and pelvic disease progression-free rate were 83.8% (95% CI, 75.1% to 92.6%) and 89.6% (95% CI, 82.3% to 96.9%), respectively. The 2-year overall survival rate was 92.7% (95% CI, 86.4% to 98.9%). The 2-year cumulative late complication rates were 25% for all grades, 13.2% for grade 1, 5.9% for grade 2, 2.9% for grade 3, and 2.9% for grades 4. **Conclusions:** Concurrent chemoradiotherapy with weekly CDDP/PTX for locally advanced cervical cancer demonstrated favorable antitumor activity, and is feasible and safe with respect to the protocol-specified SAEs and AEs. Evaluation of this regimen in phase III trials is warranted. Clinical trial information: UMIN000002937.

5588 Poster Session (Board #146), Sat, 1:15 PM-4:45 PM

Phase II study of the PI3K inhibitor BKM120 monotherapy in patients with advanced or recurrent endometrial carcinoma: ENDOPIK, GINECO Study. *First Author: Pierre-Etienne Heudel, Centre Léon Bérard, Lyon, France*

Background: Patients (pts) with metastatic endometrial carcinoma have a poor prognosis and PIK3CA mutations and amplifications are common in these cancers. This study evaluated the efficacy and safety of a pure PI3K inhibitor BKM120 in advanced or recurrent endometrial carcinoma. **Methods:** This multicenter, single-arm, Phase II, double strata (histological low grade (LG) vs. high grade (HG)) open-label study enrolled pts with histologically confirmed advanced or recurrent endometrial carcinoma, who had received no more than one prior chemotherapy regimen. Primary endpoints were proportion of pts with progression-free survival (PFS) at 2 months (HG strata) or at 3 months (LG strata), objective response rate (ORR), and safety. Initial BKM120 dosage was 100 mg tablets once daily. **Results:** 40 pts were enrolled, of which 16 pts had received BKM120 at 100 mg/d. Due to high rate of grade 3/4 toxicities (cutaneous rash (54%), depressive events (47%), and anxiety (40%)), the IDMC proposed to stop recruitment at 100 mg but to continue the recruitment with a lower dose of 60 mg/d. 24 pts (median age 67 years old) were newly enrolled (14 in the LG strata, 10 in the HG strata). Rate of PFS $>$ 2months in the HG strata was 70% and $>$ 3months was 57% in the LG strata. Median PFS for all pts is 4.5 months (CI 95% 2.8 – 6.1); median PFS for LG strata is 8.3 months compared to 3.8 months for the HG strata. No objective response was reported. At 60 mg/d, 87% of patients experienced grade 3/4 toxicity. The most commonly reported treatment-related grade $\geq$ 3 AEs were cutaneous (13%), increased alanine aminotransferase (13%), HTA (17%), hyperglycemia (17%) and increased aspartate aminotransferase (21%). 5 patients (21%) stopped BKM120 for toxicity. **Conclusions:** BKM120 was associated with an unfavorable safety profile and minimal antitumor activity in monotherapy in advanced or recurrent endometrial carcinoma. The clinical trial was stopped before end of recruitment for toxicity. Clinical trial information: NCT01397877.

5589 Poster Session (Board #147), Sat, 1:15 PM-4:45 PM

Molecular profiling and targeted therapy in advanced endometrial cancer. *First Author: Michelle K. Wilson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Recurrent endometrial cancer (EC) has a poor prognosis with few effective systemic therapies. We reviewed the outcomes of advanced EC pts in an ongoing institutional molecular profiling program. **Methods**: DNA from blood and tumor (archival FFPE tissue) from EC pts (ECOG $\leq$ 1) was genotyped with a recurrent mutation(s) (mut) assay (Sequenom MassArray, 23 genes, 279 mut) or a NGS assay (Illumina TruSeq Amplicon Cancer Panel, 48 genes) in a CAP/CLIA certified laboratory. Whole exome DNA sequencing (germline and tumor) was performed in pts with exceptional responses. **Results:** From 3/2011 to 8/2014, 77 pts were enrolled: 43% type 1 endometrioid, 57% type 2 non-endometrioid. Median BMI was 29, 11 (14%) had diabetes, 69 (90%) had $\geq$ 1 line of chemotherapy. Somatic mut were seen in 64 pts (83%), 40 pts (52%) had $\geq$ 2 mut. *PIK3CA* (42%), *TP53* (32%), *KRAS* (20%), *PTEN* (16%), and *CTNNB1* (16%) were the most common mut seen. *PIK3CA* mut were seen in 39% of type 1 and 43% of type 2 EC (p = 0.74). *PTEN* mut were more common in type I EC (p = 0.02); *TP53* mut more common in type 2 (p $<$ 0.01). 31 pts (40%) had targeted therapy - 5 genotype-matched. Overall disease control rate (RR + SD at 12 weeks) was 53% with no difference seen with antiangiogenic agents (25 pts; 60%), *PI3K/AKT/MTOR* agents (7; 57%) or matched therapy (5; 40 % p = 0.64)). Time to progression on targeted therapy was not better than prior systemic therapy (HR 1.5 p = 0.09). 15% stopped due to AEs rather than PD. Of 16 pts offered a phase I trial 50% did not start, often due to ECOG decline. Two exceptional responders were identified: (i) clear cell EC (no mut) with PR for 2.6y on ixabepilone; and (ii) recurrent serous EC (3 mut: *PIK3CA*, *KRAS*, *APC*) with CR on sunitinib for 7.2y. Exome sequencing of the 2nd case found $>$ 2400 somatic coding mut (43 point mut/coding Mb) and few copy-number alterations (possible MSI-hypermutated subtype). Preliminary somatic mut of interest include: 5 in genes significantly mutated in EC; 4 in genes encoding known targets of sunitinib; and 13 in kinase domains of other proteins. **Conclusions:** Genotype-matched therapy in EC is complicated by genomic heterogeneity, comorbidities, and tolerance of therapy. Future EC trials should develop algorithms for multiple mutations and account for pt comorbidities in design. Clinical trial information: NCT01505400.

5590 Poster Session (Board #148), Sat, 1:15 PM-4:45 PM

Synergistic effects of cabozantinib to temozolomide and bevacizumab in patients with heavily pretreated relapsed uterine leiomyosarcoma. *First Author: Sayaka Ikeda, Tama-Hokubu Medical Center, Higashimurayama, Japan*

Background: Although uterine leiomyosarcoma (ULMS) has been treated with adriamycin, dacarbazine, ifosfamide, gemcitabine, docetaxel, et al, the effect is not satisfactory. We have reported the effect of temozolomide (T) combined with bevacizumab (B) in heavily pretreated relapsed ULMS (Ref.). In this study, we evaluated the effects of addition of cabozantinib (C) to T and B. **Methods:** From 2009 to 2014, total 20 patients (pts) with heavily pretreated relapsed ULMS were enrolled. Fourteen of 20 pts were treated with T (80mg/body/day, 3 week one week rest) and B (2mg/kg; days 1, 8 and 15, q4 weeks) (TB, n = 14). Since 2013, C (140mg/body/week) was added to TB (TBC, n = 6). Treatment was continued until disease progression and/or unmanageable toxicities. The response and adverse effects were evaluated using the response evaluation criteria in solid tumors (RECIST), and common terminology criteria for adverse events (CTCAE) version 3.0. **Results:** As shown in Table, four (20%) of 20 pts had complete response (CR), four (20%) had partial response (PR) and nine (45%) had stable disease (SD) for at least three months. The response rate (RR; CR+PR) and clinical benefit rate (CBR; CR+PR+SD$>$3mo) were 40% and 85%, respectively. The median progression-free survival was 10.5 (3 - 44) months. Intriguingly, when added C to TB, the effect was significantly reinforced, showing that two (33%) of 6 cases had CR, and the RR and CBR was 50% and 100%, respectively. Toxicity was mild and manageable. **Conclusions:** Addition of C to T and B resulted in synergistic effects with mild toxicity in heavily pretreated relapsed ULMS as shown in Table. These results warrant further prospective and randomized studies.

Response to TB/TBC in heavily pretreated relapsed ULMS.

	n	CR	PR	SD	PD	RR	CBR
TB/TBC	20	4	4	9	3	40%	85%
TB	14	2	3	6	3	35%	78%
TBC	6	2	1	3	0	50%	100%

Optimal debulking surgery in patients with advanced uterine carcinosarcoma: A multi-institutional retrospective study from the Japanese Gynecologic Oncology Group. *First Author: Kenichi Harano, Department of Medical Oncology, Nippon Medical School Musashikosugi Hospital, Kawasaki Kanagawa, Japan*

Background: The benefit of cytoreductive surgery for uterine carcinosarcoma (CS) is unknown. The objective of this study was to assess the impact of optimal debulking surgery on survival of advanced uterine CS patients. **Methods:** We performed a multi-institutional, retrospective study of women diagnosed with stage III–IV uterine CS between 2007 and 2012. Data were retrospectively obtained from medical records and included demographic, clinicopathologic, treatment, and outcome information. Optimal debulking surgery was defined as surgery resulting in a maximum residual tumor of less than 1 cm. The Kaplan-Meier method was used to calculate disease-free survival (DFS) and overall survival (OS), and the Cox regression model was used to examine the impact of selected factors on survival. **Results:** A total of 225 uterine CS patients (median age, 62 years) were identified including 136 (60%) patients with stage III disease and 89 (40%) patients with stage IV disease. Among them, 185 (82%) patients received the optimal debulking surgery. The median follow-up time was 19 months. The median DFS and OS for the entire cohort were 10.9 months (95% confidence interval [CI], 9.5−12.5) and 29.0 months (95% CI, 21.6−36.2), respectively. The median DFS was 11.5 months (95% CI, 10.6−13.4) for patients who received optimal debulking surgery and 8.1 months (95% CI, 5.1−9.5) for patients who received suboptimal surgery (P $<$ 0.0001). The median OS was 37.9 months (95% CI, 28.3−not reached) for patients who received optimal debulking surgery and 18 months (95% CI, 9.6−21) for patients who received suboptimal surgery (P $<$ 0.0001). In the multivariate analysis, optimal debulking surgery and pelvic lymph node dissection were associated with improved OS. **Conclusions:** Optimal debulking surgery and pelvic lymph node dissection are associated with improved OS in patients with advanced uterine CS.

5592 Poster Session (Board #150), Sat, 1:15 PM-4:45 PM

Tumor mutational analysis of GOG248, a phase II study of temsirolimus or temsirolimus and alternating megestrol acetate and tamoxifen for advanced endometrial cancer (EC): An NRG Oncology/Gynecologic Oncology Group study. *First Author: Andrea P. Myers, Novartis Institutes of Biomedical Research, Cambridge, MA*

Background: Rapamycin analogs have reproducible but modest efficacy in EC. Identification of molecular biomarkers that predict benefit from this class of agents could guide their clinical development. **Methods:** Fixed primary tissue and whole blood were collected prospectively from patients (pts) enrolled on GOG 248. DNA was isolated from macro-dissected tumors and blood; next–generation sequence analysis was performed on a panel of cancer related genes. Associations between clinical outcomes [Response rate (RR); 20% overall and progression-free survival (PFS); median 4.9 months] and common mutations (PTEN, PIK3CA, PIK3R1, KRAS, CTNNB1) and other PI3K/mTOR relevant mutations (AKT1, TSC1, TSC2, NF1, FBXW7) were explored. **Results:** Sequencing data was obtained from tumors of 55 of the 73 enrolled pts. Mutation rates were consistent with published reports: mutations in PTEN (45%), PIK3CA (29%), PIK3R1 (24%), K-RAS (16%), CTNNB1 (18%) were common and mutations in AKT1 (4%), TSC1 (2%), TSC2 (2%), NF1 (9%) and FBXW7 (4%) were less common. Increased PFS (HR 0.16; 95% CI 0.01-0.78) and RR (response difference 0.83; 95% CI 0.03-0.99) were noted for AKT1 mutation. An increase in PFS (HR 0.46; 95% CI 0.20-0.97) but not RR (response difference 0.00, 95% CI -0.34-0.34) was identified for CTNNB1 mutation. There were no statistically significant associations between mutations in PIK3CA, PTEN, PIK3R1, or KRAS and PFS or RR. Six patients had PFS > 15 months; of these, two had mutations in CTNNB1, and two had mutations in both CTNNB1 and AKT1. The pt with the longest PFS (on study over 46 cycles) had mutations of NF1, CTNNB1 and PIK3R1 in her tumor. **Conclusions:** Activating mutations in AKT1 are rare in EC, but may predict clinical benefit from temsirolimus. Consistent with a recent report of an association of CTNNB1 mutation with RR in a study of everolimus and letrozole, CTNNB1 mutations were associated with longer PFS on temsirolimus. Studies to elucidate the relationship of the Wnt/β-Catenin and mTOR pathway in EC are needed. Clinical trial information: NCT00729586.

5593 Poster Session (Board #151), Sat, 1:15 PM-4:45 PM

Onapristone (ONA) in progesterone receptor (PR)-expressing tumors: Efficacy and biomarker results of a dose-escalation phase 1 study. *First Author: Paul H. Cottu, Institut Curie, Paris, France*

Background: ONA is a type I PR antagonist, which prevents PR-induced DNA transcription. Immediate release (IR) 100 mg ONA was active in multiple preclinical models and in patients (pts) with breast cancer (BC). We conducted a phase 1 study of extended release (ER) ONA to (i) determine a recommended dose and (ii) explore the role of transcriptionally-activated PR (APR), detected as an aggregated subnuclear distribution pattern, as a predictive immunohistochemical (IHC) biomarker. **Methods:** An open-label, multicenter, randomized, parallel-group, phase 1 study (target n=48; NCT02052128) included female pts ≥18 years with PR^{pos}tumors. APR analysis was performed on archival tumor tissue. Pts were randomized to 5 cohorts of ER ONA tablets 10-50 mg BID, or IR 100 mg QD until progressive disease or intolerability. This abstract reports the APR IHC analysis and clinical benefit (PR/SD≥24 wks). **Results:** Phase 1 is complete (n=52). Tumors (n) were: endometrial carcinoma (EC) 13; breast cancer (BC) 20; ovarian cancer (OC) 13; other 6. Median age was 66 (37-85). No dose limiting toxicity was observed with only transient liver function test elevation, mostly related to liver metastases. PR^{pos}/APR^{pos}tumors (n/n) were: EC 11/6, BC 8/3, OC 5/1, other 2/0 and 8 pts (6 BC) had missing/non evaluable IHC. Median therapy duration was 8 wks (range 2-44), and 8 pts had clinical benefit ≥24 weeks (see Table). **Conclusions:** Clinical benefit was seen in heavily-pretreated pts with EC, OC and BC. Data support ongoing ONA development at 50mg ER BID in APR^{pos} uterine endometrioid cancer with clinical validation of the APR diagnostic. Meanwhile, further development of APR IHC is needed in OC and BC. Clinical trial information: NCT02052128.

Response and stable disease for ≥24 weeks.

Does metformin use affect transporter, hormone receptor and mTOR pathway target expression in endometrial cancers of women with Type II diabetes mellitus? *First Author: Dario R. Roque, UNC Durham Division of Gynecologic Oncology, Durham, NC*

Background: Metformin, has been found to decrease proliferation and inhibit downstream targets of the mTOR pathway in a phase 0 trial in endometrial cancer (EC) patients. Given this, we aimed to determine molecular differences between ECs from patients with Type II diabetes (T2DM) taking metformin versus those not on metformin. **Methods:** Patients with T2DM who underwent surgical staging for EC were divided into two cohorts based on whether or not they were on metformin. The use of insulin and other anti-diabetic agents was recorded. Tissue microarrays (triplicate cores) were constructed from formalin-fixed, paraffin-embedded hysterectomy specimens. Expression of the estrogen receptor (ER), progesterone receptor (PR), PTEN, LKB1, phosphorylated (p)-AKT, p-4EBP-1, p-S6, p-insulin growth factor-1 receptor (pIGF1R), p-insulin receptor substrate-1 (P-IRS1), PMAT, MATE1 and MATE2 was measured by immunohistochemistry. **Results:** Of 162 EC patients with T2DM, 102 (63%) were taking metformin and 60 (37%) were not on metformin. There was no significant difference in tumor stage, grade or histology between the two groups. Expression of transporters, hormone receptors, and mTOR pathway targets was similar between the two groups. However, when adjusting for age, BMI, race, tumor grade and stage, there was a trend towards decreased p-AKT expression in metformin users (0.7, 95% CI 0.4-1.1). In addition, BMI > 30 was associated with increased expression of p-S6 (2.8, 95% CI 1.2-6.7) and a trend towards higher p-4EBP-1 expression (2.0, 95% CI 1.0-4.1). **Conclusions:** We did not find a strong relationship between metformin use and transporters, hormone receptors or mTOR pathway targets in EC patients with T2DM. However, metformin use trended towards decreased p-AKT expression, which is consistent with its ability to inhibit the mTOR pathway. Obesity is known to activate the mTOR pathway, and was associated with increased expression of p-S6 and p-4EBP-1 in ECs. Further studies should focus on identifying molecular biomarkers in patients with T2DM that may predict response to metformin as an anti-tumorigenic agent.

5595 Poster Session (Board #153), Sat, 1:15 PM-4:45 PM

Molecular profile comparison of endometrial, renal and ovarian clear cell carcinoma: Is it the same disease at different sites? *First Author: Robert Debernardo, Cleveland Clinic, Cleveland, OH*

Background: Clear cell carcinomas (CCC) are histologically similar, however their clinical course varies widely based on the organ of origin. Clear cell uterine carcinoma (CCUC) accounts for approximately 5% of endometrial carcinomas and exhibit aggressive clinical behavior with poor outcomes. Clear cell ovarian cancers (CCOCs) are a subtype of epithelial ovarian cancers that are chemo-resistant with a poorer prognosis than other subtypes. 70% of renal cell carcinomas are clear cell (CCRCs), and respond to TKIs and mTOR inhibitors. It's unknown if these CCC rely on similar molecular pathways. Tumor profiling was used to identify subsets of CCC that may benefit from different therapies. **Methods:** 139 CCUCs, 409 CCOCs and 94 CCRCs were tested using a commercial multiplatform profiling service (Caris Life Sciences, Phoenix, AZ). Specific tests performed included sequencing (Sanger, NGS), protein expression (IHC) and gene amplification (CISH or FISH). **Results:** CCUCs had more TP53 mutations than CCOCs and CCRCs (40% vs 16% vs 14%). Compared to CCUCs and CCOCs, CCRCs had fewer mutations in the mTOR pathway (PIK3CA – 4% vs 25% vs 40%; PTEN - 1% vs 26% vs 3%) and the MAPK pathway (KRAS – 0% vs 14% vs 11%). VHL mutations were only seen in CCRCs (47% vs 0% vs 0%). ER and PR overexpression was more common in CCUCs than CCOCs and rare in CCRCs (ER – 35% vs 8% vs 0%; PR – 22% vs 13% vs 2%). AR overexpression was more common in CCRCs (26% vs 7% vs 5%). In contrast to CCUC and CCOC, no Her2 alterations measured by IHC, ISH or SEQ were seen in CCRCs.TOP2A, TS and RRM1 were expressed at a higher rate in CCUCs and CCOCs than CCRCs (TOP2A – 81% vs 63% vs 27%; TS - 46% vs 51% vs 16%; RRM1 – 22% vs 19% vs 2%). All CCC types had some immune-positivity for PD-1 (73%,47%, 68%) or PD-L1 (13%, 6%,29%). **Conclusions:** While CCUCs and CCOCs share similarities, the molecular profiling shows significant differences compared with CCRCs. This data suggest blockade of the mTOR and/or MAPK pathways may be important in CCUCs and CCOCs. Further, anti-angiogenic agents are more likely to be of benefit in CCRCs. Immunotherapies warrant further investigation in selected CCC patients. Future studies are needed to correlate these markers with sensitivity to chemotherapy.

5596 Poster Session (Board #154), Sat, 1:15 PM-4:45 PM

Clinical outcomes in advanced cervical cancer (CC) and endometrial cancer (EC) patients (pts) treated in phase I trials of novel molecularly targeted agents (MTAs). *First Author: Angela George, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom*

Background: The prognosis for advanced CC and EC pts is poor, with relapse to approved chemotherapies inevitable. In view of the high rate of putative driver mutations, novel MTAs in phase I trials may benefit such pts. **Methods:** Retrospective study of pt records of CC (01/03-12/14) and EC (11/98-12/14) pts allocated to Phase I trials including efficacy expansion phases of MTAs in the Drug Development Unit at the Royal Marsden. **Results:** 93 CC pts were allocated to 51 trials (186 events); allocation was based on mutational profiles whenever possible. 57 (61%) pts began $\geq$ 1 trials (134 events). 36 (39%) pts did not start; 22 (24%) due to rapid progressive disease (PD), 7 (7.5%) due to other therapy options and 7 (7.5%) due to other reasons. 14 (10%) RECIST responses were seen; chemotherapy/MTA combinations (1 complete response and 7 partial responses [PR]), anti-angiogenics (AA) (2 PR), PI3K/AKT inhibitors (i) (2 PR) and immunotherapy (2 PR) in molecularly selected CC pts. 20 (15%) pts had RECIST stable disease $>$ 4 months (SD $>$ 4m), for a clinical benefit rate (CBR) of 25%. Mean survival was improved in CC pts with CR/PR (662 days) versus (vs) pts who did not start trial (257 days) ($p < 0.001$). Treatments were well tolerated: of 169 toxicities - G1/2: 127 (69%); G3/4: 42 (31%). 78 EC pts were allocated to 39 trials (93 events); 35 (45%) pts began $\geq$ 1 trials (48 events). Of 43 (55%) pts who did not start, 34 (44%) had rapid PD, 5 (6%) had other therapies and 4 (5%) for other reasons. There were 5 (10%) PRs observed in molecularly selected EC pts with mTORC1/2i, IGF-1Ri, AA, RAF/MEKi, and immunotherapy (all n = 1); a further 4 pts (8%) had SD $>$ 4m, for a CBR of 18%. Mean survival was improved in EC pts with PR/SD $>$ 4m (402 days) vs pts with PD (174 days) and pts who did not start trial (178 days) ($p < 0.0001$). Treatments were well tolerated: of 83 toxicities - G1/2: 67 (81%); G3/4: 16 (19%). **Conclusions:** Signs of pt benefit to novel MTAs in phase I trials were observed in molecularly selected pts with advanced EC and CC. A large proportion of pts allocated to such trials did not start treatment due to rapid PD. These data suggest that earlier phase I trial referral and knowledge of mutational profiles may improve pt outcomes.

5597 Poster Session (Board #155), Sat, 1:15 PM-4:45 PM

PET/MRI in cervical cancer: Insights into tumor biology. *First Author: Katja Pinker-Domenig, Medical University Vienna, Vienna, Austria*

Background: To investigate molecular imaging of cervix cancer with combined multiparametric positron emission tomography - magnetic resonance imaging (3T MP PET-MRI) using multiple MRI techniques and PET tracers for an improved understanding of tumor biology and heterogeneity. **Methods:** Ten patients with cervix cancer scheduled for radiation therapy were included in this IRB-approved prospective study. All patients were examined with combined 3T MP PET-MRI. The MRI protocol consisted of a high-resolution T2-weighted, a diffusion-weighted and a T1-weighted sequence with fat-sat before and after the application of contrast agent. All patients underwent ^{18}F-FDG/^{18}F-FMISO PET/CT. Patients were injected with approximately 330 MBq ^{18}F-FDG and ^{18}F-FMISO on different days and scanning was started 45 min after injection of ^{18}F-FDG and 180 min after injection of ^{18}F-FMISO. PET and MR image registrations were performed using Mirada RTx (Mirada Medical, Oxford, UK , ver. 1.4.0.23) software. 3T MP PET-MRI was assessed for tumor size, enhancement (EH)-kinetics, restricted diffusivity and ^{18}F-FDG/^{18}F-FMISO-avidity. **Results:** Molecular imaging with 3T MP PET-MRI was successfully performed in all ten patients. Tumor volumes ranged from 6.2-440.0cc (median 125.5cc). All tumors demonstrated restricted diffusivity (mean 0.75 x 10^{-3} mm^2/sec). All tumors showed a strong initial EH and followed by either a wash-out (n = 6) or a plateau (n = 4). All tumors were highly ^{18}F-FDG-avid (SUV_{max} mean17.3). None of the tumors were highly ^{18}F-FMISO-avid (SUV_{max} mean 3.3). In eight patients, ^{18}F-FMISO PET identified ^{18}F-FMISO-avid spots within the ^{18}F-FDG-avid lesion, indicative of areas of tumor hypoxia. There was a weak correlation for tumor volume and ^{18}F-FDG and ^{18}F-FMISO SUV_{max}, indicating that ^{18}F-FMISO-avidity is independent of tumor volume. **Conclusions:** Molecular imaging with 3T MP PET-MRI in patients with cervix cancer is feasible and provides unique complementary information on tumor biology and heterogeneity. 3T MP PET-MRI can identify areas of tumor hypoxia, which are more resistant to radiation therapy and necessitate dose-escalation, and thus might improve therapy planning and assessment of treatment response.

5598 Poster Session (Board #156), Sat, 1:15 PM-4:45 PM

Feasibility of a physical activity intervention for ethnically diverse endometrial cancer survivors. *First Author: Amerigo Rossi, Long Island University - Brooklyn, Brooklyn, NY*

Background: To determine the feasibility of a 12-week physical activity (PA) intervention guided by social cognitive theory for ethnically diverse endometrial cancer (EC) survivors and to evaluate whether such an intervention might improve PA behavior, physical function, waist circumference, and quality of life. **Methods:** Out of 119 potential participants contacted via telephone, 54 did not respond, 29 declined, and 6 expressed interest but did not complete baseline testing. 30 obese EC survivors (40% non-Hispanic black, 33% Hispanic, 17% non-Hispanic white) were placed into a PA intervention (INT, n = 15) or wait-list control (CON, n = 15). Group classes consisted of 30 min of behavioral counseling and a 60 min exercise program. CON was assigned to usual care. Participants attended classes 1-2x/week and were provided with a 90 min/week at-home exercise program. The intervention data from each group were pooled and the change scores were compared to CON using independent samples t-tests. Data are presented as mean $\pm$ sd. Statistical significance was $p \leq 0.05$. **Results:** Mean age was 64 $\pm$ 8 years and Body Mass Index was 36.5 $\pm$ 6.9 kg$\cdot$m^{-2}. Three control participants did not attend follow-up. For the INT groups (n = 27), 16 attended 75-100% of the weeks, 4 attended 50-67%, 4 never attended, and 3 dropped out due to unrelated illness/injury. Additionally, 13 participants regularly attended twice per week with 85% attendance. Participants reported walking 117 $\pm$ 77 minutes per week at home. There were no reported differences in PA (Yale Physical Activity Survey). However, waist circumference (-5.1 cm vs: 2.6 cm, $p < 0.001$), 6-min walk test (22m vs. 0.3m, $p = 0.007$) and quality of life (FACT-En: 7.9 vs. -0.5, $p = 0.048$) all improved significantly following the intervention compared to the control. **Conclusions:** About 25% of potential participants entered into the study, demonstrating the challenges of working with this population. However, once enrolled, the drop out rate was modest and adherence was high, demonstrating the acceptability and feasibility of this PA intervention in a diverse urban population of EC survivors. Furthermore, the results show promising effects that will need to be confirmed in a larger randomized control trial.

5599 Poster Session (Board #157), Sat, 1:15 PM-4:45 PM

The use of adjuvant treatment in stage I endometrioid endometrial cancer in the National Cancer Database (NCDB). *First Author: Angela Jain, Fox Chase Cancer Ctr, Havertown, PA*

Background: Women with Stage I endometrioid endometrial carcinomas (EEC) tumors have excellant long term survival. Women may be offered adjuvant radiation if high-risk features are present in the resected tumor. Whole pelvic radiation (EBRT) or vaginal brachytherapy (VB) reduce local recurrence, but do not improve survival. GOG249 looked at the use of chemotherapy with VB in high-grade tumors (HGT). This is a retrospective study using the National Cancer Database to understand national trends in using surgery, radiation and chemotherapy in Stage I EEC. **Methods:** We identified women with EEC diagnosed between 1998 and 2012 and treated with surgery and/or chemotherapy and/or radiation using the National Cancer Database, with known grade status. Using Chi-squared tests and multivariate logistic regression, we analyzed pathologic stage of EC by age, grade, histology, facility type, race, payor status, income, location, Charlson score, year of diagnosis and facility location. Due to data availability, survival analysis was restricted to patients diagnosed between 2003 and 2007. We used Kaplan-Meier curves and proportional hazards regression to assess overall survival in patients treated with adjuvant EBRT vs VB. **Results:** Among 241,350 patients identified, patients with HGT had decreased use of EBRT over time from 17% to 5%; the use of VB increased from 7% to 24% ($p = 0.0001$). There were no significant changes for the use of radiation in patients with low-grade tumors. Patients with age $>$ 70 were more likely to receive radiation than patients $<$ 70, but less likely to receive chemotherapy ($p = 0.0001$). The use of chemotherapy in all patients increased from 1% to 14% over time. Multivariate analysis demonstrated that patients with HGT had 84% 5 year survival with VB vs 78% for patients receiving EBRT (HR 0.85 vs 1.16, $p = 0.0001$). In patients with low grade tumors there was no advantage for the use of VB and ERBT decreased survival. The use of chemotherapy did not improve survival. **Conclusions:** The use of VB and chemotherapy has been increasing over time for patients with HGT. However, the use of chemotherapy may not improve survival in this highly curable population, while the use of EBRT is demonstrated to decrease survival.

5600 Poster Session (Board #158), Sat, 1:15 PM-4:45 PM

A limited access phase I trial of paclitaxel, cisplatin and ABT-888 in the treatment of advanced, persistent, or recurrent carcinoma of the cervix: An NRG/GOG study. *First Author: Premal H. Thaker, Washington Univ School of Medicine, St. Louis, MO*

Background: The poly (ADP-ribose) polymerase (PARP) family of proteins is a family of nuclear enzymes required for the repair of single-stranded DNA damage. Preclinical studies demonstrate that PARP inhibition (PARPi) not only augments the apoptotic response in cervical cancer cell lines, but also sensitizes cells to the effects of alkylating agents like cisplatin. Given the use of cisplatin and paclitaxel as primary treatment for advanced, recurrent or metastatic cervical cancer before the findings of the benefit of adding bevacizumab in GOG 240, we aimed to evaluate whether PARPi can enhance the chemotherapy effectiveness in the treatment of cervical cancer. **Methods:** Patient eligibility criteria: Females age ≥ 18 years with persistent or recurrent squamous or adenocarcinoma of the cervix with documented disease progression (disease not amenable to curative therapy). Patients were not required to have measurable disease; have had concurrent chemotherapy and radiation for management of their disease; and have adequate organ function. The trial is a standard 3 + 3 phase I dose escalation with patients receiving paclitaxel 175mg/m2 on day 1, cisplatin 50mg/m2 on day 2, and ABT-888 50mg po bid days 1-7 at dose level 1 and escalating by 50mg every dose level until dose level 8 at 400mg po bid days 1-7. **Results:** Thirty-seven patients were enrolled from 6/1/11-1/8/14, but only 34 are evaluable. Dose limiting toxicities (DLTs) were assessed during cycle on 1 of each dose level of ABT-888 and the three DLTs were as follows: grade 4 dyspnea which was possibly related to the ABT-888 in dose level 2, grade 3 neutropenia > 3 weeks in dose level 4, and febrile neutropenia in dose level 8. Cycles were repeated every 21 days until disease progression. At all dose levels the response rate [complete and partial] (RR) was 34% (95%CI: 20-53%); at the maximum dose level the RR was 60% (95%CI: 23-88%). Translational studies evaluating defects in the Fanconi Anemia pathway are ongoing. **Conclusions:** PARPi plus chemotherapy appears to have significant clinical benefit in cervical cancer therapy and warrants further investigation with bevacizumab in a clinical trial. Clinical trial information: NCT#01281852.

5601 Poster Session (Board #159), Sat, 1:15 PM-4:45 PM

Evaluation of biomarker alterations in small cell cervical cancer identifies therapeutic options. *First Author: Jennifer K. Burzawa, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Small cell cervical cancer (SCCC) is an extremely rare and aggressive form of cervical cancer, accounting for only 1% of all cervical cancer cases, or ~150 cases/yr. 70% of patients will recur, even when diagnosed with early stage disease and there are few therapeutic options in this setting. We evaluated tumor samples obtained from a large repository to determine prevalent targetable molecular aberrations in these rare tumors. **Methods:** Seventy-eight SCCC samples were profiled, 53 of those on a commercial multiplatform, including a combination of gene sequencing (Sanger or NGS, up to 47 genes), amplification (CISH or FISH), and protein expression (IHC). Twenty-five samples were analyzed at a cancer center using a 50 gene NGS platform (CMS50). The profiles were compared to ~800 HPV+ cervical cancers (CC), neuroendocrine tumors (NET, all sites), and small cell lung cancers profiled at the same laboratory. **Results:** TOP2A (85%) and TOPO1 (55%) had high overexpression, while ERCC1 had low expression (11%) in SCCC samples. SCCC tumors had higher protein expression of KIT (26%) than HPV+ non-SCCC (7%, $p < 0.05$), but similar expression of KIT to small cell lung cancers (37%). HER2 amplification was identified in 4.5% of SCCC and 8% of HPV+ CC. EGFR amplification was not seen in SCCC but was identified in 10% of HPV+ CC. Gene sequencing identified higher mutation rates for TP53 (27%) and KRAS (18%) in SCCC compared to HPV+ CC (12% and 7%, respectively) but lower rates of PIK3CA (17% vs. 28%). Comparatively, small cell lung cancers had mutations in TP53 in 34% of cases and in KRAS in 5% of cases. NGS evaluation of 51 cases also identified 3 GNAS and RB1mutations (6%), 2 CTNNB1 and SMAD4 mutations (4%), and single gene mutations in BRCA1, PTEN, MET, SMARCB1, APC, ATM, HNF1A, and FBXW7 (2% each). **Conclusions:** Multiplatform tumor profiling identified high expression of TOP2A and TOPO1 in SCCC, which may explain the sensitivity to etoposide and topotecan, while low levels of ERCC1 raise concern for cisplatinum resistance. Potential druggable mutations include AKT1, KRAS, PIK3CA, and TP53. We have identified one patient with a KRAS mutation treated with a MEK inhibitor who had a complete response and remains in remission at 12 months.

5602 Poster Session (Board #160), Sat, 1:15 PM-4:45 PM

Comprehensive genomic profiling (CGP) of cervical squamous cell carcinoma (cSCC) to identifiy targeted therapy options. *First Author: Julia Andrea Elvin, Foundation Medicine, Inc., Cambridge, MA*

Background: High risk HPV initiates neoplasia in cSCC and progression requires additional genomic alterations (GA). Treatment of localized cSCC is effective but the response to systemic therapy for metastatic disease is inadequate. CGP of 99 advanced stage cSCC was undertaken to identify GA associated with targeted therapeutic options relevant to the systemic treatment of cSCC. **Methods:** DNA was extracted from 99 FFPE cSCC clinical specimens. Hybridization captured libraries of 236 (FoundationOne, n = 66) or 305 (FoundationOne, n = 33) genes, plus select introns frequently rearranged in cancer were sequenced to high (> 450x), uniform coverage. HPV16 and HPV 18 viral sequences were detected, but other hrHPVs were not assayed. All classes of genomic alterations (base subs, small in/dels, rearrangements, and copy number alterations) were evaluated and reported. CRGA were defined as GA associated with on-label targeted therapies and targeted therapies in mechanism-driven clinical trials. **Results:** 99 samples (54% primary,45% metastasis) from women (avg 47.7y) with predominantly advanced stage cSCC were profiled. 368 total GA were identified (3.7 GA per tumor) involving 80 different genes, of which 257 were CRGA (2.57 per tumor). 91% of cSCC cases featured > 1 CRGA, including 67 (67%) cases with CRGA in the *PI3K/Akt/mTOR* pathway. The most common CRGAs observed were: *PIK3CA* (41%), *MLL2* (18%), *PTEN* (16%), *STK11* (14%), *FBXW7 (11%), FGFR3 (4.6%), ERBB2 (4.6%), KRAS (4.6%).* To date, we are aware of one patient with abdominal and thoracic nodal metastases and a CGP-identified inactivating mutation in *FBXW7* who showed a 6-months partial response to everolimus treatment. *FGFR3-TACC3* gene fusions were rarely identified (3%); one late lung recurrence case showed stable disease on a multikinase inhibitor targeting FGFR. **Conclusions:** Most advanced stage cSCC demonstrate CRGAs, most commonly in the *PI3K/Akt/mTOR* pathway, and clinical response to mTOR inhibition can be achieved. Other driver events, including *FGFR3* fusions, present alternatives for targeted therapy. Patients who have exhausted other SOC for metastatic cSCC have achieved clinical benefit from CGP-directed therapeutic decision-making.

5603 Poster Session (Board #161), Sat, 1:15 PM-4:45 PM

Weekly administration of bevacizumab, eribulin, and oxalilplatin in patients with platinum-resistant ovarian carcinomas: A phase II study with biomarker analysis. *First Author: Yuji Ikeda, The University of Tokyo, Tokyo, Japan*

Background: Eribulin, inhibiting a protein component of tubulin, is a candidate for paclitaxel-refractory breast cancers, and Bevacizumab (B) is known to enhance efficacy of anti-cancer agents in ovarian cancers. A phase II study to evaluate weekly administration of B with eribulin and oxaliplatin (EriOX) in patients with platinum-resistant and refractory ovarian carcinomas (PR-ROC) was performed. **Methods:** Eligible patients were as follows: (a) ECOG PS = 0~2 (b) histologically confirmed epithelial ovarian cancer (c) diagnosed as platinum-resistant ovarian cancer (d) written informed consent. Patients were treated with weekly-B-EriOX consisting of B (2mg/kg), eribulin (1mg/m2) and oxaliplatin (30mg/m2), three weeks on and on week off, q4weeks. Response was evaluated with RECIST 1.1, and adverse effects were assessed by CTCAE v4.0. Biomarker analyses including serum VEGF and BNP were also conducted. **Results:** A total of 30 patients were enrolled in the present study. There were no cases that discontinued the therapy due to toxicities. Median age of the patient was 60 years (range: 35-71). Median number of previous regimen was 5 (range: 2-9). Two patients (7%) had a complete response (CR), 5 patients (17%) had a partial remission (PR) and 15 patients (50%) had a stable disease (SD). The response rate and clinical benefit rate (CR+PR+SD) were 23% and 73%, respectively. Median progression-free survival was 3 months (range: 1-10+). Hematological adverse effects (AE) with grade 3/4 were observed in 4 patients (13%). Hypo albuminemia and edema with grade 3 were in 1 patient (3%), respectively. However, all AE were manageable and tolerable. There was no significant difference of serum level of VEGF according to the response evaluation. **Conclusions:** Weekly B and EriOX administration had significant activity with mild AE in patients with PR-ROC. These results warrant further prospective study with biomarker analyses.

5604 Poster Session (Board #162), Sat, 1:15 PM-4:45 PM

Impact of older age on chemotherapy toxicity and quality of life in women with advanced or recurrent cervical cancer: A NRG Oncology-GOG Ancillary Study. *First Author: Emily Meichun Ko, University of Pennsylvania, Philadelphia, PA*

Background: To evaluate chemotoxicity and quality of life (QOL) in older women undergoing treatment for recurrent and advanced cervical cancer within Gynecologic Oncology Group (GOG) phase III chemotherapy trials. **Methods:** 5 trials (GOG 110, 149, 169, 179, 204) were used to characterize chemotoxicity profiles by age. 'Older' was defined as age ≥ 65. Toxicity was based on GOG or CTC scales. Concordant chemotherapy arms between trials were pooled: Cisplatin (C), cisplatin/ifosfamide (CI); cisplatin/topotecan (CT); cisplatin/paclitaxel (CP). Categorical variables were compared using the Pearson chi-square test. The Cox PH model was used to evaluate prognostic factors (at baseline or before a landmark) and to estimate the adjusted effects on survival. Poisson models of toxicity as a function of age were examined. Associations between age and QOL using Fact-G and Fact-Cx (GOG 169,179, 204) were assessed with linear mixed models. **Results:** 1201 women were evaluated (C: 407; CI: 288; CT: 255; CP: 251). Median age was 65 (IQR 58–71) and 107 were age ≥ 65. Being older was associated with improved PFS for C (HR 0.99, 95%CI .98-1.00) and CT (HR 0.98, 95%CI 0.96-0.99); and improved OS in CP (HR0.98, 95CI 0.97-1.00) and CT (HR 0.98, 95%CI0.97-0.99) in adjusted models. The most frequent grade ≥ 3 toxicities in those age ≥ 65 were leukopenia (85% for CP; 80% for CT; 92% for CI), anemia (40% for CT) and thrombocytopenia (40% in CT). Neuropathy and neurologic toxicity did not differ by age for any regimen. Grade ≥ 3 toxicities that differed significantly by age and were most frequent in older women included leukopenia (85%, p = 0.058) for CP; nausea-vomiting (30%, p = 0.03) and metabolic (25%, p = 0.04) for CT. However, age was not associated with overall toxicity for any regimen in the adjusted models. Toxicity did not confound age-dependent outcomes on PFS or OS. QOL did not differ by age group for any regimen. **Conclusions:** Older age was not associated with severe toxicity or poorer quality of life in women who underwent chemotherapy for advanced or recurrent cervical cancer in phase III national consortia trials. Older patients should be encouraged to participate in cervical cancer trials.

TPS5605 Poster Session (Board #163a), Sat, 1:15 PM-4:45 PM

EUTROC PiSARRO: A phase Ib study combining APR-246 with standard chemotherapy in platinum sensitive relapsed high grade serous ovarian carcinoma (HGSOC). *First Author: Charlie Gourley, University of Edinburgh Cancer Research UK Centre, Edinburgh, United Kingdom*

Background: p53 mutations are associated with increased chemoresistance. APR-246 is a small molecule that restores mutant p53 to wild type conformation and function (Lambert et al., Cancer Cell. 2009; 15(5):376-88). APR-246 also increases reactive oxygen species levels and ER stress; acts synergistically with DNA damaging drugs *in vitro*; resensitizes ovarian cancer cells to cisplatin and doxorubicin *in vitro* and reduces glutathione levels thereby decreasing cellular drug efflux. APR-246 showed no end-organ toxicity in the non-clinical toxicity studies but C_{max} related reversible CNS effects were identified. In a previous single agent dose finding study recommended phase II dose and safety profile was determined and signs of clinical activity and p53-dependent biological effects were observed in several patients (Lehmann et al., J Clin Oncol. 2012; 30(29):3633-9). As in animals dose limiting toxicity (DLT) was mainly C_{max} related reversible CNS effects. PK was linear and displayed no accumulation. APR-246 was concluded to have a safety and PK profile suitable for further development in combination with chemotherapeutic drugs. The rationale for this study was that p53 mutation occurs in > 97% of HGSOC, thus identifying an appropriate study population for targeted therapy. **Methods:** Patients with relapsed platinum sensitive HGSOC and positive p53 immunostaining were treated with APR-246 in combination with carboplatin AUC 5 and pegylated liposomal doxorubicin 30 mg/m^{2}every 4 weeks for 6 cycles. APR-246 was dosed as a 6h IV infusion on 4 consecutive days; on day 4, chemotherapy was given concomitantly with APR-246. A 3+3 dose escalation design with 3 dose levels (35, 50 and 67.5 mg/kg) was used. Endpoints include determination of the appropriate combination APR-246 dose, safety, PK, progression free survival, response rate, overall survival and multiple translational readouts (transcriptomic and proteomic). Matched pre-treatment and on-treatment radiologically guided biopsies are mandatory. The first two dose cohorts have been recruited with one DLT (GI perforation) in cohort 2. Recruitment to cohort 3 commenced in December 2014. Clinical trial information: NCT02098343.

TPS5606 Poster Session (Board #163b), Sat, 1:15 PM-4:45 PM

A phase III study of trabectedin (T) plus pegylated liposomal doxorubicin (PLD) versus PLD for treatment of advanced-relapsed epithelial ovarian, primary peritoneal, or fallopian tube cancer. *First Author: Robert L. Coleman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ovarian cancer (OVC) is the eighth most common cancer among women globally, with approximately 60%–70% of cases being diagnosed at an advanced stage (III or IV). Five-year survival rate for advanced stages is under 40%. In a previous pivotal trial, patients with OVC who relapsed after first-line platinum-based chemotherapy (PCT) demonstrated superior progression free survival when treated with the T+PLD combination vs. PLD monotherapy (7.3 vs. 5.8 months; HR = 0.79; p = 0.019). In a subgroup analysis by platinum free interval, T+PLD showed an improved overall survival (OS) for patients with Platinum Free Interval of 6–12 months (HR = 0.64) (J Clin Oncol. 2010 28:3107-14.). Given this demonstrated efficacy, we are conducting a global phase III registration trial to investigate the OS of T+PLD vs. PLD in patients with platinum sensitive epithelial OVC, peritoneal or fallopian tube cancer, in the third-line setting. **Methods:** In this open-label, active-controlled trial, approximately 670 women who have received 2 prior lines of PCT will be enrolled at approximately 135 sites in 9 countries. Key inclusion criteria: all women must be platinum sensitive (defined as no evidence of disease progression for ≥ 6 months after the last dose of first-line PCT), and demonstrated a partial or complete response to second line PCT. Key exclusion criteria: OVC with mucinous histology and > 2 prior lines of chemotherapy. Patients will be stratified by Platinum Free Interval, ECOG performance status, BRCA 1 or 2 mutation status, and prior PLD therapy. Stratified patients will be randomized (1:1) to receive PLD (30 mg/m2, 1.5 h, i.v.) followed by T (1.1 mg/m2, 3 h, i.v.) every 3 weeks or PLD alone (50 mg/m2, 1.5 h, i.v.) every 4 weeks. Primary endpoint is OS. Secondary endpoints include progression free survival, overall response rate (ORR), safety, and pharmacokinetics of T. Planned study duration is 64 months. An interim OS analysis is planned after 308 events. Final OS analysis will be done after ≥ 514 events have been observed. As of 19 January 2015, 145 patients have been randomized (ClinicalTrials.gov #: NCT01846611). Clinical trial information: NCT01846611.

TPS5607 Poster Session (Board #164a), Sat, 1:15 PM-4:45 PM

ENGOT-OV24-NSGO/AVANOVA: Niraparib versus bevacizumab-niraparib combination versus bevacizumab and niraparib as sequential therapy in women with platinum-sensitive epithelial ovarian, fallopian tube, or peritoneal cancer. *First Author: Mansoor Raza Mirza, NSGO, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Multiple Phase 1 and 2 clinical studies of PARP inhibitors used as monotherapy to treat patients with recurrent ovarian cancer (ROC) suggest that the agents are active in this population and there is level one evidence that bevacizumab is beneficial In the same population. A phase two randomized study demonstrated that the addition of a PARP inhibitor to an anti-angiogenic drug cediranib improves Progression-free survival (PFS). Our aim is to compare tolerability and efficacy of niraparib alone versus niraparib-bevacizumab combination versus sequential bevacizumab and niraparib. **Methods:** The ENGOT-OV24-NSGO/AVANOVA study comprises of two parts. Part 1 is a classic phase 1 trial of niraparib and bevacizumab combination. Part 2 is a three-arm, open-label, phase II, 1:1:1 randomized study of niraparib and/or Niraparib-bevacizumab combination against bevacizumab followed by niraparib in women with platinum-sensitive ROC. BRCAmut and or high-grade serous/endometrioid carcinoma patients with platinum-sensitive ROC are eligible. Patients must have disease that is measurable according to RECIST or assessable according to the GCIG CA-125 criteria. Primary objective of phase 1 part is to evaluate the safety and tolerability of bevacizumab-niraparib combination therapy and determine the Recommended Phase 2 Dose (RP2D) of bevacizumab-niraparib. Primary objective of phase 2 part is to obtain preliminary evidence of efficacy of bevacizumab- niraparib combination or sequential therapy or niraparib single agent treatment. Primary end-point is PFS. Secondary end-points include PFS in each group according to trial stratification factors; PFS comparison of sequential versus concomitant bevacizumab and Niraparib; Objective response rate; Disease control rate (DCR); Patient Reported Outcomes (PROs); Time to subsequent chemotherapy and survival. Study status: The study is activated and sites are invited to participate. ClinicalTrials.gov Identifier: NCT02354131 Clinical trial information: NCT02354131.

TPS5608 Poster Session (Board #164b), Sat, 1:15 PM-4:45 PM

Multicenter randomized Phase II study of AZD1775 plus chemotherapy versus chemotherapy alone in patients with platinum-resistant TP53-mutated epithelial ovarian, fallopian tube, or primary peritoneal cancer. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: WEE1 is DNA damage cell-cycle checkpoint protein that inactivates cyclin-dependent kinase 1 (CDC2) and is overexpressed in a variety of malignancies. Pts with deficient p53 expression rely on the WEE1 kinase to arrest cell-cycle progression at the G2 checkpoint for DNA repair. AZD1775, a highly selective, adenosine-triphosphate (ATP) competitive, small-molecule inhibitor of the WEE1 kinase, is being developed for the treatment of advanced solid tumors with TP53-mutated malignancies. Inhibition of WEE1 allows CDC2 phosphorylation and subsequent cell-cycle progression despite DNA damage. This G2 checkpoint abrogation thus sensitizes cells to cytotoxic agents. Preliminary efficacy data have been promising when AZD1775 is used in combination with chemotherapy. In this randomized, phase II trial in pts with platinum-resistant, TP53-mutated cancers, AZD1775 will be added to a standard chemotherapy regimens (paclitaxel, gemcitabine, or carboplatin), with the goal of improving efficacy when compared to chemotherapy alone. The primary endpoints are response rate (Part 1), and progression-free survival (Part 2). **Methods:** In Part 1, up to 69 pts will be randomized to receive AZD1775 plus paclitaxel, gemcitabine or carboplatin (Arm A: AZD1775 175 mg PO BID Days 1, 2, 8,9,15, and 16 plus gemcitabine 1000 mg/m^2 IV Days 1, 8, and 15; Arm B: AZD1775, 5 doses of 225 mg PO BID Days 1-3, 8-10, and 15-17 plus paclitaxel 80 mg/m2 IV Days 1, 8, and 15; Arm C: AZD1775, 5 doses of 225 mg PO BID Days 1-3 plus carboplatin AUC 5 IV Day 1). In Part 2, up to 108 pts will be randomized 1:1 to the most efficacious AZD1775/chemotherapy combination identified in Part 1, or chemotherapy alone. Pts will be restaged every 2 cycles and continue treatment until disease progression or unacceptable toxicity. Key eligibility includes: platinum-resistant TP53-mutated epithelial ovarian, fallopian tube, or primary peritoneal cancer, measurable disease per RECIST v 1.1, ECOG PS 0 or 1, QTc $<$ 470 msec, and no known CNS disease. Tumor samples will be collected for evaluation of specific biomarkers. Clinical trial information: NCT02272790.

TPS5609 Poster Session (Board #165a), Sat, 1:15 PM-4:45 PM

A phase 2, open-label study of niraparib in women with advanced, relapsed, high-grade serous epithelial ovarian, fallopian tube or primary peritoneal cancer after ≥3 previous chemotherapy regimens. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Niraparib is a potent, orally active PARP-1 and -2 inhibitor in development for the treatment of tumors that exhibit defects in the PARP-mediated homologous recombination DNA repair pathway. In preclinical experiments, niraparib has shown activity against germ line BRCA mutated (gBRCA^{mut}) ovarian cancer cells (OvCa) and other High-Grade Serous OvCa (HGSC) cells. At the recommended dose of 300 mg, 50% of patients with BRCA-mutant ovarian cancer who had received more than 3 lines of prior chemotherapy achieved RECIST responses in the phase 1 study. **Methods**: This is a multicenter (approximately 35 sites), open-label, Phase 2 study of niraparib in up to 225 women with advanced, relapsed, high-grade serous epithelial ovarian, fallopian tube, or primary peritoneal cancer. Eligible pts must have received $\geq$ 3 previous chemotherapy regimens (prior exposure to PARP inhibitors and/or prior anti-angiogenesis inhibitors are not excluded). The primary objective is to evaluate the antitumor activity of niraparib. Secondary objectives are 1) durability of antitumor activity; 2) antitumor activity in Homologous Recombination Deficiency (HRD)-positive pts and in pts with gBRCA^{mut}; 3) disease control rate; 4) progression-free survival; and 5) safety and tolerability. Exploratory objectives are 1) QTc interval in a subset of niraparib-treated OvCa pts; 2) population pharmacokinetics for niraparib and its major metabolite; and 3) potential biomarkers of PARP inhibitor sensitivity and tolerability. Niraparib 300 mg is administered orally once daily on a 28 day cycle until discontinuation.. The overall analysis will use a 1-proportion statistical test that the ORR is $\geq$ 30%. The ORR will be evaluated in the HRD-positive and gBRCA^{mut} subsets. The sample size at 1-sided alpha of 0.025 and $>$ 80% power for the pooled subsets would be N = 200 using a normal approximation with continuity correction. The HRD-positive or gBRCA^{mut} subset represents 100 patients of the total sample population. Clinical trial information: NCT02354586.

TPS5610 Poster Session (Board #165b), Sat, 1:15 PM-4:45 PM

The MILO (MEK inhibitor in low-grade serous ovarian cancer)/ENGOT-ov11 study: A multinational, randomized, open-label phase 3 study of binimetinib (MEK162) versus physician's choice chemotherapy in patients with recurrent or persistent low-grade serous carcinomas of the ovary, fallopian tube, or primary peritoneum. *First Author: Bradley J. Monk, University of Arizona Cancer Center and Creighton University School of Medicine at Dignity Health St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Background: Low-grade serous (LGS) carcinomas of the ovary, fallopian tube and primary peritoneum are a unique subset of serous carcinomas for which current therapies (chemotherapy, hormonal) have demonstrated limited efficacy. KRAS or BRAF mutations, which activate the RAS/RAF/MEK/ERK signaling pathway, are present in many LGS carcinomas. Binimetinib is a potent inhibitor of MEK1/2, a key component of the RAS/RAF/MEK/ERK pathway, and has demonstrated activity in other disease settings where dysregulation of this pathway is present. **Methods:** This is a 2-arm, open-label, 2:1 randomized Phase 3 study of binimetinib vs physician's choice chemotherapy (pegylated liposomal doxorubicin, paclitaxel or topotecan) in patients with LGS carcinomas. Eligible patients must have LGS carcinoma that is recurrent or persistent following at least 1 prior platinum-based chemotherapy and no more than 3 prior lines of chemotherapy, and must have RECIST v1.1-defined measurable disease confirmed by blinded independent central review (BICR). Prior to randomization, confirmation of LGS diagnosis is required. Patients are eligible regardless of RAS/RAF mutational status; however, tumor tissue will be retrospectively analyzed for mutations in RAS/RAF and other genes. Prior treatment with a MEK inhibitor or BRAF inhibitor is prohibited. Randomization is stratified by last platinum-free interval and number of prior systemic therapy regimens. The primary endpoint is progression-free survival as determined by the BICR; secondary endpoints include overall survival, overall response, duration of response, disease control rate, safety, quality of life and pharmacokinetics of binimetinib. Binimetinib is administered 45 mg BID orally. Patients receive therapy until disease progression or unacceptable toxicity. Crossover is permitted from physician's choice chemotherapy to binimetinib upon BICR-confirmed progression. This study will enroll 300 patients worldwide (NCT01849874). Clinical trial information: NCT01849874.

TPS5611 Poster Session (Board #166a), Sat, 1:15 PM-4:45 PM

A phase I/II study of Enadenotucirev, an oncolytic Ad11/Ad3 chimeric group B adenovirus, administered intraperitoneally (IP): Dose finding and proof of concept in platinum-resistant epithelial ovarian cancer. *First Author: Iain A. McNeish, Institute of Cancer Sciences, University of Glasgow, Glasgow, Scotland*

Background: Enadenotucirev (EnAd) is a tumor selective Ad11/Ad3 group B adenovirus that has demonstrated preclinical activity in a model of platinum-resistant ovarian cancer. Synergy has also been reported between oncolytic adenoviruses and microtubule manipulating drugs (Ingemarsdotter, Oncogene, 2010, 29(45)). EnAd is suited to IP delivery as it avoids its elimination by the liver and retains it in the peritoneal cavity, where ovarian cancer metastases are principally located. This study aims to establish the maximum-tolerated dose (MTD) of EnAd delivered IP, both as a monotherapy (Phase [Ph.] Ia) and combined with paclitaxel (Ph. Ib) and provide early proof of concept data (Ph. II). **Methods:** Ph. I follows a standard 3+3 dose escalation scheme and Ph. II is a single arm. Patients (pts) with platinum-resistant ovarian cancer receive EnAd as 3 separate weekly IP doses followed by 1 week rest (one cycle) in Ph.Ia and EnAd IP on d1, 8 and 15 ($\pm$1 d) and weekly paclitaxel (80 mg/m2) IV on d9, 16 and 23 ($\pm$1 d) of each 28-day cycle. The starting dose for EnAd in Ph. Ia is 1 x 10^{12} vp. The MTD determined in Ph. Ib is to be tested in 20-23 pts in Phase II. Primary endpoints include determination of MTD for Ph.I (alone and in combination) and progression-free survival (PFS) using RECIST v1.1 for Ph. II. Secondary endpoints include safety and tolerability, blood kinetics, IP distribution, clearance and replication, shedding, blood and IP immune response to EnAd, blood cytokine response as well as response rate, duration of response, clinical benefit rate and PFS using immune-related response criteria (irRC) and GCIG CA-125 criteria. Exploratory endpoints include assessment of IP cytological changes (inflammatory cell infiltrates) in response to EnAd, and EnAd replication in cancer tissues in selected patients. To date, 3 pts have been treated in Ph. Ia and recruitment is ongoing. Clinical trial information: EUDRACT 2013-001276-38. Clinical trial information: NCT02028117.

TPS5612 Poster Session (Board #166b), Sat, 1:15 PM-4:45 PM

Open label phase II clinical trial of orteronel (TAK-700) in metastatic or advanced non-resectable granulosa cell ovarian tumors: The Greko II study—GETHI 2013-01. *First Author: Jf. Rodriguez-Moreno, Centro Integral Oncológico Clara Campal, Madrid, Spain*

Background: Granulosa-cell tumors (GCT) of the ovary are a rare entity characterized by presenting a punctual mutation at the FOXL2 gene 402C→G (C134W) in most cases. Such mutation is responsible for a disregulation and overstimulation of the steroidogenic pathway, that ultimately leads to hormone overproduction. A prior trial by our group (GREKO I trial-GETHI 2011-03; NCT01584297) showed promising activity of ketoconazole, a CYP17 inhibitor used to control steroidogenesis in several conditions. Thus, we aim to assess the activity of Orteronel (TAK700), a selective inhibitor of 17, 20-lyase, in GCT. **Methods:** An open-label phase II single arm clinical trial has been designed for women with metastatic or locally advanced non-resectable granulosa cell ovarian tumor that harbors the somatic mutation FOXL2 402C→G (C134W) and who have not received prior treatment with any CYP17 inhibitor. Treatment will consist on Orteronel 300mg BID, given orally, continuously in a 28-day treatment cycle. The primary objective is clinical benefit rate; secondary objectives are response rate, progression free and overall survival, assessment of the impact of Orteronel in reducing hormonal overproduction and toxicity. Sample size calculation is based on a a two stage Simon´s design that will lead to enroll 12 evaluable participants in stage one and 4 participants in stage two if one or more participants achieved a CR, PR or stable disease longer than 6 months. 16 subjects will allow a 80% power to differentiate between a 5% and a 25% clinical benefit rate. Probability of early termination of the trial is .54. 20% of losses have been assumed thus 20 patients will be enrolled in 9 spanish institutions (members of hte Spanish Group for Research in Orphan and Unfrequent Tumors-GETHI). Key inclusion criteria are histological diagnosis of GCT, advanced disease (meseaurable or evaluable by RECIST), availability of biopsy material for centralized pathologist review and assessment of the FOXL2 mutation. Key exclision criteria is prior therapy with orteronel, ketoconazole, abiraterone, aminoglutethimide or enzalutamide. Two patients have already been included. Clinical trial information: NCT02101684.

TPS5613 Poster Session (Board #167a), Sat, 1:15 PM-4:45 PM

A randomized, placebo-controlled phase II trial comparing gemcitabine monotherapy to gemcitabine in combination with AZD 1775 (MK 1775) in women with recurrent, platinum-resistant epithelial ovarian, primary peritoneal, or Fallopian tube cancers: Trial of Princess Margaret, Mayo, Chicago, and California consortia. *First Author: Stephanie Lheureux, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Platinum resistant ovarian cancer (OC) remains a therapeutic challenge. The majority of high grade serous OC (HGSOC) harbor *TP53* mutations leading to increased dependency on S- and G2-phase checkpoints. Wee1 inhibition with AZD 1775 (MK 1775) induces G2 checkpoint escape. Gemcitabine is an antimetabolite therapy that kills cells undergoing DNA synthesis and blocks the progression of cells through the G1/S phase boundary. Preclinical data have shown that the addition of AZD 1775 to gemcitabine increased activity in platinum resistant OC cell lines and xenograft models. We propose to evaluate the combination of gemcitabine/AZD 1775 in patients (pts) with platinum resistant OC. **Methods:** A multicenter 2:1 randomized phase 2 trial was designed to evaluate the progression free survival (PFS) of subjects with recurrent platinum-resistant/refractory OC receiving gemcitabine in combination with AZD 1775 compared to subjects receiving gemcitabine in combination with placebo (NCT02151292). Eligibility requires measurable disease with progression and disease amenable to a paired biopsy for correlative analyses. There is no limitation in the number of prior lines of therapy, but pts with prior gemcitabine are excluded. All histologic subtypes are eligible, but only pts with HGSOC are considered for the statistical analysis. AZD 1775/Placebo is given orally at 175mg on D1-2, D8-9 and D15-16 with gemcitabine 1000mg/m^2 IV D1, D8 and D15 in a 28-day cycle until progression or unacceptable AE. The primary objective is an improvement in median PFS (from 3.5 to 7 months). Integrated biomarkers will evaluate loss-of-function *TP53* mutations by three complementary methodologies: Sanger sequencing, TAm-Seq and IHC as potential predictive factors of benefit to AZD 1775 and gemcitabine. The concordance of *TP53* mutations in tumor specimens is also determined and followed by TAm-Seq in ctDNA. Current status: This trial was activated in Sept 2014. A total of 10 pts with a median age of 66 are enrolled, all HGSOC. Clinical trial information: NCT02151292.

TPS5614 Poster Session (Board #167b), Sat, 1:15 PM-4:45 PM

Targeting VEGFRi resistance through HIF-1á suppression: Phase II clinical trial evaluating CRLX101 as monotherapy and in combination with bevacizumab in recurrent platinum resistant ovarian cancer. *First Author: Carolyn N. Krasner, Massachusetts General Hospital, Boston, MA*

Background: Ovarian cancer (Ov.Ca.) is the leading cause of death among gyn malignancies. Limited treatment options exist for women whose tumors have become platinum resistant. Hypoxia Inducible Factor-1α (HIF-1α) is a master regulator of key cancer cell survival pathways and facilitates resistance to anti-angiogenic therapies. CRLX101, a novel nanoparticle-drug conjugate that differentially delivers camptothecin into cancer cells, durably suppresses HIF-1α and the combination of CRLX101 with anti-angiogenic drugs incl. bevacizumab (Avastin, Genentech/Roche)(BEV) achieves notable drug-drug synergy in pre-clinical models. Phase 2 monotherapy results achieved with CRLX101 and presented at ASCO 2014 exceeded expectations in this setting and established the basis for this follow-on study. **Methods:** This phase 2 open label, two-stage clinical trial evaluates the combination of CRLX101 plus BEV in pts. with epithelial ovarian, tubal or primary peritoneal cancer progressing through prior platinum-containing chemotherapy. Eligible pts. must have platinum-resistant measurable disease and may have received 1 or 2 prior regimens of chemotherapy that includes no prior topo-1 inhibitors or BEV. Pts. receive CRLX101 15 mg/m2 IV plus BEV 10 mg/kg IV on days 1 and 15 of their 28-day cycles. All pts. undergo CT-based tumor evaluations every 2 cycles. The primary endpoint is progression free survival (PFS) at 6 months (PFS6) and secondary objectives include response rate and assessment of toxicity. A 2-stage design is being employed with the study terminated if $\leq$ 2/18 stage 1 pts. achieve the PFS6 endpoint. As this gate has now been met, a 2nd stage will enroll 25 additional pts. and the treatment will be considered worthy of further investigation if $\geq$ 8/43 total pts. achieve PFS6. Enrollment is ongoing and to-date the drug appears well tolerated with no drug-related SAEs, treatment discontinuations, or deaths observed. Clinical trial information: NCT01652079.

TPS5615 Poster Session (Board #168a), Sat, 1:15 PM-4:45 PM

A phase I dose-escalation and pharmacokinetic study of hyperthermic intraoperative intraperitoneal chemotherapy (HIPEC) carboplatin at the time of primary cytoreductive surgery for advanced ovarian, fallopian tube, and peritoneal carcinomas. *First Author: Leslie M. Randall, UC Irvine, Tustin, CA*

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) administered at the time of cytoreductive surgery (CRS) for ovarian cancer has the potential to permit immediate regional therapy to the lowest achievable disease burden. Though evidence supporting its efficacy in ovarian cancer is lacking, HIPEC is gaining popularity in the clinical setting. Doses and agents administered are chosen empirically without pharmacokinetic (PK) data. Therefore, we are conducting a phase I dose-escalation and pharmacokinetic study of HIPEC carboplatin (NCT02199171) to inform a follow-on randomized phase II study. **Methods:** Women (n = 30) with presumed stage IIC-IVA ovarian, tubal, or peritoneal carcinomas who are planned for primary or interval CRS following neoadjuvant chemotherapy are eligible. Those optimally or completely cytoreduced and stable for continued anesthesia receive a 60-minute, closed-abdomen infusion of carboplatin at 41ºC according to a novel, continual reassessment dose escalation schema that is flexible to interpret adverse events attributable to surgery vs. those of HIPEC. Serum and peritoneal perfusate are collected for PK studies at time 0 and at every 15 minutes for the duration of the infusion. DNA platinum uptake is measured by inductively coupled plasma mass spectroscopy (ICP-MS). Median, range and interquartile range will be reported for the amount of carboplatin absorbed from the perfusate, the rate of drug absorption from the peritoneal cavity into the systemic circulation, the 0-to-60 min AUC's for peritoneal and plasma platinum concentration curves, the total body clearance, and regional advantage. Three small, easily resectable tumors are left in situ during the perfusion for correlative studies which include direct measurement of tissue temperature in tumors and control avascular mesentery, levels of platinated DNA by ICP-MS in tumors exposed to HIPEC, and expression of Hsp90 in tumors before and after HIPEC. Clinical trial information: NCT02199171.

TPS5616 **Poster Session (Board #168b), Sat, 1:15 PM-4:45 PM**

Phase 2 clinical study of onapristone (ONA) in patients (pts) with uterine endometrioid adenocarcinoma (EC) expressing the activated progesterone receptor (APR^{pos}). *First Author: Jacques Bonneterre, Centre Oscar Lambret, Lille, France*

Background: ONA is a type I PR antagonist, which prevents PR-induced DNA transcription. Presence of transcriptionally-activated PR (APR), seen as an aggregated subnuclear PR distribution pattern, is being explored as a predictive biomarker for ONA activity. The proposed IHC companion diagnostic could select pts with uterine EC most likely to respond to ONA. An extended-release (ER) formulation has been developed to provide constant target exposure to the anti-progestin and address previously-observed liver function test abnormalities. ONA anti-cancer activity has been documented in multiple preclinical models. Pts with APR^{pos} EC, breast and ovarian cancers have experienced clinical benefit (PR or SD $\geq$ 6 months) on ONA, with excellent tolerability. The current study was designed to test the hypothesis that the APR companion diagnostic identifies the pts most likely to respond to ONA, with 80% power to detect a response rate of 30%. **Methods:** This is an ongoing multi-center, open-label, randomized, parallel-group, 2-part phase 1-2 study. The randomized phase 1 dose-finding portion is complete (n = 52). Results are presented in separate abstracts. ONA 50 mg ER was selected as the recommended phase 2 dose. The phase 2 portion focuses on post-menopausal female pts $\geq$ 18 years with recurrent or metastatic uterine EC that is APR^{pos}. APR status is determined by IHC on biopsy at study entry; slides are stained at a central lab using a technically-validated procedure, then centrally interpreted by trained pathologists. PR positivity is defined as $\geq$ 10% cells PR^{pos} by IHC and APR positivity as $\geq$ 5% of cells showing the aggregated pattern. Pts are treated with ONA 50 mg ER BID until progressive disease or intolerability. The primary endpoint is objective response rate by RECIST 1.1. Secondary endpoints include relationship between extent of APR expression and ONA activity, safety and tolerability, duration of response, PFS and OS. A Simon 2-stage design includes 10 patients in the first stage. If $\geq$ 2 pts respond, the study will recruit a further 19 pts (stage 2) to confirm anti-tumor activity. As of February 2015 the study is actively recruiting pts with APR^{pos} uterine EC. Clinical trial information: NCT02052128.

TPS5617 **Poster Session (Board #169a), Sat, 1:15 PM-4:45 PM**

Phase II clinical trial of eribulin in advanced or recurrent cervical cancer (CC). *First Author: Jocelyn Garcia, Los Angeles County Hospital/ University of Southern California, Los Angeles, CA*

Background: Eribulin (E), a Halichondrin B analog from the marine sponge H. okadai shows anticancer effects via G2/M cell cycle arrest, mitotic spindle disruption, and apoptosis. E has efficacy in pretreated metastatic breast cancer (BC) patients (pts), and preclinical antitumor activity in squamous cell carcinoma (SCC) tumor models. Microtubules (MT) have a dynamic and critical role in cancer growth and metastasis. Increasing data support their role in endoplasmic reticulum stress (ERS) and the unfolded protein response. The glucose-regulated protein-78 (GRP78), a key regulator of the ERS response, is upregulated by taxane-chemotherapy (CT) and is associated with clinical outcome. Previous reports show that high GRP78 levels predict response to MT inhibitors (paclitaxel) in BC. Given the novel tubulin-specific mechanism of action of E and its activity in SCC, we conducted a 2-stage phase 2 study of E in pts with advanced/recurrent CC to examine the clinical activity and potential predictors of response (e.g., MT-associated proteins, GRP78). We hypothesize that (1) primary CC tumors with higher GRP78 levels may be associated with better response (i.e., longer time to progression) to E; (2) pts with increasing levels of serum GRP78 during E-treatment will show improved clinical responses to E. **Methods:** Pts with recurrent/advanced CC after $\leq$ 1 prior CT regimens, measurable disease and ECOG performance status $\leq$ 2 were treated with E (1.4mg/m^2 IV day 1 and 8 every 21 days) with tumor assessments every 2 cycles. Primary endpoint was 6-month progression free survival (PFS_6); secondary were best overall response (RECISTv1.1), toxicity (CTCAEv4.03), and overall survival; and exploratory were associations of tumor and serum GRP78 as well as tubulin sub-types with clinical activity. This study has 80% power when the true PFS_6= 26% with a 1-sided $\alpha \leq 0.1$ (H_0: PFS_6= 10%). A prespecified futility analysis gating stage 2 was set if 0/15pts showed at least stable disease at 6 months. Archival tumor samples were evaluated by immunohistochemistry for GRP78, τ, and Tubulin-α, -β, -βIII,-βIV. Serum GRP78 levels were quantified by ELISA. The first pt was enrolled in Nov. 2012. Stage 2 began in Dec. 2014. Currently, 16 of the 30 planned pts have been enrolled. Clinical trial information: NCT01676818.

TPS5618 **Poster Session (Board #169b), Sat, 1:15 PM-4:45 PM**

A single arm, single stage phase II trial of trametinib (GSK1120212) and GSK2141795 in persistent or recurrent cervical cancer. *First Author: Ursula Matulonis, Dana-Farber Cancer Inst, Boston, MA*

Background: In the US, invasive cervical cancer (CC) will affect 12,710 women/year with ~4290 deaths; global deaths from CC are ~275,000 women per yr. Though treatment options for recurrent/metastatic (met) CC have improved by adding bevacizumab to chemotherapy, pts with met CC will eventually have cancer progression (Tewari et al ,*NEJM* 2014), and effective therapies are few. Data from our own institution (Wright et al, *Cancer* 2013) found *PIK3CA* mutations in 32% of adenocarcinomas of the cervix (ACC) and in 35% of squamous cell cancers of the cervix (SCC). *KRAS* mutations were present in 17% of AC's and 0% of SCC. Thus, therapies targeting the PIK3CA and RAS-ERK pathways have rationale for treating met CC; this phase II study is testing a MEK and an AKT inhibitor combination. Pre-clinical studies support dual PI3Ki and MEKi given pathway redundancy and negative feedback loops. **Methods:** Trametinib (GSK1120212) is a reversible/selective inhibitor of MEK1/MEK2. GSK2141795 is an AKT1-3 inhibitor. Objectives of this study: RECIST 1.1 activity of trametinib and GSK2141795 in pts with recurrent CC; other objectives include assess PFS and OS duration, toxicities, mutation and co-mutation rates of PI3K and RAS-ERK signaling pathway genes using high throughput mutational analysis on FFPE samples, and mutational status with clinical benefit from trametinib and GSK2141795. Eligibility: recurrent or met CC (any histology eligible), receipt of 1 prior chemotherapy, and up to 1 add'l regimen, no prior use of PI3K or RAS-ERK pathway inhibitor, ECOG PS 0-2, normal organ function, and availability of FFPE tissue. The treatment regimen is as follows: trametinib 1.5 mg and GSK2141795 50 mg, both given PO and daily. Cycle length is 28 days and pts are assessed for RR every 2 cycles. The study opened in 10/2013, and as of 2/2015, 12 pts have been enrolled. Target accrual is 35 pts; there is a 91% power to detect an improvement in RR from 0.07 to 0.22 using a one-sided 0.09-level exact binomial test. The null hypothesis will be rejected if 5 or more pts respond to trametinib and GSK2141795; the null hypothesis of 0.07 is based on a weighted average of the observed RR from the 11 cohorts enrolled to GOG 127 and 227 series. Clinical trial information: NCT01958112.

TPS5619 **Poster Session (Board #170a), Sat, 1:15 PM-4:45 PM**

Phase I trial of nelfinavir added to cisplatin chemotherapy with concurrent pelvic radiation for locally advanced cervical cancer. *First Author: Arlene Esther Garcia-Soto, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Despite platinum based chemoradiation (C-XRT), 40-50% of women with locally advanced cervical cancer will die from their disease. Nelfinavir (NFV), a protease inhibitor, has been shown to target the Akt pathway sensitizing cancer cells to chemoradiation. The objective of this Phase I trial was to determine dose-limiting toxicities (DLT) and genomic and proteomic effects of NFV in combination with standard concurrent C-XRT in locally advance cervical cancer. **Methods:** After obtaining IRB approval, previously untreated patients with clinical stage IIA to IVA cervical cancer were identified. Patients with HIV were excluded from the trial. Cohort dose level 1 (Dose Level (DL) 1) has been completed. NFV 875 mg PO BID with a 7 day run-in prior to initiating C-XRT. NFV was continued with weekly cisplatin 40 mg/m^2 and pelvic radiation. Patients received a total dose of approximately 80 Gy to the pelvis. Toxicity was evaluated during treatment and every 3 months for 1 year. Pathologic and clinical responses by RECIST 1.1 were also assessed at 3 months intervals for a period of one year. Tumor biopsies were obtained at baseline, after one week of NFV, after 4 and 6 weeks of NFV plus C-XRT and at 3 month follow up for IHC, gene expression analysis and RPPA analysis. Clinical trial information: NCT01485731.

6000 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Phase III randomized trial of standard fractionation radiotherapy (SFX) with concurrent cisplatin (CIS) versus accelerated fractionation radiotherapy (AFX) with panitumumab (PMab) in patients (pts) with locoregionally advanced squamous cell carcinoma of the head and neck (LA-SCCHN): NCIC Clinical Trials Group HN.6 trial. *First Author: Lillian L. Siu, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Concurrent administration of anti-EGFR monoclonal antibody with radiotherapy (RT) increases survival compared to RT alone in pts with LA-SCCHN. No prospective data are available comparing bioradiotherapy to standard chemoradiotherapy. **Methods:** Pts with TanyN+M0 or T3-4N0M0 LA-SCCHN were randomized 1:1 to receive SFX (70Gy/35 over 7 weeks) plus CIS at 100 mg/m^2 intravenous (IV) for 3 doses on weeks 1, 4 and 7 (Arm A) versus AFX (70Gy/35 over 6 weeks) plus the anti-EGFR monoclonal antibody PMab at 9 mg/kg IV for 3 doses on weeks -1, 3 and 6 (Arm B). Primary endpoint was progression-free survival (PFS). A total of 320 patients were accrued from 12/2008 to 11/2011 with a median follow-up of 46.4 months (range: 0.1-64.3). Due to an observed declining event rate, the protocol was amended to analyze data with a clinical cut-off date of October 31, 2014. **Results:** Of 320 pts randomized, 5 did not receive protocol treatment, 156 received Arm A and 159 Arm B. Demographics: median age = 56 (range 35-80); male = 84%; ECOG 0:1 (%) = 71:29; primary site: oropharynx (81%), larynx (11%), hypopharynx (6%), oral cavity (2%); smoking history > 10 pack-years (58%). Of 259 oropharynx pts p16 status was known in 217 (84%), with 176 (81%) positive and 41 (19%) negative. A total of 93 PFS events occurred. By intention-to-treat, 2-year PFS was 73% (95% CI: 65-79%) in Arm A and 76% (95% CI: 68-82%) in Arm B, hazard ratio (HR) = 0.95; 95% CI: 0.6-1.5; p = 0.83. Upper bound of HR's 95% CI exceeded the pre-specified non-inferiority margin. Two-year OS was 85% (95% CI: 78-90%) in Arm A and 88% (95% CI: 82-92%) in Arm B, HR = 0.89; 95% CI: 0.54-1.48; p = 0.66. By multivariable analysis, anatomic location, ECOG PS, p16 status, and T category were significant predictors of PFS ($p < 0.05$). Incidence of any > grade 3 non-hematologic adverse event (AE) was 88% in Arm A and 91% in Arm B (p = 0.25). QOL is reported separately. **Conclusions:** With a median follow-up of 46.4 months, PFS of PMab+AFX was not superior to CIS+SFX in LA-SCCHN and non-inferiority was not proven. Clinical trial information: NCT00820248.

6001 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Weekly paclitaxel, carboplatin, cetuximab (PCC), and cetuximab, docetaxel, cisplatin, and fluorouracil (C-TPF), followed by risk-based local therapy in previously untreated, locally advanced head and neck squamous cell carcinoma (LAHNSCC). *First Author: Erminia Massarelli, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We designed a randomized phase II trial to determine the efficacy of two induction chemotherapy (ICT) cetuximab (C) containing regimens with demonstrated efficacy and acceptable toxicity in previously untreated LAHNSCC. ICT was followed by risk-based definitive local therapy, where risk was defined by Human Papillomavirus (HPV) status and stage and stratification by smoking status (low vs intermediate/high). Primary endpoint was 2-year progression free survival (2yr PFS). **Methods**: 136 patients (pts) median age 58 years, 84% males, 89% caucasian, 66% ECOG PS 0, 40% never smokers, with stage IV (40% T3-4, 98% N2b-c/N3), 77% HPV-positive, HNSCC (oropharynx 79%, others 21%) were randomized 1:1 to receive PCC [paclitaxel 135 mg/m2, carboplatin AUC 2 weekly (wy) and C 400 mg/m2 week (w) 1 then 250 mg/m2 wy] for 6 weeks or C-TPF [docetaxel 75 mg/m2, cisplatin 100 mg/m2 day (d) 1, fluorouracil 700 mg/m2 24-hr infusion d 1-4 every 3 w and C 400 mg/m2 w 1 then 250 mg/m2 wy] for 9 weeks. **Results**: As of January 2015 with a median follow-up of 18.4 months and 128 evaluable pts, 14 pts recurred (5 in PCC, 9 in C-TPF) and 4 died (2 per arm). Median PFS has not been reached yet. Sites of recurrence were: primary site (3 in PCC, 6 in C-TPF), cervical lymph nodes (1 in PCC, 3 in C-TPF) and lung metastasis (1 in PCC). Overall grade 3-4 toxicities were seen in 90% PCC pts vs 88% C-TPF pts. C-TPF pts were more likely to experience dehydration (31% vs 12% p = 0.006), nausea (25% vs 9% p = 0.01), hypokalemia (21% vs 2% p = 0.0005), but less likely rash (3% vs 35% $p < 0.0001$), compared to PCC pts. **Conclusions**: Overall ICT with C, a platinum and a taxane combination, followed by risk-based local therapy has promising results with a manageable toxicity profile. Survival results are excellent and distant failure is very uncommon. Formal comparison with historical data within risk groups and predictive biomarker analysis are ongoing. Clinical trial information: NCT01154920.

		PCC (%)	C-TPF (%)
Response Rate (RR) post ICT		78	82
Overall RR (post local therapy)		94	85
Estimated 2yr PFS rate	All pts	89	80
	HPV-positive	94	78
	HPV-negative	76	83
	Low risk	95	82
	Intermediate/high risk	72	75

6002 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

Long-term results of GORTEC 2000-01: A multicentric randomized phase III trial of induction chemotherapy with cisplatin plus 5-fluorouracil, with or without docetaxel, for larynx preservation. *First Author: Guillaume Janoray, Centre Hospitalier et Régional Universitaire, Henry S. Kaplan Center, Clinique d'Oncologie et de Radiothérapie, Tours, France*

Background: To compare the long-term efficacy and safety of induction chemotherapy with cisplatin (P) and 5-fluorouracil (F) with or without docetaxel (T) for larynx preservation. **Methods:** Operable patients with untreated stage-III or -IV larynx or hypopharynx invasive squamous-cell carcinoma and who required a total laryngectomy were randomly assigned to receive three cycles of induction chemotherapy with either TPF or PF, followed by radiation therapy for responders. The primary endpoint was 3-year larynx-preservation rate. Secondary endpoints included larynx dysfunction-free survival (LDFFS), overall survival, disease-free survival, locoregional control rate, cause of death, and later toxicity rates. **Results:** Two hundred and thirteen patients were treated with a median follow-up for surviving patients of 105 months. The 5- and 10-year larynx preservation rates were, 74.0% (95%CI, 0.64–0.82) vs. 58.1% (95%CI, 0.47–0.68) and 70.3% (95%CI, 0.58–0.8) vs. 46.5% (95%CI, 0.31–0.63, $p = 0.01$) in TPF versus PF arm, respectively. The 5- and 10-year LDFFS rates were 67.2% (95%CI, 0.57–0.76) vs. 46.5% (95%CI, 0.36–0.57) and 63.7% (95%CI, 0.52–0.74) vs. 37.2% (95%CI, 0.24–0.52, $p = 0.001$), respectively. Overall survival, disease-free survival, and locoregional control rates were not statistically improved in the TPF vs. the PF arm. Significantly fewer grade 3–4 late toxicities of the larynx occurred with the TPF regimen compared to the PF arm (9.3% vs. 17.1%, g-test, $p = 0.038$). **Conclusions:** Long-term follow-up confirms that induction chemotherapy with TPF increased larynx-preservation and larynx dysfunction-free survival. In this larynx preservation approach using induction chemotherapy, TPF should be recommended, followed by radiation therapy. Clinical trial information: NCT00169182.

6003 Oral Abstract Session, Mon, 1:15 PM-4:15 PM

The effect of age on outcome in prospective, phase III NRG Oncology/RTOG trials of radiotherapy (XRT) +/- chemotherapy in locally advanced (LA) head and neck cancer (HNC). *First Author: Julie Ann Kish, Moffitt Cancer Center, Tampa, FL*

Background: The effect of advanced age on outcome for single agent XRT and combined modality therapy in LA-HNC is not well defined. **Methods:** The effect of age (< 70 vs ≥ 70 years) on survival and toxicity was examined in LA-HNC patients (pts) on RTOG 9003 testing 3 altered fractionation (fx) XRT schedules versus standard daily XRT (SFX); RTOG 0129 comparing concurrent SFX + cisplatin (DDP) to accelerated fx with concomitant boost XRT (AFX-C) + DDP; and RTOG 0522, testing AFX-C + concurrent DDP +/- cetuximab. **Results:** Secondary analysis included 2,688 pts. Median followup for surviving pts was 5.2 years (range 0.01 to 20.3) overall, 14.1 yrs in RTOG 9003, 7.9 years in RTOG 0129, and 4.6 years in RTOG 0522. Pts age ≥ 70 were more likely to be female with poorer PS, heavier smoking history and p16 (-) status ($p < 0.001$ each). Adjusting for covariates, patients age ≥ 70 had worse survival regardless of smoking or p16 status. Adverse effect of patients age ≥ 70 may have been worse in p16 (+) pts (HR 2.07 vs. 1.30; interaction p = 0.09), (n = 34). Maximum grade stomatitis and other toxicities were similar by age cohort and tx arms on RTOG 9003. In the DDP-based studies, the elderly experienced more grade 3-5 thrombocytopenia (p = 0.02), anemia (p = 0.03), nephrotoxcity (p = 0.01) and possibly ototoxicity (p = 0.06) but less mucositis (p = 0.04). **Conclusions:** Pts age ≥ 70 were under-represented in RTOG trials evaluating tx for LA-HNC relative to their population overall. Their survival was inferior compared to pts age < 70; this was more apparent in combined modality, DDP-based trials, which featured heightened nephrotoxicity, myelosuppression, and ototoxicity. Delineation of causes of death and tx compliance will provide insight into future trial design. NCI grants U10CA21661, U10CA180868, U10CA180822, U10CA37422 and UG1CA189867. Funded in part under grant with PA Dept of Health which disclaims responsibility for any analyses, interpretations or conclusions and BMS.

Trial	Total accrual	N(%) ≥ 70 yrs	Hazard Ratio(HR) for death(95% CI)	P Value
9003	1076	207(19.2)	1.34(1.15-1.57)	< 0.001
0129	721	48(6.7)	2.34(1.68-3.26)	< 0.001
0522	891	54(6.1)	2.45(1.69-3.53)	< 0.001
Combined	2688	309(11.5)	1.55(1.35-1.77)	< 0.001

6004 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

A prospective phase II trail of de-intensified chemoradiotherapy for low-risk HPV-associated oropharyngeal squamous cell carcinoma. *First Author: Bhishamjit S. Chera, UNC Chapel Hill, Chapel Hill, NC*

Background: This is a prospective multi-institutional phase II study of a substantial decrease in chemoradiotherapy (CRT) intensity as concurrent primary treatment for favorable risk oropharyngeal squamous cell carcinoma. **Methods:** The major inclusion criteria were: 1) T0-T3, N0-N2c, M0, 2) HPV or p16 positive, and 3) ≤ 10 pack-years smoking history. Treatment was limited to 60 Gy Intensity Modulated Radiotherapy with concurrent weekly intravenous cisplatin (30 mg/m^2). The primary study endpoint was pathologic complete response rate (pCR) based on required biopsy of the primary site and dissection of pretreatment positive lymph node regions, regardless of radiographic response. Power computations were performed for the null hypothesis that the pCR rate is 87% and N = 40 (type I error = 14.2%). Secondary endpoint measures included physician reported toxicity (CTCAE), patient reported symptoms (PRO-CTCAE), quality of life (EORTC QLQ-C30 & H&N35), and penetration aspiration scale (PAS) scores for modified barium swallow studies. **Results:** The study population is 43 patients. The pCR rate was 86% (37/43). Median time to biopsy/neck dissection was 9 weeks (7 - 14 weeks). All 6 non-pCR cases were limited to microscopic foci of residual cancer: 1 primary site, 5 nodal. All patients are alive with no evidence of disease (median follow-up 15 months, 4 - 31 months). Incidence of CTCAE acute Grade 3/4 toxicity and PRO-CTCAE severe/very severe symptoms were: mucositis 34%/45%, pain 5%/48%, nausea 18%/52%, vomiting 5%/34%, dysphagia 39%/55%, and xerostomia 2%/75%. Grade 3/4 hematological toxicities were 11%. 39% required a feeding tube, for a median of 15 weeks (5 - 22 weeks). Mean pre- and post-CRT EORTC QOL scores were: Global 80/69 (lower worse, $p < 0.01$), Pain 15/20 (higher worse, p = NS), Swallowing 11/18 (p = 0.04), Coughing 17/22 (p = NS), Dry Mouth 16/64 ($p < 0.001$), and Sticky Saliva 6/49 ($p < 0.001$). There were no significant differences in PAS scores before and after CRT. **Conclusions:** Cancer control following 60 Gy of IMRT with weekly cisplatin 30 mg/m^{2}is likely to be very high in favorable risk oropharyngeal squamous cell carcinoma. (ClinicalTrials.gov, NCT01530997). Clinical trial information: NCT01530997.

6005 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Prognostic implication of persistent HPV16 DNA detection in oral rinses for HPV-positive oropharyngeal carcinoma. *First Author: Eleni Marie Rettig, Johns Hopkins School of Medicine, Department of Otolaryngology-Head and Neck Surgery, Baltimore, MD*

Background: Human papillomavirus-positive oropharyngeal carcinoma (HPV-OPC) has a favorable prognosis; however, 10-25% of HPV-OPC cases recur. Oral HPV DNA detection is associated with HPV-OPC, but its value as a prognostic biomarker is unclear. **Methods:** Patients with incident HPV-OPC treated with curative intent were enrolled from October 2009-May 2013 at four centers. Oral rinses were collected at baseline (diagnosis) and post-therapy at 9, 12, 18 and 24 months after diagnosis. Oral rinses were evaluated for 36 types of HPV DNA. Survival analyses were performed using Kaplan Meier method and Cox regression models. Disease free survival (DFS) and overall survival (OS) were estimated. **Results:** 151 patients were included and 124 (79%) had one or more post-treatment oral rinse (median three). Oral HPV16 DNA was common at baseline (N = 85, 56%). In contrast, oral HPV16 DNA was detected in only six patients in follow up (5%), including five who had HPV16 DNA at baseline (persistent oral HPV16 DNA) and one who did not. Two-year DFS and OS were 92.2% and 97.5%, respectively for all 151 cases. Persistent oral HPV16 DNA was associated with significantly worse DFS (adjusted HR 34.0, 95%CI 7.9-146) and OS (adjusted HR 16.9, 95%CI = 3.1-93). Among patients who recurred (n = 15, 10%), median time to recurrence was 15 months from diagnosis. All five patients with persistent oral HPV16 DNA recurred. Three of these cases included local recurrence. Median time from earliest post-treatment oral HPV16 DNA detection to recurrence was seven months (range 3-11). Among 108 patients with a post-treatment oral rinse collected 9-12 months after diagnosis, detection of persistent oral HPV16 DNA had 100% positive predictive value (3/3), 96% negative predictive value (4/108), 43% sensitivity (3/7) and 100% specificity (104/104) for predicting recurrence between 12-24 months. **Conclusions:** Oral HPV16 DNA detection in oral rinses is common at baseline but rare after treatment for HPV-OPC. Our data suggest that persistent oral HPV16 DNA in post-treatment rinses is strongly associated with poor prognosis, may have high positive and negative predictive value for recurrence, and is a potential tool for long-term tumor surveillance.

6006 **Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

Mutational patterns of HPV+ and HPV- squamous cell carcinomas of the head and neck (SCCHN) and their interference with outcome after adjuvant chemoradiation: A multicenter biomarker study of the German Cancer Consortium Radiation Oncology Group. *First Author: Inge Tinhofer, Dpts. for Radiation Oncology, Comprehensive Cancer Center, Charite University Medicine Berlin, Berlin, Germany*

Background: The genetic landscape of SCCHN is currently being unravelled, but the role of distinct mutations for treatment outcome remains largely unknown. We compared mutational patterns of HPV+ and HPV- tumors with outcome after uniform chemoradiation. **Methods:** Archival tumor specimens from 208 patients with carcinomas of the hypopharynx, oropharynx or oral cavity, all uniformly treated with surgery and adjuvant cisplatin-based radiochemotherapy, were included in this study. An in-house gene panel for semiconductor-based next-generation ultra-deep sequencing, covering 211 exons from 45 genes frequently altered in SCCHN was used for mutational analysis. Genetic alterations were correlated with HPV status and patient outcome. **Results:** Mutational profiles were successfully established for 185 SCCHN cases. Interestingly, HPV+ carcinomas were significantly enriched for activating mutations in driver genes (*PIK3CA* 27%, *KRAS* 8%, *NRAS* 4%, *HRAS* 2%) compared to HPV- cases ($P = 0.002$). Conversely, HPV- tumors showed an increased frequency of loss-of-function alterations in tumor suppressor genes (*TP53* 67%, *CDKN2A* 30%, *PTEN* 4%, *SMAD4* 3%) compared to HPV+ cases ($P < 0.001$). After a median follow-up of 55 months, alterations in tumor suppressor genes significantly increased the risk of death (HR 2.9, 95% CI 1.5-5.8, $P = 0.001$), locoregional recurrence (HR 5.4, 95% CI 1.6-18.1, $P = 0.006$) and distant metastasis (HR 2.3, 95% CI 1.0-5.1, $P = 0.04$). The occurrence of activating driver gene mutations did not influence outcome in the total cohort of patients; however, they were associated per trend with increased risk of locoregional recurrence and death (HR 3.7, 95% CI 0.7-20.6, $P = 0.12$) in HPV+ oropharyngeal carcinomas. **Conclusions:** Overall, loss-of-function tumor suppressor gene mutations negatively interfere with efficacy of adjuvant cisplatin-based chemoradiation, whereas activating driver gene mutations define poor risk specifically in HPV-driven SCCHN. These genes and their signalling pathways might represent therapeutic targets for improving cure rates of SCCHN.

Serial early post-IMRT undetectable plasma EBV DNA to predict outcomes in non-metastatic nasopharyngeal cancer. *First Author: Victor HF Lee, Department of Clinical Oncology, Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong*

Background: The relationship between early undetectable plasma EBV DNA after intensity-modulated radiation therapy (IMRT) for NPC and long-term survival remains unclear. Early post-IMRT undetectable plasma EBV DNA is a proposed efficacy endpoint which warrants investigation as a predictor of long-term survival. We prospectively explored the predictive power of post-IMRT 8th week and 6th month undetectable plasma EBV DNA for 3-year survival outcomes in patients with non-metastatic NPC. **Methods:** Two hundred and sixty patients with non-metastatic NPC were treated with IMRT +/- concurrent /induction/adjuvant platinum-based chemotherapy. Plasma EBV DNA was taken at diagnosis and then 8 weeks and 6 months after IMRT. Time-dependent Receiver-Operating Characteristics (TD-ROC) were used to obtain C_τ indices. Cox regression models identified interaction between undetectable post-IMRT 8th week and 6th month plasma EBV DNA and outcomes including progression-free survival (PFS), cancer-specific survival (CSS) and overall survival (OS). **Results:** A strong relationship was shown between post-IMRT 8th week and 6th month undetectable plasma EBV DNA with PFS, CSS and OS (TD-ROC revealing higher C_τ indices for stage IVA–B compared to stage I–III). Cox regression showed that post-IMRT 8th week and 6th month undetectable plasma EBV DNA were prognostic of PFS ($p < 0.001$ and $p < 0.001$, respectively), CSS (p = 0.006 and p = 0.004, respectively) and OS (p = 0.039 and p = 0.012, respectively). Baseline plasma EBV DNA was not prognostic of any survival outcome. **Conclusions:** Our study showed a strong relationship between post-IMRT 8th week and 6th month undetectable plasma EBV DNA and 3-year survival outcomes. This suggested the use of early plasma EBV DNA as a predictor of survival in this setting.

	Post-IMRT 8th week plasma EBV DNA		Post-IMRT 6th month plasma EBV DNA

Antitumor activity and safety of pembrolizumab in patients (pts) with advanced squamous cell carcinoma of the head and neck (SCCHN): Preliminary results from KEYNOTE-012 expansion cohort. *First Author: Tanguy Y. Seiwert, The University of Chicago, Chicago, IL*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 PM (EDT) on Friday, May 29, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

6009 **Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

PET-NECK: A multi-centre, randomized, phase III, controlled trial (RCT) comparing PETCT guided active surveillance with planned neck dissection (ND) for locally advanced (N2/N3) nodal metastases (LANM) in patients with head and neck squamous cell cancer (HNSCC) treated with primary radical chemoradiotherapy (CRT). *First Author: Hisham Mohamed Mehanna, InHANSE, School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom*

Background: Planned ND after radical CRT for LANM remains controversial. 30% of ND specimens show histological evidence of tumour, albeit tumour viability cannot be confirmed. Consequently, many clinicians still practice planned ND. In mainly retrospective single-institution studies, FDG-PETCT demonstrated high negative predictive values for persistent nodal disease, providing a possible alternative paradigm to ND. This study aimed to determine the efficacy and cost-effectiveness of PETCT guided surveillance, compared to planned ND, in a multicentre randomised setting. **Methods:** *Eligibility:* Patients with LANM of oro-, hypo-pharynx, larynx, oral or occult HNSCC receiving CRT and fit for ND. *Randomisation (1:1)*: to planned ND before or after CRT (control), or CRT followed by FDG-PETCT 10-12 weeks post CRT with ND only if PETCT showed incomplete or equivocal response of nodal disease (intervention). Balanced by centre, planned ND timing, CRT schedule, disease site, T / N stage. *Primary outcome:* Overall Survival (OS), minimum follow-up 2 years. *Analysis:*560 patients needed to detect non-inferior OS in the intervention arm with 80% power, Type I error 5%, defining non-inferiority as having a hazard ratio (HR) no higher than 1.50. Intention to treat analysis was performed by Cox proportional hazards model. **Results**: 564 patients recruited (282 ND arm, 282 surveillance arm; 17% N2a, 61% N2b, 18% N2c, 3% N3). 84% had oropharyngeal cancer. 75% of tested cases were p16+ve. Median follow-up 36 months. The HR for OS was 0.92 (95% CI: 0.65, 1.32) indicating non-inferiority. HR margin of 1.50 lies at the 99.6 percentile of this estimate, $p = 0.004$. There were no differences by p16 status. There were 54 NDs performed in the surveillance arm with 22 surgical complications; 221 NDs in the ND arm with 85 complications. **Conclusions:** PETCT guided active surveillance showed similar survival outcomes to ND arm, but resulted in considerably fewer NDs, and fewer complications, supporting its use in routine practice. Clinical trial information: 13735240.

6010 **Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

Is PET-CT guided management for patients with locally advanced head and neck squamous cell cancer (HNSCC) cost-effective? Results from a UK non-inferiority phase III randomized trial. *First Author: Alison Florence Smith, University of Leeds, Leeds, United Kingdom*

Title: Despite ongoing controversy, planned node dissection (ND) remains a common treatment strategy after radical chemoradiotherapy (CRT) for locally advanced nodal metastases in patients with HNSCC. Accurate detection of persistent disease using combined Positron Emission and Computerised Tomography (PET-CT) could reduce unnecessary and expensive node dissections (ND) in low-risk patients and potentially improve overall outcomes. **Methods:** 564 patients with N2/N3 oropharyngeal, laryngeal, oral, hypopharyngeal or occult HNSCC were randomized (1:1) to receive either planned ND (before or after CRT), or PET-CT surveillance (CRT followed by PET-CT, with ND administered if incomplete response in the neck nodes). To accurately inform reimbursement decisions, individual patient data from the trial was used to assess within-trial (2-year) cost-effectiveness of PET-CT surveillance versus planned ND from an NHS secondary care perspective. Health benefit was measured using quality-adjusted life-years (QALYs) and costs are reported in 2015 GBP. Probabilistic analysis was conducted using bootstrap methods. **Results:** PET-CT surveillance was cost-effective over the trial period, producing an average per-person cost saving of £1,415 (95% CI: -607 to -2,218) and a health gain of 0.07 QALYs (95% CI: -0.04 to 0.19) compared to planned ND. The average cost was £12,127 (95% CI: 11,601 to 12,686) for PET-CT surveillance vs. £13,542 (95% CI: 12,968 to 14,131) for planned ND; the average QALYs were 1.26 (95% CI: 1.18 to 1.34) vs. 1.19 (95% CI: 1.10 to 1.27). At a £20,000 per QALY threshold, the probability that PET-CT was the cheapest, most effective and most cost-effective strategy was 99%, 91%, and 98%, respectively. Expanding the analysis to include additional NHS, personal social services and societal costs increased the expected costs for each arm but did not alter the overall cost-effectiveness of PET-CT surveillance. **Conclusions:** Results of the economic evaluation indicate that PET-CT surveillance is cost-effective over a short time horizon. Clinical trial information: NCT00720070.

6011 **Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

Establishing quality indicators for neck dissection: Correlating the number of lymph nodes with oncologic outcomes, NRG Oncology/RTOG 9501-0234. *First Author: Vasu Divi, Stanford University, Palo Alto, CA*

Background: Quality of head and neck surgery has thus far focused on adherence to clinical national guidelines and margin status. For other solid tumors, an association has been found between lymph node counts from regional nodal dissection and overall survival; as such, lymph node counts have been proposed as measure of quality. Yet, for neck dissection, no prospective metrics for surgical quality have been established for mucosal squamous cell carcinoma. The purpose of this study is to investigate the association between lymph node counts from primary neck dissection, local-regional recurrence, and overall survival (OS). **Methods:** Secondary analysis of patients in RTOG trials 9501 and 0234 was performed. The number of lymph nodes counted from regional nodal dissection was evaluated for its prognostic impact on overall survival using a multivariate Cox model adjusted for demographic, tumor, and lymph node data, and stratified by postoperative treatment group: (1) radiation or (2) chemoradiation on RTOG 9501 or (3) chemoradiation and cetuximab on RTOG 0234. Models were compared by Akaike Information Criterion (AIC). **Results:** Five hundred and seventy-two patients were analyzed. Median follow-up for surviving patients was eight years. Median number of lymph nodes recorded on the left and right sides were 24 and 25. Fewer than 18 nodes was associated with significantly worse OS relative to $\geq$ 18 nodes (hazard ratio 1.38, 95%CI 1.09-1.74, $p = 0.007$). The model with this cut point had minimum AIC of all possible models. The difference appears to be driven by local-regional failure (HR 1.46, 95%CI 1.02-2.08, $p = 0.04$) but not distant metastasis (HR 1.08, 95%CI 0.77-1.53, $p = 0.65$). Limited to RTOG 0234, adding p16 status to the model does not affect the hazard ratio for sampled nodes and the effect of nodes is not different by p16 status (p-value for interaction 0.99). **Conclusions:** Identifying 18 or more lymph nodes was associated with improved overall survival and lower rates of local-regional failure. The benefit is seen in both p16-positive and p16-negative patients. The removal and identification of at least 18 lymph nodes should be considered as a measure of quality in neck dissections for mucosal squamous cell carcinoma.

Final overall survival analysis of EXAM, an international, double-blind, randomized, placebo-controlled phase III trial of cabozantinib (Cabo) in medullary thyroid carcinoma (MTC) patients with documented RECIST progression at baseline. *First Author: Martin Schlumberger, Institut Gustave Roussy, Villejuif, France*

Background: Cabo inhibits tyrosine kinases including MET, VEGFR2, and RET. EXAM, a randomized double-blind placebo (P)-controlled study in patients (pts) with progressive, locally advanced, or metastatic MTC (NCT00704730), met its primary end point with a statistically significant improvement in progression-free survival (PFS) (hazard ratio [HR] = 0.28, $p < 0.001$) (Elisei et al, JCO, 2013). This report contains the final analysis of the secondary endpoint, Overall Survival (OS). **Methods:** Eligible pts were required to have documented RECIST progression within 14 months (mo) of screening, and were randomized 2:1 to receive Cabo (140 mg qd) or P. Crossover between treatment arms was not allowed. The primary endpoint was PFS assessed by RECIST via independent review. The study was designed with 80% power to detect a HR of 0.667 for the secondary endpoint of OS. **Results:** At the final analysis, median follow up time was 52.4 mo. 218 events were recorded in the intent-to-treat (ITT) population (N = 330). The estimated median OS was 26.6 mo for Cabo vs 21.1 mo for P (stratified HR = 0.85; 95% CI 0.64-1.12; p = 0.241). For 126 pts with known RET M918T mutations, median OS was 44.3 mo for Cabo vs 18.9 mo for P (HR = 0.60, p = 0.026). 32% of Cabo-treated pts received subsequent systemic anticancer therapy vs 50% for P-treated pts. The median duration of treatment was 10.8 mo for Cabo and 3.5 mo for P. 46% and 26% of Cabo-treated pts remained on study treatment for over 1 year and 2 years, and 10% and 1.8% for P, respectively. The most common serious adverse events ($\geq$ 2%) on the Cabo arm were pneumonia (4.2%), pulmonary embolism (3.3%), mucosal inflammation (2.8%), hypocalcemia (2.8%), hypertension, dysphagia, dehydration and lung abscess (2.3% each). **Conclusions:** The secondary endpoint of improved OS was not met, with a median OS 5.5 mo longer with Cabo compared to P that did not reach significance in the ITT population. OS improvement with Cabo was greatest in patients with RET M918T mutations, with a 25.4-month increase in median OS compared to P. The safety profile of Cabo remained consistent with longer term exposure. Clinical trial information: NCT00704730.

Efficacy and safety of lenvatinib for the treatment of patients with ^{131}I-refractory differentiated thyroid cancer with and without prior VEGF-targeted therapy. *First Author: Kate Newbold, Royal Marsden Hospital National Health Service Trust, London, United Kingdom*

Background: Lenvatinib (LEN), an oral multikinase inhibitor of VEGFR1–3, FGFR1–4, PDGFRα, RET, and KIT, significantly prolonged progression-free survival (PFS) vs placebo in the phase 3 SELECT trial of patients (pts) with ^{131}I-refractory differentiated thyroid cancer (RR-DTC). Here we report the prespecified analysis of LEN-treated pts based on prior VEGF-targeted therapy exposure. **Methods**: Pts with measurable RR-DTC and independent radiologic documentation of disease progression within 13 months were randomized 2:1 to LEN (24 mg/d; 28-d cycle) or placebo. Pts were stratified by age, region, and prior VEGF-targeted therapy (0 [VEGF-naive] or 1 [prior-VEGF]). **Results**: 195/261 (75%) LEN-treated and 104/131 (79%) placebo-treated pts were naive to VEGF-targeted therapy. 93 Pts had received prior-VEGF therapy: sorafenib, 77%; sunitinib, 9%; pazopanib, 5%; other, 9%. LEN prolonged PFS vs placebo in both groups (Table; VEGF-naive: HR 0.20; 95% CI 0.14–0.27; P<0.0001; prior-VEGF: HR 0.22; 95% CI 0.12–0.41; P<0.0001). Objective response rates (ORR) were similar between both groups (Table). VEGF-naive pts received more cycles of LEN than prior-VEGF pts (medians of 16 and 12.5 cycles, respectively), but had lower overall daily dose intensity (16.1 and 20.1 mg/d, respectively). The proportion of LEN-treated pts with at least 1 dose reduction was similar (VEGF naive: 87%; prior-VEGF: 82%), but VEGF-naive pts had an earlier median time to first dose reduction than pts with prior-VEGF (8.9 and 14.8 weeks, respectively). Most common LEN-emergent adverse events for VEGF-naive and prior-VEGF pts were, respectively: hypertension (72% and 62%), diarrhea (70% and 61%), decreased appetite (54% and 55%), decreased weight (52% and 49%), and nausea (45% and 52%). **Conclusions**: In SELECT, LEN conferred comparable efficacy in pts with and without prior exposure to VEGF-targeted therapy, with similar safety profiles. Clinical trial information: NCT01321554.

	Lenvatinib		Placebo	
	VEGF-naive n=195	Prior-VEGF n=66	VEGF-naive n=104	Prior-VEGF n=27
Median PFS, months (95% CI)	18.7 (16.4–NE)	15.1 (8.8–NE)	3.6 (2.1–5.3)	3.6 (1.9–3.7)
ORR, n (%)	128 (65.6)	41 (62.1)	1 (1.0)	1 (3.7)

Pharmacodynamic biomarkers of outcomes in the phase III study of lenvatinib in ^{131}I-refractory differentiated thyroid cancer (SELECT). *First Author: Makoto Tahara, Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Lenvatinib (LEN)–an oral multikinase inhibitor of VEGFR1–3, FGFR1–4, PDGFRα, RET, and KIT—significantly prolonged progression-free survival (PFS) vs placebo (PBO) in the SELECT study. Baseline (BL) Ang2 levels were previously identified as prognostic and predictive of LEN response, and increase in FGF23 levels is a surrogate pharmacodynamic biomarker of FGFR1 inhibition. Here we investigated serum circulating cytokine/angiogenic factors (CAFs) as potential pharmacodynamic biomarkers of LEN efficacy and disease progression in SELECT. **Methods:** Blood samples from 387/392 (99%) randomized patients (pts) were collected at baseline, cycle 1 day 15 (C1D15), day 1 of subsequent cycles, and treatment end. TG and CAF levels (Ang2, VEGF, sTie2, and FGF23) were measured by ELISA. **Results:** From cycle 1,VEGF levels were consistently elevated for pts on LEN, whereas Ang2 and sTie2 levels were consistently decreased compared with PBO. FGF23 levels increased by 20.8% (C1D15) and 28.6% (C2D1). Although TG decreases in LEN pts were correlated with tumor shrinkage (TS; $P < 0.0001$) and objective response rate (ORR; $P < 0.05$, through C9D1), TG decreases also occurred in pts with stable or progressive disease. Increased VEGF ($P < 0.0001$) and decreased Ang2 ($P < 0.0001$) and sTie2 ($P < 0.0001$) levels also correlated with TS, but not with ORR. Amongst LEN-treated pts with disease progression, decreased levels of TG (31/34 pts, $P < 0.0001$), Ang2 (32/38 pts, $P < 0.0001$), and sTie2 (39/42 pts, $P < 0.0001$) at C2D1 compared to BL were observed. However, at treatment end, increased levels of TG, Ang2, and sTie2 from C2D1 were observed in 79.4%, 78.9%, and 81.0% of these pts, respectively. In some cases, these increases occurred prior to disease progression. **Conclusions:** TG changes were correlated with TS and ORR in the LEN arm of SELECT; CAF analyses may provide additional information.Increased levels of VEGF and FGF23 may indicate that LEN is targeting these signaling networks in pts with RR-DTC in SELECT. Preliminary analyses of pts who progressed on LEN indicated elevated levels of Ang2 and sTie2. Further analyses of the Ang2/Tie2 axis using serum biomarkers are warranted. Clinical trial information: NCT01321554.

Analysis of tumor growth rate for radioiodine (RAI)-refractory differentiated thyroid cancer patients receiving placebo and/or sorafenib in the phase III DECISION study. *First Author: Christian Kappeler, Bayer Pharma AG, Berlin, Germany*

Background: In the phase III DECISION trial, patients were randomized to receive double-blind (DB) sorafenib (SOR) or placebo (PLC) until tumor progression, at which time PLC patients were allowed to switch to open-label (OL) SOR and SOR patients to continue OL. We conducted an exploratory analysis of target lesion size over time to gain insight into tumor growth rate during treatment. **Methods:** Target lesions were assessed by central radiologic review every 8 weeks based on RECIST criteria. Changes in target lesions over time were approximated by a parabola-like 3-parametric model and tumor growth rates (TGR) derived for DB and OL treatment periods. TGR was defined as % change per month of sum of target lesion diameters. **Results:** Patients receiving SOR DB and then OL totaled 207 and 55, and patients receiving PLC DB and then SOR OL totaled 210 and 150, respectively; patients evaluable for TGR were 176, 38, 189 and 123, respectively. For SOR patients, TGR was typically negative early reflecting target lesion shrinkage from baseline [-3.9 (-4.7, -3.1), mean % change/mo (95% CI)] and then positive from nadir to progression [2.6 (1.9, 3.3)] reflecting tumor growth, as was TGR for the subgroup of SOR patients continuing OL treatment from 2nd baseline [1.7 (-0.9, 4.3)]. For PLC patients, TGR was typically positive [5.0 (2.2, 7.8)], as was TGR for the subgroup prior to switching to SOR at progression [6.1 (1.9, 10.3)]. The TGR pattern of PLC patients on OL SOR was similar to the DB SOR pattern, i.e. negative post second baseline [-4.4 (-5.6, -3.2)] and positive from nadir to progression [1.8 (0.5, 3.1)]. **Conclusions:** SOR reversed tumor growth (negative TGR) during the DB period and for PLC patients switching to SOR. TGR from nadir to progression for patients receiving SOR or post-progression for patients continuing on SOR was less than for patients on PLC, suggesting that despite evidence of tumor growth or prior RECIST progression, SOR continued to slow tumor growth relative to growth in its absence. The clinical relevance of these findings for treatment decisions needs to be further investigated. TGR may be an additional efficacy parameter to consider when monitoring SOR treatment. Clinical trial information: NCT 00895674.

Enriched expression of PD-L1 and other immune targets after epithelial-mesenchymal transition (EMT) in squamous head and neck and lung cancers. *First Author: Milena Perez Mak, Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil*

Background: Epithelial-to-mesenchymal transition (EMT) is associated with poor prognosis and resistance to EGFR inhibitors. To determine molecular alterations and novel targets associated with EMT in head and neck squamous cell cancers (HNSCC), we conducted a comprehensive analysis of molecular alterations associated with EMT, using our previously established EMT gene signature. **Methods:** 504 HNSCCs from two independent patient cohorts and 178 lung squamous (LUSC) tumors were scored using the EMT gene signature. EMT score was correlated with mRNA, miRNA, and protein (reverse phase protein array, RPPA) levels (Spearman correlation) and with mutations and HPV status (t-test). Ingenuity Pathway Analysis (PA) software was used for PA. **Results:** Mesenchymal (M) HNSCCs had higher expression of known EMT markers, such as vimentin and fibronectin, lower levels of E-cadherin and miR-200 family members ($p < 0.001$ for all), and a higher frequency of TP53 mutations ($p = 0.016$). In contrast, epithelial (E) tumors were more commonly HPV positive ($p = 0.019$) and were associated with better survival ($p = 0.054$). At the protein level, the receptor tyrosine kinase (RTK) Axl was overexpressed in M tumors ($p < 0.001$), whereas other RTKs, such as pHer2 ($p = 0.005$) and pEGFR ($p = 0.02$) were higher in E tumors. PA revealed a striking enrichment in genes involved with immune trafficking and inflammatory response in M tumors from HNSCC and LUSC. In a supervised analysis, of 20 targetable immune checkpoints, 18 were overexpressed in M tumors, including PD-L1, ADORA2, CCL2, CD276 ($r > 0.44$, $p < 0.001$ for all). PD-L1 overexpression was confirmed by RPPA ($p < 0.001$). Consistent with these results, EMT was positively correlated with scores from ESTIMATE, which assesses stromal and immune infiltrates in tumor samples ($r = 0.63$, $p < 0.001$). **Conclusions:** Among several molecular alterations associated with EMT, we found a strong enrichment in targetable immune checkpoints (mRNA and protein) and immune cell infiltrates in HNSCC and LUSC cohorts. Given our recent findings that EMT promotes immune escape in lung cancer, our data suggests that EMT status could improve patient selection for immune targeting.

Inflamed-phenotype gene expression signatures to predict benefit from the anti-PD-1 antibody pembrolizumab in PD-L1+ head and neck cancer patients. *First Author: Tanguy Y. Seiwert, The University of Chicago, Chicago, IL*

Background: Immunotherapy with anti-PD-1 checkpoint blockade shows encouraging activity in head and neck squamous cell carcinoma (HNSCC). We tested 4 multi-gene expression signatures previously derived in melanoma patients (pts) in PD-L1$^+$HNSCC pts from the KEYNOTE-012 (NCT01848834) study as candidate predictive biomarkers. **Methods:** 43 of 61 pembrolizumab-treated patients had RNA expression profiling and survival data; 40 were evaluable for objective response. FFPE-extracted RNA was analyzed on the NanoString nCounter system. Four previously established gene signatures (1) "interferon-γ," (2) "TCR signaling," (3) "expanded-immune," and (4) "de novo" were examined as possible predictors for formal hypothesis testing prior to unblinding clinical outcome data. **Results:** Overall response (OR) rate was 9/40 = 23%. Three signatures showed significant ($P < 0.05$) association with OR; all 4 signatures showed strong associations ($P < 0.005$) with PFS. Signature scores and PFS readily segregated into 2 groups (>5 versus <5 months PFS). Using an optimal cutoff for the top-performing interferon-γ signature, positive predictive value (PPV) for response was 40.0%, and negative predictive value (NPV) was 95.0%; AUC = 0.80 [95% CI, 0.61-0.95]. When evaluating the individual signature genes, T-cell–mediated interferon-γ inducible MHC-II expression appeared to be the immune biological connection. Interferon-γ signature correlated strongly with the previously independently discovered inflamed/mesenchymal HNSCC intrinsic subtype (Keck/Seiwert CCR 2015) (R = 0.9). **Conclusions:** "Inflamed phenotype" signatures are strong predictors of clinical benefit from anti-PD-1 treatment for HNSCC even among a group of patients already considered to be PD-L1$^+$. Clinical trial information: NCT01848834.

	Nominal 1-sided *P* value[a]	
Signature	OR N = 40	PFS N = 43
IFN-γ (6-gene)	0.005	< 0.001
TCR signaling (13-gene)	0.071	0.002
Expanded-immune (18-gene)	0.015	< 0.001
De novo (33-gene)	0.018	< 0.001

[a]From logistic or Cox regression for overall response and progression-free survival, respectively.

PDL1-expressing circulating tumor cells (CTCs) in head and neck squamous cell carcinoma (HNSCC). *First Author: George Koutsodontis, Attikon Hospital, National Kapodistrian, University of Athens, Athens, Greece*

Background: Blockade of PD-1/PD-L1 immune checkpoint pathway emerged as promising novel therapeutic strategy for cancer. Predictive biomarkers for response to anti-PD1 therapy are lacking. Because therapy with checkpoint inhibitors is cost intensive, noninvasive tools for early prediction of responders are of major interest. We assessed gene expression of *PDL1* in CTCs at baseline and posttreatment in HNSCC patients (pts). **Methods:** 70 pts with locally advanced (n = 58) or recurrent/metastatic (n = 12) HNSCC were included in this analysis. Patients with locally advanced disease were treated with cisplatin chemoradiotherapy +/- TPF induction chemotherapy (IC). We assessed *PDL1* expression at baseline, after completion of induction chemotherapy, at end of chemoradiotherapy and at relapse. We quantified PDL1 gene transcripts in immunomagnetically positively selected CTCs and 20 healthy individuals. A quantitative real time RT-qPCR assay for *PDL1* was developed based on de novo in-silico design of primers and Taqman probes. The specificity was first tested by homology searches in the nucleotide database (NCBI, nucleotide BLAST). To assess univariate differences of study parameters according to *PDL1* expression chi-square test was used for the categorical clinicopathological variables, while patients' survival curves according to *PDL1*expression were generated by Kaplan-Meier analysis and tested for significance using the Mantel-Cox log-rank test. **Results:** From 88 total evaluable CTC samples, 26 of 46 were PDL1+ at baseline, 6 of 17 post-IC, 11 of 23 at end of treatment and 1 of 2 at relapse. The assay sensitivity was evaluated using external quantification calibrators ranging from 105 copies/μL to 10 copies/μL. There was trend ($p = 0.07$) for adverse association between PDL1 expression at baseline and progression-free survival. **Conclusions:** We report for the first time a highly sensitive, specific and reproducible quantitative real-time RT-qPCR assay for the assessment of *PDL1* expression in CTCs. The assay is currently validated in CTCs isolated from a large number of HNSCC pts. Serial *PDL1* expression assessment has potential to select and monitor pts for PD-1 targeted therapies.

Utilization and outcomes of low dose versus high dose cisplatin in head and neck cancer patients receiving concurrent radiation. *First Author: Stuart J. Wong, Medcl Coll of Wisconsin, Milwaukee, WI*

Background: Although level I evidence supports the use of high dose (HD) intermittent cisplatin with concurrent RT for locally advanced head and neck squamous cell carcinoma (LA-HNSCC), low dose (LD) weekly cisplatin has been adopted, including in recently activated national clinical trials. We sought to examine patterns of care and outcomes of cisplatin in this setting using a US prospective observational registry. **Methods**: We utilized Longitudinal Oncology Registry of Head And Neck Carcinoma (LORHAN). Patients (pts) included in the analysis had newly diagnosed, stage III or IV, non-metastatic HNSCC, received RT and chemotherapy, were ≥ 18 years and had provided written informed consent. Pts were enrolled to the LORHAN Registry from 2005 to 2010, with data available through 2011. Propensity score weighting was applied to adjust for confounding in comparisons between dose groups. **Results**: 1,091 pts received cisplatin plus concurrent RT and were categorized by initial cisplatin dose received: LD (≤ 40 mg/m2) cisplatin (N = 334) or HD (≥ 75 mg/m2) cisplatin (N = 757). The total cumulative dose of cisplatin was 322.5 mg (standard deviation SD = 108.6) for the LD group and 475.8 (SD = 160.5) for the HD group. This difference was statistically significant for both the unadjusted and the propensity-score adjusted analysis between cohorts ($p < 0.001$). The cumulative dose was also significantly different, for the subset of pts with oropharyngeal cancers (n = 806): 328.6 mg (SD =114.6) for those in the LD group versus 486.6 mg (SD = 156.6) for the HD cisplatin, $p<0.001$. A significant difference in overall survival favoring the HD group (log rank test, $p<0.001$) was observed, although this analysis was limited by incomplete follow-up data (> 75% censored in both cohorts). **Conclusions**: In contrast to anticipated results, a higher cumulative dose of cisplatin was observed in LA-HNSCC pts treated with RT who initiated therapy with HD compared to LD cisplatin. No definitive conclusions can be made regarding the impact of cisplatin dose and schedule upon survival; however our hypothesis generating observations suggest further study of this question is warranted. Clinical trial information: NCT01080313.

Differential impact of cisplatin dose intensity on human papillomavirus (HPV)-related (+) and HPV-unrelated (−) locoregionally advanced head and neck squamous cell carcinoma (LAHNSCC). *First Author: Anna Spreafico, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Definitive radiotherapy with concurrent cisplatin (CDDP) is a standard treatment for patients (pts) with LAHNSCC. We evaluated the impact of CDDP dose intensity (mg/m^2) on overall survival (OS) of HPV+ and HPV- LAHNSCC pts. **Methods:** Princess Margaret Cancer Centre (PM) and Istituto Nazionale dei Tumori (INT) LAHNSCC cohorts treated from 2000 to 2012 were reviewed. Kaplan-Meier method was used to estimate the 5-year (yr) OS in HPV+ vs HPV− pts. HPV status was determined by p16 staining or in situ hybridization HPV DNA for all oropharyngeal (OPC), unknown primary (UNK), and ≤ 10 pack-year (PY) smoking laryngo-hypopharyngeal cancer (LHC). Untested p16, >10 PY LHC pts were assumed HPV−. Multivariable analysis (MVA) with Cox regression identified OS predictors for HPV+ and HPV− pts. **Results:** A total of 659 pts (584 PM; 75 INT) were evaluated. Pts characteristics included: median age 58 (range: 27-81); primary site: OPC 73%, LHC 24%, UNK 3%; non-smokers 27%; stage: T4 25%, N2c-N3 60%; HPV+ 404 (61%), HPV− 255 (39%) pts. Median CDDP dose was 200 mg/m^2 for both HPV+ and HPV− cohorts. Median follow-up was 4.3 yrs. Five year OS was inferior for HPV− CDDP ≤ 200 vs > 200 mg/m^2 (44 vs 62%, p < 0.01), while no difference was detected in HPV+ CDDP ≤ 200 vs > 200 mg/m^2 (83 vs 87%, p = 0.30), confirmed by MVA (Table). In N3 or T4 HPV+ pts, a trend on OS in CDDP >200 mg/m^2(HR = 0.62, 95% CI: 0.30-1.31) was observed. **Conclusions:** In this large multicenter cohort study, CDDP dose intensity ≤ 200 mg/m^{2}had a detrimental impact on OS in HPV− LAHNSCC pts. The impact of CDDP dose intensity on HPV+ pts was not significant. These results warrant prospective validation.

MVA for OS in HPV+ and HPV– pts.

HR (95% CI) & p value

	CDDP (mg/m^2) > 200 vs ≤ 200	Age 1 yr increment	Smoking 10 PY increment	T HPV+: T4 vs T0-3 HPV−: T3-4 vs T1-2	N HPV+: N2c-3 vs N0-2b HPV−: N2b-3 vs N0-2a	Disease Site Non-OPC vs OPC

Symptom reduction from IMRT dose deintensification: Results from ECOG 1308 using the Vanderbilt Head and Neck Symptom Survey version 2 (VHNSS V2). *First Author: Anthony Cmelak, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: The prevalence, severity, and functional implications of high-dose radiation for locally advanced head and neck cancer (HNC) are substantial. E1308 allowed dose reduction of IMRT (54Gy) in HPV+ patients if a complete clinical response were obtained to induction chemotherapy (IC). The VHNSS V2 instrument was used to quantify symptom burden following treatment. **Methods:** The VHNSS V2 is a 50-item survey, scored 0 (none) to 10 (severe) arranged into symptom clusters. The tool was utilized pre-treatment, and at 6 and 12 months to pts with resectable stage III/IVa,b HPV+ oropharyngeal HNC who received IC q3 weeks x 3 with paclitaxel 90mg/m2 days (D) 1,8, 15, cisplatin 75mg/m2 D1, and standard weekly cetuximab (C). IC response determined IMRT dose independently at primary site and involved nodes: C-IMRT 54Gy/27 if cCR and 69.3Gy/33 if < cCR. Only pts who completed ≥ 50% of the items in a given symptom cluster were considered evaluable for that cluster **Results:** 80 pts were enrolled (3 did not receive IMRT) with 44 pts classified as NED at 12 months post-treatment (35 received ≤ 54Gy and 9 received > 54Gy). Moderate to severe average symptom cluster scores (scores ≥ 2) appeared numerically reduced with lower IMRT dose: mouth pain 6% vs. 25%, general pain 27% vs. 50%, nutrition 6% vs. 40%, taste/smell changes 37% vs. 50%, voice 13% vs. 25%, teeth 17% vs. 33%. Difference in difficulty swallowing solids 35% vs. 100% reached statistical significance (p = 0.01). A composite analysis evaluating moderate to severe symptoms at 12 months for any of these 3 clusters (difficulty swallowing solids, dry mouth, taste/smell changes) was 70% vs. 100%. Difficulty swallowing liquids 6% vs. 0%, and mucous 27% vs. 25% did not appear to be reduced by the lower IMRT dose. **Conclusions:** The VHNSS V2 instrument provides granular analysis of specific symptoms experienced by HNC patients. Reduction of IMRT dose from 69.3Gy to 54Gy appeared to ameliorate late toxicities in locally advanced HPV+ HNC. This dose reduction in pts with cCR to IC was associated with favorable long-term DFS. VHNSS V2 will be used in subsequent ECOG-ACRIN studies to evaluate treatment effects prospectively. Clinical trial information: NCT01084083.

Safety analysis of a phase III randomized trial of chemotherapy with or without bevacizumab (B) in recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN). *First Author: Athanassios Argiris, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: The addition of B, an anti-VEGF monoclonal antibody, to chemotherapy has improved outcomes in several solid tumors. Pemetrexed plus B in R/M SCCHN showed promising efficacy but significant incidence (15%) of grade 3-5 bleeding (Argiris et al. JCO 2011). **Methods:** Patients (pts) with performance status (PS) 0-1, adequate laboratory parameters, no history of bleeding, not receiving anticoagulation or having blood vessel invasion were randomized to: A) one of 4 regimens (investigator's choice): A1, cisplatin (C) 100 mg/m^2, 5-FU 1000 mg/m^2/day x 4 days; A2, carboplatin (Cb) AUC 6, 5-FU 1000 mg/m^2/day x 4 days; A3, C 75 mg/m^2, docetaxel (D) 75 mg/m^2; A4, Cb AUC 6, D 75 mg/m^2, every 3 weeks, or B) the same regimen (B1, B2, B3, B4) plus B 15 mg/Kg IV, every 3 weeks, until progression. All pts received prophylactic antibiotics. Chemotherapy could be stopped after 6 cycles after maximum response. The primary endpoint was overall survival with a planned sample size of 400. **Results:** We report safety results from a total of 357 pts, 183 in Arm A (A1 = 15; A2 = 10; A3 = 88; A4 = 68) and 174 in Arm B (B1 = 12; B2 = 8; B3 = 85; B4 = 66). PS 1, 55%; female, 14%; age ≥ 65, 25%. Grade (G) 5 treatment-related adverse events (AEs), 5% in arm A vs 8% in arm B (p = 0.23), causes (%): febrile neutropenia, 1 vs 0; cardiac arrest, 0 vs 1; gastric hemorrhage, 0 vs 1; tracheal/tracheostomy hemorrhage, 0 vs 2; laryngeal/pharyngeal/bronchial hemorrhage, 0 vs 3; lung infection 1 vs 0; sepsis, 0 vs 1; nervous system/other 0 vs 2. G 5 bleeding AEs, all reported, 1% vs 4% (p = 0.06); treatment-related, 0 vs 3.6 (p = 0.007); G 3-5 bleeding AEs, all reported, 3.6 vs 7.8 (p = 0.08); treatment-related, 0.5 vs 7.3 (p = 0.0004). G 3/4 treatment-related AEs in arm A vs B (%): febrile neutropenia, 7/2 vs 9/6; fatigue, 9/0 vs 17/0; diarrhea, 1/0 vs 5/0; mucositis, 4/0 vs 15/1; vomiting 4/0 vs 6/1; neutropenia, 1/25 vs 7/32; thrombocytopenia, 1/5 vs 5/3; hypertension, 0/0 vs 5/0; thromboembolic, 0/0 vs 4/1. Female gender, age ≥ 65 and PS 1 were risk factors for G 3-5 bleeding with B. **Conclusions:** The incidence of G 5 toxicities was similar to previous phase III ECOG trials. B increased grade 3-5 bleeding but not overall G 5 AEs. Clinical trial information: NCT00588770.

6023 Poster Discussion Session; Displayed in Poster Session (Board #346), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Biomarker analysis in recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) patients (pts) treated with second-line afatinib versus methotrexate (MTX): LUX-Head & Neck 1 (LUX-H&N1). *First Author: Ezra E. W. Cohen, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: In the Phase III LUX-H&N1 trial, afatinib improved PFS (median 2.6 vs 1.7 months; HR 0.80; p = 0.03) vs MTX in second-line R/M HNSCC pts. As there are no accepted predictive biomarkers in this setting, the association of pre-specified biomarkers with clinical outcomes was explored. **Methods:** Pts were randomized 2:1 to 40 mg/d afatinib or 40 mg/m^2/wk MTX. The primary endpoint was PFS. Tumor biomarker analyses included human papillomavirus status assessed by p16 immunohistochemistry (IHC), EGFR amplification (FISH), HER3 (IHC) and PTEN (IHC) on archival tissue, and the VeriStrat proteomic signature (classifying pts likely to have good or poor outcomes with EGFR inhibitors) on plasma samples. **Results:** Of 483 ptsenrolled, 301 (62%) provided plasma and 234 (48%) provided tissue for biomarker analyses. A more pronounced PFS benefit with afatinib vs MTX was observed in p16-negative vs p16-positive, PTEN-high vs PTEN-low, and HER3-low vs HER3-high disease (Table). A trend towards prolonged PFS was observed with afatinib vs MTX in EGFR-amplified tumors. PFS was similar with afatinib and MTX in VeriStrat good and poor groups. Further tumor samples are being analyzed and updated results of PFS and OS will be presented. **Conclusions:** Subgroups of R/M HNSCC pts who may achieve increased benefit from afatinib vs MTX were preliminarily identified based on biomarkers. PFS benefit with afatinib was more pronounced in pts with p16-negative, PTEN-high, HER3-low, and EGFR-amplified disease. Clinical trial information: NCT01345682.

Subgroup	No. of pts (Afatinib vs MTX)	Median PFS, mos (Afatinib vs MTX)	HR (95% CI) (Afatinib vs MTX)	p-value
p16-neg	135 vs 64	2.7 vs 1.6	0.70 (0.50, 0.97)	0.029
p16-pos	23 vs 12	2.0 vs 2.3	0.81 (0.39, 1.69)	0.564
EGFR-amplified	48 vs 17	2.8 vs 2.2	0.64 (0.34, 1.20)	0.162
EGFR not amplified	47 vs 19	1.6 vs 2.1	1.25 (0.70, 2.23)	0.455
HER3-low	49 vs 17	2.9 vs 2.0	0.47 (0.25, 0.86)	0.014
HER3-high	64 vs 26	1.7 vs 2.4	1.33 (0.79, 2.24)	0.289
PTEN-high	30 vs 12	2.9 vs 1.4	0.36 (0.16, 0.81)	0.014
PTEN-low	82 vs 33	2.6 vs 2.7	1.01 (0.65, 1.58)	0.965
VeriStrat: good	127 vs 69	2.7 vs 2.0	0.79 (0.57, 1.09)	0.145
VeriStrat: poor	70 vs 35	1.5 vs 1.5	0.91 (0.58, 1.43)	0.678

6024 Poster Session (Board #347), Sat, 1:15 PM-4:45 PM

Ultra-deep targeted sequencing to identify *HRAS*, *TP53*, and *CDKN2A* somatic mutations as molecular prognostic markers in patients with advanced oral squamous cell carcinoma. *First Author: Tzu-Chen Yen, Nuclear Medicine and Molecular Imaging Center, Chang Gung Memorial Hospital, Taoyuan, Taoyuan, Taiwan*

Background: Ultra-deep targeted sequencing (UDT-Seq) was used to identify somatic mutations predicting disease-specific survival (DSS) in patients with advanced oral squamous cell carcinoma (OSCC). **Methods:** Formalin-fixed paraffin-embedded primary tumor specimens were collected from 249 node-positive OSCC patients, including 147 patients with (ECS+) and 102 without (ECS-) extracapsular spread. Mutational hotspots of 45 cancer-related genes were examined with UDT-Seq at an average depth of 1000×. Kaplan-Meier plots and Cox regression analyses were used to investigate the association between the mutation status and DSS. **Results:** Non-synonymous variants were identified in 179 (71.9%) specimens. *TP53*, *CDKN2A*, *HRAS* and *PI3KCA* were the most frequently mutated genes. The presence of ECS did not statistically significantly influence the mutation spectrum. *HRAS* mutations were strongly associated with poor DSS independent of ECS. Mutations in *TP53* (especially located in the DNA-binding domain) and *CDKN2A* predicted poor DSS in ECS- and ECS+ patients, respectively. No association between *PI3KCA* mutations and prognosis was detected. **Conclusions:** Our findings demonstrate that *HRAS, TP53* and *CDKN2A* mutations identified by UDT-Seq predict DSS in advanced OSCC, potentially serving as molecular markers for individualized patient care through risk-adapted therapy.

6025 Poster Session (Board #348), Sat, 1:15 PM-4:45 PM

New aspects regarding the induction chemotherapy with TPF and radio chemotherapy in head and neck cancer. *First Author: Edwin Boelke, University of Duesseldorf, Duesseldorf, Germany*

Background: Induction chemotherapy with docetaxel, cisplatin, and 5 FU (TPF) before radiotherapy (RT) or radio-chemotherapy (RT-CHX) improves the overall survival rate compared to induction chemotherapy with cisplatin and 5 FU in locally advanced squamous cell carcinoma of the head and neck (SCCHN). If TPF induction before RT-CHX improves clinical outcome in comparison to RT-CHX alone is still uncertain. Recently, the results of 5 randomized trials addressing this question have become available. **Methods:** 1060 patients with locally advanced SCCHN were randomly assigned to receive either TPF induction CHX followed by concurrent RT-CHX or concurrent RT-CHX alone. Platin or taxane based CHX was used during RT. 53,4% of patients had oropharyngeal, 17,3% hypopharyngeal, 6,4% laryngeal, 18,5% oral cavity and 4,4% other SCCHN. Published hazard ratios and hazard ratios extracted from available survival curves for overall survival (OS) and progression free survival (PFS) were basis of the meta-analysis. Meta-analysis of the effect sizes on OS and PFS was performed using a random effects model based on parameter estimates of log hazard ratios in Cox models and their standard errors. **Results:** Additional induction CHXwith TPF before RT-CHX did not result in a significant improvement of overall survival (Hazard Ratio: 0.950, 95% confidence limits (CL) 0.791-1.140 p = 0.579). **Conclusions:** Additional induction CHX with TPF before RT-CHX does not improve overall survival in SCCHN.

6026 Poster Session (Board #349), Sat, 1:15 PM-4:45 PM

Phase I trial of intravenous attenuated vaccinia virus (GL-ONC1) with concurrent chemoradiotherapy (CRT) for locoregionally advanced head and neck carcinoma. *First Author: Loren K. Mell, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: We aimed to test the safety of GL-ONC1, an attenuated vaccinia virus, delivered intravenously (IV) with concurrent CRT for locoregionally advanced head and neck carcinoma (LA-HNC). Secondary objectives were to test for tumor susceptibility to viral infection in baseline specimens and for tumor infection on mid-treatment biopsies. **Methods:** This was a 3+3 phase I dose escalation trial for unresected LA-HNC, excluding HPV-positive oropharyngeal cancer (NCT01584284). CRT was given in 33-35 fractions of 2.00-2.12 Gy over 6.5-7 weeks using IMRT with concurrent cisplatin 100 mg/m^2 given on days 1, 22, and 43. Escalating doses of GL-ONC1 were given as follows: cohort 1, 3×10^8 pfu on day 3; cohort 2, 1×10^9 pfu on day 3; cohort 3, 3×10^9 pfu on day 3; cohort 4, 3×10^9 pfu on days 3 and 8; and cohort 5, 3×10^9pfu on days 3, 8, 15, and 22. Dose-limiting toxicity (DLT) was defined as grade $\geq$ 4 toxicity or grade $\geq$ 3 mucositis or skin reaction persisting $>$ 6 weeks after CRT attributed to GL-ONC1. **Results:** From May 2012 to Dec 2014, 24 patients consented (19 enrolled, 5 screen failures). 18 patients completed CRT, with 1 currently on treatment. Mean age was 56 years. 74% had stage IVA and 26% had stage IVB disease. 26% were HPV-positive. One DLT occurred in cohort 4. Maximum tolerated dose was not reached. Adverse events included grade $\geq$ 2 rigors (47%), grade $\geq$ 2 thrombocytopenia (32%), grade $\geq$ 2 fever (26%) and grade $\geq$ 1 rash (21%). The rash was confirmed to be viral in origin in 2 patients. Viral tumor infection was confirmed by qPCR for A21L gene in 4 patients. No viral shedding was detected on urine or oral swab 1-2 days post infusion of GL-ONC1. Serious adverse events considered unrelated to GL-ONC1 were myocardial infarction (1), pulmonary embolism (1), syncope (1), grade 3 emesis (1), and grade 3 neutropenia (1). Of 18 patients completing CRT, 78% had 3 cycles of cisplatin and 22% had 2 cycles. With median 17 month follow-up, Kaplan-Meier estimates of 1-year (2-year) PFS and OS were 82% (75%) and 87% (75%) respectively. **Conclusions:** This is the first trial to establish the safety of IV GL-ONC1 for LA-HNC patients undergoing concurrent CRT. A phase II trial in this population is warranted. Clinical trial information: NCT01584284.

6027 Poster Session (Board #350), Sat, 1:15 PM-4:45 PM

Can somatic copy number alterations detected by ultradeep targeted sequencing predict prognosis in oral squamous cell carcinoma? *First Author: Tzu-Chen Yen, Nuclear Medicine and Molecular Imaging Center, Chang Gung Memorial Hospital, Taoyuan, Taoyuan, Taiwan*

Background: Targeted sequencing technologies have greatly advanced our knowledge of the incidence and functional significance of somatic genomic copy number alterations (CNA) in various malignancies. To understand the underlying genetic alterations in oral squamous cell carcinoma (OSCC) and aid in molecular classification of OSCC and patient prognosis, CNA were analyzed using ultradeep-targeted sequencing (UDT-Seq) with DNA from formalin-fixed paraffin-embedded (FFPE) OSCC specimens. **Methods:** First, a linear model was developed to overcome uneven coverage across target regions. We then designed 189 primer pairs to selectively amplify mutational hotspots targeting 46 cancer-relevant genes. Samples were obtained from 310 FFPE tissue specimens from OSCC resections and 14 control samples. The 5-year rates of local recurrence, distant metastases, and overall survival served as the main outcome measures. We finally confirmed the prognostic signatures by profiling an additional 105 primary OSCC samples. **Results:** We found that CNA burden across 16 targeted genes was associated with clinical outcomes in the two cohorts. *FGFR1* and *PIK3CA* amplifications were significant predictors of prognosis independent of traditional risk factors. Moreover, we identified CNA in genes involved in proteoglycan metabolism as well as *FOXO* and *PI3K-AKT* signaling pathways, for which targeted drugs are already available or under development. **Conclusions:** We observed that CNA detected by UDT-Seq may predict prognosis in OSCC patients, complementing the clinicopathological information. Prognostically detrimental CNA can provide added value in the combined molecular and clinical prognostication of OSCC.

6028 Poster Session (Board #351), Sat, 1:15 PM-4:45 PM

Adjuvant chemo-radiotherapy (CRT) versus radiotherapy (RT) alone for locally advanced salivary gland carcinoma among older population: SEER-Medicare analysis. *First Author: Tawee Tanvetyanon, H Lee Moffitt Cancer Ctr and Rsrch Inst, Tampa, FL*

Background: Salivary gland carcinoma is an uncommon malignancy. For locally advanced or high risk disease, current standard of care consists of surgery followed by adjuvant RT. Limited data on the efficacy of adjuvant CRT exists. We sought to compare the effectiveness of adjuvant CRT vs. RT alone among older patients in real world setting. **Methods:** SEER-Medicare database (1992-2009) was searched for beneficiaries 66 years of age or older with Medicare coverage ≥ 1 year following a diagnosis of locally advanced (T3-4 and/or N1-3, M0) major or minor salivary gland carcinoma. Patients must have had definitive surgery within 4 months from diagnosis and adjuvant RT or CRT within 6 months from diagnosis. **Results:** Analyses included 741 patients: 100 received CRT and 641 received RT. The most common concurrent chemotherapy agents used were Cisplatin or Carboplatin (37%), Carboplatin plus Taxane (19%) and Cetuximab (18%). Patients in CRT group were younger (median age 74.2 vs. 76.8 years, $p = 0.01$), with greater node positive disease (73% vs. 64%, $p = 0.05$) than RT group. The median overall survival was 24.0 months with CRT vs. 41.0 months with RT, $p = 0.012$. Multivariable analysis adjusting for patient-, tumor- and treatment-related factors still showed that CRT increased mortality over RT alone: HR 1.40 (95% CI: 1.08, 1.81). Hospitalization with treatment-related toxicity was more frequent in the CRT group, 27.0% vs. 11.5%, $p < 0.01$. An effect modification (*p-interaction* = 0.02) between histology and CRT was present such that an increase in mortality from CRT was observed only among adenoidcystic, mucoepidermoid or acinic cell carcinoma, but not adenocarcinoma or squamous cell carcinoma. Sensitivity analysis performed by changing the adjuvant definition to within 4 months from diagnosis or restricting analytic cohort to those receiving RT within 2 months post-surgery showed results robust. **Conclusions:** In this older, population-base cohort, there existed a wide variation in the practice of adjuvant CRT. Adjuvant CRT, when compared with adjuvant RT alone, was associated with an increased risk of mortality and hospitalization with treatment-related toxicity.

6029 Poster Session (Board #352), Sat, 1:15 PM-4:45 PM

Application of a robust and novel ex vivo platform mimicking patient heterogenous tumor microenvironment for personalized cancer treatment. *First Author: Kanaka Govind Babu, Kidwai Memorial Institute of Oncology, Bangalore, India*

Background: Predicting clinical response to anticancer drugs remains a major challenge in the management of cancer. Recent advances show that Tumor Micro Environment (TME) and heterogeneity impact therapy outcomes; indicating the limitations of biomarker-guided strategies for personalizing therapy. There is a need for platforms that can predict treatment outcome with high fidelity by contextually integrating tumor heterogeneity and phenocopying the TME. **Methods:** Tumor and grade-matched matrix support along with autologous sera from individual patients were used to engineer personalized Tumor Ecosystems (TE) in head and neck, breast and colorectal cancers. We evaluated functional outcomes as a measure of response to a panel of anticancer drugs in this platform. In the training data set obtained from a cohort of 109 patients, TE read-outs were integrated with their corresponding clinical outcomes for generation of a machine learning (M-score) algorithm to predict clinical response to these drugs. This algorithm was further validated in a test group of 55 new patients. **Results:** Histopathological and molecular characterization of the tumor slices cultured in TEs revealed a close approximation to the parental tumor at baseline as confirmed by Ki-67 index, critical phosphoproteomic status, global transcriptomic profiles and balance in active components of tumor and stromal phenotypes. The M-score algorithm when applied to the test cohort of more than 100 patient tumors assessed in the functional TE achieved 100% sensitivity while keeping specificity in a desired high range for predicting short term clinical outcome. **Conclusions:** The high specificity and sensitivity observed in predicting clinical outcomes using the TE supports the use of this novel platform for personalized cancer treatment. (Part of the data is accepted in Nature Communication).

6030 Poster Session (Board #353), Sat, 1:15 PM-4:45 PM

Response rates, toxicity, and quality of life for locally regionally advanced head and neck squamous cell carcinoma after induction chemotherapy with weekly *nab*-paclitaxel, carboplatin, and cetuximab. *First Author: Jared Weiss, Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC*

Background: Although induction studies of TPF have been negative, phase II studies of weekly carboplatin (CbP), paclitaxel and cetuximab (C225) have shown positive results. *Nab*-paclitaxel-based chemotherapy has demonstrated a higher response rate (RR) than solvent-based paclitaxel in SCC of the lung with favorable toxicity. **Methods:** Patients with treatment naïve SCCHN of any site with ≥ N2b disease or that was unresectable by strict criteria were eligible. Subjects were screened for risk of anaphylaxis to C225 with ELISA for IgE antibodies against galactose-α-1,3-galactose (alphagal); negativity was required for subjects residing in the SE of the US. Patients were treated with *nab*-paclitaxel 100mg/m^2, CbP AUC 2 and C225 400mg/m^2 week 1 then 250mg/m^{2}for six weeks, followed by standard of care (SOC) chemoradiotherapy (CRT). Herein we report the results of induction, including the primary endpoint of RR. **Results:** 62 subjects were screened; 20 were excluded due to positivity for alphagal, 1 withdrew consent and 5 were excluded due to other reasons; 36 were eligible and 35 have completed induction chemotherapy. Primary sites were: oropharynx (OPX) (23), larynx (3) and oral cavity (OC) (9). Grade 3/4 toxicity included rash (8), decreased neutrophil count (4), decreased white blood cells (2), fatigue (1), palmar-plantar erythrodysesthesia syndrome (1), and febrile neutropenia (1); there was no anaphylaxis to C225. All patients proceeded to SOC CRT. RRs to induction were: primary site 66%, nodal 79%, ORR 74%, CRR 26%, OPX 78%, p16+ OPX (17/19 with known status) 77%, larynx 100%, OC 56%. FACT-HN scores were (mean improvement in points, p): overall (5.3, NS) head/neck subscale (4.7, .046), swallow naturally and easily (1.6, 0.002) and voice quality and strength (0.9, .06). 24 patients are alive and NED, 3 are alive with PD, and 8 have died; median follow up of survivors is .7 years. **Conclusions:** The combination of *nab*-paclitaxel, CbP and C225 is very active against locally advanced SCCHN and toxicity is low. SCCHN-specific quality of life improved, particularly in speech and swallowing. Clinical trial information: NCT01412229.

6031 Poster Session (Board #354), Sat, 1:15 PM-4:45 PM

A phase II study of axitinib in patients with recurrent or metastatic nasopharyngeal carcinoma (NPC). *First Author: Edwin Pun Hui, Partner State Key Laboratory of Oncology in South China, Sir Y K Pao Centre for Cancer, Department of Clinical Oncology, Hong Kong Cancer Institute and Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong*

Background: Axitinib has demonstrated potent in vitro and in vivo activity in preclinical models of NPC [*Cancer Res 2012;72(8 Suppl):Abstract 1373*]. We aimed to validate the findings in NPC patients (pts). **Methods:** This is an open label, single arm, phase II study of axitinib monotherapy in recurrent or metastatic NPC pts who failed at least one line of platinum based chemotherapy. Pts with Eastern Cooperative Group (ECOG) 0-1, adequate organ functions, and without local recurrence or tumor close to major vessels, received a starting dose of axitinib at 5 mg twice daily in continuous 4-weeks cycles until progression or unacceptable toxicity. Primary endpoint was clinical benefit rate (CBR), defined as % of pts achieving complete response (CR), partial response (PR) or stable disease (SD) by RECIST for > 12 weeks. Secondary endpoints included time to progression (TTP), overall survival (OS), safety and plasma axitinib pharmacokinetics (PK). Simon's Minimax two-stage phase II design (P0 = 0.50, P1 = 0.70, type I error 0.05, power 80%) was used to calculate the sample size (n = 37). **Results:** 37 pts were accrued. Median age was 53 (22-74). M:F = 32:5. Pts received a median of 3 lines of prior chemotherapy (range 1-6). 36 pts (97%) had prior radiotherapy and 2 pts (5%) had prior surgery for NPC. Axitinib treatment was delivered for a median of 4 cycles (range 1-21, 3 pts were still on treatment), with 15 pts (41%) received ≥ 6 cycles, 6 pts ≥ 10 cycles and 2 pts ≥ 18 cycles. 10 pts had dose reductions and 8 pts had dose escalations. Of 34 pts evaluable for response, CBR = 73.5% (95% CI: 60.7%-86.3%; 1 confirmed PR, 4 unconfirmed PR, 20 SD >12 weeks). Median TTP 5.4 months (95% CI: 3.9-5.9). Median OS 10.4 months (6.5-19.0). 1-year survival rate 43.6%. Treatment-related adverse events (AEs) by CTCAE v3, all grades (Gr) in ≥ 25% of pts: hypothyroidism 46% (Gr 3: 3%), fatigue 43% (Gr 3: 3%), hand-foot 43% (Gr 3: 3%), hypertension 32% (Gr 3: 5%), diarrhea 27% (Gr 3: 3%), mucositis 27% (Gr 3: 0%). Gr 3 AEs were uncommon (≤ 5%) and there was no Gr 4 or above treatment-related AE. All hemorrhages (16%) were Gr 1. PK data will be presented. **Conclusions:** Single agent axitinib achieved prolonged disease control with a good safety profile in this cohort of heavily pretreated NPC pts. Clinical trial information: NCT01249547.

6032 Poster Session (Board #355), Sat, 1:15 PM-4:45 PM

A gene expression profile to predict recurrence of advanced tongue squamous cell carcinoma (TSCC): Discovery and external validation. *First Author: Tomohiro Enokida, Division of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Extracapsular spread and positive microscopic surgical margins are known high risk factors of recurrence in head and neck cancer patients. However, molecular biological markers to predict recurrence have not been identified. Here, we aimed to identify markers of recurrence using DNA microarray profiling in patients with squamous cell carcinoma of the tongue (TSCC). **Methods:** We conducted exploratory Affymetrix gene expression profiling using 26 primary tumor tissue samples from patients meeting the following criteria: 1) histologically confirmed TSCC, 2) surgical resection of the primary tumor and lymph node dissection, and 3) follow-up for longer than one year after surgery. Median age and pathological stage were 60 years (37-85) and pStageIII/IV = 8%/92% (pT: 2/3/4a = 3/1/22, pN: 0/1/2a/2b/2c = 5/5/0/8/8), respectively. The relationship between gene expression pattern and relapse-free survival (RFS) was examined. Predictive candidate genes were independently validated using published survival and gene expression data similarly derived from 23 patients with oral SCC (http://www.ncbi.nlm.nih.gov/geo, GSE31056). **Results:** Cases were classified into clusters A (n = 10) and B (n = 16) by unsupervised hierarchical clustering analysis. RFS of cluster B was longer than that of cluster A (median RFS: not reached vs. 111days, p= 0.025) with a median follow-up period of 253 days (58-1341). The number of genes highly expressed by more than two-fold their expression in the opposite cluster was 175 in cluster A and 400 in cluster B. We then identified 27 genes with the most predictive value for recurrence, 5 genes highly expressed in the low-risk group (e.g. ALDH3A1) and 22 highly expressed in the high-risk group (e.g. MMP-10). Clustering into high- and low-risk groups based on this 27-gene expression in a validation study also showed a significant association with recurrence (median RFS: low-risk not reached vs. high-risk 25.1 months, p = 0.046) with a median follow-up of 13.27 months (1.43-59.67). **Conclusions:** We identified27 genes which could predict recurrence, indicating a promising candidate factor for high-risk relapse. A larger prospective study is warranted.

6033 Poster Session (Board #356), Sat, 1:15 PM-4:45 PM

Genomic landscape of anaplastic thyroid cancer. *First Author: Jaume Capdevila, Vall d'Hebron Institute of Oncology, VHIO, Barcelona, Spain*

Background: Anaplastic thyroid cancer (ATC) is a rare and highly lethal malignancy. Chemotherapeutic agents and surgery have had no impact on local control or prognosis and novel actionable therapeutic targets are needed. Genetic instability of ATC has been often reported but comprehensive genomic landscape is unclear. **Methods:** We have performed Exome-seq on 13 cases of ATC (matched tumor-normal tissue/ peripheral blood), including two cases of concomitant papillary thyroid cancer (PTC) and ATC in the same patient (PTC, ATC, normal). **Results:** We identified several mutations in genes previously related with ATC, including TP53 (30%), RAS (29%), PIK3CA (23%), STAT (23%), BRAF (15%), and mutations in genes involved in SWI/SNF (15%), CDK (15%), and hedgehog (15%) pathways. The analysis of the two cases of concomitant PTC and ATC present in the same thyroid gland showed a significantly different genomic background with few common root mutations between both tumor entities (3 and 9 mutations respectively were present with a similar allelic frequency in both tumors). Clonal oncogenic BRAF and NRAS mutations were enriched in PTC but decreased in ATC, while other well-known driver mutations were only detectable in the ATC samples, including TP53, PI3KCA, STAT and PDGFR. Globally, our results suggest an early clonal divergence of PTC and ATC during tumor evolution. **Conclusions:** To our knowledge this is the first time where an early divergence on genomic evolution from PTC to ATC is suggested challenging the hypothesis of a multistep mutational model that leads from follicular thyroid cell to PTC and ATC. Candidate therapeutically actionable alterations have been identified.

6034 Poster Session (Board #357), Sat, 1:15 PM-4:45 PM

The SMART strategy: Subdividing M1 stage and aiming remission for target nasopharyngeal carcinoma patients with metachronous metastasis. *First Author: Lujun Shen, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Metastatic nasopharyngeal carcinoma (mNPC) varied greatly from potentially curable to incurable. This study set out to identify the target patients with chance of cure through extensive M1 stage subdivision and treatment response assessment. **Methods:** 1172 NPC patients with metachronous metastasis from three medical centers in Southern China were retrospectively analyzed (916 pts in derivation dataset; 256 pts in validation dataset). Various metastatic features were assessed, including involvement of specific locations, n of metastatic locations and n of metastatic lesions. A new nomenclature system for precise M staging was designed based on the independent prognostic factors. The best treatment response was assessed based on RECIST 1.1 or the modified RECIST criteria. **Results:** Multivariate analysis in derivation cohort showed that n of metastatic lesions, n of metastatic locations, liver involvement, bone involvement, together with age, UICC N stage, local recurrence, were independent prognostic factors for overall survival (OS). Subdividing the population by n of metastatic lesions and n of metastatic locations could result in subgroups with highly significant differences in OS. The external validation by two independent datasets showed congruent results. A new nomenclature system (M [n of locations]-Location [n of lesions in location]; B, bone; L, lung, H, liver, N, node) was designed, our data showed that mNPC patients with isolate metastatic lesion (M1-B_1, M1-L_1, M1-H_1, M1-N_1), and those with two lesions in liver only (M1-H_2) had high rates of complete remission (CR) or complete surgical resection (cSR), and 3-year OS after treatment (CR+cSR, > 30%; 3-yr OS, > 50%); for patients with more than three metastatic lesions in specific location (M1-B_m, M1-H_m) or multiple-location metastasis, the treatment response was generally poor, and the rates of cSR and 3-yr OS were low (CR, < 4%; cSR, 0%; 3-yr OS, < 30%). **Conclusions:** The SMART strategy could serve as a powerful tool in identifying the mNPC patients with chance of cure. More trials are needed to evaluate the feasibility and significance of achieving complete remission among the target patients.

6035 Poster Session (Board #358), Sat, 1:15 PM-4:45 PM

A meta-analysis of weekly cisplatin versus three weekly cisplatin chemotherapy plus current radiotherapy for advanced head and neck cancer. *First Author: Yue Zhang, Department of Radiation Oncology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: Cisplatin based chemoradiotherapy (CRT) is the standard treatment for advanced head and neck cancer (HNC), currently the recommended doses are 30-40 mg/m^2 every week or 80-100mg/m^2 every three weeks. However, there has no meta-analysis to evaluate the adverse effects and survival events of the two schedules for HNC patients **Methods:** We conducted a systematic review and meta-analysis by searching PubMed, MEDLINE, ScineceDirect, Cochrane Library and China National Knowledge Infrastructure (CNKI) databases (1982-2015). Study endpoints included overall survival (OS), locoregional recurrence-free survival (LRFS), and grade ≥ 3 adverse events. Hazard ratios with 95% confidence intervals (95%CIs) were calculated for OS and LRFS, and risk ratios were for adverse events. Kaplan-Meier curves were read by Engauge-Digitizer, and RevMan 5.2 software was used to perform this meta-analysis. **Results:** 779 patients of 10 studies were eligible. There was no significant difference on OS (2-year: HR 1.05, 95%CI 0.61-1.81; 3-year: HR 1.12, 95%CI 0.68-1.85; 5-year: HR 1.79, 95%C 0.97-3.31) and LRFS (1-year: HR 1.26, 95%CI 0.46-3.46; 2-year: HR 1.14, 95%CI 0.51-2.56) between the patients treated with weekly and three weekly cisplatin CRT. Risk ratios of neutropenia, dermatitis and anemia were similar in the two groups. There was a trend that patients treated with weekly cisplatin had less gastrointestinal reactions than those of three weekly (RR = 0.59, p = 0.06). In subgroup analysis, patients in weekly group had more grade ≥ 3 mucositis when the primary disease located in oral cavity, oropharynx, hypopharynx or larynx (RR = 1.72, p = 0.01). In addition, the occurrence of therapy related delay or interrupt was obviously higher in weekly cisplatin compared to three weekly (RR = 2.37, P = 0.01). **Conclusions:** Three weekly cisplatin CRT didn't differ with weekly in OS and LRFS. Weekly cisplatin had higher risk in dermatitis, therapy delay and interrupt, but lower in gastrointestinal reactions. In subgroup analysis, threeweekly cisplatin had less grade ≥ 3 mucositis in non-nasopharynx of HNC patients, it might be more easily accepted by patients in terms of comfort or financial burden.

6036 Poster Session (Board #359), Sat, 1:15 PM-4:45 PM

A meta-analysis comparing cisplatin-based to carboplatin-based chemotherapy in moderate to advanced squamous cell carcinoma of head and neck (SCCHN). *First Author: Qinyang Li, Department of Radiation Oncology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: The cisplatin (CDDP)-based CT is considered as the standard regimen for the treatment of moderate to advanced SCCHN. Recently, an alteration is made to carboplatin (CBDCA) because of its similar mode of action. We conducted a meta-analysis to compare the efficacies and toxicities of these two treatments. **Methods:** The search strategy included Pubmed, Science Direct, the Cochrane Library, China National Knowledge Internet Web. Statistical analyses were performed using RevMan 5.2. The primary endpoint was overall survival (OS) with secondary endpoints of locoregional control (LRC) and severe toxicity (grade $\geq$ 3). Hazard ratio (HR) and risk ratio (RR) were calculated using random- or fixed-effect models. Kaplan-Meier curves were read by Engauge-Digitizer. **Results:** Overall 12 studies and 1165 patients were included. CDDP-based CT significantly improved 5-year OS (HR = 0.67,95%CI 0.49-0.91;P = 0.01) compared to the CBDCA group. No difference in 3-year OS/LRC was observed (P = 0.08;P = 0.64), but a subgroup analysis showed a better 3-year OS in the CDDP arm for non-nasopharynx carcinoma (non-NPC) SCCHN (HR = 0.66,95%CI 0.48-0.91;P = 0.01). The CDDP-based CT was associated with more gastrointestinal toxicities (RR = 4.58,95%CI 1.57-13.37;P = 0.005) and nephrotoxicity (4/110 = 3.6%) compared to the CBDCA group, but less hematologic toxicities (anemia, leukopenia and thrombocytopenia) with RRs of 0.27 (95%CI 0.12-0.63),0.71 (95%CI 0.52-0.96),0.28 (95%CI 0.15-0.54). Risk of skin toxicity was identical. Moreover, we found that for non-NPC SCCHN, mucositis occurred more frequently and severely in CDDP-based treatment (RR = 3.55,95%CI 1.42-8.88;P = 0.007), whereas less for NPC (RR = 0.20,95%CI 0.09-0.45;P $<$ 0.0001). **Conclusions:** Patients with CDDP-based CT can achieve a higher OS, but there is no significant difference in LRC. The CDDP-based CT is associated with less hematologic toxicities but more gastrointestinal toxicities and nephrotoxicity compared to the CBDCA arm. Risk of mucositis in the CDDP group is higher for non-NPC SCCHN, but lower for NPC. The precise roles of CDDP and CBDCA in the management of SCCHN remain to be determined.

6037 Poster Session (Board #360), Sat, 1:15 PM-4:45 PM

Phase II study with conventional radiotherapy (RT) + cetuximab in patients with advanced larynx cancer who responded to induction chemotherapy (IC): An organ preservation TTCC study. *First Author: Ricard Mesia, Institut Catala d'Oncologia, Barcelona, Spain*

Background: IC with docetaxel/cisplatin/fluorouracil (TPF) is superior to PF in organ preservation. Bioradiotherapy (BRT) is superior to RT alone in the loco-regional control of locally-advanced head and neck tumors. The aim of our study was to evaluate the efficacy and safety of IC followed by BRT for functional larynx preservation. **Methods:** Phase II, open-label, multicenter study in patients with stage III-IVA laryngeal carcinoma candidates to total laryngectomy (TL). Study was designed to evaluate the laryngo-esophageal dysfunction–free survival (LEDFS) rate at 3 years. Using the one arm survival sample size program (SWOG), calculated recruitment: 94 patients (α .05; ß .1). Critical value $>$ 59%. Patients received 3 cycles of IC with TPF (75/75/750 mg/m^2): those who responded received conventional BRT (70 Gy/7 weeks) with cetuximab. Patients without response underwent TL + RT. Neck dissection was planned in patients with residual nodal disease at 2 months after BRT. **Results:** A total of 93 patients started TPF from October/2008 to February/2011: median age 59.4; 92% male; all PS: 0-1; 35% glottis / 65% supraglottis; 51% stage III / 49% IVA. Response to IC on larynx target lesion: 37 (40%) CR, 34 (37 %) PR, 8 (9 %) SD, 2 (2%) PROG and 12 (13%) not evaluated (2 death, 6 AEs, 3 missing, 1 lost follow-up). Overall response 72 (86 %). 73 (78%) patients followed by BRT: 68 as per protocol, but 2 with only SD and 3 without any response evaluation. Median follow-up: 48 months. 3-year actuarial rates: LEDFS: 69.5% (95%CI: 60-79%); laryngectomy-free survival: 71.2% (95% CI: 61-81%); overall survival: 77.2% (95%CI: 69-86%); disease-free survival: 47.9% (95%CI: 38-58%). TL was performed in 18 patients: 9 (9.7 %) after preservative treatment failure and 9 (9.7 %) in the follow-up (recurrences). The toxicity observed during both IC and BRT were as expected, with only 1 toxic related death (local bleeding during BRT). **Conclusions:** LEDFS rate was clearly higher than the critical value and with an acceptable toxicity with this protocol, so it is warranted to move to a phase III trial. Clinical trial information: 2008-000332-40.

6038 Poster Session (Board #361), Sat, 1:15 PM-4:45 PM

Bioradiotherapy for head and neck cutaneous squamous cell carcinoma. *First Author: Joshua David Palmer, Kimmel Cancer Ctr Thomas Jefferson Univ Hosp, Philadelphia, PA*

Background: Locally advanced, high-risk head and neck cutaneous squamous cell carcinomas (CSCC) are typically aggressive. We sought to compare treatment tolerability, disease control and survival between radiotherapy alone and radiotherapy plus cetuximab in CSCC patients. **Methods:** Patients diagnosed with high-risk CSCC based on NCCN criteria between 2006-2013 were included. Patients were divided into two groups: radiotherapy alone versus radiotherapy plus cetuximab. Primary analysis examined disease-free and overall survival, freedom from local and distant recurrence in the propensity score matched cohort. Propensity score analysis was performed with weighted factors including: Charlson Comorbidity Index score (age-adjusted), age. KPS, primary location, T and N stage, recurrent status, margin status, LVSI, PNI and grade. Toxicity was assessed using the CTCAE v4.0. **Results:** Among 68 patients meeting study criteria, we identified 29 treated with cetuximab plus RT and 39 with RT alone. Median follow-up for living patients was 30 months. Patients in the cetuximab group were more likely to have advanced N stage, positive margins and recurrent disease. After propensity score matching the groups were well balanced. OS and DFS were not statistically significant between the two groups but there were 37% more survivors free of disease in the cetuximab group. Loco-regional control was 77% and 54% in the cetuximab and radiation alone groups, respectively. The rate of distant metastases was lower in the cetuximab group 6.8% versus 17%. The incidence of grade 2-3 toxicity was 41% in the cetuximab group. There was one grade 3 cetuximab acneiform rash, one grade 4 dysphagia and no grade 5 toxicity. **Conclusions:** Although limited by small numbers; this therapy was well tolerated and there were more long-term survivors as well as less distant metastasis in the cetuximab group. This is the largest known report of CSCC patients treated with radiotherapy and cetuximab. These promising findings warrant further studies to establish the benefit of combined cetuximab and radiation in head and neck CSCC.

Disease-free survival by year in propensity score adjusted cohorts.

Years:		1	2	3	4	5
Weighted	Cetuximab	86%	72%	72%	66%	66%
	No Cetuximab	77%	53%	43%	39%	29%

6039 Poster Session (Board #362), Sat, 1:15 PM-4:45 PM

Alliance A091104: A phase II trial of MK-2206 in patients (pts) with progressive, recurrent/metastatic adenoid cystic carcinoma. *First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recurrent/metastatic adenoid cystic carcinoma (ACC) is a rare, incurable disease with no standard treatments. MYB is an oncogenic driver in ACC that is often overexpressed via a t(6;9) translocation. Based on preclinical data that Akt inhibition with the allosteric inhibitor MK-2206 (Merck) can decrease MYB expression, we conducted this NCI/CTEP, Alliance cooperative group trial of MK-2206 in ACC pts. **Methods:** Pts with incurable ACC were enrolled. Radiographic or symptomatic progression documented within 6 months (mo) of enrollment was required. MK-2206 150 mg weekly was given; escalation to 200 mg was allowed. Primary endpoint was response (RR); secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. A Simon-Optimal two-stage design was used to detect a 20% RR (vs. 5%) (alpha = 10%; beta = 90%). $>$ 1 response(s) in the first 12 would trigger accrual to 37; $>$ 4 responses would be considered promising. Archival tissues were analyzed for MYB expression and rearrangement. Pre-/post-MK-2206 biopsies were obtained in 5 pts. **Results:** 16 pts were enrolled (10 F, 6 M). 12 of 16 were escalated to 200 mg. 9 of 16 pts (56%) had a grade 3/4 treatment-related adverse event (rash (38%), fatigue (19%) hyperglycemia (13%)). 14 pts were evaluable for efficacy. Best response included 13 stable disease and one disease progression. PFS at 12 mo was 9.2% (95% CI: 0.6-33.3%); median PFS (mPFS) was 9.2 mo (95% CI: 3.8-11.0). With a median follow-up of 17.1 mo, OS at 12 mo was 77.4% (95% CI: 44.9-92.1%). 12 of 14 tumors had detectable MYB by IHC; 8 of 14 had *MYB* gene rearrangement by FISH. Analysis of serial biopsies revealed Akt inhibition and MYB downregulation with MK-2206 therapy in 4 of 5 cases. **Conclusions:** The study was stopped after no PR was observed in the first stage. In this limited sample, the 9.2 mo mPFS may reflect disease stabilization in progressive pts that compares favorably to other ACC trials (axitinib phII: 3 PRs, mPFS 5.7 mo). Correlative tissue analyses provide the first *in vivo* evidence that clinical Akt inhibition can diminish MYB levels. Future studies should focus on PFS and further elucidate the therapeutic relevance of MYB suppression. (NCI-supported) Clinical trial information: NCT01604772.

6040 Poster Session (Board #363), Sat, 1:15 PM-4:45 PM

Comprehensive genomic profiling of salivary gland adenocarcinomas to reveal frequency of druggable targets. *First Author: Matthew J. Hawryluk, Foundation Medicine Inc., Cambridge, MA*

Background: Salivary gland adenocarcinomas (SAC) are a distinct group of frequently aggressive epithelial tumors. We queried whether the genomic alterations (GA) identified by comprehensive genomic profiling (CGP) in refractory and metastatic SAC could lead to potential targeted therapy selection. **Methods:** DNA was extracted from 40 microns of FFPE sections from 92 clinically advanced SAC. Comprehensive genomic profiling was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 682X for 3,230 exons of 236 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer. The results were evaluated from each sample for all classes of genomic alterations. **Results:** There were 2 grade 1, 27 grade 2 and 63 grade 3 relapsed/refractory SAC in 30 (33%) female and 62 (67%) male patients with a median age of 59.6 years (range 25 to 84 years). There were 27 Stage III and 65 Stage IV cases. The majority (88%) of SAC harbored at least 1 clinically relevant alteration (mean 1.9 per patient) with a mean of 3.7 GA per tumor. GA occurred in 49 different genes including: *PIK3CA* (25%); *HRAS* (20%); *CDKN2A* (17%); *ERBB2* (15%); and *PTEN* and *NF1* (9%), *NOTCH1* and *MCL1* (8%), *EGFR* (5%), *KRAS* (4%) and *RICTOR*, *HGF*, *FBXW7* and *CDK4* (3%). The greater frequency of *ERBB2* alterations (15%) observed in SAC was significantly higher than observed in 110 similarly studied specialized salivary carcinomas including acinic cell, adenoid cystic and mucoepidermoid carcinomas (1%) ($p = 0.0001$). A similar increase in *HRAS* alterations of 18/92 (20%) SAC vs 4/110 (4%) in the specialized tumor group was also observed ($p = 0.008$). *PIK3CA*was altered in 25% of SAC vs. 5% in 110 specialized tumors ($p = 0.001$). **Conclusions:** SAC are a clinically aggressive and pathologically distinctive subset of salivary gland carcinomas. These tumors also differ significantly from the specialized salivary gland tumors in their genomic landscape. The high frequency of clinically relevant alterations in SAC including the 15% *ERBB2* alteration frequency suggests that continued molecular analysis of this tumor type has the potential to lead patients to clinical trials employing both established and novel targeted therapies.

6041 Poster Session (Board #364), Sat, 1:15 PM-4:45 PM

Hepatitis C virus seropositivity and head and neck cancers: A new trio. *First Author: Parag Mahale, Department of Infectious Diseases, Infection Control, and Employee Health, The University of Texas M.D. Anderson Cancer Center, Houston, TX*

Background: Hepatitis C virus (HCV) infection is associated with hepatocellular carcinoma [odds ratio (OR), 17] and non-Hodgkin lymphomas (NHL) (OR, 2). In 2009, we established the first clinic in US devoted to managing HCV-infected cancer patients (pts) where we observed a large number of pts with head and neck cancers (HNC). We aimed to test the association between HCV seropositivity (HCV-Ab$^+$) and HNCs. **Methods:** Medical records of cancer pts who were tested for HCV antibodies at MD Anderson between 6/2004 – 5/2014 were identified. Cases had first primary oropharyngeal cancers (OPCs) and non OPCs (cancers of oral cavity, nasopharynx, hypopharynx, and larynx). Lymphomas of OP/non OP region were excluded. Controls had smoking-associated cancers of lung, esophagus, and urinary bladder. Biopsy reports of OPCs tested for HPV by in-situ hybridization were obtained. Multivariable logistic regression models were constructed. **Results:** Of 34,545 cancer pts tested for HCV antibodies, 409 cases [OPC, 164 (40%); non OPC, 245 (60%)] and 694 controls [lung, 378 (55%); esophagus, 168 (24%); urinary bladder, 148 (21%)] were identified. OPC pts were mostly males (82% vs 68%; $p = .001$), with cancer diagnosed at younger age [median (yrs), 59 vs 63; $p < .0001$], better educated [$\geq$ bachelor's degree, 57% vs 38%; $p < .0001$], smoked fewer cigarettes [median pack-years (py), 24 vs 36; $p = .0001$] but more alcohol intake [drinks/week > 28, 23% vs 13%; $p = .002$] than controls. Non OPC pts were mostly males (77% vs 68%; $p = .01$), with cancer diagnosed at younger age [median (yrs), 59 vs 63; $p < .0001$], smoked fewer cigarettes [median py, 30 vs 36; $p = .2$], more alcohol intake [drinks/week > 28, 29% vs 13%; $p = .002$], and more HIV co-infected (4% vs 1%; $p = .05$) than controls. Adjusted models showed significant association of HCV-Ab$^+$ with OPCs (OR 2.1; 95% CI 1.1 – 4.2; $p = .02$) and non OPCs (OR 2.8; 95% CI 1.4, 5.7; $p = .005$). However, it was significant with only HPV$^+$ OPCs (OR 4.4; 95% CI 1.9 – 10.5; $p = .001$) but not HPV$^-$OPCs (OR 1.1; 95% CI 0.4 – 3.1; $p = .82$). **Conclusions:** HCV-Ab$^+$ may be associated with non-liver cancers such as HNCs, particularly HPV$^+$ OPCs. The strength of this association is as high as the one reported for NHLs. Further studies are warranted to explore this association and interaction of HPV with HCV.

6042 Poster Session (Board #365), Sat, 1:15 PM-4:45 PM

The role of cetuximab in induction chemotherapy: Comparison of APF-C (*nab*-paclitaxel, cisplatin, 5-FU + cetuximab) with APF, both followed by chemoradiation therapy (CRT), in patients with locally advanced head and neck squamous cell carcinoma (HNSCC). *First Author: Douglas Adkins, Washington University School of Medicine, St. Louis, MO*

Background: Cetuximab (C) improved overall survival (OS) in patients (pts) with HNSCC when added to definitive RT or to palliative chemotherapy; however, the role of cetuximab in induction chemotherapy is unclear. We hypothesized improved OS, disease-specific survival (DSS), and lower relapse rates with the addition of C to APF given as induction chemotherapy before CRT. A *nab*-Paclitaxel-based induction chemotherapy regimen was chosen because we observed better survival outcomes in comparison to a docetaxel-based regimen (*Cancer Medicine*2014). **Methods:** Two consecutive prospective phase II trials (APF and APF+C) were performed: 30 pts were treated with APF (weekly *nab*-paclitaxel 100 mg/m^2 and every 3 week cisplatin 75 mg/m^2 and 5-FU 750 mg/m^2/day x 3) and 30 pts were treated with APF+C (APF + weekly cetuximab 250 mg/m^2). Pts were scheduled to receive three cycles followed by CRT (with cisplatin). **Results:** Pt and tumor characteristics for all 60 pts are as follows: median age 57 (38-74) yrs, smoking history 83% (50 pts), p16+ Oropharynx (OPSCC) 57% (34 pts), T classification (T2-16 pts; T3-24 pts; T4-20 pts) and N classification (N0/1-11 pts; 2-38 pts; 3-11 pts). The distributions of age, smoking history, p16+ OPSCC, T and N classifications were similar between the two treatment groups. Two year OS (APF-C 90%, APF 93%) and DSS (APF-C 97%, APF 97%) were excellent in both treatment groups and not significantly different (Table); however, disease relapse occurred in five pts in the APF+C group vs 1 pt in the APF group ($p = .61$, log rank). When stratified for p16+ OPSCC and p16-HNSCC, no significant differences in 2 year OS or DSS occurred between the two treatment groups. **Conclusions:** Two year OS and DSS were similar between APF+C and APF, even when stratified for p16 status. These preliminary data do not support the addition of cetuximab to APF. Clinical trial information: NCT01566435 and NCT00736944.

	APF (n = 30)	APF+C (n = 30)	
Survival Endpoint	**%**	**%**	**p value**
2 yr OS	93%	90%	.99*
2 yr DSS	97%	97%	.99
p16+ OPSCC 2 yr OS	94%	94%	.99
p16+ OPSCC 2 yr DSS	94%	100%	.99
p16- HNSCC 2 yr OS	92%	83%	.59
p16-HNSCC 2 yr DSS	100%	92%	.48

6043 Poster Session (Board #366), Sat, 1:15 PM-4:45 PM

A phase I trial of the addition of the CDK 4/6 inhibitor palbociclib to cetuximab in patients with incurable head and neck squamous cell carcinoma (HNSCC). *First Author: Loren S. Michel, Washington Univ School of Medicine, St. Louis, MO*

Background: Overexpression of cyclin D1 and inactivation of p16 occur in the majority ($> 90\%$) of HPV-unrelated HNSCC. Resistance to cetuximab and cisplatin, the two most effective systemic agents in HNSCC, is in part attributable to cyclin D1 overexpression which can be targeted with inhibitors of the cyclin D axis. Palbociclib is a selective inhibitor of CDK4/6. **Methods:** A phase I trial was performed to determine the maximum tolerated dose (MTD) of palbociclib added to cetuximab. Palbociclib was given orally q.d. on days 1-21 of each 28 day cycle and cetuximab was given weekly (400 mg/m^2, then 250 mg/m^2). Palbociclib was given at 100 mg/d (level 1) or 125 mg/d (level 2: max dose). Fibonacci (3+3) design was utilized. Eligible patients (pts) had incurable HNSCC (p16 -or +) and adequate organ function. Correlative studies included total and p- Rb (IHC), p16 (IHC), and PK analysis of palbociclib. Tumor response assessment using RECIST criteria 1.1 was performed every 2 cycles. **Results:** Nine pts were enrolled (5 platin and cetuximab-resistant and 1 cetuximab-resistant ; 5 p16- and 4 p16+): 3 pts on dose level 1 and 6 pts on dose level 2. Mild (grade 1/2) neutropenia and thrombocytopenia occurred in 2 pts on dose level 1 and in 4 and 3 pts, respectively, on dose level 2. The MTD was not reached as there were no dose limiting toxicities and no AE-related treatment discontinuations. Tumor response assessment following cycle 2 showed partial response in 2 pts (both at dose level 2; both p16 – HNSCC; one with cetuximab- and platin-resistant disease), stable disease in 5 pts (one with cetuximab-resistant disease with an 18% decrease in target lesions), progression in 1 pt, and not yet evaluable in 1 pt. Median time-to-progression was 112 (range: 28-182) days. **Conclusions:** The MTD of palbociclib was not reached during the phase I study; 125 mg/d given on days 1-21 of a 28 day cycle when added to cetuximab, was determined as the recommended phase II dose. Impressively, tumor responses occurred in pts with cetuximab- and platin-resistant HNSCC. Phase II of the trial is enrolling pts with p16-/Rb+ HNSCC on Arm 1 (platin-resistant disease) and Arm 2 (cetuximab-resistant disease). Clinical trial information: NCT02101034.

6044 Poster Session (Board #367), Sat, 1:15 PM-4:45 PM

Augmenting pre-operative risk of recurrence stratification in differentiated thyroid carcinoma using machine learning and high dimensional transcriptional data from thyroid FNA. *First Author: Steven I. Sherman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In addition to improving survival, a risk adapted approach to thyroid cancer therapy should minimize risk of recurrence. Currently, patients are classified post-operatively as high, intermediate or low risk of recurrence using 2009 ATA staging. Though clinically useful, this anatomic staging cannot be assessed pre-thyroidectomy, and does not include molecular predictors of outcome. Our goal was to determine if transcriptional data obtained from FNA of malignant thyroid nodules augment risk stratification before thyroidectomy. **Methods:** We used FNA material from 81 samples preoperatively collected in a previous study and post-surgically diagnosed as PTC. Each patient was categorized as either ATA low risk or ATA intermediate/high risk using established guidelines for recurrence risk stratification. Microarray expression data were obtained on all samples and supervised learning was used to train classifiers (Support Vector Machine (SVM), Random Forest (RF), penalized logistic regression (PLR), and an ensemble of the 3). Performance was measured using 10-fold cross-validation on the training cohort. **Results:** Classifiers were built using the top 70 genes from LIMMA models that controlled for BRAF status. Maximum classification performance of ATA low risk vs. ATA intermediate/high risk was observed for an ensemble classifier with a maximal area under the ROC curve (AUC) of 0.83. All the classifiers achieved similar AUCs: SVM 0.82, RF 0.82, and PLR 0.82. Genes useful in classification belong to transmembrane signaling pathways including ECM-receptor interaction, focal adhesion, and cell adhesion molecules. When applied to the training cohort, the ensemble classifier correctly identified 72.4% (21/29) of ATA low risk tumors and 82.6% (43/52) of ATA intermediate/high risk tumors. **Conclusions:** Transcriptional data from FNA of thyroid nodules may improve the pre-operative prediction of risk for post-operative recurrence. If independently validated in a sufficiently large number of patients, such molecular classifiers may augment initial risk stratification and individualization of patient care.

6045 Poster Session (Board #368), Sat, 1:15 PM-4:45 PM

Prognostic value of HPV detection with three primer sets in 255 Head-Neck cancers. *First Author: Cristiana Lo Nigro, Laboratory of Cancer Genetics and Translational Oncology, Oncology Dept, S. Croce Teaching Hospital, Cuneo, Italy*

Background: HPV-related patients (pts) with locally advanced head and neck cancers (LA-HNCs) have a better prognosis than the HPV-negative ones. This study aimed to investigate the prevalence of HPV infection in a series of LA-HNCs and to compare the prognostic value of E1, E6 and L1 genomic viral fragments, each other, in order to find the best prognosticator among them in terms of Overall Survival (OS) and Progression Free Survival (PFS). **Methods:** HPV was searched in 255 LA-HNC pts, 89 Oropharyngeal cancers (OPCs) and 166 non-OPCs, by DNA-PCR on formalin-fixed paraffin-embedded (FFPE) tissues using three specific primer pairs for type 16. Each pt was analysed simultaneously for the three viral primer sets and for a housekeeping gene to determinate the integrity of tumour DNA samples. **Results:** One hundred and thirty six out of 255 pts (53.3%) were HPV positive with at least one of the primer pairs used; pos E6 (51%) and L1 (29.8%) samples were the most common; while pos E1 samples were lower (13.7%). OPCs showed a significant higher % of pos samples compared to non-OPCs for each primer set tested and the prevalence proportions for each fragment analysed were kept in both groups, with the highest for E6 and the lowest for E1. Therefore each pt highlighted variable positivity for E1, L1 and E6 viral fragments. In this sense OPCs showed the higher % of pos pts for the three viral fragments concurrently (31.5%) compared to non-OPCs (4.2%), moreover E1 detection was always associated with E6 and L1 one. In term of prognostic value analysed for each fragment by itself, only E1 pos OPC pts showed improved OS ($p = 0.012$) and PFS ($p = 0.036$), while pos L1 and E6 ones did not show any gain according with either viral status. **Conclusions:** Though prevalence in HPV infection by DNA-PCR was significantly higher for E6 and L1 primer sets, the detected pos viral fragments seemed very weak prognosticators; on the contrary E1 might become a stronger prognostic marker for OS and PFS in OPC pts. In conclusion E1 by DNA-PCR appears to be clinically relevant in the present series of pts.

6046 Poster Session (Board #369), Sat, 1:15 PM-4:45 PM

Association of head and neck cancer (HNSCC) subgroups defined by HPV RNA status, gene expression patterns, and *TP53* mutations with lymph node metastasis and survival. *First Author: Andreas Dietz, University of Leipzig, Leipzig, Germany*

Background: Classification of HNSCC based on HPV16 DNA and RNA status, gene expression patterns, and mutated candidate genes may facilitate patient stratification. **Methods:** We compared tumors differing in HPV16 DNA and RNA (E6*I) status from consecutively recruited HNSCC patients by gene expression profiling (n = 270, Illumina HT12) and targeted sequencing (n = 226; 50 genes, Ion Torrent). Gene expression was analyzed unsupervised using consensus clustering. **Results:** HPV16 DNA+RNA+ tumors are molecularly distinct from HPV-negative (HPV DNA-) HNSCC, have elevated expression of cell cycle genes and carry rarely *TP53* mutations (3.6%, 1/28). HNSCC without transcriptionally active HPV16 (DNA+RNA-) are similar to HPV DNA- tumors in gene expression and *TP53* mutation frequency (47%, 8/17, and 43%, 72/167). We identify four gene expression clusters significantly differing in overall survival (OS; P = 0.04, adjusting for UICC stage, age, tumor site, treatment, pack-years smoked, alcohol use, HPV16 status). One cluster with high expression of immune response genes (IR) contains most (77%, 27/35) HPV16 DNA+RNA+ HNSCC. The IR cluster and disruptive *TP53* mutations ($TP53^{mut}$) are associated with lymph node metastasis (OR = 5.7; CI95% 2.2-18.0; P < 0.001, and OR = 2.6; CI95% 1.2-6.0; P = 0.01) independent of HPV16 status and tumor site. This validates the associations identified by Walter et al. (2013). Consistent with earlier studies, $TP53^{mut}$ has unfavorable prognosis (OS: HR = 2.0; CI95% 1.1-3.6; P = 0.03; PFS: HR = 1.9; CI95% 1.2-3.2; P = 0.01), adjusting for the UICC stage, age, tumor site, treatment, pack-years smoked, alcohol use, HPV16 DNA RNA status. **Conclusions:** Elucidation of HPV16 E6*I and $TP53^{mut}$ status are required for patient stratification. The IR gene expression cluster and $TP53^{mut}$ in HNSCC are associated with lymph node metastasis.

6047 Poster Session (Board #370), Sat, 1:15 PM-4:45 PM

Prognostic value of mid-treatment total lesion glycolysis in p16+ oropharyngeal cancer. *First Author: Erqi L. Pollom, Stanford University Medical Center, Stanford, CA*

Background: To determine whether total lesion glycolysis (TLG) measured during radiation for locally advanced oropharyngeal cancer (OPC) correlates with outcomes. **Methods:** Patients with Stage III-IVB, intact OPC treated with definitive chemoradiation were included if they underwent both pre- and mid-treatment planning PET scans. The TLG, defined as summation of the total standardized uptake values within the tumor volume, was extracted from within the primary and nodal tumor volumes contoured by the treating physician. TLG velocity was defined as the relative difference between pre- and mid-treatment TLG divided by weeks between the scans. **Results:** In total, 67 patients who fulfilled inclusion criteria were treated from February 2009 to January 2014 at Stanford. Median age was 59 years (range 27-83). p16 status was positive in 58 patients, negative in 8 patients, and unknown in 1 patient. Ten patients received induction chemotherapy; the majority of patients (58%) received platinum-based chemotherapy concurrently. Patients were treated to a median dose of 70 Gy (range 63.6-70 Gy, in 30-35 fractions). Median follow-up was 18.8 months (range 3.3-67.2 months). Two-year progression-free survival (PFS) and overall survival (OS) were 90% and 98%, respectively. Age, smoking status, p16 status, stage and chemotherapy did not predict for PFS or OS. Higher pre- and mid-treatment nodal TLG predicted for worse PFS/OS, while higher pre- and mid-treatment combined primary and nodal TLG predicted for worse PFS, regardless of receipt of induction chemotherapy. For the entire cohort, faster decrease in nodal TLG trended toward improved PFS (p = 0.09, HR 0.004, 95% CI 0-2.5). In the p16+ subset, faster decrease in nodal TLG predicted for improved PFS (p = 0.049, HR 0.001, 95% CI 0-0.98). When dichotomized by the lower quartile of nodal TLG velocity, p16+ patients who had > 3% decrease of nodal TLG/week had better PFS than those who did not (p = 0.009, HR 0.23, 95% CI 0.09-0.7), even with controlling for type of chemotherapy. **Conclusions:** Metabolic response, as characterized by nodal TLG velocity, during radiotherapy predicts for PFS in p16+ OPC patients and may aid with risk-adapting treatment.

6048 Poster Session (Board #371), Sat, 1:15 PM-4:45 PM

Effect of age and lenvatinib treatment on overall survival for patients with ^{131}I-refractory differentiated thyroid cancer in SELECT. *First Author: Marcia S. Brose, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Lenvatinib (LEN) significantly prolonged progression-free survival (PFS) vs placebo (PB) in the phase 3 SELECT trial of patients (pts) with ^{131}I-refractory differentiated thyroid cancer (RR-DTC)–a benefit maintained in both younger ($\leq$ 65, median 56 years [y]) and older ($>$ 65, median 71 y) pts. In SELECT, median overall survival (OS) was not reached at data cutoff, and OS was not significantly different between LEN and PB (HR 0.73; 95% CI 0.50-1.07; $P = 0.103$). Here we examine the effect of age on OS in SELECT. **Methods:** Pts with RR-DTC and independent radiologic documentation of disease progression were stratified by region, prior VEGF-targeted therapy, and age (younger: LEN, n = 155; PB, n = 81 vs older: LEN, n = 106; PB, n = 50) and randomized 2:1 to LEN or PB. Median follow-up was 17.1 months at primary data cutoff (Nov 15, 2013); 83% of pts on PB crossed over to LEN following confirmed disease progression. **Results:** Median OS was not reached in any group except in older PB-treated pts (18.4 months; 95% CI, 13.3-20.3). A significant difference in OS was observed in older pts, favoring LEN (HR 0.53; 95% CI 0.31-0.91; $P = 0.020$). In a related analysis, there was no difference in OS between older and younger pts who received LEN (HR 0.78; 95% CI 0.49-1.26; $P = 0.304$), but there was a statistically significant difference in the PB arm, favoring younger pts (HR 0.48; 95% CI 0.27-0.85; $P = 0.010$). We examined possible reasons for this difference. There were no statistically significant differences between the age groups for the following factors: baseline ECOG performance status (LEN, $P = 0.56$; PB, $P = 0.46$), proportion of pts with prior VEGF-targeted therapy (LEN, $P = 0.270$, PB, $P = 0.757$), proportion of PB-treated pts who crossed over to receive LEN ($P = 0.441$), or the proportion of pts who received post-SELECT anticancer therapy (LEN, $P = 0.567$, PB, $P = 0.112$). Older pts did have a nonsignificant larger baseline median sum of target lesions (older: 64.9 mm; younger: 58.3 mm; $P = 0.113$). **Conclusions:** Older PB-treated pts with RR-DTC had worse OS than younger PB-treated pts in SELECT. This effect of age was completely mitigated by LEN treatment resulting in improved overall survival for pts $>$ 65 y treated with LEN. Clinical trial information: NCT01321554.

6049 Poster Session (Board #372), Sat, 1:15 PM-4:45 PM

Clinical trials outcomes of combined BKM120 and cetuximab compared to BKM120 in recurrent and/or metastatic squamous cell carcinoma of head and neck (R/M-SCCHN). *First Author: Hye Ryun Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: To investigate clinical activity, safety and biomarkers of a pan-PI3K inhibitor BKM120 in R/M-SCCHN and identify optimal combinations by conducting co-clinical trials. **Methods**: Patients with R/M-SCCHN who had progressed on platinum chemotherapy were eligible and treated with BKM120 100mg/day. The primary endpoint was DCR at 8 weeks. Secondary endpoints were RR, PFS, OS and safety. Patient-derived xenografts (PDXs) and cell lines (H01, H02) with genomic annotations were established from study patients to evaluate novel drug combinations. **Results:** A total of 37 patients were enrolled and evaluable for efficacy and toxicity. Patient characteristics included median age (55years); male (84%); ECOG 0/1 (19%/76%); locoregional/metastatic (30%/38%); oral cavity/oropharynx (38%/27%); prior chemotherapy regimens 1/ $\geq$ 2 (40%/60%). DCR at 8 weeks was 64.8% and RR was 2.7%. A responder harboring *PIK3CA*^{E542K}mutation had response duration of 53 weeks. Common toxicities were anorexia (62%) and hyperglycemia (59%). Median PFS and OS were 7.4 weeks and 19.2 weeks. In 3 PDXs established from patients showing progression, BKM120 was tested alone or in combination with cetuximab, afatinib, paclitaxel. All PDXs showed resistance to single-agent BKM120, resembling the responses of corresponding human cancers. Combined treatment of BKM120 and cetuximab showed strong synergistic inhibition of tumor growth, compared with either agent alone. Cell viability assay showed synergistic growth inhibition with combined BKM120 and cetuximab, compared with either agent alone. BKM120-induced AKT suppression did not attenuate FoxO phosphorylation, suggesting FoxO-mediated transcriptional upregulation of EGFR may not be responsible for synergy of combined PI3K and EGFR inhibition. Based on the integrated clinical and preclinical data, study protocol had been revised to combine BKM120 and cetuximab to explore whether cetuximab increases the efficacy of BKM120 in R/M-SCCHN. **Conclusions:** BKM120 showed modest efficacy in R/M SCCHN.A co-clinical trial provided a rationale to combine BKM120 and cetuximab for the treatment of R/M-SCCHN. Clinical trial information: NCT01527877.

6050 Poster Session (Board #373), Sat, 1:15 PM-4:45 PM

Response-adapted volume de-escalation (RAVD) of radiotherapy (RT) using induction chemotherapy (IC) in locally advanced head and neck squamous cell cancer (LA-HNSCC). *First Author: Victoria Meucci Villaflor, University of Chicago Med Ctr, Chicago, IL*

Background: Risk stratified treatment approaches are needed in LA-HNSCC. This study determined if RT volumes can be significantly reduced in IC responders without compromising disease control. **Methods:** Patients (pt) with measurable LA-HNSCC regardless of HPV status were treated with 2 cycles of IC (cisplatin 75 mg/m2, paclitaxel 175 mg/m2 day 1, and weekly cetuximab, with or without everolimus). Response to IC determined the extent of RT reduction. Pt with "good" response (GR), $\geq$ 50% reduction in the sum of gross tumor diameters, received TFHX (paclitaxel, fluorouracil, hydroxyurea, and twice daily RT to 75 Gy), with the planning target volume (PTV1) encompassing exclusively gross disease (RAVD). Pt with $<$ 50% response (NR) were treated with volumes encompassing PTV1 and the next nodal station at risk (PTV2) to 45 Gy, followed by a sequential boost to PTV1 to 75 Gy. **Results:** 94 pt were enrolled 5/2010 – 3/2014, median age 58 (range 27-76), 84% male, 58 pts HPV+ oropharynx (OP), 11 pt HPV- OP, 53% $>$10pk yrs tobacco use, 97% stage IV (56% T3/T4, 84% $\geq$ N2b). Everolimus was discontinued for futility at interim analysis after 25 pt. There were 37 (39%) GR to IC.At a median follow-up of 2 years, 79 pts are alive, 20 patients experienced failure. Site of first failure was locoregional in 10 (1 GR, 9 NR), distant in 7 (2 GR, 5 NR), and both in the remaining 3 pt (1 GR, 2 NR). Ultimate LRC was 91.5% on intention to treat analysis. Of 15 pts who experienced a component of LRF at any time, 14 (2 GR, 12NR) were within the RT treatment volume. One GR experienced LRF both within and outside the treated RT volume. Acute grade 3+ toxicities included 10% neutropenia, 22% dermatitis, 53% stomatitis. Rate of gastrostomy tubes (PEG) placement was 24% less during RT and 14% less at 1-yr follow up in RAVD pt. **Conclusions:** RAVD is a novel approach that uses response to IC to guide extent of RT volume reduction in both HPV (+) and (-) LA-HNSCC. In this trial, it appears that outcomes with RAVD are not compromised and long term toxicity may be improved. Further investigation is warranted. Clinical trial information: NCT01133678.

	1-year	2-year
OS	88.4% + 3.5	80.8% + 4.6
PFS	87.6% + 3.5	79.1% + 4.6
GR- PFS	89% + 5.1	86% + 5.8
NR-PFS	79% + 5.8	70% + 7.3

6051 Poster Session (Board #374), Sat, 1:15 PM-4:45 PM

Randomized phase II study of cabazitaxel versus methotrexate in patients with recurrent or metastatic squamous cell carcinoma of the head and neck (SCCHN) previously treated with platinum-based therapy. *First Author: Sylvie Rottey, Ghent University Hospital, Ghent, Belgium*

Background: Cabazitaxel (caba) is a second-generation taxane that improves overall survival (OS) of patients with metastatic castrate resistant prostate cancer who progress on/after docetaxel. Caba has activity in SCCHN cell lines as well as in taxanes-resistant cell lines. We investigated cabazitaxel in recurrent SCCHN patients. **Methods:** Patients with non-curable SCCHN with an ECOG 0-2 and progressive disease within 1 year after platinum-based therapy were randomized between caba every 3 weeks (1st cycle : 20 mg/m2, increased to 25mg/m2 for the subsequent cycles, if no adverse event (AE) $>$ grade 3 during the 1st cycle) and methotrexate (MTX) (40 mg/m2/week). Stratification parameters were ECOG PS (0-1vs 2) and prior chemotherapy given for palliation versus the curative treatment. The primary endpoint was the progression free survival rate (PFSR) at 18 weeks (central review). This trial was a randomized phase II trial (P0 = 0.15, P1 = 0.3, a = 0.1, b = 0.1; Fleming one stage). **Results:** 101 patients (53 in caba and 48 in MTX) were randomized. The median age was 58 years (range 46-80), 63% had received prior platinum for recurrent disease and 37% as part of the multimodal therapy. 17% were ECOG PS 2. 37% had been previously treated with taxanes. PFSR at 18 weeks was 13.2 % (95% IC : 5-25%) for caba and 8.5% (95% IC : 2-20%) for MTX. Median PFS was 1.9 months in both arms. Median OS was 5 and 3.6 months for caba and MTX, respectively. No objective responses were recorded in both arms. More patients experienced Serious AE in caba than in MTX (54 vs 34%). The most common grade ¾ AE in the caba arm was febrile neutropenia (17.3%). Otherwise, the toxicity profile was as expected in both arms. **Conclusions:** This study did not meet the primary endpoint. Caba has low activity in recurrent SCCHN. Clinical trial information: NCT01528163.

6052 Poster Session (Board #375), Sat, 1:15 PM-4:45 PM

Predictive and prognostic values of post chemoradiotherapy PET/CT and the effect of salvage surgery on survival in head and neck squamous cell carcinoma (HNSCC). *First Author: Ryul Kim, Seoul National University Hospital, Seoul, Korea, Seoul, South Korea*

Background: The accuracy of ^{18}F-fluorodeoxygluocose positron emission tomography/computed tomography (PET/CT) for predicting immediate failure after radical chemoradiotherapy (CRT) in HNSCC remains poorly characterized. The purpose of this study was to evaluate 1) predictive and prognostic values of PET/CT for immediate failure after CRT, and 2) their impact on clinical decision making for salvage surgery. **Methods:** From 2005 to 2013, medical records of 132 consecutive LA-HNSCC patients who received radical CRT were analyzed. PET/CTs were taken before CRT and 3-months after CRT. Immediate failure was defined residual disease or locoregional/ systemic relapse within one year. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of SUV for predicting immediate failure were estimated. Overall survival (OS) of patients who had/had not salvage surgery according to SUV were compared. **Results:** Of the 132 patients, 71 (53.8%) achieved metabolic complete response (mCR) in post CRT PET/CT. mCR group had better OS comparing with non-mCR group (3-year OS rate 95.8% *vs.* 66.6%, $P < 0.001$), as well as progression-free survival (PFS) (3-year PFS rate 89.5% vs. 56.9%, $P < 0.001$). Immediate failure occurred in 4/71 patients with mCR, 24/61 patients with non-mCR ($P < 0.001$). Among the various metabolic values, the post CRT maximum SUV (postSUVmax) was found to be optimal for predicting immediate failure with corresponding cutoff point of 3.9. The area under the receiver operating curve was 0.82 (95% confidence interval [CI] 0.73-0.92). The sensitivity, specificity, NPV, and PPV were 71.4%, 83.7%, 91.6%, and 54.1%, respectively. Salvage surgery was conducted in 9 of 37 patients with postSUVmax $\geq$ 3.9. There was no significant difference in OS by immediate salvage surgery based on post CRT PET/CT compared with no immediate salvage operation (3-year OS rate 66.7% *vs.* 58.1%, $P = 0.719$). **Conclusions:** Post CRT PET/CT has prognostic value for OS and is useful for predicting immediate failure with high NPV. However, early detection of immediate failure and salvage surgery based on post CRT PET/CT does not seem to lead OS benefit.

6053 Poster Session (Board #376), Sat, 1:15 PM-4:45 PM

Quality of life (QOL) in a phase III randomized trial of standard fractionation radiotherapy (SFX) with concurrent cisplatin (CIS) versus accelerated fractionation radiotherapy (AFX) with panitumumab (PMab) in patients (pts) with locoregionally advanced squamous cell carcinoma of the head and neck (LA-SCCHN): NCIC Clinical Trials Group HN.6 (NCT00820248). *First Author: Jolie Ringash, Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Addition of concurrent anti-EGFR monoclonal antibody to radiotherapy alone did not worsen QOL (Curran 2007). We compared standard chemoradiotherapy (cRT) to bioradiotherapy (bRT). **Methods:** Pts with T any N+M0 or T3-4N0M0 untreated LA-SCCHN were randomized 1:1 to receive SFX (70Gy/35/7 weeks) plus CIS at 100 mg/m^{2}intravenous (IV) for 3 doses on weeks 1, 4 and 7 versus AFX (70Gy/35/6 weeks) plus the anti-EGFR monoclonal antibody PMab at 9 mg/kg IV for 3 doses on weeks -1, 3 and 6. QOL was collected at baseline, end of RT, and 2, 4, 6, 12, 24 and 36 months post-RT using validated instruments FACT-H&N, MDADI and SWAL-QOL. All analyses were intent-to-treat. We hypothesized a 6-points more favourable change in FACT-H&N score from baseline to 1 year post-treatment in the bRT arm relative to cRT. **Results:** From 12/2008 to 11/2011, 320 pts were randomized, 160 to cRT and 160 to bRT, with median follow-up of 46.4 (range: 0.1-64.3) months. Median age 56, 84% male, ECOG PS 0 (71%), 1 (29%). Primary site was oropharynx in 81% (p16 +68%, - 11%, missing 21%), larynx (11%), hypopharynx (6%), oral cavity (2%). Smoking history was $>$ 10 pack-years in 58%, $<=$ 10 in 12%; 28% were never-smokers. All compliance exceeded 80%. Baseline scores did not differ by arm (cRT/bRT): FACT-H&N 110/110, MDADI Global 83/77, SWAL-QOL General 67/68. At 1 year, no statistically or clinically significant difference was seen between arms in FACT-H&N change from baseline: cRT 4.23, bRT 1.88, p = 0.129. Differences were only seen during the last week of radiotherapy, for (cRT: bRT): FACT-Physical Well-Being (-11.6, -10, p = 0.049), MDADI Physical subscale (-40.4, -33.9, p = 0.045), and SWAL-QOL Eating Duration (-61.2, -51.2, p = 0.02), Eating Desire (-53.3, -43.9, p = 0.031) and Mental Health (-42, -32.6, p = 0.009). No differences by arm on any scale were seen post-treatment. **Conclusions:** Despite transient benefits at the end of RT, the combination of PMab with AFX did not durably improve QOL as compared to SFX with CIS. Clinical trial information: NCT00820248.

6054 Poster Session (Board #377), Sat, 1:15 PM-4:45 PM

Long-term outcomes for radiotherapy alone verse combined chemoradiotherapy for patients with stage II nasopharyngeal carcinoma in the era of intensity-modulated radiotherapy. *First Author: Man Hu, Department of Radiation Oncology, Shandong Cancer Hospital, Jinan, China*

Background: The use of chemotherapy (CT) in the treatment of stage II nasopharyngeal carcinoma (NPC) is controversial. And the reports especially about intensity-modulated radiotherapy (IMRT) have been limited. The purpose of this study is to evaluate the long-term survival outcomes for stage II NPC treated with radiotherapy alone verse combined chemoradiotherapyin the era of IMRT. **Methods:** We reviewed records between January 2002 and December 2013 and identified 182 patients who were histologically diagnosed as stage II NPC received RT with or without CT in Shandong Tumor Hospital. Among these patients, 52 were restaged $T_2N_0M_0$ and the other 130 were restaged $T_{1\text{-}2}N_1M_0$. One hundred and fifty-nine (38 in $T_2N_0M_0$ and 121 in $T_{1\text{-}2}N_1M_0$) received RT with CT (RT/CT) and 23 (14 in $T_2N_0M_0$ and 9 in $T_{1\text{-}2}N_1M_0$) underwent RT alone. The overall survival (OS), progression-free survival (PFS), locoregional failure-free survival (LRFF), and disease metastasis-free survival (DMF) were calculated with Kaplan-Meier method. **Results:** With a median follow-up of 63.6 months (range 9.4 to 145.7), the 3-year, 5-year and 10-year OS of all stage II patients were 93.2%, 87.5% and 65.4%. For patients with staged $T_2N_0M_0$, the corresponding rates were 92.3%, 89.9%, 82.6% and for those with $T_{1\text{-}2}N_1M_0$, they were 93.6%, 86.6%, and 63.2%, respectively. No significant difference in OS, PFS, LRFF and DMF were observed between RT/CT group and RT alone group ($p = 0.217, 0.768, 0.340$ and 0.415, *respectively*). All locoregional recurrence occurred in the first 3 years and all distant metastases were developed in patients staged $T_{1\text{-}2}N_1M_0$, referring more aggressive therapy such as chemotherapy may be indicated for these patients. **Conclusions:** This is the largest cohort of patients with stage II NPC in the era of IMRT with long follow-up. Chemotherapy showed no additional benefit for patients with stage II NPC. Patients staged $T_2N_0M_0$ had an excellent outcome treated with RT alone. And for those staged $T_{1\text{-}2}N_1M_0$ who had a higher risk for distant metastasis, additional chemotherapy may be perferred.

6055 Poster Session (Board #378), Sat, 1:15 PM-4:45 PM

Concurrent chemoradiation using weekly versus tri-weekly cisplatin in locally advanced squamous cell carcinoma of the head and neck (SCCHN): A comparative analysis. *First Author: AMR MOHAMED, Morehouse School of Medcn, Atlanta, GA*

Background: Cisplatin based chemoradiation (CRT) is the standard of care for most patients with locally advanced SCCHN. We conducted a systemic review to compare the efficacy and safety profile of weekly versus tri-weekly cisplatin administration in patients with locally advanced SCCHN **Methods:** All prospective studies between 1970- 2013 were independently identified by three authors for inclusion. Studies were excluded if induction therapy was part of the treatment regimen, 5-FU or other targeted therapy was used, cisplatin has been used intra-arterially, orally or in the post-operative setting or if the total dose of cisplatin was less than 180mg/m^2, or radiation dose of less than 60 GY. Clinical outcomes were extracted and analyzed using weighted estimates. Two-tailed T-test was used for all comparisons with a significance level of 0.05 **Results:** Out of 120 studies, 23 with a total of 2,303 patients qualified for inclusion. The number of patients treated with weekly cisplatin was 915 (84% males) and tri-weekly was 1388 (84% males). Both groups received median dose of radiation of 70 Gy. Overall response rate for weekly cisplatin was 88% (CI 0.73-0.95) and 63.5% (CI 0.47-0.76) for tri-weekly cisplatin (P = 0.06). The 2-y, 5-y survival rate (SR) and weighted median overall survival (OS) for weekly vs. tri-weekly cisplatin were 89% vs. 75% (P = 0.28), 81% vs 63% (P = 0.18), and 28 vs 27 mos. (P = 0.33), respectively. The 2-y PFS rate was 81% vs 62%, P = 0.26 for weekly and tri-weekly cisplatin, respectively while locoregional failure free rate was 39% (CI 0.16- 0.67) vs. 44% (CI 0.24-0.65); P = 0.8. Grade 3-5 toxicity was 46% in weekly vs 56.5% in tri-weekly cisplatin (P = 0.23) **Conclusions:** Weekly cisplatin combined with radiation in locally advanced SCCHN is comparable in efficacy and safety to tri-weekly based regimens. Our analysis provides supportive evidence for the use of either weekly or triweekly regimens. Based on our results, tolerability ought to be a key factor in determining the choice of cisplatin schedule in locally advanced SCCHN

6056 Poster Session (Board #379), Sat, 1:15 PM-4:45 PM

Genomic landscape of salivary gland tumors. *First Author: Sheryl Krevsky Elkin, N-Of-One, Inc., Lexington, MA*

Background: Effective targeted treatment options for advanced salivary gland tumors are lacking. In order to better understand these tumors, we assessed their genomic landscape. **Methods:** We studied 117 patients with salivary gland tumors that were, on physician request, tested in a Clinical Laboratory Improvement Amendments (CLIA) laboratory (Foundation Medicine, Cambridge, MA) using next-generation sequencing (182 or 236 genes), and analyzed by N-of-One, Inc. (Lexington, MA). **Results**: There were 354 total aberrations, with 240 distinct aberrations identified in this patient population. Only 10 individuals (8.5%) had a molecular portfolio that was identical to any other patient (with four different portfolios amongst the ten patients). The median number of aberrations/patient was three (range, 0 to 10). The most common abnormalities involved the *TP53* gene (36/117 [30.8% of patients]), cyclin pathway (*CCND1*, *CDK4/6* or *CDKN2A/B*) (31/117 [26.5%]) and PI3K pathway (*PIK3CA, PIK3R1*, *PTEN* or *AKT1/3*) (28/117 [23.9%]). In multivariate analysis, statistically significant co-existing aberrations were observed as follows: *TP53* and *ERBB2* ($p = 0.01$), cyclin pathway and *MDM2* ($p = 0.03$), and PI3K pathway and *HRAS* ($p = 0.0001$). We were able to identify possible cognate targeted therapies in most of the patients (107/117 [91.5 %]), including FDA-approved drugs in 80/117 [68.4%]. **Conclusions:** Salivary gland tumors are characterized by multiple aberrations that mostly differ from patient to patient. Significant associations between aberrations in *TP53* and *ERBB2*, the cyclin pathway and *MDM2,* and *HRAS* and the PI3K pathway were identified. Most patients had actionable alterations. These results provide a framework for tailored combinations of matched therapies.

6057 Poster Session (Board #380), Sat, 1:15 PM-4:45 PM

The phase III clinical study about the effect of Kangfuxin Solution (Chinese herbal medicine compound preparation) on the radiation induced oral and upper gastrointestinal mucositis in nasopharyngeal carcinoma patients. *First Author: Jin Yi Lang, Sichuan Cancer Hospital and Institute, Chengdu, China*

Background: The incidence of oral mucotitis was high in NPC patients treated with radiation. Till now, there was no efficient drug to prevent and treat it. Kangfuxin solution was the Chinese herbal medicine compound preparation, and it could promote angiogenesis and repair mucosa. We aim to observe the effect of it on radiotherapy-induced oral mucositis (OM) and upper gastrointestinal mucositis in NPC patients. **Methods:** 240 pathological confirmed squamous NPC patients from five multi-centers clinical departments were included in this study. They were randomized divided into the control group and treatment group in. Stage I, II, III and IV were all included (AJCC 2010). All the patients received radical chemoradiotherapy. The treatment group used the traditional Chinese medicine (Kangfuxin Solution, 10ml tid) for mouthwash from the beginning of radiotherapy. The control group used Compound Borax Solution (10ml tid) for mouthwash. CTCAE v3.0 and verbal rating scales (VRS) was used to evaluate the incidence and OM grade, upper gastrointestinal mucositis and the pain grade during in different phases of radiation. **Results:** 230 effective patients were used for clinical effects evaluation in the study. Compared to control group, the incidence and grade of OM was significantly lower in treatment group ($p< 0.01$). The time from beginning of radiation to different grade of mucositis occurance (Grade 1, 2, 3) was longer in treatment group ($p< 0.05$), and the accumulated radiation dose was also higher in treatment group comparing to the control group ($p< 0.05$). For upper gastrointestinal mucositis and pains, the grade was lower in treatment group during radiation comparing to the control group ($p< 0.05$). There was no side effect of Kangfuxin solution in the study. **Conclusions:** Kangfuxin solution could prevent and treat the radiotherapy-induced oral and upper gastrointestinal mucositis to some extent. The incidence and grade were all decreased in the Kangfuxin group. This traditional Chinese medicine was safe and effective, and it might be widely used in the clinical practice in the future.

6058 Poster Session (Board #381), Sat, 1:15 PM-4:45 PM

Mucoadhesive clonidine (Clonidine Lauriad) in the prevention of severe radiomucositis in head and neck cancer patients: A phase II randomized trial. *First Author: Jordi Giralt, Hopital General Val D Hebron Barcelone, Barcelone, Spain*

Background: Oral mucositis (OM) is the most frequent and severe complication of chemoradiotherapy (CRT) in head and neck cancer patients. There is currently no effective mechanistically-targeted intervention for CRT-induced OM. NF-κB plays a central role in the signaling cascades and pathways responsible for OM. Clonidine reduces NF-κB activation and the subsequent expression of pro-inflammatory cytokines. In preclinical studies, topical clonidine reduced the incidence and duration of severe OM (SOM). The safety and efficacy of 2 doses of clonidine MBT were evaluated in patients with head and neck cancer receiving postoperative CRT. **Methods:** This phase 2, multicenter, double-blind, randomized, placebo-controlled, 3-arm study compared clonidine MBT 50μg, 100μg, and placebo. Clonidine MBT and matching placebo were applied to the gum once daily 1-3 days prior to RT until the end of CRT. The primary endpoint was the cumulative radiation dose at the onset of SOM (WHO grade 3 or 4) analyzed by the Kaplan-Meier method and the log-rank test. Safety was evaluated by monitoring AEs, clinical laboratory parameters, vital signs, and physical examinations. **Results:** Clonidine MBT was administered to 121 patients and placebo to 62. SOM developed in 45.3% of patients in the clonidine MBT group and in 60.0% of patients in the placebo group ($p = 0.064$). Patients developed SOM at a median radiation dose of 60.0 Gy and 48.0 Gy for the clonidine MBT and placebo groups, respectively (HR = 0.754 [0.484; 1.175]; $p = 0.211$). The percentage of AEs was similar between placebo (98.4%) and clonidine MBT groups (90.8%) with less nausea (49.6% vs 71%) and dysphagia (32.8% vs 48.4%) in the clonidine MBT groups vs placebo. **Conclusions:** Here, we present for the first time, that clonidine MBT treatment in head and neck cancer patients undergoing postoperative CRT reduces SOM with minimal toxicity. However not statistically significant, the observed differences in the incidence and time to occurrence of SOM support the initiation of future confirmatory studies. Clinical trial information: NCT01385748.

6059 Poster Session (Board #383), Sat, 1:15 PM-4:45 PM

Molecular profiling of tumour budding to implicate TGF-β mediated epithelial-mesenchymal transition as a therapeutic target. *First Author: David Hebbelstrup Jensen, Rigshospitalet, Copenhagen, Denmark*

Background: Tumor budding is an adverse prognostic factor in many types of cancer and understanding of the molecular basis of this phenomenon may provide new therapeutic options. **Methods:** The number of tumor buds in 199 oral squamous cell carcinoma (OSCC) patients was correlated to metastases, disease-free and overall survival. Tumor buds and paired central-tumor areas were laser-capture-microdissected from 5 OSCC specimens and examined with RNA-sequencing and miRNA-qPCR arrays. Results were validated with immunohistochemistry in 199 and *in situ* hybridization (ISH) in 20 OSCC samples. **Results:** The number of tumor buds was predictive of the presence of lymph node metastasis at presentation, and was an *independent* predictor of overall survival. Compared to cells in the central parts of the tumors, budding cells exhibited a particular gene expression signature comprising factors involved in epithelial-to-mesenchymal transition (EMT) and activated TGF-β signaling. Transcription factors *ZEB1* and *PRRX1* were upregulated concomitantly with a decreased expression of mesenchymal-to-epithelial (MET) transcription factors such as *OVOL1* in addition to Krüppel-like factors and Grainyhead-like factors. Moreover, the *miR-200* family members, was identified to be down-regulated in budding tumor cells. Five markers of the EMT/MET process were validated with immunohistochemistry and ISH. **Conclusions:** Taken together the results imply that therapeutics based on the inhibition of TGF-β signaling may prove useful in the treatment of oral squamous cancers.

6060 Poster Session (Board #384), Sat, 1:15 PM-4:45 PM

A randomized phase II trial of the MET inhibitor tivantinib + cetuximab versus cetuximab alone in patients with recurrent/metastatic head and neck cancer. *First Author: Everett E. Vokes, Department of Medicine, University of Chicago, Chicago, IL*

Background: MET signaling has been proposed as a mechanism of resistance to anti-EGFR therapy. MET expression is common in Head and Neck Squamous Cell Carcinomas (HNSCC) (*Seiwert et al, Cancer Res 2009*). We compared the oral MET inhibitor tivantinib (ARQ197) (T) in combination with cetuximab (C), with C monotherapy, in patients (pts) with recurrent/metastatic (r/m) HNSCC. **Methods:** 78 cetuximab-naïve pts after platinum failure were enrolled from 2012-2014, 40 on the T+C arm, and 38 on the C control arm. 31 pts (40%) were HPV-positive/p16-positive oropharyngeal (OP) cancers. T was given orally 360mg BID, C 500mg/m2 every two weeks. Cross-sectional imaging was performed every 8 weeks. Primary outcome was response rate (RECIST 1.1), and secondary outcomes included survival. **Results:** In 75 pts currently assessable for response, the response rate in the T+C arm was 8.5% (N = 3, including one CR), and 5.3% (N = 2) in the C alone arm (NS). Of note the response rate in HPV-positive/p16-positive oropharyngeal HNSCC pts was 0% in both arms in a combined 31 HPV-positive/p16-positive OP HNSCC. The response rate in HPV-negative pts was 12.5% (T+C)/ 8.5% (C) (NS). Median PFS in both arms was 4 months (NS), median OS 8 months (NS). Both treatments were well tolerated with a trend towards increased hematological toxicities in the T+C arm (12.5% of pts experience grade 3 leukopenia). **Conclusions:** Tivantinib + Cetuximab given in an unselected population of r/m HNSCC pts does not significantly improve response rate and survival. Consistent with other recent reports (Fayette et al ESMO 2014; Machiels et al ESMO 2014), EGFR inhibitors, including cetuximab appear to be less active/inactive in HPV-positive/p16-positive oropharyngeal HNSCC patients. Clinical trial information: NCT01696955.

6061 Poster Session (Board #385), Sat, 1:15 PM-4:45 PM

Evaluation of the impact of tumor HPV status on outcome in patients with locally advanced unresectable head and neck squamous cell carcinoma (HNSCC) receiving cisplatin, 5-Fluorouracil with or without docetaxel: retrospective analysis of EORTC24971 study. *First Author: Amanda Psyrri, Attikon Hospital National Kapodistrian University of Athens, Athens, Greece*

Background: EORTC 24971 was phase III trial demonstrating superiority of induction regimen TPF over PF, in terms of progression-free (PFS) and overall survival (OS) in locally advanced unresectable HNSCC. We conducted prospective-retrospective analysis with the aim to evaluate whether only HPV negative patients(pts) derive benefit from adding docetaxel to PF, in which case de-intensifying induction treatment in HPV+ patients could be considered. **Methods:** HNSCC specimens were collected from 1999 until 2002. Pre-therapy tumor biopsies (blocks or slides) were assessed for high risk (HR) HPV by p16 immunohistochemistry, PCR and quantitative PCR (qPCR). HPV DNA+ and/or p16+ tumors were subjected to in situ hybridization (ISH) and HPV E6/7 oncogene expression analysis by quantitative reverse transcriptase. The primary and secondary objectives were to evaluate the value of HPV/p16 status as predictive factor of treatment benefit in terms of PFS and OS, respectively. The predictive effect was analyzed based on the model used in the primary analysis of the study with the addition of a treatment by marker interaction term and tested at two-sided 5% significance level. **Results:** A total 120 of 358 patients had available tumor samples and 59 of them had oropharyngeal cancer. Median follow-up was 8.7 years and data updated through 2011. Sixteen of 119 (13%) evaluable samples were p16 positive and 20 of 79 (25%) evaluable tumors were HPV+ by PCR or qPCR. 12/31 pts assessed with HPV DNA ISH were positive and 12 of 28 pts assessed for HPV16mRNA were positive. The pre-planned analysis showed no statistical evidence of predictive value of p16/HPV status for PFS ($p = 0.287$) or OS ($p = 0.118$). **Conclusions:** The incidence of HPV positivity was low in EORTC 24971 cohort. In this prospective- retrospective analysis only powered to detect a large treatment by marker interaction there was no statistical evidence that treatment effect found overall was different in magnitude in HPV positive or HPV negative patients. These results do not justify selection of TPF versus PF according to HPV status.

6062 Poster Session (Board #386), Sat, 1:15 PM-4:45 PM

Treatment-associated mortality in head and neck cancer receiving chemotherapy and radiation: Meta-analysis of published trials. *First Author: Paolo Bossi, Head and Neck Cancer Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Concurrent chemoradiation (CTRT) produces an advantage in survival as compared with RT alone in locally advanced head and neck squamocellular cancer (HNSCC), while exposing patients (pts) to more severe toxicities. CTRT associated early mortality rate (during and until 90 days after treatment end) has not been consistently described. **Methods:** We conducted a meta-analysis of phase II-III randomized controlled trials (RCTs), observational studies or case series of HNSCC matching these criteria: concurrent CTRT; conducted in both radical and postoperative setting; published from 1/2000 to 6/2014; involving 100+ pts; with available toxicity data. Case series were considered only if presenting homogeneous treatment modalities. Early death incidence was analyzed and related to the following variables: radical vs postoperative setting, induction chemotherapy, poly vs mono CT concurrent with RT, conventional vs altered RT fractionation and study design (RCT vs observational vs case series). **Results:** Of 732 papers identified, 36 were included in the analyses (13 case series, 7 observational, 16 RCTs). Data regarding population, acute toxicities and deaths were extracted. A total of 9164 pts were considered with 183 early deaths (incidence rate 2.1% (95% CI 1.5% – 2.8%). Subgroups analyses on the basis of type of study design revealed differences between treatment-associated deaths reported in observational studies (0.8%; 95% CI 0.5% – 1.5%) compared to RCTs (2.7%; 95% CI 1.8% - 4.0%) and case series (2.7%; 95% CI 1.7% - 4.2%). A quantitative interaction seems to exist when the size of the effect is related to the radical intent with respect to postoperative setting (mortality rate 2.4% vs 0.2%; p value 0.03), but no interaction is found with induction chemotherapy, poly or mono CT and conventional or altered RT regimens. **Conclusions:** CTRT in HNSCC resulted in about 2% of early death, with higher rate in the radical setting. Observational studies underestimate mortality, probably due to bias selection or to inconsistent reporting. Early mortality rate reduction may imply better patient selection and more intensive supportive care programs.

6063 Poster Session (Board #387), Sat, 1:15 PM-4:45 PM

***MLH1*, *MSH2*, *MSH3* and *EXO1* polymorphisms and head and neck squamous cell carcinoma risk and prognosis.** *First Author: Gustavo Jacob Lourenco, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil*

Background: *MLH1* c.-93G > A, *MSH2* c.211+9C > G, *MSH3* c.3133G > A, and *EXO1* c.1765G > A polymorphisms have been associated with inefficient DNA mismatch repair (MMR). However, it is unknown whether they are involved with increased risk and prognosis of head and neck (HN) squamous cell carcinoma (SCC), therefore, this study aimed to clarify this issue. **Methods**: Genomic DNA from 450 HNSCC patients and 450 controls was analyzed by PCR-RFLP or real time PCR for discrimination of genotypes. The differences between groups were analyzed by χ^2 or Fisher's exact test. Multivariate analysis using the logistic regression model served to obtain age and tobacco status adjusted crude odds ratios with 95% confidence intervals (CI), and to assess the associations between genotypes and HNSCC. Relapse-free survival (RFS) and overall survival (OS) times were calculated using Kaplan-Meier estimate probabilities and differences between survival curves were analyzed by the log-rank test. The prognostic impact of genotypes was examined using univariate and multivariate Cox regression analyses. **Results**: *MSH2* GG plus *MSH3* GG (31.7% vs. 18.7%, P= 0.003) genotypes were higher in laryngeal SCC (LSCC) patients than in controls. Carriers of the respective combined genotype were under a 3.69 (95% CI: 1.54-8.81)-fold increased risk of LSCC. The median follow-up time of overall HNSCC patients enrolled in study was 46.0 months (1.6-166.0). At 60 months of follow-up, RFS was shorter in patients with *EXO1* GG genotype (54.8% vs. 61.1%, P= 0.03) and OS was shorter in patients with *MSH3* GG genotype (42.8% vs. 52.5%, P= 0.02) compared to those with other genotypes, respectively. After multivariate Cox analysis, patients with *EXO1* GG and *MSH3* GG genotypes had worst RFS (HR: 1.50, 95% CI: 1.03-2.20, P= 0.03) and OS (HR: 1.59, 95% CI: 1.19-2.13, P= 0.002) than those with the remaining genotypes, respectively. **Conclusions**: Our data present, for the first time, evidence that inherited *MLH1* c.-93G > A, *MSH2* c.211+9C > G, *MSH3* c.3133G > A, and *EXO1* c.1765G > A abnormalities of DNA MMR pathway are important determinants of HNSCC and predictors of patient outcomes. Our findings, once validated in additional studies, will contribute to personalize the therapy of HNSCC patients.

6064 Poster Session (Board #388), Sat, 1:15 PM-4:45 PM

Outcomes of head and neck squamous cell carcinomas (HNSCC) treated with reirradiation (RRT) at Mayo Clinic. *First Author: Kelly Kevelin Curtis, Mayo Clinic, Scottsdale, AZ*

Background: RRT is offered as definitive (DRRT) or post-operative (PRRT) treatment for patients (pts) with loco-regionally recurrent (LRR) or new primary (NP) HNSCC in previously irradiated volumes. We report the results of a retrospective chart review of all consecutive pts with LRR and NP HNSCC treated with DRRT and PRRT at Mayo Clinic. **Methods:** We included LRR and NP HNSCC pts treated with DRRT/PRRT from 2003-2011 at all Mayo Clinic campuses. Patient and treatment related data were collected. Loco-regional recurrence rate (LR) and distant metastases rate (DM) at 2 years, and overall survival (OS) from end of RRT using Kaplan-Meier methods, were calculated. **Results:** We identified 89 pts (68 M, 21 F). 67 pts had LRR; 22 NP. Treatment included salvage surgery with PRRT (47 pts) and DRRT (42 pts). 30 pts received concurrent chemotherapy (CT) with PRRT; 33 DRRT pts received CT. Median prior RT dose was 66 Gy (26.4 – 79.2 Gy). Median PRRT dose was 60 Gy (11 – 70 Gy). Median DRRT dose was 69.6 Gy (18 – 76.8 Gy). LR occurred in 42 pts (47%) after RRT; 35 pts (39%) had LR by 2 years (95% CI, 30 – 50%). DM occurred in 20 pts (22%) after RRT; 16 pts (18%) had DM by 2 years (95% CI, 11 – 27%). Median OS was 22.2 mos (95% CI, 17.0 – 29.8 mos), with 2- and 5-year OS 47% and 16%. No difference in OS between LRR- and NP-HNSCC or PRRT and DRRT was found. CT was associated with shorter time to LR (4.3 vs. 12.1 mos, $p = 0.008$), but not with time to distant metastases or OS. At last follow-up (median 78.1 mos) 21 pts (24%) were alive, with 43.3 mos (95% CI, 27.6 – 52.9 mos) median OS from time of LRR/NP. Among surviving pts, 2 cases of osteoradionecrosis (10%) and 1 carotid artery pseudoaneurysm with sentinel bleed (5%) were reported, with no reported spinal cord injuries. OS was better among 70 pts treated to at least 60 Gy ($n = 70$) vs. pts treated with less than 60 Gy (median OS 25.2 mos, 95% CI, 19.4 – 32.0 mos; vs. median OS 9.5 mos, 95% CI, 6.8 – 28.7 mos; $p = 0.06$). **Conclusions:** RRT cures a small number of pts. 2-year OS of LRR/NP HNSCC pts treated with RRT in the time frame of this study appears superior to published outcomes. Shorter time to LR among pts receiving CT warrants further study, but may signify selection bias toward more aggressive therapy for pts with high risk LRR/NP HNSCC.

6065 Poster Session (Board #389), Sat, 1:15 PM-4:45 PM

Use of chemotherapy with IMRT reirradiation: MDACC experience. *First Author: Mark A. Edson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The benefits of adding chemotherapy to radiation, combined with the ability to spare more normal tissue with conformal radiation techniques have led to an increased interest in reirradition of head and neck cancers (HNC). However, similar to the use of chemotherapy in unirradiated patients with HNC, the use and delivery of systemic therapy in the reirradiation setting is not standardized. We evaluated our 15-year institutional experience using intensity modulated radiation therapy (IMRT) for reirradiation of recurrent HNC, focusing on chemotherapy-related outcomes. **Methods:** We retrospectively reviewed the records of 206 patients treated between 1999-2014 with IMRT reirradiation to definitive doses ($>$ 60 Gy). The Kaplan-Meier method was used to estimate locoregional control (LRC), progression-free survival (PFS), and overall survival (OS). The log-rank test was used to compare variables of interest. **Results:** Median follow-up was 25 months. Of the 134 patients (65%) who received chemotherapy (CT), 124 (93%) received concurrent chemotherapy (CCT), and 50 (37%) received induction chemotherapy (iCT). The use of CT was associated with worse OS (5Y 35% vs 49%; $P = 0.04$), but not LRC (N.S.) or PFS (N.S.). The use of CCT was associated with improved LRC (5Y OS 55% vs 69%; $P = 0.05$) but not PFS (N.S.) or OS (N.S.). Sub-group analysis of patients who received CCT showed that the use of platinum-containing doublets ($n = 24$) was associated with improved LRC (5Y 82% vs 57%; $P < 0.05$). The use of iCT did not impact clinical outcomes. However, patients who experienced a radiographic complete response after iCT had improved 5-year PFS (5Y 43% vs 9%; $P < 0.01$) and OS (5Y 44% vs 18%; $P < 0.01$) but not LRC (N.S.). CT use was associated with increased grade 3 toxicity (5Y 59% vs 345; $P = 0.02$), and for those receiving concurrent chemotherapy platinum-based CCT was associated with increased grade 4-5 toxicity (28% vs 8%; $P < 0.05$). Prior CT use, and type or number of cycles did not affect clinical outcome or toxicity after reirradiation. **Conclusions:** Chemotherapy given concurrently with IMRT-based reirradiation for HNC appears to improve LRC but not OS. The potential for increased toxicity associated with combined modality treatment warrants careful patient selection.

Double blind multicenter phase III GORTEC trial evaluating the efficacy of oral immune modulating formulae therapy during adjuvant radiochemotherapy in head and neck squamous cell carcinoma (HNSCC). *First Author: Pierre Boisselier, Institut régional du Cancer Montpellier, Montpellier, France*

Background: A previous phase II study showed that an oral immunomodulating formula could reduce severe toxicities and increased survival for HNSCC with concomitant cisplatin and irradiation treatment (1). We conducted a double blind prospective phase III multicenter trial. **Methods:** In 20 GORTEC centers after surgery with curative intent and previous standard radiochemotherapy (2, 3), 180 patients were randomly assigned to receive oral supplementation (3 bags/day, a formula enriched with L-arginine, ω-3 fatty and ribonucleic acids *vs* an isocaloric isonitrogenous control) for 5 days before each cycle of cisplatin. Statistical analysis was done according to an intent-to-treat (ITT) and per protocol (PP) principle. Acute mucositis (RTOG and WHO scales) and 24-months survival were analyzed. **Results:** ITT included 172 patients and PP, the 109 patients with a product compliance $\geq$ 75%. No difference was identified one month after the end of radiochemotherapy on grade 3-4 mucositis, for ITT and for PP, with both scales, RTOG (p = NS) and WHO (p = NS). In accordance with the phase II study, disease-free survival was significantly improved by the immunomodulating formula ($p = 0.004$) in PP patients, and a statistical trend was observed in overall survival ($p = 0.07$). In ITT patients, both overall and disease-free survivals were not significant ($p = 0.22$ and $p = 0.07$, respectively). Median disease-free and overall survivals were not reached. **Conclusions:** Oral supplementation with an immunomodulating formula did not reduce grade 3-4 mucositis but showed significant increase of disease-free survival in product compliant patients (PP). Long term follow-up of our study along with further investigations are needed to confirm these findings and perhaps could open a new avenue for standard treatment of HNSCC. Is there a role for induction chemotherapy in the setting of concomitant chemoradiation in locally advanced head and neck cancer: A systematic review and meta-analysis of randomized controlled trials. *First Author: Aron Popovtzer, Davidoff Cancer Center, Rabin Medical Center, Petach Tiqva, Israel*

Background: :There is a controversy regarding the role of induction chemotherapy (IC) prior to concomitant chemoradiation (CCRT) in locally advanced head and neck cancer (LAHNC). We performed a systematic review and meta-analysis(MA) of all randomized controlled trials (RCTs) which assessed the addition of IC in this setting. **Methods:** We included RCTs that compared IC followed by CCRT to CCRT alone for LAHNC. The Cochrane Library, MEDLINE and conference proceedings were systematically searched (2000-11/2014). The primary outcome was overall survival (OS). Secondary outcomes were progression free survival (PFS), disease control (DC), complete response (CR) rate and adverse events. Relative risk (RR) for dichotomous data and hazard ratio (HR) for time to event data were estimated and pooled. **Results:** Five RCTs met the inclusion criteria, with a total of 1229 patients with stage III or IV LAHNC. Median age was 55y (35-75). IC consisted of docetaxel, platinum and 5FU (TPF) in 4 trials, and platinum-5FU (PF) in one trial. No statistically significant effect on OS was shown, though a trend towards the IC-CCRT group was observed - HR 0.85 (95%CI 0.71-1.02,$p = 0.07$). There was no significant difference in PFS HR 0.84 (0.57-1.24). Yet, patients treated with IC had a better DC compared to CCRT alone (HR of progression, treatment failure or death 0.64 (95%CI 0.52-0.8). The rate of CR improved with IC compared to CCRT, RR 1.66 (95%CI 1.02-2.69). The risk of any grade 3-4 adverse event, fever and neutropenia increased in the IC-CCRT group. The risk of mucositis (4 trials, 922 patients) increased with IC followed by CRT- RR 1.24 (95%CI 1.05-1.46, I2 of heterogeneity73%). In a sensitivity analysis using a random-effects model no such difference was shown RR 1.30 [0.91-1.85] **Conclusions:** MA of RCTs showed no significant effect on OS or PFS. However, the advantage in CR and DC, as well as a trend to improved OS in the IC group, imply that selected patients may benefit from the addition of IC. Since the patient population varied in the extent of disease, future studies are warranted to evaluate the role of IC in subpopulations of patients with LAHNC.

6069 Poster Session (Board #393), Sat, 1:15 PM-4:45 PM

Combination of everolimus and sorafenib in the treatment of thyroid cancer: Update on phase II study. *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Everolimus is an oral inhibitor of the mammalian target of rapamycin complex 1 (mTORC1). Laboratory data suggests that mTORC1 activity is required for the growth promoting effects of the oncoproteins RET/PTC, RAS, and BRAF in rat thyroid PCCL3 cells. Sorafenib, an oral kinase inhibitor with activity against multiple targets, is FDA-approved for the treatment of radioactive iodine-refractory (RAIR) thyroid cancer. We conducted a clinical trial evaluating everolimus plus sorafenib for RAIR follicular cell derived thyroid cancers (DTC) and medullary thyroid cancers (MTC). **Methods:** This single institution study used a two-stage phase II design and was initiated on 9/21/10. Primary objective was response rate. Eligible patients (pts) had progressive, RAIR/fluorodeoxyglucose (18-F)-avid, recurrent/metastatic, non-anaplastic, thyroid cancer; RECIST measurable disease. Sorafenib was given at 400 mg orally twice a day and everolimus at 5 mg orally once daily. 41 pts were enrolled; 38 were eligible for the primary endpoint of response and 3 were evaluable for toxicity only at the data cutoff date of 1/21/15. 7 pts are still on study. **Results:** Of the 41 eligible pts, median age-61 years (35-79). 15 patients received prior VEGF-targeted systemic therapy. Grade 4-5 adverse events at least possibly related to drug: grade 4- hepatic enzyme increase (1 pt): grade 4- Hyperglycemia (1 pt): grade 4-Hypertriglyceridemia (1 pt). Histology and response data by partial response, confirmed and unconfirmed, (PR), stable disease (SD), progression of disease (POD), and days on study (DOS) are shown in the Table. **Conclusions:** The combination of sorafenib and everolimus demonstrates activity that rivals the best reported data, and surpasses that for sorafenib alone, in all evaluated thyroid cancer subgroups. A randomized study of sorafenib +/- everolimus is indicated in both pts with DTC and MTC. Clinical trial information: NCT01141309.

Histology	#	PR	SD	POD	Median DOS (range)
Papillary	9	5 (56%)	3 (33%)	1 (11%)	484 (27-854+)
Hurthle Cell	9	7 (78%)	2 (22%)	0	553 (55-1419+)
Follicular	2	1 (50%)	1 (50%)	0	136 (80-192)
Poorly Diff	8	4 (50%)	4 (50%)	0	262 (142-863+)
MTC	10	4 (40%)	4 (40%)	2 (20%)	209 (31-1517+)
DTC only	28	17 (61%)	10 (36%)	1 (4%)	430 (27-1419+)
Total	38	21 (55%)	14 (37%)	3 (8%)	373 (27-1517+)

6070 Poster Session (Board #394), Sat, 1:15 PM-4:45 PM

Characteristics of PD-L1, PD-1 expressions and CD8+ tumor infiltrating lymphocyte in EBV-associated nasopharyngeal carcinoma. *First Author: Komkrit - Mahaprom, Ramathibodi Hospital, Bangkok, Thailand*

Background: Early phase clinical studies showed promising activities of anti-PD1/PD-L1 antibody in squamous cell carcinoma of head and neck (SCCHN). PD-L1 expression is a potential biomarker of these drugs. Tumor Infiltrating Lymphocyte (TIL) was a prognostic marker of HPV+ SCCHN and potentially associated with response of immunomodulatory drugs. Most clinical trials of anti-PD1/PD-L1 often excluded nasopharyngeal carcinoma (NPC). We evaluated characteristics of PD-L1 expression and CD8+ TIL for a future development of anti-PD1/PD-L1 antibody in NPC. **Methods:** NPC patients were identified through the Ramathibodi Cancer Registry database between 1/2007 and 12/2012. PD-L1 and PD-1 expressions were characterized by immunohistochemistry (IHC) from formalin-fixed paraffin-embedded tumor samples. PD-L1 expression was defined by using a cut-off of ≥1% (≥1-9%=1+, 10-49%=2+, ≥50%=3+). Mean number of CD8+TILs following the analysis of 2-4 images was assessed quantitatively by 2 individual pathologists blinded to outcomes. Tumor EBV status was analyzed by using EBV encoded RNA (EBER) in situ hybridization. **Results:** 119 NPC samples were analyzed. Overall, PD-L1 expression was positive in 72% (13% IHC 3+). PD1+ was observed in 11% of patients. Most patients had EBER+ tumors (96%). Characteristics were summarized in the table. PD-L1+ was highly observed in male (p=0.02). Mean CD8+ TIL count was significantly deceased with stage at diagnosis (p=0.02). There was no significant correlation between PD-L1 and CD8+ TILs observed. **Conclusions:** More than 70% of EBV+ NPC expressed PD-L1. These results support future development of anti-PD1/PD-L1 antibody in NPC.

Characteristics	PD-L1 (%) -	PD-L1 (%) +	P-value	Mean CD8+ TIL count (±SD)	P-value

A pilot, single arm, prospective trial using neoadjuvant rapamycin prior to definitive therapy in head and neck squamous cell carcinoma. *First Author: Keisuke Shirai, Medical University of South Carolina, Charleston, SC*

Background: Deregulated PI3K-AKT-mTOR signaling is one of the most common abnormalities in head and neck squamous cell carcinoma (HNSCC). We previously showed that mTOR inhibition with rapamycin significantly inhibited the growth of human HNSCC xenografts and oral cancers in multiple genetically-defined and chemically-induced mouse models. A pilot trial of neoadjuvant rapamycin treatment was developed to assess its effect on clinical response and mTOR signaling. **Methods:** Patients with untreated stage II-IVA HNSCC received 21 days of rapamycin treatment (15 mg on day 1, 5 mg on days 2-21) prior to definitive treatment with surgery or chemoradiation. Treatment responses were assessed clinically and radiographically with CT and FDG-PET. Pre- and post-treatment biopsies and blood were obtained for toxicity, immune monitoring and immunohistochemical assessment of mTOR signaling. **Results:** Sixteen patients (8 oral cavity, 8 oropharyngeal) completed rapamycin and definitive treatment (15-surgery, 1-chemoradiation). Half of patients were p16 positive. Fifteen of 16 patients showed clinical improvement. One patient had pathological CR. two met RECIST criteria for response (1 CR, 1 PR, 14 SD). Treatment was well tolerated with no grade 4 or unexpected toxicities. Two grade 3 toxicities (1 post-operative wound complication, 1 hypokalemia) and 3 grade 2 toxicities (1 wound infection, 1 mucositis, 1 hyperglycemia) were seen. The most common toxicity was grade 1 thrombocytopenia (n = 5). Two asymptomatic patients required dose reduction due to elevated rapamycin levels. No significant immune suppression was observed. The level of phosphorylated S6 (pS6) showed statistically significant decrease in all evaluable (13/16) patients (34-87% decrease). Inhibition of phosphorylated AKT^{S473} ($pAKT^{S473}$) was observed in 12/13 evaluable patients (27-97% decrease in 12 patients, 16% increase in one patient). **Conclusions:** Rapamycin treatment was well tolerated and resulted in significant clinical responses despite the brief treatment duration. Significant reduction in pS6 and $pAKT^{S473}$ supported successful inhibition of mTOR signaling. Clinical trial information: NCT01195922.

6072 Poster Session (Board #396), Sat, 1:15 PM-4:45 PM

A phase II study of everolimus (E) and sorafenib (S) in patients (PTS) with metastatic differentiated thyroid cancer who have progressed on sorafenib alone. *First Author: Marcia S. Brose, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Recently, S became the first drug FDA-approved in 40 years to treat progressive, RAI-refractory thyroid cancer. S inhibits VEFR, PDGFR, Kit and RET. With S, patients achieve a median PFS of 10.8 months. We observed that pts may progress in some sites while maintaining stability in others. We hypothesized that progression on S may depend on increased activity of the AKT/MTOR pathway. Therefore we conducted a Phase II study to see if the addition of everolimus (E), an oral mTOR inhibitor, to S would have activity in pts who had progressed on S alone. **Methods:** 35 pts with evidence of progression by RECIST criteria on S were enrolled. Pts were started on a dose of S 200mg/d lower than their previously tolerated dose, combined with E 5mg/d. Pts were followed for toxicity; if tolerated, the dose of E and then S were incrementally increased to a maximum daily dose of S 800mg/day and E 10mg/day. The primary endpoint was progression-free survival (PFS). Response was evaluated by RECIST every 8 weeks. **Results:** Of 35 pts enrolled, 33 were evaluable for PFS and response. 17 pts had papillary, 9 had Hu¨rthle Cell, 1 had follicular and 6 had poorly differentiated subtypes. 13 pts were successfully dose escalated to full dose of both agents: S 800mg/d and E 10mg/d, 5 pts reached S 600mg/d and E 10mg/d, and 8 pts reached S 600mg/d and E 7.5 mg /d. While increased severity of hand foot skin reaction was anticipated, it was rarely seen. The median PFS was 13.7 mos (95% CI: 7.15-24.75). No complete responses were observed, 1 pt achieved a partial response and 18 achieved a best response of stable disease for > = 6 mos. for a clinical benefit rate (CR+PR+SD > = 6 mos.) of 58%. **Conclusions:** The addition of everolimus to sorafenib at the time of progression was tolerable and allowed pts an additional median of 13.7 mos. of disease stability. The addition of everolimus did not result in dose-limiting hand foot skin reaction as had been seen in prior studies in which both were started at the same time, demonstrating that these agents may be successfully combined if started sequentially. Our approach may have implications in other diseases where the combination of a VEGFR inhibitor and mTOR inhibitor may have added activity. Clinical trial information: NCT01263951.

6073 Poster Session (Board #397), Sat, 1:15 PM-4:45 PM

Landscape of genetic alterations in non-smoking patients with oral tongue carcinoma: An analysis of The Cancer Genome Atlas (TCGA) head and neck squamous cell carcinoma data. *First Author: Nabil F. Saba, Winship Cancer Inst Emory Univ, Atlanta, GA*

Background: Despite the overall decreased incidence of oral cavity carcinoma a recent surge in the diagnosis of oral tongue cancers (OTC) in younger predominantly female non-smokers has been noted. We sought to explore the landscape of mutational and transcriptional alterations in non-smoking patients with OTC using the TCGA data. **Methods:** We queried the TCGA data utilizing a novel R-based software Cancer Genome ExploreR (http://sourceforge.net/projects/cancergenomeexplorer/) to compare coding mutations, mutation spectra, gene expression and copy number profiles between groups of interest. **Results:** Sixty two female lifelong non-smokers or current reformed smokers ($>$ 15 years) having cancers of the oral cavity including OTC (n = 29), oral cavity not otherwise specified (n = 17), floor of mouth (n = 6), alveolar ridge (n = 4), buccal mucosa (n = 3) or hard palate (n = 3) were identified in the TCGA clinical data. Seventy life-long non smoker or reformed smoker male with a similar distribution of oral site cancers were also identified (n = 33, 18, 5, 8, 5, 1 cases respectively). Female versus male OTC exhibited very similar genomic profiles, as did a combined analysis of all of the above sites between males and females. The genomic differences we did detect came primarily from expression and mutation of X and Y chromosome genes. However, male and female OTC (n = 62) had several genomic features that distinguished them from other oral cavity sites (n = 77). These included relative differences in the frequency of CDKN2A, CASP8 and NOTCH1 coding mutations and differential rates of deletion of chromosomes 11q and 13q. **Conclusions:** Our results point to genomic differences in non-smoking OTC patients when compared to all other oral cavity tumors from non-smokers regardless of gender. These results present an opportunity to develop better understanding of the biology of OTC in non-smokers in addition to an exploration of targeted therapeutic approaches in this group. (This research was supported by a grant NCI R21 CA182661-01A1 to NFS and GZC).

6074 Poster Session (Board #398), Sat, 1:15 PM-4:45 PM

Phase I study of cetuximab, intensity-modulated radiotherapy (C-IMRT), and intratumoral EGFR antisense (AS) DNA in patients with locally advanced head and neck cancer (HNC). *First Author: Julie E. Bauman, University of Pittsburgh, Pittsburgh, PA*

Background: Epidermal growth factor receptor (EGFR) is a validated therapeutic target in HNC. The combination of C-IMRT is a standard for locally advanced HNC; however, failure of locoregional control (LRC) remains the primary cause of cancer-related death. Intratumoral injection of EGFR-AS DNA oligonucleotide was safe and associated with promising lesional response in a phase I study. We conducted a phase I trial to evaluate the safety of C-IMRT and EGFR-AS DNA injections in patients with locally advanced HNC. **Methods:** Eligible patients had Stage IVa-IVc HNC, ECOG 0-2, no prior RT, and a measurable lesion accessible for repeated injection. Treatment course was 9 wks. C was loaded wk 1 then administered 250 mg/m^2/wk for 8 wks. EGFR-AS DNA (11.92mg/1.78mL; no dose modifications) was injected weekly into the selected lesion starting wk 1 until complete response (CR) or a maximum of 7 injections. IMRT (70 Gy; 2 Gy/fraction) was delivered wks 3-9. Biopsies of injected lesions were obtained at baseline and after 2 injections. The primary endpoint was safety; a $\geq$ 20% rate of grade 3/4 adverse events (AEs) attributable to EGFR-AS DNA was considered unsafe. EGFR signaling in paired biopsies was evaluated by reverse phase protein array (RPPA). **Results:** Between Apr 2013 and June 2014, 6 patients (4 male; 2 female) were treated. Stage: IVa (4); IVc (2). Primary site: oropharynx (4; HPV+/HPV-/HPV$_{unk}$ 1/1/2); hypopharynx (1); oral tongue (1). Lesion selected for injection: lymph node (LN; 2); oropharynx (3); oral tongue (1). No grade $\geq$ 2 AEs were attributed to EGFR-AS DNA; 2 of 6 reported grade 1 injection site pain. Expected rates of acneiform rash, RT dermatitis, and mucositis were observed. All patients completed IMRT and 8-9 doses of C. Best lesional response was CR (4), partial response (1), or progression (1). A patient with T2N2cM1 hypopharynx primary had CR in the injected 5 cm LN but only PR in a contralateral 1.5 cm non-injected LN. RPPA results will be presented. **Conclusions:** The combination of C-IMRT plus EGFR-AS DNA injections was well tolerated. The lesional response pattern is intriguing. A phase II efficacy trial evaluating LRC as the primary endpoint is planned. Clinical trial information: NCT00903461.

6075 Poster Session (Board #399), Sat, 1:15 PM-4:45 PM

Effect of the extent of lymph node dissection on overall survival in patients treated for oral cavity squamous cell carcinoma. *First Author: Jennifer Lobo Shah, Stanford Cancer Inst, Stanford, CA*

Background: Limited recently published data has suggested that resection of at least 18 lymph nodes improves outcomes for patients treated with oral cavity cancer. We sought to determine if further survival benefit could be derived from a more extensive nodal dissection in these patients. **Methods:** We retrospectively reviewed 551 consecutive patients treated at the Stanford Cancer Institute from 1998-2013 for oral cavity squamous cell carcinoma with surgical resection followed by adjuvant therapy if indicated. Patients treated for recurrent disease and metastatic disease were not included. Of this cohort, 278 patients underwent neck dissection as a component of their initial surgical management. For this study, we defined a select neck dissection as 0-19 lymph nodes, a standard dissection as 20-39 lymph nodes, and a comprehensive dissection as 40 or more lymph nodes. **Results:** Within the 278 patients who underwent neck dissection, 85 patients had a select dissection, 100 patients had a standard dissection, and 93 patients had a comprehensive dissection. In this cohort, there was an overall survival benefit to having a comprehensive dissection compared to a select or standard dissection (p = 0.05). Of the patients who underwent adjuvant radiation therapy (RT), 24% had a select dissection, 35% had a standard dissection, and 40% had a comprehensive dissection. For patients who had RT, there was overall survival benefit to having a comprehensive dissection compared to select or standard (p = 0.05). This survival benefit was further seen patients with T2 and T3 tumors (p = 0.005, p = 0.04), N2 nodal involvement (p = 0.01), extracapsular extension (p = 0.04), and perineural invasion (p = 0.06). The extent of neck dissection did not impact survival for patients who did not undergo radiation therapy, even when analyzed by T and N stage. **Conclusions:** For patients requiring radiation therapy for oral cavity squamous cell carcinoma, a comprehensive neck dissection including the resection of at least 40 lymph nodes confers overall survival benefit.

6076 Poster Session (Board #400), Sat, 1:15 PM-4:45 PM

Outcomes of elderly patients treated for oral cavity squamous cell carcinoma. *First Author: Jennifer Lobo Shah, Stanford Cancer Inst, Stanford, CA*

Background: Implementing standard treatment recommendations for oral cavity cancer in the elderly population can be challenging due to the comorbidities seen in this population. We sought to compare outcomes in patients of age 70 years or older compared to their counterparts. **Methods:** We retrospectively reviewed 551 consecutive patients treated at the Stanford Cancer Institute from 1998-2013 for oral cavity squamous cell carcinoma with surgical resection followed by adjuvant therapy if indicated. Patients treated for recurrent disease and metastatic disease were not included. Of this cohort, 188 patients were elderly, defined as age 70 years or above, and 363 patients were younger than age 70. Survival estimates were determined using the Kaplan-Meier method, and recurrence rates were determined using cumulative incidence estimates including competing-risk analyses. **Results:** At 2 years after diagnosis, overall survival was 55% in the elderly group compared to 75% in those younger than age 70 ($p < 0.0001$). Loco-regional recurrence at 2 years was 29% in the elderly group compared to 34% in the younger group (p = 0.09). Freedom from progression was 32% in the elderly group compared to 36% in the younger group (p = 0.11). Within the elderly group, 69 patients underwent neck dissection as a component of their initial surgical resection. Overall survival at 2 years was 50% for elderly patients who underwent neck dissection compared to 58% for elderly patients who did not (p = 0.09). **Conclusions:** Consistent with life expectancy, elderly patients age 70 years or older treated for oral cavity cancer had worse overall survival compared to younger patients. Loco-regional recurrence and freedom from progression, however, were lower in the elderly population. Less aggressive management may be acceptable in this population.

6077 Poster Session (Board #401), Sat, 1:15 PM-4:45 PM

Low pre-operative absolute monocyte count to predict overall survival benefit for oral cavity squamous cell carcinoma. *First Author: Timothy Bui, Stanford University, Stanford, CA*

Background: With the advent of immunotherapy, the role of the immune system in cancer patients is increasingly being investigated. The role of lymphocytes as indicators of the adaptive immune response has been reported; however, the relevance of the innate immune response is unclear. Monocytes are the precursor cells to dendritic cells and macrophages. As a crude metric, we sought to determine the predictive value of the pre-operative absolute monocyte count (AMC) in patients being treated for oral cavity squamous cell carcinoma. **Methods:** We retrospectively reviewed 551 consecutive patients treated at the Stanford Cancer Institute from 1998-2013 for oral cavity squamous cell carcinoma with surgical resection followed by adjuvant therapy if indicated. Patients treated for recurrent disease and metastatic disease were not included. The reference range for AMC is 0.3-0.95 K cells per microliter. For this study, a low AMC was defined as less than 0.5 K cells per microliter. Survival estimates were determined using the Kaplan-Meier method, and recurrence rates were determined using cumulative incidence estimates including competing-risk analyses. **Results:** In this cohort, 160 patients had a low AMC, and 391 patients had an AMC greater than or equal to 0.5 K cells per microliter. There was no statistically significant difference in T stage and N stage between patients with a low AMC compared to the remainder of the cohort. For the 119 patients who underwent adjuvant radiation therapy, those with a low AMC had improved overall survival at 2 years, 83% vs 53%, and at 5 years, 62% vs 33% ($p = 0.02$). For patients who did not undergo adjuvant radiation therapy, low AMC did not impact overall survival ($p = 0.24$). **Conclusions:** In addition to the adaptive immune system, the innate immune system may be relevant to cancer outcomes. Further investigation is required to understand the mechanisms leading to these observations.

6078 Poster Session (Board #402), Sat, 1:15 PM-4:45 PM

Patterns of CD8+ T-cell infiltration and immune escape mechanisms in head and neck cancer. *First Author: Vassiliki Saloura, University of Chicago, Chicago, IL*

Background: Immunotherapy with PD-1/PD-L1 axis blockade has shown promising preliminary results in patients with head and neck squamous cell carcinomas (HNSCC) (Seiwert ASCO 2014). Using a 12-gene chemokine expression signature (Harlin/Gajewski 2009) 33-47% of HNC have a T-cell inflamed phenotype (TCIP-High) characterized by CD8+ TIL enrichment and PD-L1 expression in both HPV(+) and HPV(-) HNC. In this study, we sought to identify patterns of CD8+ tumor infiltration and describe immune escape mechanisms. **Methods:** We evaluated the patterns of infiltration of CD8+ TILs in a subset of tumors ($N = 73$) from the Chicago HNC Genomics (CHGC) cohort using IHC. 58 were also stained for PD-L1 expression. 55 tissues were evaluated with dual CD8/FOXP3 staining. To assess potential mechanisms of immune escape, we interrogated the different patterns of CD8+ TIL infiltration in conjunction with the TCIP-high signature. **Results:** 27% (20/73) of CHGC tumors showed either no CD8+ T-cells (Immunologic Ignorance (II), 8%, 6/73) or CD8+ T-cells limited to the tumor periphery (Excluded Immune Infiltrate (EII), 19%, 14/73). Of these tumors, 75% (15/20) were PD-L1 negative and 25% (5/20) were PD-L1+. 73% (53/73) of tumors showed intratumoral CD8+ TILs. Of these tumors, 38 had available PD-L1 staining results and 63% (24/38) were PD-L1+ (Functional Immune Response (FIR)), while 37% (14/38) were PD-L1 negative (Non-Functional Immune Response (NFIR)). FIR tumors (intratumoral CD8+, PD-L1+) with strong PD-L1 positivity showed significantly higher immune cytolytic activity, by *GZMA* and *PRF1* gene expression, compared to NFIR tumors. Tumors with intratumoral CD8+ TIL infiltrate correlated with the TCIP-High phenotype in both HPV(+) and HPV(-) tumors. FOXP3 staining was significantly higher in HPV(+) tumors. **Conclusions:** 73% of HNC attract intratumoral CD8+ TILs and 63% of these tumors seem to activate a functional immune response. PD-L1 upregulation may serve as a compensatory immune escape mechanism, making this subset a rational target for PD-L1 blockade. T-regulatory cells seem to play an additional role in immune evasion of HPV+ HNC, suggesting that a combinatorial approach with a T-reg depleting strategy warrants clinical investigation.

6079 Poster Session (Board #403), Sat, 1:15 PM-4:45 PM

Correlation of specific genetic aberrations and signaling pathways with T-cell inflamed phenotype (TCIP) in head and neck cancer and as novel candidate biomarkers for checkpoint blockade therapy. *First Author: Zhixiang Zuo, The University of Chicago, Chicago, IL*

Background: Anti-PD-1/PD-L1 blockade is active in patients (pts) with head and neck squamous cell carcinoma (HNSCC) (Seiwert ASCO 2014). The T-cell inflamed phenotype (TCIP)/INF-g driven gene expression delineates a group of HNSCC that are likely to benefit from anti-PD-1 therapy (Seiwert ASCO 2015). We examined the genetically annotated TCGA cohort to determine genetic aberrations and signaling pathways associated with TCIP HNSCC, and validated findings *in vitro*, in order to identify novel candidate genetic biomarkers for immunotherapy and possible combination strategies. **Methods:** 416 HNSCC tumors from the TCGA cohort were used to calculate T-cell inflamed phenotype (TCIP) (Saloura ASCO 2014). Mutation/copy number data, expression intrinsic subtypes (Keck CCR 2015), and KEGG pathways were evaluated for correlation with TCIP in a hypothesis-forming analysis. In-vitro validation was performed in cell lines with similar genetic background. **Results:** Aberrations in the histone-methyl-transferase NSD1, altered in 41% of HNSCC via mutation/deletion. Considering HPV(-) tumors only, both NSD1 mutation and NSD1 deletion were strongly correlated with non-TCIP ($p = 0.0035$ and $p = 6.60e-09$, respectively). NSD1 mutation distribution suggested loss of function. Secondly, EGFR amplification occurred in non-TCIP tumors ($p = 3.88e-11$) and overlapped with active EGFR signaling in the Basal (BA) intrinsic subtype. BA cell lines treated with an EGFR inhibitor (gefitinib) consistently showed an increase in PD-L1 expression by immunoblotting. Pathway analysis identified WNT signaling as significantly associated with non-TCIP. CD274 (PD-L1)/JAK2 co-amplified in 101 out of 416 HNSCC tumors, which was significantly enriched in TCIP ($p = 5.93e-13$). **Conclusions:** NSD1 aberration,EGFR amplification, basal subtype, and WNT signaling are biomarkers of non-TCIP tumors, CD274/JAK2 amplification of TCIP tumors. These newly identified candidate biomarkers for immunotherapy require additional clinical and functional validation. Combination therapy with anti-EGFR and anti-PD-1/PD-L1 should be further explored.

6080 Poster Session (Board #404), Sat, 1:15 PM-4:45 PM

Comparison of two large, genetically and clinically annotated head and neck cancer (HNC) cohorts (TCGA, CHGC) and differential treatment effects on TP53 mutated, as well as oral cavity cancers. *First Author: Johannes Bragelmann, Medical Clinic III; Department of Oncology, Hematology and Rheumatology; University Hospital Bonn, Bonn, Germany*

Background: Whileeffects of specific genetic aberrations on outcome in HNC have been described (Poeta 2007, Gross 2014), the impact of therapies in genetic subgroups remains unknown. We therefore examined in an exploratory, hypothesis-forming analysis two large, genetically annotated cohorts, which preferentially employed different treatment regimens, with respect to impact on outcome in certain genetic backgrounds. **Methods:** Data of 238 patients (pts) from the Cancer Genome Atlas (TCGA), and 131 pts of the Chicago HNC Genomic Cohort (CHGC) receiving curative intent treatment for locoregionally-advanced HNC were included. Subgroups of patients were analyzed evaluating anatomic site, HPV status, TP53 mutation status, and survival in an exploratory, hypothesis-forming study. **Results:** Pts in both cohorts were largely treated at high-volume North American referral centers. Pts in CHGC received more frequently induction chemotherapy and primarily taxane/FHX, non-platinum containing regimens and less frequently surgery. The genetic profiles were very similar when controlling for HPV status. In both cohorts HPV-positive and HPV-negative tumors 5-year survival rates were similar (NS), however with improved outcomes in the HPV-positive pts in CHGC compared to HPV-positive pts in TCGA ($p = 0.02$). In HPV-negative tumors in TCGA TP53 mutations conferred a negative prognosis, while in CHGC pts with TP53 mutations showed an increased survival. Furthermore in CHGC outcome in oral cavity cancers was improved (5-year survival CHGC 59%, TCGA 41%, $p = 0.046$). **Conclusions:** While bias due to differences in cohort composition and lack of standardization of treatment cannot be controlled for, this analysis provides for the first time hypotheses regarding the interaction of treatment choices with genetic background in the curative intent setting. In particular the possible impact of taxane-containing induction chemotherapy or non-platinum based taxane/FHX regimens on worse prognosis TP53 mutant tumors, as well as non-surgical approaches for oral cavity/laryngeal Stage IV tumors deserves additional study.

6081 **Poster Session (Board #405), Sat, 1:15 PM-4:45 PM**

Notch1 mutations to define a subgroup of adenoid cystic carcinoma (ACC): Tumor stage, propensity to bone and liver metastasis, risk of relapse, and overall survival. *First Author: Renata Ferrarotto, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ACC is chemotherapy refractory and there is no standard of care treatment for patients (pts) with metastatic disease. ACC genotyping revealed alterations in the Notch (N) pathway in 13-29% of cases. An ACC patient identified in our institution with an activating Notch1 (N1) mutation achieved a partial response after 2 cycles of a N1 inhibitor in a phase I trial. In this study, we investigate the clinical and pathologic characteristics of N1 mutant ACC. **Methods:** N1 sequencing was performed in 97 pts (71 using whole-exome sequencing and 26 using a 50 gene panel including N1 exons 26, 27, 34). Comparisons between tumor characteristics and clinical outcomes in pts with or without activating N1 mutations (PEST or HD domain) were performed. **Results:** N1 mutations were identified in 13 pts. Pathway activation was confirmed by IHC for N1 intracellular domain. N1 ACC pts had significantly higher disease stage at diagnosis ($p = 0.009$, Fisher's exact test), and solid histologic subtype ($p = 0.027$). Only 1/38 pts who presented with stage I-III disease had N1 mutation compared with 4/12 pts (33%) who presented with distant metastasis. Although lung is the most common site of metastasis in ACC, N1 mutants developed bone (odds ratio [OR] = 7) and liver (OR = 4.5) metastasis more frequently than lung (OR = 0.44). Recurrence-free survival and OS were significantly shorter in the N1 mutant subgroup (p-value = 0.025, Log-rank test). The clinical correlations identified for the N1 mutants were maintained in an extended analysis that included SPEN and N2 mutations (4 pts), with an even higher impact in OS ($p = 0.007$). **Conclusions:** A subgroup of ACC harbors N1 (13.4%) or other N pathway activating mutations (17%). N activation defines a more aggressive phenotype, with a distinct pattern of metastatic spread, higher risk of relapse, and shorter OS. The identification of genetic events that activate N and the encouraging response observed in an index case suggest an immense opportunity to further explore this pathway as a therapeutic target in ACC.

6082 **Poster Session (Board #406), Sat, 1:15 PM-4:45 PM**

Systematic review and meta-analysis of the safety and efficacy of minimally invasive compared to open thymectomy for thymic malignancies. *First Author: Adam J. Friedant, Fox Chase Cancer Center, Philadelphia, PA*

Background: Complete resection is the standard of care for the treatment of thymoma. The use of minimally invasive surgery remains controversial. **Methods**: We searched online databases and identified studies from 1995 to 2014 comparing minimally invasive (MIS) (video assisted or robotic-assisted) to open thymectomy for thymic tumors. Study endpoints included operative blood loss, operative time, pulmonary complications, atrial fibrillation, length of stay (LOS), R0 resection, and tumor recurrence. We summarized outcomes across studies using random-effects meta-analysis to account for study heterogeneity. We calculated odds ratios (OR) for binary outcomes and standardized mean differences for continuous outcomes. We calculated incidence rate ratios (IRR) for the number of recurrences, accounting for total person-time observed in each study. **Results**: 36 studies (with 935 patients) were analyzed. Masaoka stage I-II comprised 88.5% (n = 522) of MIS patients and 80.4% (n = 413) of open. Mean tumor size was 4.49 cm (MIS) and 4.99 (open). 32/522 (6.13%) MIS cases were converted to open. MIS patients had significantly less blood loss (226 vs. 169 mL, std diff = -0.78, 95% CI -0.97 – 0.57, $p < 0.01$) but no significant difference in operating time (164.92 vs. 147.18 min, std diff = 0.13, 95% CI -0.28 – 0.54, $p = 0.53$), cardiac complications (7 MIS vs. 21 open, OR = 0.73, 95% CI 0.28 – 1.92, $p = 0.52$), respiratory complications (13 MIS vs. 38 open, OR = 0.79, 95% CI 0.29 – 2.16, $p = 0.64$), or overall complications (32 MIS vs. 63 open, OR = 0.90, 95% CI 0.41 – 1.93, $p = 0.78$). LOS was shorter for MIS patients (8d MIS vs. 9d open, std diff = -0.88, 95% CI -1.52 – -0.24, $p < 0.01$). Analyzing Masaoka I - II patients only, there was no difference in R0 resection rate (97.36% vs. 97.25%, OR = 0.98, 95% CI 0.23 – 4.14, $p = 0.88$) or overall recurrence rate (2.86% vs. 2.91%, IRR = 2.10, 95% CI 0.39 – 11.25, $p = 0.39$). There was one postoperative death (open group). **Conclusions**: The results of this unadjusted meta-analysis of published reports comparing MIS to open thymectomy suggest that MIS thymectomy is safe and can achieve similar oncologic outcomes to open thymectomy in selected patients with thymic malignancy.

TPS6083 **Poster Session (Board #407a), Sat, 1:15 PM-4:45 PM**

A phase I study to evaluate the safety, tolerability, PK, pharmacodynamics, and preliminary clinical activity of MEDI0562 in patients with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN). *First Author: Rom Samuel Leidner, Earl A. Chiles Research Institute, Providence Cancer Center, Portland, OR*

Background: Co-stimulatory signals delivered via binding to OX40 on T cells increase T-cell survival, proliferation, and effector function, and result in the generation of long-lived memory T cells. Experience to date with a human OX40 agonist murine antibody (MEDI6469) suggests targeting this pathway may provide antitumor activity with a manageable safety profile. In a Phase I study in advanced solid tumors, a single cycle of MEDI6469 had both an acceptable toxicity profile and regression of ≥ 1 metastatic lesion in 12 of 30 treated patients (pts)(Curti B, et al. Cancer Res 2013;73:7189–98). Humanized OX40 agonists are anticipated to have reduced immunogenicity relative to murine antibody, which may allow for repeat-dosing, potentially enhancing biologic and antitumor activity. MEDI0562 was developed through humanization of MEDI6469, and specifically binds to and activates signaling by human OX40. **Methods:** This is a Phase I, multicenter, open-label study (NCT02318394) in adults with R/M SCCHN. The primary endpoint is safety. Secondary endpoints include antitumor activity (objective response and disease control by immune-related RECIST, duration of response, progression-free survival, and overall survival), PK, immunogenicity, and pharmacodynamics. In the dose-escalation phase, sequential cohorts will receive 1 of 6 dose levels (3+3 design) of MEDI0562 IV for up to 48 weeks or until progressive disease (PD). Based on available data, any dose level not exceeding the maximum tolerated dose can be expanded. A dose-expansion phase may be initiated at the sponsor's discretion in SCCHN pts to further examine MEDI0562 at the dose level and treatment schedule determined during dose escalation. Upon evidence of PD in follow up, pts in both dose escalation and expansion cohorts may have 1 round of MEDI0562 re-treatment according to their previous regimen. All pts will be followed for survival through to study end. Enrollment of ~50 pts (≤ 36 in dose escalation; ≤ 14 in dose expansion) is ongoing. Clinical trial information: NCT02318394.

TPS6084 **Poster Session (Board #407b), Sat, 1:15 PM-4:45 PM**

KEYNOTE-040: A phase III randomized trial of pembrolizumab (MK-3475) versus standard treatment in patients with recurrent or metastatic head and neck cancer. *First Author: Ezra E. W. Cohen, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: Prognosis of patients with recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC) is poor, with limited treatment options and survival rates of 6-9 months following standard-of-care (SOC) therapies. Pembrolizumab, a humanized IgG4 monoclonal antibody against PD-1 designed to block the interaction between PD-1 and its ligands PD-L1 and PD-L2, has demonstrated clinical efficacy by investigator review (confirmed and unconfirmed responses) in a phase I study of R/M HNSCC. Preliminary PD-L1 biomarker data suggest that response rate may be greater in PD-L1–positive patients. **Methods:** In this global open-label, phase III KEYNOTE-040 (NCT02252042) trial, 466 subjects with recurrent or metastatic HNSCC that have failed prior platinum therapy will be randomized (1:1) to pembrolizumab (200 mg Q3W) vs investigator's choice SOC (single-agent methotrexate, docetaxel, or cetuximab). Randomization will be stratified by ECOG PS (0 vs 1), human papillomavirus (HPV) status in oropharyngeal cancer by p16 immunohistochemistry testing (positive vs negative), and centralized PD-L1 status (positive vs negative). Pembrolizumab will be given for ≤ 24 months or until disease progression, unacceptable toxicity, or investigator decision. AEs will be assessed according to NCI CTCAE, v4.0. Imaging will occur per RECIST v1.1 at 9 weeks and every 6 weeks thereafter. Modified RECIST, which allows for continued treatment after initial radiographic progression until confirmation imaging ≥ 4 weeks, will be used to account for unique responses seen with pembrolizumab. Radiographic responses will be confirmed by independent central review by RECIST v1.1 and modified RECIST and analyzed in real time for verification of progressive disease by RECIST v1.1. Survival follow-up will occur every 12 weeks. Primary end points are progression free survival (PFS) and overall survival (OS); secondary end points include ORR, DOR and PFS, OS, and ORR in PD-L1$^+$ patients. Treatment differences in PFS and OS will be assessed using stratified log-rank test; Hazard ratios with 95% confidence intervals will be estimated using stratified Cox proportional hazard models. Clinical trial information: NCT02252042.

TPS6085 **Poster Session (Board #408a), Sat, 1:15 PM-4:45 PM**

Ceritinib in anaplastic thyroid cancer (ATC) with ALK abnormalities. *First Author: Saad A. Khan, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: ATC is a rare tumor of thyroid epithelium affecting several hundred patients annually, but causing death in almost 100% of them. It has a dismal prognosis with currently ineffective treatment options, particularly in metastatic disease. BRAF V600E mutations have been identified and then targeted with novel agents, which led to striking activity in patients (Rosove et al, NEJM 2013). ALK overexpression and mutation have also been identified in ATC in 11% of patient samples (Murugan et al, Cancer Res 2011). Patients treated with ALK inhibitors show dramatic tumor response (Godbert et al, JCO 2014). Ceritinib is a well-tolerated, highly potent oral ALK-inhibitor that is FDA-approved for use in ALK-rearranged lung cancer. It is critical to develop a framework by which anaplastic tumor samples can be collected, actionable mutations identified and novel agents rapidly tested. **Methods:** This multicenter, open label trial (NCT02289144) is collecting tissue from 100 patients with ATC/UTC. A genomic profile will be created by next generation sequencing of all 100 tumor samples. 10 of these patients are predicted to demonstrate ALK abnormalities; either by overexpression, mutations or rearrangements. Upon confirmation of metastatic or unresectable disease, patients with ALK-abnormalities will get 750 mg ceritinib daily. Prior therapy does not affect eligibility. Primary endpoint is progression free survival of 3.5 months, compared to historical controls. As patients are screened, their tumor tissue genomic profile will be collected and analyzed for future targets. As genomic profiling provides more information about actionable targets in ATC patients, additional therapeutic arms/sub-studies with other novel agents will be added to this trial. This protocol may serve as the basis by which newer therapies may be tested in this challenging disease. Clinical trial information: NCT02289144.

TPS6086 **Poster Session (Board #408b), Sat, 1:15 PM-4:45 PM**

A Phase 2, multicenter, single-arm, global study of MEDI4736 monotherapy in patients with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN): HAWK (NCT02207530). *First Author: Dan Paul Zandberg, University of Maryland Marlene and Stewart Greenebaum Cancer Center, Baltimore, MD*

Background: Patients (pts) with R/M SCCHN have a poor prognosis, with current systemic therapy options after failure of first-line platinum-based chemotherapy yielding objective response rates (ORRs) of approximately 10% and an overall survival (OS) of 6 months. In SCCHN, tumors create a highly immunosuppressive environment and evade immune detection by exploiting inhibitory immune checkpoints such as the programmed cell death-1 (PD-1)/programmed cell death ligand-1 (PD-L1) axis. Upregulation of PD-L1 by SCCHN tumor cells is associated with inhibition of antitumor T-cell responses. Thus, therapeutic intervention with immune-modulating agents targeting this pathway holds promise. MEDI4736 is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD-80 with high affinity and selectivity. Evidence of clinical activity for MEDI4736 in R/M SCCHN has been seen in a Phase 1 study (NCT01693562), with initial data indicating that PD-L1 expression is associated with a higher ORR. A comprehensive clinical development program of MEDI4736 in SCCHN is underway. Here we describe the HAWK study (NCT02207530), a trial with registrational potential, assessing MEDI4736 monotherapy in pts with PD-L1$^+$ R/M SCCHN. **Methods:** In this Phase 2, open-label, single-arm, multicenter study, 112 PD-L1$^+$ pts will be enrolled from North American and European sites to investigate the efficacy and safety of MEDI4736 (10 mg/kg IV every 2 weeks for up to 12 months). Eligible pts, who are immunotherapy naïve and have tumor progression or recurrence during or after treatment with 1 platinum-containing regimen for R/M disease, will receive MEDI4736 monotherapy. The primary outcome measure is ORR (RECIST v1.1), based on independent central review. Secondary outcome measures will further assess disease control rate, duration of response, progression-free survival, and OS (using RECIST v1.1 and immune-related RECIST criteria); safety (CTCAE v4.03) and tolerability; and health-related quality of life. Exploratory outcomes include PK, immunogenicity, and potential biomarkers of response to MEDI4736. Recruitment is ongoing. Clinical trial information: NCT02207530.

TPS6087 **Poster Session (Board #409a), Sat, 1:15 PM-4:45 PM**

TPExtreme randomized trial: TPEx versus Extreme regimen in 1st line recurrent/metastatic head and neck squamous cell carcinoma. *First Author: Joel Guigay, Centre Antoine-Lacassagne, Nice, France*

Background: The EXTREME regimen (6 cycles of 5FU–cisplatin-cetuximab followed by cetuximab maintenance) is currently the standard first line in recurrent/metastatic (R/M) HNSCC. The GORTEC trial evaluating the TPEx regimen (4 cycles of docetaxel–cisplatin-cetuximab followed by cetuximab maintenance) demonstrated good results (median OS 14 months, ORR 54%) with acceptable safety profile, excellent dose intensity, high rate of patients who started maintenance. The aim of the current trial is to compare TPEx and EXTREME regimens. **Methods:** International, randomized, open-label trial. Main inclusion criteria are: histologically confirmed R/M HNSCC not suitable for locoregional treatment, age 18-70 years, PS $<$ 2, creatinine clearance $>$ 60 ml/min, prior total dose of cisplatin $<$ 300 mg/m^2. The control arm EXTREME : 6 cycles, every 21 days, of cisplatin 100 mg/m^2 day1, 5FU 4000 mg/m^2 continuous infusion day1-4, and weekly cetuximab 250 mg/m^2 (1st loading dose 400 mg/m^2) followed by weekly cetuximab 250 mg/m^2 maintenance. The experimental arm TPEx: 4 cycles, every 21 days, of docetaxel 75 mg/m^2 day1, cisplatin 75 mg/m^2 day1, and weekly cetuximab 250 mg/m^2 (1st loading dose 400 mg/m^2), followed by cetuximab 500 mg/m^2 maintenance every 2 weeks. If cisplatin is not tolerated or its total cumulative dose reaches 600 mg/m^2, it must be replaced by carboplatin AUC5. G-CSF prophylactic administration is mandatory for each cycle in the TPEx arm. Only patients with CR/PR/SD will continue the cetuximab maintenance until PD or unacceptable toxicity. The primary endpoint is OS. Assuming a 2-sided type I error of 0.05, observing 295 deaths will provide a 80% power to detect a hazard ratio of 0.72. 295 deaths are expected out of 416 patients (208 per arm). Secondary endpoints are ORR, best response rate, PFS, TTP, toxicity and QoL. Tumor response assessments (Weeks 6, 12 and 18, then every 8 weeks until PD) will be reviewed by a blinded central image review committee. HPV central analysis and cost-effectiveness study are ancillary studies. GORTEC (France), AIO-Studien-gGmbH (Germany), TTCC (Spain) joint trial in collaboration with French GETTEC, GERCOR, H&N UNICANCER groups. Unrestricted grant from Merck Serono. Clinical trial information: NCT02268695.

TPS6088 **Poster Session (Board #409b), Sat, 1:15 PM-4:45 PM**

Window of opportunity trial of HPV E7 antigen-expressing *Listeria*-based therapeutic vaccination prior to robotic surgery for HPV-positive oropharyngeal cancer. *First Author: Brett Miles, Department of Otolaryngology, Mount Sinai Medical Center, New York, NY*

Background: The incidence of human papilloma virus-associated oropharyngeal cancer (HPVOPC) has rapidly risen over the past two decades. Foreign viral antigens make HPVOPC an attractive target for immunotherapy. One exciting approach is the use of live attenuated *Listeria monocytogenes* bioengineered to express the HPV16 E7 protein (LmE7) and elicit a vigorous immune response. We designed a phase II "window of opportunity" trial with robust correlative endpoints to determine the effect of LmE7 vaccination on anti-tumor immunity in the tumor microenvironment and peripheral blood, as well as safety and tolerability in the HPVOPC population. **Methods:** **Trial Design:** Non-randomized single-arm phase II clinical trial utilizing a Simon's two-stage design. HPVOPC patients receive two cycles of LmE7 over 5 weeks prior to standard-of-care transoral surgical resection of their tumor with or without neck dissection. The primary objective is to determine the rate of post-vaccination T cell responses by measuring the pre- and post-treatment mean frequency of peptide-specific IFN-γ expressing T cells in the peripheral blood by ELISPOT. We will conclude that LmE7 is likely highly immunogenic and worth further investigation if post-treatment responses are seen in $>$ 75% of patients. **Inclusion Criteria:** Previously untreated surgically-resectable stage II-IV HPVOPC, HPV-positive by PCR-based testing. **Exclusion Criteria:** Prior history of cancer within 3 years, or any history of systemic cancer therapy; immunosuppressive disorder or medications; medical contraindications to therapy. **Correlative Studies:** The pattern of immunocyte infiltration in the tumor and draining lymph nodes will be assessed by multiplex immunofluorescence; expression profile of immune-related genes assessed by nanostring; and T cell receptor diversity by deep sequencing. These tissue-based changes will be correlated with comprehensive analysis of immune changes in the peripheral blood **Status:** Open, actively accruing. 8 of a maximum 22 (9 in first stage, 13 in second stage) vaccinated patients, and 0 of a maximum 10 untreated observational cohort patients have been enrolled. Clinical trial information: NCT02002182.

6500 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

The Technology Enhanced Navigation (TEN) Trial among low-income patients with breast cancer. *First Author: Kathy J. Helzlsouer, The Prevention and Rsrch Ctr, Baltimore, MD*

Background: Socioeconomic disparities negatively impact adjuvant breast cancer treatment completion. A web-based knowledge application was developed in collaboration with breast cancer survivors and evaluated in a randomized clinical trial for the impact on treatment adherence with and without virtual navigator support. The application provides direct links to vetted websites for both study arms, and, for the intervention arm, tailored documents, short instructional videos, and navigator visits via videoconference or phone are provided. **Methods:** Eligible patients were newly diagnosed with non-metastatic breast cancer, low-income (U.S. Department of Housing and Urban Development guidelines) Maryland residents, and recommended to have adjuvant treatment. Patients were given a netbook computer, training, and 12 months of wireless Internet access and randomized to either the application alone (control arm) or to the application and nurse/social worker navigation support (intervention arm). Adherence was assessed by medical record review and measured by percent initiating/completing recommended treatment. Baseline characteristics and results were compared by study arm using t-tests, chi-square, and Poisson regression analyses. **Results:** Of 150 eligible patients, 101 were enrolled; 49 on each arm evaluable. The majority were non-white (67%) and unemployed/on disability (68%); 47% had a high school education or less. Over 70% of participants on both arms agreed that the computer application was easy to use; confidence in using the application was high (71% intervention arm; 67% control arm). On the control arm, 10 adjuvant treatments were refused totally or in part among 6 patients; 2 on the intervention arm ($p = 0.04$). Three control-arm patients refused multiple treatments: one refused surgery and radiation; another refused radiation and hormone therapies and discontinued chemotherapy; another refused chemotherapy and hormone therapy. One patient on the intervention arm refused post-mastectomy radiation and another completed chemotherapy, initiated hormone therapy, but discontinued radiation therapy. **Conclusions:** Among low-income patients with breast cancer, adherence to adjuvant therapy was improved with navigator support compared to application-access alone. Clinical trial information: NCT01596179.

Financial burden of cancer clinical trials: Impact of an equity program intervention. *First Author: Ryan David Nipp, Dana-Farber / Harvard Cancer Center, Boston, MA*

Background: Cancer patients (pts) often experience financial burden, but little is known about the additional burden of clinical trial (CT) participation. Additionally, CT enrollment among underserved groups is lacking. We sought to examine the impact of a cancer care equity program (CCEP) on CT enrollment and to assess pt-reported barriers to CT participation. **Methods:** We implemented a CCEP at Massachusetts General Hospital (MGH) in 2014 to help fund non-clinical expenses related to CTs (e.g. travel, lodging). To determine the impact of the CCEP on CT enrollment, we compared CT enrollment in 2014 (after initiating the CCEP) to 2012 and 2013. We used multiple regression analysis to evaluate changes in CT enrollment. To assess financial barriers to CT participation, we administered surveys to CCEP pts and a comparison group of non-CCEP pts. We used chi-square tests to compare CCEP and non-CCEP pts. **Results:** In 2014, cancer CT enrollment increased by 17% and 40% compared to 2012 and 2013. Adjusting for CT availability, phase, and cancer type, CT enrollment increased significantly from 2013 to 2014 ($p = 0.02$). In 2014, CT enrollment increased among racial minorities ($p < 0.01$) and those living > 50 miles from MGH ($p < 0.01$). Comparing CT pts who enrolled in CCEP to those who did not, more CCEP pts were female (68% vs 51%, $p < 0.01$), under age 65 (74% vs 64%, $p = 0.05$), with metastatic disease (90% vs 72%, $p < 0.01$), incomes $<$ \$50k/yr (24% vs 15%, $p = 0.03$), and in phase I CTs (76% vs 50%, $p < 0.01$). Of 87 pts who completed the financial barriers survey (61% response rate), we received responses from 49 CCEP pts and 38 non-CCEP pts. More CCEP pts reported financial concerns (56% vs 11%, $p < 0.01$). Compared to non-CCEP pts, more CCEP pts reported concerns with medical costs (47% vs 14%, $p < 0.01$), travel (69% vs 11%, $p < 0.01$), lodging (60% vs 9%, $p < 0.01$), and insurance coverage (43% vs 14%, $p = 0.01$) related to CT participation. **Conclusions:** CT enrollment increased after the implementation of a CCEP, particularly among underserved groups. While CTs often represent the best option for pts with cancer, pts served by the CCEP report significant financial barriers to CT participation. These findings stress the need to recognize and address the financial burden of CT participation.

Trends in resource utilization and costs during implementation of a lay navigation program. *First Author: Gabrielle Betty Rocque, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: Lay navigators provide support to patients from diagnosis through survivorship or end of life. We hypothesized that integrating lay navigators into the care team would lead to reduced healthcare utilization and cost. **Methods:** Medicare claims data were obtained for patients ≥ 65 years old diagnosed with cancer in 2008-2014 within the UAB Health System Cancer Community Network (UAB CCN) (12 cancer centers in AL, MS, TN, GA, FL) to identify the percentage with ≥ 1 ER visit, hospitalization, ICU admission, or hospice admission. Analysis period runs from 1/1/2012 to 6/30/14. The first patient was enrolled in the navigation program in March 2013, and ~30% of patients were navigated by June 2014. Costs for Medicare were assessed, excluding prescription drugs. We used general linear models to evaluate changes in both health care utilization and cost from the pre- (1/1/12-2/28/13) to the post- implementation period (3/1/13-6/30/14). **Results:** We observed decreases after implementation from 13.4% to 11% for hospitalizations (18% decrease, $p < 0.01$), 8.0% to 7.1% for ER visits (12% decrease, $p < 0.01$), 2.9% to 2.5% for ICU admissions (14% decrease, $p = 0.04$) and an increase of 3.9% to 4.3% for hospice (9.2% increase $p = 0.37$). Costs decreased about \$158 per quarter per beneficiary over the analysis period. A significant pre-post decrease of \$952 per beneficiary ($p < 0.01$) lead to an estimated total reduction in Medicare costs of \$18,406,920 for the 19,335 beneficiaries in the UAB CCN for the five quarters post-implementation. **Conclusions:** Thislay health navigator program may increase hospice use and reduce health care use and costs. Further analysis of its direct impact is warranted. *The project described was supported by Grant Number 1C1CMS331023 from the Department of Health and Human Services, Centers for Medicare & Medicaid Services. The contents of this abstract are solely the responsibility of the authors and do not necessarily represent the official views of the U.S. Department of Health and Human Services or any of its agencies.*

How should we estimate costs of care attributable to cancer? *First Author: Aileen B. Chen, Dana Farber Cancer Inst, Boston, MA*

Background: Costs of care attributable to cancer are distinct from total costs of medical care, and transparent methods are needed to inform decisions about value of interventions. We measure how alternative strategies for specification of cancer-free control cohorts influences estimation of cancer-attributable costs. **Methods:** Using SEER-Medicare data, we calculated mean Medicare spending from one month prior until 11 months following diagnosis among patients > 66 diagnosed with lung, breast, prostate, and colorectal cancers from 2007-2009. Cancer attributable costs were estimated by subtracting monthly costs for cancer patients from one of 3 alternative reference cohorts: 1) non-cancer Medicare patients individually matched by age, gender, race, and SEER region, 2) non-cancer Medicare cohort matched on demographic factors with the addition of modified Charlson comorbidity score, 3) monthly costs from 2 to 13 months prior to diagnosis, using cancer patients as their own control. **Results:** Cancer-attributable costs were highest for all patients when using their own pre-diagnosis costs as comparison. Cancer-attributable costs were higher among breast and prostate, but lower among lung and colorectal patients, when using non-cancer controls and matching by comorbidity in addition to demographic characteristics. The greatest variation was seen for prostate cancer, with 39-73% of total costs attributed to cancer depending on reference cohort. Meantotal and cancer-attributable costs are summarized in the Table. **Conclusions:** Choice of reference group can have a substantial impact on proportion of total costs attributed to cancer and should be clearly delineated in analyses of cost and value.

Mean Medicare costs in year 1 (\$).

		Cancer-attributable costs, by reference group (% total costs attributed to cancer)		
	Total costs	Non-cancer patients, demographic match	Non-cancer patients, demographic and comorbidity match	Cancer patients as own control, year prior to diagnosis
Lung n = 43,196	47,366	31,703(67)	28,725(61)	35,476(75)
Breast n = 33,674	30,958	14,653(47)	15,242(49)	22,749(73)
Prostate n = 42,079	25,126	9,774(39)	11,048(44)	18,320(73)
Colorectal n = 29,075	54,144	38,184(71)	37,235(69)	43,621(81)

6504 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Cost of chemotherapy for metastatic colorectal cancer with either bevacizumab or cetuximab: Economic analysis of CALGB/SWOG 80405. *First Author: Deborah Schrag, Dana-Farber Cancer Institute, Boston, MA*

Background: CALGB/SWOG 80405, a phase III trial, found that adding either bevacizumab or cetuximab to standard first-line chemotherapy for metastatic colorectal cancer (mCRC) resulted in similar survival. We compared the economics of treatment on each arm. **Methods:** Patients were assigned to standard chemotherapy (Cx) and randomized to either bevacizumab (B, N = 559) or cetuximab (C, N = 578).Quality of life was assessed at baseline and at 8 week intervals using the EQ5D on a representative subgroup of participants (N = 56 for B and N = 55 for C) to estimate utilities. Because survival and quality of life were similar in each arm, cost-minimization rather than cost-effectiveness analysis was performed. Chemotherapy utilization was tracked from randomization to progression and drug costs were estimated using 4thquarter 2014 average sales price from the US Center for Medicare and Medicaid Services. Resource utilization of acute care including hospitalizations, emergency room visits and ICU care were tracked while patients were on study and costs assigned based on CMS estimates for mCRC patients. End of life and downstream costs were assumed to be comparable per survival month. Out of pocket costs were not tracked. All cost estimates are in 2014 USD. **Results:** Acute care costs were similar but drug costs were higher in the cetuximab arm (Table). Results were robust to sensitivity analyses and did not change whether the chemotherapy backbone included oxaliplatin or irinotecan. **Conclusions:** For first-line chemotherapy treatment of patients with kras wild type mCRC, based on US 2014 drug costs, bevacizumab is preferable to cetuximab from a health economic standpoint. Clinical trial information: NCT00265850.

Mean Costs of treatment for participants in CALGB 80405	Chemo+B N=559	Chemo+C N=578	Difference (95% CI)
Protocol-directed chemotherapy	$37,124	$75,845	$-38,720 (-45,699 to -31,740)
Acute care on study	$28,951	$29,494	$-543 (-2831 to +1,745)
Chemo and acute care costs	$66,076	$105,339	$-39,264 (-46,521 to -32,005)

6505 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Necitumumab in metastatic squamous non-small cell lung cancer (mSqN-SCLC): Establishing a value-based cost. *First Author: Daniel A. Goldstein, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: The SQUIRE trial demonstrated that adding necitumumab to chemotherapy for patients with mSqNSCLC produces a median overall survival benefit of 1.6 months (hazard ratio 0.84). The objective of this study was to evaluate the range of drug costs for which adding necitumumab to chemotherapy could be considered cost-effective. **Methods:** We developed a Markov model to compare the incremental cost-effectiveness of standard chemotherapy with or without necitumumab in the first-line treatment of mSqNSCLC. In the model, patients received gemcitabine and cisplatin for 6 cycles or gemcitabine, cisplatin, and necitumumab for 6 cycles followed by maintenance necitumumab. The clinical inputs were the survival benefits and frequency of adverse events (AEs) described in the SQUIRE trial. Weibull models were fitted to the survival curves in the SQUIRE trial. The cost inputs included drug costs based on the Medicare average sale prices, and costs for drug administration and the management of AEs based on Medicare reimbursement rates (all in 2014 US $). Model robustness was addressed by probabilistic sensitivity analyses (PSA) in which we ran 10,000 Monte Carlo simulations sampling from the distributions for all variables. We performed multiple model simulations each time varying Willingness To Pay (WTP) values to evaluate the incremental cost effectiveness ratio (ICER) across a range of values for the cost of necitumumab. **Results:** In the base case analysis, the addition of necitumumab produced an incremental survival benefit of 0.15 life years (LY) and 0.11 quality-adjusted life years (QALY). The PSAs established that: when necitumumab cost < $563 per cycle there was 90% confidence that the ICER for adding necitumumab would be < $100,000/QALY; when necitumumab cost $1309 per cycle there was 90% confidence that the ICER would be < $200,000/QALY; and when the cost of necitumumab was > $6,628 per cycle there was > 99% confidence that the ICER would be > $500,000/QALY. **Conclusions:** These findings provide a value-based range for the cost of necitumumab from $563 to $1309 per cycle. This study provides a framework for establishing value based pricing for new oncology drugs entering the US marketplace.

6506 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Value of information analyses for real-time prioritization decisions within a cancer clinical trials cooperative group. *First Author: Caroline Savage Bennette, University of Washington, Seattle, WA*

Background: Cancer clinical trials groups face excess demand for limited research funds and patient populations. Value of Information (VOI) analyses are an emerging methodology that can help align research investments with areas that could have the greatest impact on patient outcomes, but many questions remain concerning its feasibility and acceptability to inform real-world research prioritization decisions. Our objective was to develop and assess a process for calculating VOI in "real time" to inform trial approval decisions within SWOG, a large US-based cancer clinical trials cooperative group. **Methods**: We developed a rapid, reproducible modeling approach to estimate VOI, and applied the method to nine phase II/III trial proposals for breast, gastrointestinal (GI) and genitourinary (GU) cancer that were reviewed by SWOG leadership between 2008-2013. The decision models for each trial proposal were based on the trial design and informed from the literature. "Clinical" (benefits only) and "economic" (treatment and trial costs) VOI estimates were calculated using Bayesian updating methods. We customized the process using stakeholder input. **Results**: VOI modeling was feasible for 8 of 9 trial proposals. Model construction and calculations took <1 week per proposal. Net VOI results varied widely from proposal to proposal (Table). SWOG leaders felt that VOI analyses would likely be useful to inform future trial proposal evaluations. **Conclusions:** We developed an efficient and customized process to calculate the expected VOI for cancer clinical trial proposals that is feasible for use in real-time decision-making and acceptable to SWOG stakeholders. Prospective use and assessment of this approach is currently underway within SWOG.

Net VOI metrics for 9 retrospective trial proposals.

Proposal ID	Phase	Sample Size	Committee	Per-Patient VOI	Population-level VOI
A	3	630	GU	$42,000	$3,100,000,000
B	3	1486	GU	-$77,300	-$4,222,364,596
C	2	200	GI	-$23,000	-$1,210,000,000
D	2	120	GI	-$14,476	-$1,900,000,000
E	2	92	GI	-$ 6,400	-$ 700,000,000
F	3	690	Breast	-$ 5,900	-$ 700,000,000
G	3	720	Breast	$ 2,600	$ 400,000,000
H	3	3400	Breast	$ 5,400	$ 400,000,000
I	3	680	Breast	-	-

6507 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Physician-driven variation in non-recommended imaging for women with early stage breast cancer. *First Author: Allison Nicole Lipitz Snyderman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Some women at low risk for metastasis receive imaging for staging of early breast cancer, despite ASCO Choosing Wisely recommendations and NCCN guidelines supporting the contrary. The objective of this study was to assess the extent to which the observed variation in use of imaging in this context reflects physician-driven practice. **Methods:** Retrospective analysis using population-based SEER-Medicare data to examine the likelihood that a woman would receive a non-recommended imaging test (i.e., CT scan, PET scan, or bone scan) if her physician's last patient received one. The cohort included women ages 66 and over diagnosed with early stage breast cancer between 2000 and 2007, who had surgery within 6 months of diagnosis (n=66,149 women). We also assessed the extent of variation in imaging between physicians using a non-linear random-effects model. **Results:** Fourteen percent of our cohort received at least one imaging test between diagnosis and surgery. Over 3,800 physicians had at least two patients assigned, representing approximately 98% patients, and were included in the analysis. The likelihood that a woman would receive an imaging test was over three fold higher if her physician's prior patient received an imaging test, adjusting for patient characteristics (adjusted odds ratios ranged by imaging test from 3.05 to 6.54) (Table). From the random effects models, a test of whether the estimated variance of the random effects is significantly different from zero provides indication of significant unexplained variation across physicians ($p<0.0001$ for all models). **Conclusions:** We observed a substantial physician-driven influence on imaging for women with early stage breast cancer. Our findings support intervening at the physician level, specifically targeting high users, to help reduce the use of these potentially harmful and costly services.

Adjusted odds ratio [95% confidence interval] of patient receiving non-recommended imaging test if the physician's prior patient received imaging test.

	Any imaging	CT scan	PET scan	Bone scan
Prior patient received imaging test	3.27 [3.09-3.45]	3.05 [2.83-3.29]	5.79 [4.63-7.24]	6.54 [6.11-7.01]

6508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Prevalence and consequences of second opinions from medical oncologists for early-stage breast cancer: Results from the iCanCare study. *First Author: Allison W. Kurian, Stanford University Medical Center, Stanford, CA*

Background: A second medical oncology opinion (SMO) may facilitate increasingly complex decision-making about use of chemotherapy. However, little is known about use of SMOs in the community or the interplay between SMOs and the quality of decision-making or chemotherapy use. **Methods:** We surveyed women newly diagnosed with early-stage invasive breast cancer in 2013-2014, accrued approximately 5 months after diagnosis through two population-based SEER registries (Georgia and Los Angeles), about their experiences with medical oncologists, their decision-making, and their use of chemotherapy. We evaluated demographic, clinical and decisional factors associated with SMO using logistic regression. **Results:** Among 1350 surveyed patients with invasive disease who consulted with a medical oncologist and answered questions about second opinions, 9.5% had SMO and 3.3% received chemotherapy from the SMO provider. On multivariable analysis that included an extensive list of demographic covariates and clinical factors, younger age (odds ratio, OR = 0.96, 95% confidence interval, CI 0.92-0.99), usage of a web-based support group (OR = 1.32, 95% CI 1.05-1.67) and education (p-value = 0.03) were significant predictors of SMO. On univariate analysis, compared to non-recipients, SMO recipients less strongly wanted their doctor to tell them what to do (none or little of the time: 27.0% vs. 18%, p-value = 0.008). Patient ratings of satisfaction with chemotherapy decision-making were high and did not differ between those who did versus did not receive an SMO (86.3% quite or totally satisfied vs 85.8%, p-value = 0.87). Chemotherapy use did not differ between SMO recipients vs. non-recipients (p-value = 0.7). **Conclusions:** SMO use and treatment by SMO clinicians was remarkably low among early-stage breast cancer patients. High decision satisfaction and no difference between SMO receipt groups suggest little unmet demand. While chemotherapy use did not vary between SMO recipients vs. non-recipients, additional measures of treatment quality will be presented. Funding: P01-CA-163233

6509 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Financial insolvency as a risk factor for mortality among patients with cancer. *First Author: Aasthaa Bansal, University of Washington, Seattle, WA*

Background: Patients with cancer are more likely to file for bankruptcy than the general population, but the impact of severe financial distress on health outcomes among cancer patients is not known. **Methods:** We linked Surveillance, Epidemiology and End Results (SEER) cancer registry records and federal bankruptcy records for Western Washington and identified patients who were diagnosed with cancer from 1995 to 2009. We used propensity score matching to account for differences between patients who filed for bankruptcy and those who did not, with respect to age, gender, race, marital status, residence type, income, stage at diagnosis, and treatment(s) received. In the propensity score matched sample, we used Cox proportional hazards models to compare overall survival between patients who filed and those who did not. **Results:** Compared to patients who did not file for bankruptcy (n = 226,868), those who filed (n = 4,728) were more likely to be younger, female, non-white, have local or regional (vs. distant) stage disease at diagnosis and have received treatment. After propensity score matching, 7,682 patients remained in the analysis, 3,841 subjects in each group. Both groups had a mean age of 53 (SD 14.7), more men than women (54%), a mean income of $49,000 (SD $12,000), and majorities of white (86%), married (60%) and urban (91%) patients. Most patients in both groups were diagnosed with local or regional stage cancer (84%) and both groups received similar first courses of treatment. Compared to cancer patients who did not file for bankruptcy, the adjusted hazard rate for mortality among patients who filed was 75% higher [HR 1.75, 95% CI (1.61, 1.91)]. Excess mortality risk following bankruptcy varied by cancer type, with colorectal, prostate, lung and thyroid cancers having the highest risk. Excluding patients who were distant stage at cancer diagnosis from the analysis had little impact on the mortality risk. **Conclusions:** Severe financial distress requiring bankruptcy protection following cancer diagnosis appears to be a risk factor for mortality. Further research is needed to understand the process by which extreme financial distress influences survival after cancer diagnosis, and to find factors that could mitigate this risk.

6510 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

The impact of patient navigation on racial and ethnic disparities: Results from the patient navigation research program. *First Author: Naomi Ko, Boston Med Ctr, Boston, MA*

Background: Disparities in cancer outcomes for racial and ethnic minorities are an ongoing problem, in part due to persistent delays in timely care for at-risk patient populations. Patient navigation was developed to address barriers to timeliness. This study explores whether patient navigation reduces racial and ethnic disparities in timely cancer care. **Methods:** This is an analysis of the multi-site Patient Navigation Research Program. Participants were age 18 or older, had an abnormal cancer screening test, and were allocated to either the navigation arm or control arm (usual care). The outcome was time to diagnostic resolution of a screening abnormality. Unadjusted median time (25^{th}, 75^{th} percentile) to resolution was calculated for each racial/ethnic group by navigation and control. Multivariable Cox proportional hazards models were fit, adjusting for sex, age, cancer screening type, and health insurance, stratifying by center of care. **Results:** Among a sample of 7,514 participants, average age was 45.1, 89% were women, 43% Hispanic, 29% Non-Hispanic White (NHW) and 28% Black. Median time to resolution was similar across control and navigated arms for NHW patients [65 days (31, 220) for control and 67 days (33, 196) for navigation] and Hispanic patients [68 days (31, 208) and 62 days (34, 120)]. Black patients had longer median time to resolution in the control arm [108 days (42, 315)], still lagging in the navigated arm [97 days (49, 230)]. In the multi-variable adjusted models of the control arm, Black race was significantly associated with increased risk of delay (HR = 0.77; 95% CI: 0.69, 0.84) compared the NHW (reference) group. Hispanic race showed a non-significant increased risk (HR = 0.98; 95% CI 0.89, 1.07). There was borderline significance of an increased benefit of navigation among the navigated Hispanic group (HR 1.10; 95% CI: 0.998, 1.2), but a continued delay in diagnostic resolution among navigated Black patients (HR = 0.85; 95% CI: 0.77, 0.94) when compared to the NHW group. **Conclusions:** This study demonstrated significant delays in timely diagnostic care among Black participants. While navigation benefited minority groups, it did not eliminate all disparities in timely care for Black populations.

6511 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Effect of organizational approaches on safety-net hospitals' cancer care quality. *First Author: Nina A. Bickell, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Safety-net hospitals, historically at higher risk for delivering poor-quality care, provide a disproportionate amount of care to vulnerable populations. Some safety-net institutions deliver excellent quality cancer care. We undertook this study to determine the impact of organizational factors on breast cancer care quality. **Methods:** We abstracted charts of 389 breast cancer patients treated in 2009-12 at 9 inner-city safety-net hospitals with high proportions of minority breast cancer patients to measure underuse of needed adjuvant treatment. We interviewed 90 key informants (n = 59 clinical; n = 16 administrative; n = 12 clerical; n = 3 other) about how care is coordinated and delivered. Using Qualitative Comparative Analysis, we defined "conditions"—handoffs, no-shows, organizational culture—that particularly impact care coordination, categorized hospitals into low (< 10%), intermediate (10-20%) and high (> 20%) underuse of needed adjuvant therapies, and calibrated each of the "conditions." Hierarchical models assess impact of organizational and patient factors on underuse. **Results:** Underuse ranged from 8% to 29%. Higher quality sites designated individuals to track & follow-up no-shows; shared clinical information during handoffs; had fully integrated EHRs enabling providers and clerks to transfer responsibility across specialties; had strong system support; paid close organizational attention to clinic patients; and allocated adequate resources for the cancer clinics. Organizations with a patient-centered culture focused on making processes easier for patients. Poor quality sites lacked these organizational characteristics. Multivariate modeling found that beyond older patient age (RR = 1.89; 1.14-3.15), hospitals with strong approaches to follow-up affect underuse rates (RR = 0.24; 0.08-0.738). **Conclusions:** At safety-net hospitals, underuse of needed cancer therapies is affected by older patient age and organizational approaches to track and follow-up treatment. These findings offer strategies to safety-net hospitals to improve cancer care quality.

Development of cost and quality composites for the 2012 ASCO Choosing Wisely measures: Methods and evidence. *First Author: Melora K Simon, Stanford University's Clinical Excellence Research Center (CERC), Stanford, CA*

Background: Oncology clinics, health care systems, and payers are considering how to gauge performance for the ASCO Choosing Wisely (CW) program. We sought to develop a clinic-level composite CW metric that accounts for adherence to the 2012 CW measures. We also measured total cost of care. **Methods:** SEER cancer registry records for western Washington State from January 2007 to May 2014 were linked with claims from a large regional commercial insurer to develop algorithms to characterize each CW measure and assign patients to their primary oncology provider. In addition, a time-based episode was developed to capture total cost of care related to each CW measure. For each clinic, we looked at the observed to expected ratio across the CW measures and the total cost of care measures, with expected defined as the average clinic rate for each measure. A composite score for each was derived by dividing the weighted observed/expected ratio by the clinic volume. **Results:** Among the 14 clinics with the highest patient volume, the number of eligible commercially insured patients ranged from 531 to 1532 depending on the CW measure. Clinic scores on the CW measures ranged from 25% to 100%. The observed to expected adherence composite scores ranged from 0.77 to 1.13 (SD-0.11) while the cost composite scores ranged from 0.68 to 1.40 (SD-0.21). Adherence and cost of care were not well-correlated. Three clinics had better than expected composite adherence score and lower than expected costs. We identified these as "high value outliers." Five clinics had better than expected composite adherence score and higher than expected costs. 3 clinics each had lower than expected composite adherence scores and either higher or lower than expected costs. **Conclusions:** Identifying high performing clinics using individual CW metrics is complex - clinics vary widely in their adherence across metrics. We intend to assess convergence between the composite score and expert opinion through site visits, while using a similar approach in other geographies to increase our sample. Our composite score approach may assist decision makers in identifying the best clinics. To better gauge value, costs of care should also be considered alongside performance.

6513 Poster Discussion Session; Displayed in Poster Session (Board #70), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Trends in antineoplastic receipt after Medicare payment reform: Implications for future oncology payment design. *First Author: Helen M. Parsons, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: The Medicare Modernization Act (MMA) changed antineoplastic reimbursement from average wholesale price to average sales price +6%, reducing many outpatient reimbursement rates and altering practice patterns for lung cancer. To further evaluate the MMA's effect, we focus on colon cancer, where longstanding fluorouracil-based regimens were augmented in 2004 with 3 newly-approved drugs (oxaliplatin, bevacizumab, and/or cetuximab). **Methods:** Using the 2000-2009 SEER-Medicare data, we examined trends in chemotherapy use and type of antineoplastic received among 59,642 stages II-IV colon cancer patients. Logistic regression models tested the effect of time (pre-post the 2005-2006 reimbursement change) and setting (physician offices implemented reimbursement changes in 2005 vs hospital outpatient departments (OPD) in 2006); interaction terms tested for differential effects of MMA implementation in the 2 settings. Models controlled for patient demographic and tumor characteristics. **Results:** Overall, 16.3% of stage II, 52.4% stage III and 39.6% stage IV colon cancer patients received antineoplastics. After the reimbursement change in 2007-09 relative to 2000-03, stages II (marginal probability (MP) = -0.06, $p < 0.01$) and III (MP = -0.04, $p < 0.01$) patients decreased antineoplastic use, while stage IV patients increased use (MP = 0.03, $p < 0.01$). While use of fluorouracil-based therapy decreased slightly after reimbursement changes (MP:-0.07 stage II; -0.04 stage III; -0.04 stage IV; $p < 0.01$ for all), use of new drugs increased substantially (MP: 0.47 stage II; 0.67 stage III, 0.77 stage IV; $p < 0.01$ for all). Use of new drugs for stage IV cancer occurred earlier in physician offices compared to OPDs ($p < 0.01$). **Conclusions:** Colon cancer patients saw small decreases in treatment with fluorouracil-based chemotherapy, but large increases in newly approved drugs after the MMA. Trends suggest slightly earlier increases in physician office settings for stage IV patients, consistent with an MMA effect. The identifiable effects of the MMA are relatively small, but highlight the responsiveness of providers to changes in reimbursement, and the need to integrate new drugs into payment schema.

A randomized controlled trial (RCT) to improve enrollment to cancer clinical trials. *First Author: Catriona Parker, Cancer Council Victoria, Melbourne, Australia*

Background: The proportion of adults with cancer recruited to clinical trials is low. Cancer Council Victoria awards funding to clinical trial sites through its Clinical Trials Management Scheme (CTMS). With this state-wide scheme, there appeared to be a temporal relationship between growth or stability in funding and the number of patients recruited. We undertook a RCT to evaluate the hypothesis that additional funding would improve trial recruitment. **Methods:** Participating sites (n = 34) were stratified into four strata based on 2011 recruitment numbers. Control sites (n = 18) received usual CTMS funds only while intervention sites (n = 16) received usual funds plus additional funds, proportional to the number of patients recruited in 2011. Additional funding was a median increase of 300% (IQR: 112.5%, 459%) relative to usual CTMS funds and was an average 11.8% (IQR: 8%, 12.3%) increase in a site's budget. Additional funds were provided in early 2013. Sites were to use funds with the aim of increasing recruitment. The primary study endpoint was the number of new participants recruited to clinical trials in 2013 relative to recruitment in 2012. Negative binomial regression analysis was used to model the endpoint in intention-to-treat analysis adjusting for any imbalance in randomized groups' features and historical recruitment. An online survey was used to assess strategies employed to increase recruitment. **Results:** The median number of new trial recruits in 2013 was 21 (IQR: 5, 39) in the control arm and 12.5 (IQR: 3.5, 44.5) in the intervention arm. The ratio of the annual recruitment rate of new trial recruits at the intervention sites compared to control sites in 2013 adjusting for 2012 numbers and institution type was 0.99 (95%CI: 0.69, 1.43, p = 0.96). We found no evidence of a differential intervention effect across strata of higher pre-trial recruitment ($\chi^2_3 = 2.27$, p = 0.5). The survey revealed most intervention sites utilized funds for increased staffing. **Conclusions:** Additional funding at a site level did not lead to a contemporaneous increase in trial recruitment. A lag-effect may become apparent. In our setting, simply providing more funding without targeting and managing its use does not immediately increase trial accrual.

Psychosocial outcomes of the electronic self-report assessment for cancer-II randomized trial. *First Author: Donna Lynn Berry, Dana-Farber Cancer Institute, Boston, MA*

Background: TheElectronic Self-Report Assessment for Cancer (ESRA-C), a web-based intervention, is known to improve patient-provider communication and reduce overall cancer symptom distress in adults on active cancer therapy. ESRA-C provides patients with self-monitoring of cancer symptoms and quality of life, self-care instructions, and communication coaching, and gives clinicians a color coded summary. **Methods:** Secondary data analysis of the ESRA-C II randomized trial data explored the effect of ESRA-C on psychosocial outcomes during therapy in 581 adults with various cancers.Role (RF), social (SF) and emotional function (EF) were assessed with the Quality of Life Questionnaire-Core 30 (QLQ-C30) (higher score, better function), and depression outcomes by the Patient Health Questionnaire -9 (PHQ9) (lower score, less depression). Outcome scores were compared between groups using analysis of covariance (ANCOVA) and regression adjusting for baseline scores and selected variables. **Results:** Significantly lower PHQ9 scores were observed (p = 0.02) for the intervention group. Marginally significant higher functional scores in the intervention group were detected for RF (p = 0.07) and SF (p = 0.1). Results remained after adjusting for age, clinical service and working status. Working at enrollment contributed to higher role (p = 0.008), emotional (p = 0.09) and social function (p = 0.02) and lower depression (p = 0.05). **Conclusions:** Self-monitoring, self-care education, communication coaching plus a simple clinician summary, resulted in significantly better psychosocial outcomes for patients receiving active cancer therapy.The association of working status with positive outcomes may reflect a benefit for work-able individuals. Clinical trial information: NCT00852852.

Patient-reported care coordination and outcomes of colorectal cancer surgery. *First Author: Sarah T. Hawley, University of Michigan, Ann Arbor, MI*

Background: Care coordination is an essential component of effective, patient-centered cancer care. Yet little is known about the impact of patient reported care coordination on clinical outcomes, such as postoperative complications following high risk colorectal cancer surgery. **Methods:** In 2011-13, we surveyed Stage III colorectal cancer patients from Detroit and Georgia SEER registries 4-12 months after diagnosis. The primary outcome was self-report of a postoperative complication. We adapted a validated 6-item scale to assess perceived coordination across the overall continuum of cancer care (range 6-30). We used a separate 7-item scale to assess perceived care coordination specifically pre- and postoperatively (range 7-35). We compared the association between postoperative complications and overall and pre- /postoperative care coordination with chi-square tests. We assessed associations between complications and coordination in each phase of care in separate models, using logistic regression to control for age, race, education and insurance. **Results:** Among 1465 patients who returned surveys (RR = 66%), 23.1% reported a postoperative complication. Most respondents perceived their care coordination to be good overall (mean: 25.9, SD: 3.7), as well as pre- (mean: 29.5, SD 4.6) and postoperatively (mean: 30, SD 4.3). Older, minority and those with more comorbidities significantly more often perceived poor care coordination ($P < 0.001$). In adjusted analyses, postoperative complications were inversely associated with perceptions of good care coordination overall (OR: 0.72, 95% CI: 0.59-0.97) and with better pre- and post-operative coordination (OR = 0.96, 95% CI = 0.93-.98; OR = 0.93, 95% CI = 0.91-0.97, respectively). **Conclusions:** Similar to other large studies, complications in this sample were common after colorectal cancer surgery. Reported care coordination was good for most patients, but less so for certain vulnerable subgroups. Better care coordination was associated with lower rates of surgical complications. Such findings indicate that better care coordination may lead to better clinical outcomes, however further work to confirm and expand these results is needed.

Family perspectives on aggressive cancer care near the end of life. *First Author: Alexi A. Wright, Dana-Farber Cancer Institute, Boston, MA*

Background: Advanced cancer patients are receiving increasingly aggressive medical care near death, despite growing concerns that the use of hospital-based services at the end of life (EOL) reflects poor quality of care. **Methods:** We surveyed bereaved family members of 1,159 older patients participating in the Cancer Care Outcomes Research and Surveillance study (CanCORS; a national, prospective, observational cohort study) who were diagnosed with or recurred with advanced lung or colorectal cancer, and who died by 2011. We assessed whether bereaved family members' perceptions of the quality of patients' EOL care were associated with claims-based measures of aggressive medical care before death, adjusted for patients' demographic and clinical characteristics, mental illness, and treatment preferences. **Results:** Bereaved family members of patients who enrolled in hospice ≥ 3 days before death (n = 601) were more likely to report excellent quality of EOL care compared with those who enrolled later or did not receive hospice care (n = 558; adjusted proportion: 58.5% vs. 42.7%, $P < 0.001$). In contrast, family members of patients admitted to the ICU within 30 days of death (n = 153) were less likely to report excellent quality of EOL care than those who were not (n = 1,006; adjusted proportion 44.4% vs. 52.9%, P = 0.03), as were family of patients who died in the hospital (n = 467; adjusted proportion 41.8% vs. 57.1%, $P < 0.001$). Frequent use of the emergency department in the last month of life was not associated with lower family-reported ratings of EOL care quality (n = 92 with ≥ 2 visits; adjusted proportion 50.5% vs. 50.9%, P = 0.79); nor was the receipt of chemotherapy within 2 weeks of death (n = 77; adjusted proportion 48.7% vs. 51.1%, P = 0.80). **Conclusions:** Our findings suggest that efforts to improve earlier hospice enrollment, reduce ICU admissions at the EOL, and avoid terminal hospitalizations are important to improve the quality of cancer care and families' experiences. While existing quality measures characterize the repeated use of emergency visits and chemotherapy near death as poor quality care, we could not detect a difference in family ratings of care by these measures.

Use of online communication and social media by newly diagnosed breast cancer patients: Results from the iCanCare Study. *First Author: Sarah T. Hawley, University of Michigan, Ann Arbor, MI*

Background: Online communication (OC) and social media (SM) could be used to enhance cancer treatment decision-making and care support. Yet, virtually nothing is known about whether and how newly diagnosed cancer patients use different forms of OC and SM during the treatment decision process. **Methods:** A weighted random sample of breast cancer patients newly diagnosed in 2013-14 were identified from Los Angeles and Georgia SEER registries and surveyed approximately 6 months after diagnosis (current response rate 68%). Respondents were asked whether they used different forms of OC (email or texting) or SM (facebook, twitter or blogs), how often, and for what purpose. We evaluated patient factors (age, education, race, stage, family history) associated with some/frequent use using logistic regression. We assessed purpose of OC and SM by patient factors using chi-square tests. **Results:** In a preliminary sample (n=2,021), 37% reported some or frequent use of either OC or SM to discuss the diagnosis, treatment decisions, or care support. There was a strong inverse relationship between increasing age and use (Table). Patients most likely to use any form (vs. never) were younger (age < 45 and 45-54) (OR: 4.0; 95% CI 2.8-5.7 and OR: 2.5; 95% CI 1.8-3.4), more highly educated (OR: 2.5, 95% CI: 1.9-3.5), and white (OR: 2.4; 95% CI 1.8-2.9). Of some/frequent users, the most common reasons were for letting people know about the diagnosis (69%), getting advice about treatments (56%), and for dealing with negative feelings/emotions (46%). Less common reasons were for sharing opinions about doctors (31%) or deciding on doctors (22%). More frequent users more often reported a deliberative decision process and had higher decision satisfaction ($P<0.05$) than never users. **Conclusions:** The substantial use of OC and SM for treatment decision and care support suggests growing opportunities to incorporate these modes into clinical practice. Future research should address optimal ways to incorporate these modes of engagement to improve experiences for all patients. Funding: NCI P01CA163233

Email communication practices and preferences among patients and providers in a large comprehensive cancer center. *First Author: Natalie Cook, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Little is known about how email is currently used in healthcare to facilitate patient care. The objective of our study was to understand current practices and preferences of patients (pts) and physicians (MDs) for email communication. **Methods:** Separate cross-sectional surveys were administered to pts and MDs (staff physicians and clinical fellows) at Princess Margaret Cancer Center. Survey domains included current email and internet use practices, digital literacy skills, perceived barriers and preferences regarding email use to facilitate care. Logistic regression was used to identify factors associated with current email use. Chart review was conducted to assess the impact of email communication on care. **Results:** The survey was completed by 833 pts, of which 50% reported previous email contact with a healthcare professional (HCP) including administrative assistants (52%), MDs (51%: 36% with specialist; 18% with primary care; 3% both) and nurses (45%). Most pts (87%) were satisfied with this method of communication. Patient factors associated with higher likelihood of email contact with a HCP included younger age ($p<0.0001$), higher education ($p<0.0001$) and higher income ($p<0.0001$). Enrollment in clinical trials ($p<0.0001$), receipt of multiple treatments ($p=0.001$) and receipt of chemotherapy ($p=0.0006$) were also associated with higher likelihood of email contact. Pts had less concerns about using email for health care if they had prior email contact with HCPs compared to those with no prior email contact (60% vs. 70%; $p=0.004$). Of the 80 MDs who responded to the survey (response rate 30%), 80% had previous contact with a pt via email although only 24% felt this should be used regularly to communicate with pts. All MDs reported email contact with other HCPs about pt related matters and all felt this to be an effective way to communicate. 962 pt charts were reviewed with email correspondence documented in 9% of cases. **Conclusions:** Email is commonly used for pt care but poorly documented and there may be a mismatch between pt/MD preferences. The use of email in this setting can be developed with appropriate guidance, however there may be concerns about widening the gap for certain groups of pts.

Disease-specific hashtags for online communication about cancer care. *First Author: Matthew S. Katz, Radiation Oncology Associates, Lowell, MA*

Background: A majority of patients and health care professionals are now online. Our hypothesis is that disease-specific cancer hashtags may be a way to access accurate health information and positive interactions. **Methods:** Based upon two de novo hashtags, #bcsm and #btsm, an organized system of hashtags, the cancer tag ontology (CTO) was designed in July 2013 for online use. We conducted a retrospective study of 25 hashtags used on Twitter April 2011 – September 2014 using data from Symplur, LLC. We classified up to 100 most active users of each hashtag as follows: patient; doctor; non-doctor health care professional (HCP); individual NOS (I); healthcare organization (HCO), other organization (OO); or spam. Tweet activity was analyzed quarterly for all tags. **Results:** During the study period, there were a total of 531,765 tweets from 77,454 users. The two original hashtags #bcsm and #btsm had the most use with 249,312 and 110,465 tweets, respectively. The other tags were used almost exclusively starting Q3 2013 onward. Overall, the most active new tags were those with organized Twitter-based chats: #ayacsm; #gyncsm; #lcsm; #mmsm; and #pancsm. These seven accounted for 93% of total Twitter activity. In the cohort, 11% were patients, 20% doctors, 3% HCP, 32% I, 30% HCO, 1% OO, and 3% spam. The most active top users were patients with an median of 46 tweets. Activity increased from 13,778 tweets in Q3 2011 to 75,960 tweets in Q3 2014. For the 23 structured tags, quarterly use increased from 18,098 tweets in Q3 2013 to 39,761 tweets in Q3 2014. **Conclusions:** We have demonstrated the feasibility and growth of organized, cancer-specific hashtags on Twitter used by a variety of stakeholders in cancer care. Use of the CTO indicates potential value of online interaction. Further study is needed to determine whether the CTO has any impact on access, outcomes or as a model for other areas of medicine.

Machine-learning prediction of cancer survival: A prospective study examining the impact of combining clinical and genomic data. *First Author: David M. Ashley, Andrew Love Cancer Centre, Geelong, Australia*

Background: Accurate prediction of survival in patients with cancer remains a challenge due to the ever-increasing heterogeneity and complexity of cancer at the molecular level, in treatment options and patient populations. Data mining using machine learning techniques (MLT) may enhance our ability to deal with such complexity. The current work tests the hypothesis that by combining digital data contained in a rich purpose-built epidemiological and clinical cancer registry with patient specific genomic data, using MLT, we could enhance our previously published methods in predicting clinical outcomes. **Methods:** Cancer 2015 is a large-scale prospective epidemiological, clinical and molecular cohort study in which tumors underwent mutational analysis from using the Illumina TruSeqAmplicon 48 gene Cancer Panel. Data from 1002 patients were used to model survival at 12 months. Machine-learning prediction using comprehensive data that included demography, tumor stream information, co-morbidities, past history and patient presentation details was then compared using the Area Under the Curve (AUC) with a model combining the same data and the mutational status results for each tumor. **Results:** Of the 48 genes examined mutations in only 4 genes present in patient samples significantly contributed as independent risk factors in predictions of survival, these included: FGFR2 (odds ratio = 4.1304), RB1 (odds ratio = 2.7295), BRAF (odds ratio = 2.2513), KIT (odds ratio = 2.2464). However, when considering this entire population the addition of all genomics data did not significantly improve 12 month prediction of survival. Combined clinical and genomics data model yielded an AUC of 0.8502 (0.8468-0.8536) whilst the clinical data model alone yielded an AUC of 0.8464(0.8429- 0.8498). **Conclusions:** Whilst the presence of some specific mutations contributed to the prediction of survival, overall genomic information in this group did not enhance survival prediction by MLT beyond that of clinical and epidemiological data alone.

Predicting low accrual in the Clinical Trials Cooperative Group Program's phase II/III oncology trials. *First Author: Caroline Savage Bennette, University of Washington, Seattle, WA*

Background: Although general barriers to clinical trial accrual are well described, the extent to which trial-level factors differentially influence accrual to individual trials has not been comprehensively studied. Our objective was to study the empirical relationship and predictive properties of a broad set of putative risk factors for low accrual among NCI's Clinical Trials Cooperative Group Program (CTCG), now the National Clinical Trials Network. **Methods**: Data from 787 phase II/III adult CTCG trials that opened 2000-2011 were used to develop a logistic regression model to predict low accrual, defined as trials that closed with or were accruing at < 50% of target; 46 trials opened 2012-2013 were used for validation. Candidate predictors of accrual were identified from a literature review and expert interviews. Model performance was evaluated by calibration and discrimination via the area under the curve (AUC). **Results**: The multivariable model (Table) had good calibration and discrimination to predict trials with low accrual (AUC in trials launched in 2012-2013: 0.73; 95% CI: 0.58, 0.88). Results were robust to different definitions of accrual success and model selection strategies. **Conclusions**: Prospectively, a prediction tool based on multiple trial-level risk factors may help quantify the risk of low accrual for cooperative group trials. Such a tool could inform trial design, aid prioritization decisions, and help target limited resources to support accrual where most needed.

Multivariable model to predict low accrual in CTCG phase II/III trials.

Risk Factor	Odds Ratio	95% CI

Colonoscopy versus less invasive approaches for colorectal cancer (CRC) screening (Scr): A strategic perspective. *First Author: Afsaneh Barzi, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Colonoscopy (CS) is an effective approach to Scr for CRC. Given its invasive nature, interest exists to find other Scr strategies (STs) with DNA stool testing being the most recent. Stool tests (STT) are dichotomous and a positive test typically results in a CS and then a negative CS would dictate the future Scr regime. We compared Scr STs in terms of their effectiveness (E), costs (C), and cost effectiveness (CE) to define the characteristics of a test or ST that can successfully compete or replace CS. **Methods**: Using a societal perspective, 12 STs and No Scr were compared. Using a Markov model 100,000 simulated individuals (SIs) 50 to 75 years of age with average risk of CRC were followed for up to 35 years. E (life years gained- LYG) and C (C of Scr and CRC) were calculated per SI. **Results**: CS dominates all other STs and has the highest LYG and lowest C even compared to No Scr. Under various sensitivity analyses (SA) we find that the results remain stable, primarily due to the high sensitivity (Sen) and specificity (Spe) of CS. DNA testing is not competitive, even among STT, given its high C and minimal improvement on E. For DNA to be competitive compared to other STT, its C must decrease or its Sen must improve. **Conclusions**: CS remains the unrivaled Scr test for CRC. Given CS's impact on incidence by detecting and eliminating precancerous polyps, dichotomous stool testing strategies are at a disadvantage. Value proposition for a new Scr ST is in a departure from dichotomous reporting and providing risk levels that can identify precancerous polyps and influence the Scr regime after a negative CS. This should be regarded as the focus of Scr research and development.

6524 Poster Session (Board #81), Mon, 1:15 PM-4:45 PM

Developing a CAncer genomics Digital Educational Tool to assess the knowledge and expectations of patients with advanced solid tumors (CADET). *First Author: Herbert H. F. Loong, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Genomic testing in cancer (GTC) is increasingly important to guide therapy for patients (pts) with advanced cancers, as eligibility for many early-phase clinical trials is restricted to patients with specific actionable mutation(s). Using a prospectively administered GTC questionnaire, we previously found that only 48% of pts with advanced solid tumors felt that they had sufficient knowledge to make an informed decision to pursue GTC (Blanchette et al, Cancer, 2014). **Objective:** To develop a digital education tool (DET) to improve pts' knowledge of GTC, and to assess whether such tool can change pts' attitudes and expectations toward GTC. **Methods:** A 5-min video was developed highlighting background information, logistics and rationale for GTC. Pts referred for phase 1 trials and molecular profiling were recruited to view the DET and to complete an identical GTC questionnaire as used in our previous study. These were returned by mail on a voluntary basis. Questionnaire comprised of 12 knowledge of cancer & genomics and 17 attitudes & expectations questions. Results from this cohort (B) were compared with the previously reported cohort (A). **Results:** Between Aug 2013 and Feb 2014, 118 pts consented to the study with 98 pts completing the questionnaire, representing 83% of pts surveyed. Demographics were similar between the cohorts. In terms of knowledge, as an aggregate, more correct answers were identified from questionnaires administered in B vs. A (72% vs. 67%, OR 1.26; 95%CI 1.06 – 1.51, p=0.01). Multivariate analysis adjusting demographics, prior work experience in healthcare or having close family members with cancer confirmed better knowledge score in cohort B vs. A (OR 1.22, 95% CI 1.01 – 1.47; p=0.04). More pts in cohort B felt they had adequate knowledge regarding potential benefits & risks of DNA testing to make an informed decision to purse GTC (66% vs. 48%, p=0.013) and agree that DNA testing may improve cancer treatment (79% vs. 64%, p=0.037). **Conclusions:** This DET helps fulfill the support pts need, enhancing knowledge and affecting attitudes towards GTC. Evaluation of long-term effect of this DET is warranted.

6525 Poster Session (Board #82), Mon, 1:15 PM-4:45 PM

Utilization of palliative chemotherapy for advanced bladder cancer: Patterns of care in routine clinical practice. *First Author: Andrew George Robinson, Kingston General Hospital, Kingston, ON, Canada*

Background: Although palliative chemotherapy for advanced bladder cancer is recommended in clinical practice guidelines, patterns of care in routine care is not described. Here we describe utilization rates of chemotherapy and referral rates to medical oncology in the last year of life among patients who die of bladder cancer. **Methods:** A population based cohort of bladder cancer patients was identified from the Ontario Cancer Registry; the study population included those patients who died of bladder cancer 1995-2009. Electronic records of treatment and physician billing records were used to identify treatment patterns and referral to medical oncology (MO). Log-binomial and poisson regression were used to examine factors associated with chemotherapy utilization and MO consultation. **Results:** 8005 patients died of bladder cancer; 25% (1964/8005) of whom received chemotherapy in the last year of life. Use of chemotherapy was independently associated with patient age (Relative risk (RR) 0.49 70-79 vs < 50 years, $p < 0.001$), comorbidity (RR 0.61 moderate comorbidity vs none, $p < 0.001$), socioeconomic status (RR 0.84 lowest quintile vs highest, $p = 0.01$) and gender (RR 0.91 females vs males, $p = 0.012$). Utilization increased over time (from 22% to 26%, $p < 0.001$) and varied across geographic regions (range 18-30%, $p < 0.001$); these findings persisted on adjusted analyses. 68% (5426/8005) of patients were seen by MO in the last year of life. Factors independently associated referral rates to MO include age (RR 0.82 70-79 vs < 50 years, $p < 0.001$), comorbidity (RR 0.90 moderate comorbidity vs none, $p < 0.001$), socioeconomic status (RR 0.90 lowest quintile vs highest, $p < 0.001$), and gender (RR 0.96 females vs males, $p = 0.023$). Referral rates modestly increased over time (66% to 69%, $p = 0.006$) and varied widely across geographic regions (range (57% to 79%, $p < 0.001$); these findings persisted on adjusted analyses. **Conclusions:** Despite clinical practice guideline recommendations, utilization of palliative chemotherapy for bladder cancer in routine practice remains low. Treatment patterns and referral rates to MO vary substantially across geographic regions.

6526 Poster Session (Board #83), Mon, 1:15 PM-4:45 PM

Is online patient information at NCI cancer centers too complex for broad general readership? *First Author: Stephen Rosenberg, Department of Human Oncology, University of Wisconsin, Madison, WI*

Background: The NIH and the Department of Health and Human Services recommend that online patient information (OPI) be written at a 6th grade level to facilitate broad readership comprehension. We sought to assess the readability of OPI found on NCI Designated Cancer Center websites across the US. **Methods:** Cancer.gov was utilized to identify 68 NCI Designated Cancer Center websites from which we collected both general OPI and specific OPI on breast, prostate, lung, and colon cancer. We then performed a readability analysis with 10 commonly used readability tests: the New Dale–Chall Test, Flesh Reading Ease Score, Flesh-Kinkaid Grade Level, FORCAST test, Fry Score, Simple Measure of Gobbledygook, Gunning Frequency of Gobbledygook, New Fog Count, Raygor Readability Estimate, and Coleman-Liau Index. We sought to test the hypothesis that the readability of OPI from NCI Designated Cancer Centers would be written at the 6thgrade level. As a secondary analysis, we compared readability of OPI between comprehensive and non-comprehensive cancer centers, by geographic region, and to the OPI produced by the American Cancer Society (ACS). **Results:** Data from 40 comprehensive and 18 non-comprehensive NCI Designated Cancer Centers were available for analysis (7 non-clinical centers and 3 without appropriate OPI were excluded). A mean of 30,507 words (range 5,732 – 147,425) were analyzed. A composite measure of grade level was constructed using the 8 readability measures that provide a grade level. These measures were strongly correlated and formed a reliable measure (SI alpha = 0.98). The mean grade level of 12.46 (95% CI: 12.13 – 12.79) was significantly greater than the target reading level ($t(57) = 38.15$, $p < .001$). No statistically significant difference in readability was seen when comparing comprehensive vs. non-comprehensive centers (t range 0.42 – 1.19, $p = 0.24 – 0.69$). Regional differences were identified in 4 of the 10 readability metrics ($p < .05$). The ACS OPI provides easier language, 7-9th grade level, across all tests ($p < .01$). **Conclusions:** OPI found on NCI Designated Cancer websites is more complex for the readership than recommended. This may limit the reach and impact of important cancer information to the public.

6527 Poster Session (Board #84), Mon, 1:15 PM-4:45 PM

A discrete choice experiment to examine the preferences of patients with cancer and their willingness to pay for different types of health care appointments. *First Author: Shu Fen Wong, Deakin University, Waurn Ponds, Australia*

Background: Little comparative data exist on how patients with cancer make choices about accessing health care appointments. Our study used a discrete choice experiment (DCE) to better understand patient preferences regarding their cancer care and potential trade-offs between health care appointment characteristics. **Methods:** Patients diagnosed with cancer at 3 hospitals were recruited to complete a self-administered DCE. Each version of the questionnaire (n = 16) had 8 paired choice scenarios where each health care appointment scenario described 6 attributes (identified through qualitative analysis): expertise of the doctor; familiarity of the doctor with their medical history; waiting time for an appointment; permitted accompaniment by family/friends; travel times to appointments and out-of-pocket costs. Patient preferences were estimated using logistic regression; willingness to pay (WTP) estimates for different aspects were then derived. **Results:** 185 out of 512 patients (36%) returned the questionnaire. Mean age was 61 yrs (22–92 yrs), and the majority was female (60%). Mean time since cancer diagnoses was 34 mths, 90% had received cancer treatment and 61% had early stage disease. The most important attributes for determining patient preferences were the expertise and familiarity of the doctor with their medical history; distance travelled was least likely to influence patient preferences. The WTP analysis found that patients were willing to pay $705 to consult specialists with higher expertise, $572 to consult doctors familiar with their medical history, $464 for shorter waiting times for appointments, $410 to be accompanied by family/friends and $342 for shorter travelling times to appointments. **Conclusions:** Our study could guide the development of patient-centered health care models, with an emphasis on the most important appointment characteristics; models should improve patient access to experienced doctors, and support the role of primary care providers in the community. Interventions to reduce waiting and travel times for appointments and to accommodate medical escorts still influenced patient choices, but to a lesser degree.

6528 Poster Session (Board #85), Mon, 1:15 PM-4:45 PM

Impact of age on the associations between genomic testing in breast cancer (BrCA) and chemotherapy (chemo) use and costs. *First Author: Yu-Ning Wong, Fox Chase Cancer Ctr, Philadelphia, PA*

Background: The 21-gene recurrence score assay (Oncotype Dx) (RS) guides adjuvant chemo use in patients (pts) with BrCA. Since age is associated with chemo appropriateness, we sought to understand if the associations between RS receipt, chemo use, and costs varied by age. **Methods:** We identified 7665 pts diagnosed with node-negative, hormone-receptor-positive BrCA during 2007-2010 using the Pennsylvania Cancer Registry and claims from Independence Blue Cross (IBC) or Medicare for 12 months before and after diagnosis. Propensity-score-weighted regression models were used to assess the independent effect of RS receipt on chemo use and total 1-year post-diagnosis chemo costs by age group, controlling for demographics, insurance, tumor characteristics, and comorbidities. **Results:** Mean age was 71 years (range 23-100). 74% were insured by Medicare. Pts who received RS were younger, had fewer comorbidities, were more likely Stage 1, and were more likely to have IBC coverage ($p < .001$ for all). The proportion of patients undergoing RS testing increased from 17% among pts in 2007 to 28% in 2010. RS use was associated with reduced adjuvant chemo use and lower chemo spending among younger pts, but had minimal effects on chemo use and chemo spending among older pts (Table, * indicates $p < .05$). None of the RS recipients over age 85 received chemo. **Conclusions:** RS testing was associated with lower chemo use in younger pts, but had little effect on chemo use in older pts. The cost savings noted in young pts who underwent the RS test was not seen among older pts. Our results suggest that RS testing is being ordered in many elderly patients for whom chemo is not a realistic treatment option. As additional high-cost genomic tests enter clinical practice, their use should be targeted towards pts in whom the test result will influence clinical decision making.

Age	RS testing	N	Received chemo %	Difference in chemo rate	Mean chemo spending ($)	Difference in chemo spending ($)

6529 Poster Session (Board #86), Mon, 1:15 PM-4:45 PM

The influence of hospital and surgeon factors on the prevalence of axillary evaluation in ductal carcinoma in situ. *First Author: Ellie J. Coromilas, Columbia University Medical Center, New York, NY*

Background: Axillary lymph node evaluation (LND) is standard of care in the surgical management of invasive breast cancer, but benefit has not been demonstrated in ductal carcinoma in situ (DCIS). We aimed to determine the incidence of LND in women with DCIS undergoing breast conserving surgery (BCS) and mastectomy, and to identify clinical, hospital, and surgeon-related factors associated with LND. **Methods:** Perspectives database was used to identify women ages 18-90 with DCIS who underwent BCS or mastectomy between 2006-2012. Analyses were stratified by surgery type, and multivariable regression analysis was used to identify factors associated with LND. **Results:** Of 35,591 women identified with DCIS, 26,580 (74.7%) underwent BCS and 9,011 (25.3%) underwent mastectomy; 17.7% undergoing BCS and 63% undergoing mastectomy had LND. Rates increased over time with mastectomy (2006: 56.6%, 2012: 67.4%) and were relatively stable with BCS (2006: 18.5%, 2012: 16.2%). In a multivariable analysis, Medicaid insurance (RR 1.17, CI 1.05-1.30) and treatment in a non-teaching hospital (RR 1.13, CI 1.06-1.21) or urban location (RR 1.30, CI 1.09-1.55) were associated with LND with mastectomy. Among women undergoing BCS, Hispanic race (RR 1.32, CI 1.00-1.74) and treatment in a non-teaching hospital (RR 1.17, CI 1.03-1.33) influenced LND. Surgeon volume was the most significant predictor of LND with BCS (mid vs. low: RR 0.87, CI 0.70-0.94; high vs. low: RR 0.54, CI 0.44-0.65). Low volume surgeons performed LND in 26.4% of patients undergoing BCS, compared to 20.4% by mid volume and 10.4% by low volume surgeons. **Conclusions:** Despite guidelines recommending against LND in women with DCIS undergoing BCS and lack of evidence for its use with mastectomy, it is frequently performed. Given the additional morbidity and cost of these procedures, alternative surgical approaches or prospective evaluation of the clinical benefit of LND in women with DCIS is needed.

6530 Poster Session (Board #87), Mon, 1:15 PM-4:45 PM

Improving veteran access to lung cancer care (IVaLuCancerCare): A quality improvement project at the Louis Stokes Cleveland VA Medical Center (LSVAMC). *First Author: Rami Manochakian, Louis Stokes Cleveland VAMC/Case Western Reserve University, Cleveland, OH*

Background: At the LSVAMC, one of the largest VA medical centers in the USA, about 190 new cases of lung cancer are diagnosed yearly and 450 veterans are followed for lung cancer care. **"IVALuCancerCare"** is a quality improvement project supported bya grant from theVA Office of Specialty Care Transformation. Through this project, a new multidisciplinary lung cancer program launched in October 2013 to address three gaps in lung cancer care: timeliness of care, coordination of care and access to palliative care. **Methods:** To address the gaps, we targeted three specific aims and proposed the following goals: 1) Increase percentage of non-small cell lung cancer (NSCLC) patients who receive first treatment within 28 days from diagnosis from 33% to 50%. 2) Increase percentage of medical oncology visits that are associated with 2 or more additional appointments on the same day from 33% to 50%. 3) Increase percentage of advanced lung cancer patients who receive a palliative care consultation from 10% to 75% and percentage of those who receive ongoing collaborative palliative care from 0% to 30%. In order to reach our goals, we implemented through this project, and with help from the VA Center for Applied Systems Engineering, multiple interventions including a new dedicated multidisciplinary weekly lung cancer clinic, dedicated patient navigator, weekly lung tumor board and nodule rounds, new lung cancer education clinic, new lung cancer tracking tools, distress screening and management and others. **Results:** From October 2013 to July 2014, percentage of NSCLC patients who received first treatment within 28 days from diagnosis was 58%. Percentage of medical oncology visits that were associated with 2 or more additional appointments on the same day was 60%. Percentage of advanced lung cancer patients who received a palliative care consultation was 90% and percentage of those who received ongoing collaborative palliative care was 69%. **Conclusions: "IVALuCancerCare"** project at the LSVAMC significantly improved the care for veterans with lung cancer. The project's goals were met. We plan to sustain and spread the above changes and identify new ways to further enhance our program.

6531 Poster Session (Board #88), Mon, 1:15 PM-4:45 PM

Cancer pain management practices and their impact on quality of life for Asian cancer patients. *First Author: Yong-Chul Kim, Department of Anesthesiology and Pain Medicine, Seoul National University School of Medicine, Seoul, Republic of Korea, Seoul, South Korea*

Background: In order to implement more effective policies for cancer pain management, a better understanding of current practices and their effects on patients are needed. The ACHEON study was a survey-based investigation of the impact of cancer pain and management practices on patients' quality of life in 10 Asian countries. **Methods:** Patients experiencing cancer pain were randomly surveyed in 10 Asian countries with a 33-item questionnaire assessing attitudes and perceptions towards cancer pain management. Patients aged ≥ 18 years with a documented history of cancer pain in the preceding month were selected. **Results:** Of the 1,190 patients (median age; 53, male/female 805/385) surveyed, 1,026 reported moderate-to-severe pain (median duration, 12 months). The attribution of the pain was 53% from cancer, 18% from cancer-related therapy and 29% from mixed sources. 1,056 (90%) patients were treated for their cancer pain and only 308 patients were receiving opioids, to their knowledge. Patients agreed that their pain affected activities of daily living (86%), sleeping patterns (87%), concentration and focus (92%), as well as causing too much reliance on other people (67%), while only a small proportion reported having a good quality of life (34%). Only 22% of patients were employed, and 44% of those had been absent from work for more than 7 days over the past 3 months due to their cancer pain. It was reported that 42% of the patients who were unemployed had stopped working due to cancer pain. **Conclusions:** The ACHEON study results show that cancer pain significantly affects multiple aspects of quality of life for patients. The development of more effective management practices for cancer pain will require collaborative efforts from institutional, social and regulatory parties.

6532 Poster Session (Board #89), Mon, 1:15 PM-4:45 PM

State variation in Medicare Part D and choice of initial endocrine therapy for breast cancer. *First Author: Liliana E Pezzin, Medical College of Wisconsin, Milwaukee, WI*

Background: Evidence suggests that drug utilization under Medicare Part D has been uneven, varying significantly by geographic region. We sought to examine the extent to which geographic variation in Part D plan characteristics contribute to the variation in choice of initial hormone therapy agent among women with incident breast cancer. **Methods:** Two-stage multivariate regression analyses applied to 23840 Medicare beneficiaries with incident breast cancer in 06-07. The first stage determined the effect of state of residence on the probability of having an aromatase inhibitor (AI, as opposed to tamoxifen) as the initial endocrine therapy, controlling for confounders. The second stage provided estimates of state-specific Part D plan characteristics on state variation in choice of initial hormone therapy. **Results:** There was substantial *residual* geographic variation in the likelihood of using an AI as the initial endocrine therapy, despite controls for socioeconomic status, breast cancer treatment, and other factors. Regression-adjusted probabilities of starting an AI ranged from 53.4% in Wyoming to 82.4% in New York. Nineteen states (38%) had adjusted probabilities significantly different than the national mean: 13 of those were above, while the remaining six states –WY, MT, MN, IA, NH, AR-- were significantly below the national mean. Results from the second stage revealed that variation in characteristics of Part D plans across states explained over one- third (35%) of the overall state-level variability in initiating endocrine therapy with an AI. A higher number of drug plans with cost sharing above the mean, greater spread in deductible costs and a greater spread in monthly drug premiums were associated with lower adjusted state probabilities of initiating an AI. In contrast, a higher number of drug plans with monthly premiums above the state mean and higher mean cost sharing were both positively associated with likelihood of starting on an AI. **Conclusions:** This study suggests that variability in use of AIs-- the newer, more effective breast cancer oral therapy-- could be significantly reduced by changing the benefit design underlying states' Part D plans.

6533 Poster Session (Board #90), Mon, 1:15 PM-4:45 PM

Analysis of home care coordination activities in oncology: A mixed methods study. *First Author: Fatima Yatim, Gustave Roussy, Villejuif, France*

Background: Many studies point out the importance of care coordination, but there are few descriptive studies about the content of coordination activities and how it responds to the needs of patients and professionals. Objectives: To identify the skills and competencies needed to perform home care coordination activities. **Methods:** The study was conducted at Gustave Roussy (Villejuif, France), into the department coordinating outpatient care for patients who need post-discharge home care. In a first step, a data grid was developed (a focus group with the nurses and the head of the department), and then refined during an observation period. After this qualitative analysis, a quantitative analysis studied the phone calls received at the coordination platform of this department (May-June 2014). The following data were systematically collected (date; caller; reason for the call; procedure performed), and then analyzed by two researchers. They identified five categories of actions, one clinical (F1), and four related to managerial and, organizational solutions (F2 to F5), validated by the staff members of the department. **Results:** 543 calls were analyzed. The callers were patients or their relatives (38%), private nurses (35%), medical devices providers (20%), other primary care providers (7%). Five categories of coordination activities were identified: (F1) Patient monitoring and management of clinical and non-clinical alerts (side effects) (32%); (F2) Helping to understand and navigate through the clinical pathway (information about healthcare professional contacts) (21%); (F3) Managing technical problems linked to the achievement of care (problem about medical devices delivery) (17%); (F4) Explaining some elements of the care protocol (use a medical device)(16%); (F5) Collecting and transmitting the patient medical record information (medical prescriptions) (14%). **Conclusions:** The majority of requirements for patients and professionals are related to managerial and organizational issues (e.g. navigation, lack of information about specific aspects of the clinical pathway). They require the implementation of new professional managerial skills, especially among nurse navigators and other new professions.

6534 Poster Session (Board #91), Mon, 1:15 PM-4:45 PM

Patients with advanced non-small cell lung cancer (NSCLC): Are research biopsies a barrier to participation in clinical trials? *First Author: Charles Henry Lim, University of Toronto, Toronto, ON, Canada*

Background: The evolution of targeted therapy in NSCLC has led to growing complexity of clinical research and a heightened expectation of clinical benefit for participants. Clinical trials in NSCLC increasingly require mandatory tumour samples or research biopsies, both potential barriers for trial participation. We assessed the impact of performing research biopsies in advanced NSCLC on clinical trial enrollment. **Methods:** We conducted a retrospective chart review of patients with advanced NSCLC evaluated for systemic therapy clinical trials at the Princess Margaret Cancer Center from 2010 to 2014. **Results:** Of 26 clinical trials reviewed, 21 required tumour samples for enrolment. Eleven required confirmation of a pre-specified biomarker in order to receive investigational treatment. Trial participation was offered to 151 patients at 293 unique study encounters (some enrolled in multiple trials). Forty-three percent proceeded to receive study treatment. Those considering trials without mandatory biopsies or tissue requirement were more likely to proceed to study treatment than those considering trials with these requirements (75% vs. 40%, $p = 0.009$). For trials requiring mandatory tumour samples, 210 consents for participation were obtained, 170 research biopsies were ordered and 88% were performed. Participants proceeded to study treatment in 57% of encounters; 7% of biopsies yielded insufficient tissue and 34% were "biomarker-negative". The most common barriers to trial enrollment included lack of the pre-specified biomarker (40%), other study exclusion criteria (17%), patient refusal of biopsy (11%), insufficient biopsy tissue (9%), and deteriorating clinical status/death (10%). **Conclusions:** With the evolution of personalized medicine, a growing number of NSCLC trials require tumour tissue for treatment eligibility. This has emerged as a significant barrier to clinical trial enrollment. Potential solutions include routine tissue banking at diagnosis, facilitating use of available diagnostic samples (e.g. fine needle aspirates) for trials, development of circulating DNA assays for trials, and more resources for timely tissue acquisition.

6535 Poster Session (Board #92), Mon, 1:15 PM-4:45 PM

Validation of a clinical trial accrual predictive model. *First Author: Wendy R. Tate, The University of Arizona Cancer Center, Tucson, AZ*

Background: The costly and extensive process to drug approval highlights the need to streamline the drug pipeline process. We previously reported a novel predictive model with the outcome of anticipated accrual to be used when considering a prospective clinical trial at our center. Here, we present the results of the validation study. **Methods:** Eligible studies include treatment and supportive care intervention studies permanently closed to accrual between 10/2013 and 01/2015 at our center. Data abstracted from the clinical trials management system (OnCore, Forte Systems, Madison, WI) included: use of investigational drug, disease management team (DMT), use of local IRB, local start date, DMT accrual prediction value, actual total accrual, and clinicaltrials.gov (NCT) number. Abstracted from clinicaltrials.gov were protocol-specific data: number of national sites, national enrollment goal, national start date, and national date of expected primary endpoint completion. Studies were run through the model and actual accrual plotted against predicted accrual. Actual, team- and model-predicted subjects accrued; percent of trials meeting cut-off values; and model sensitivity and specificity were calculated. **Results:** Sixty-one trials met study inclusion criteria. Total accrual was 373 subjects (mean: 6.1 ± 17.2); 16 (26.2%) studies had zero accrual, 23 (37.7%) accrued 88.7% of the total subjects. The model predicted accrual of 513 subjects (138% of actual) versus the DMT predicted accrual of 1111 subjects (298% of actual). The model correctly predicted whether a study would accrue 4+ subjects 75% of the time. Twenty-seven studies (44.3%) correlated perfectly at the category level. Model sensitivity is 70%; specificity is 78%. For the 17 studies not correctly categorized using a cutoff of four, nine (60%) would have been incorrectly opened (predicted 4+, < 4 accrued) and six (40%) would have incorrectly not opened (predicted < 4, 4+ accrued). **Conclusions:** The identified national and local factors to predict clinical trial accrual at our center are valid, showing it to be an accurate, quick and valuable metric in assessing trial success as well as planning resource allocation. Further research includes national expansion of the model to cancer centers.

6536 Poster Session (Board #93), Mon, 1:15 PM-4:45 PM

Emergency diagnosis of lung cancer: An international problem. *First Author: Thomas Newsom-Davis, Chelsea & Westminster Hospital, London, United Kingdom*

Background: Lung cancer survival in the United Kingdom (UK) is lower than similar healthcare systems in Europe. 40% of UK lung cancer patients are first diagnosed with their disease during presentation to emergency or acute medical services. This emergency presentation (EP) is associated with late diagnosis and lower 1-year relative survival. The gatekeeper role of the general practitioner (GP) has been suggested as a possible cause for the high rates of EP in the UK. We investigated whether EP is a feature of other healthcare systems in Europe. **Methods:** Retrospective data was collected on all lung cancer patients diagnosed in 2012 from 11 hospitals in 8 countries: Austria, Croatia, France, Ireland, Italy, Netherlands, Portugal and UK. Where required, ethical approval was obtained prior to data collection. **Results:** 2,315 patients were included, of which 534 (23.1%) were diagnosed as part of an emergency presentation. EP rates between counties ranged from 13.2% to 47.7% and did not correlate with whether GPs act gatekeepers to secondary care services in that country. EP was associated with older age, lower performance status, higher stage of disease, and certain histological sub-types such as small cell lung cancer. EP patients were less likely to receive a histologicl diagnosis, less likely to receive any anti-cancer treatment and if they did receive treatment it was less likely to be with curative intent. 76% of EP patients had significant medical co-morbidities. 59% presented with thoracic symptoms (dyspnea, chest/shoulder pain, cough, haemoptysis). The median length of inpatient stay was 14.31 days (range 0-68 days). Further comparative analysis between countries demonstrates the inter-country variation in patient demographics, presentation and management. **Conclusions:** The emergency route to lung cancer diagnosis is common across Europe, is associated with specific patient demographics, and represents a significant burden on acute services. The gatekeeper role of the GP does not appear to govern EP rates. Establishing the causes behind EP of lung cancer should allow identification, earlier diagnosis and better outcomes for this vulnerable patient population.

6537 Poster Session (Board #94), Mon, 1:15 PM-4:45 PM

Healthcare resource utilization and cost considerations in patients with soft tissue sarcoma treated with chemotherapy. *First Author: Chris M. Kozma, CK Consulting, St. Helena Island, SC*

Background: Locally advanced or metastatic soft tissue sarcoma(STS) is frequently treated with chemotherapy when symptoms develop. Healthcare resource use(HRU) and cost in patients(pts) with STS have not been widely reported. This study provides real world evidence on HRU and costs associated with initiation of STS chemotherapy. **Methods:** Adult patients whose first claim for STS chemotherapy (doxorubicin, gemcitabine, docetaxel, ifosfamide, cyclophosphamide, paclitaxel, dacarbazine, temozolomide, pazopanib, methotrexate, epirubicin, vinorelbine, vinblastine, vincristine) within 90 days of a STS diagnosis were identified in a 2005-2013 U.S. healthcare claims database. Patients had ≥ 12 months continuous enrollment before and six months after the index date (chemotherapy initiation). STS chemotherapy combination regimens were defined as all STS therapies within 90 days of index date. HRU costs were evaluated for the six months following index date. **Results:** This analysis identified 1206 STS patients. Mean (SD) age was 55 (14) years; 50% were male. Common pre-index comorbidities included hypertension (35%), hyperlipidemia (17%), and diabetes (11%). Doxorubicin-based regimens were reported as initial therapy in 44% of patients and gemcitabine-based regimens in 39%. The mean number of months (SD) a claim for STS therapy was observed during the six month period was 3.6 (1.6) months. The proportion of patients with treatment-related claims included radiation oncology 26%, colony stimulating factors 69%, red blood cell growth factors 21%, red blood cell transfusions 16%. During the observation period, the mean (SD) number of hospitalizations was 1.0 (1.7) and mean number of hospital days was 6.2 (11.0). The overall mean (median) cost was $103,000 ($80,750). Component costs are shown in the table below. **Conclusions:** This analysis reported HRU and costs in patients with STS in the six months following initiation of chemotherapy. Such information is useful to stakeholders in understanding the management of patients with STS and those with interest in episode of care costs.

	Hospitalization	Outpatient	Pharmacy	Emergency Room
Mean component cost	$26,300	$69,100	$6,500	$1,100

6538 Poster Session (Board #95), Mon, 1:15 PM-4:45 PM

Disparity by insurance status and race in receipt of aggressive and advanced treatments for high risk prostate cancer/PCa. *First Author: Brock R. Baker, UNC Chapel Hill, Chapel Hill, NC*

Background: Young and healthy men with high-risk PCa require aggressive treatment. We examined treatment received by these men using the National Cancer Data Base, which contains 70% of incident cancers across the US. We hypothesized a disparity by race and insurance on receipt of aggressive treatment and access to advanced surgical (robotic) and RT (proton or intensity-modulated RT) techniques. **Methods:** 12,778 men age < 65 with Charlson comorbidity score 0 diagnosed with NCCN high-risk PCa from 2010-12 were included. Logistic regression examined factors associated with treatment. **Results:** 97% received definitive treatment (either radical prostatectomy or radiation). However, there was a dramatic difference in use of RP by race (White 73%, Black 50%) and insurance (Private 71%, Medicaid 38%)(Table). On multivariate analysis (MVA) which adjusted for age, facility type and regional sociodemographics, race (Black vs White, OR .45, $p < .001$) and insurance (vs private, Medicaid OR .32, uninsured .39, $p < .001$ for both) remained associated with prostatectomy as primary treatment. Among surgical patients, 73% with private insurance received robotic surgery compared to 54% Medicaid patients (Table). In MVA, insurance was significantly associated with robotic surgery (vs private, Medicaid OR .48, uninsured .42, $p < .001$ for both). In MVA for RT patients, Medicaid vs private insurance was associated with less advanced technology (OR .73, $p = .02$). Black vs White race were not significantly different in receipt of advanced surgical or RT technologies. **Conclusions:** Young/healthy men with high-risk PCa who lack private insurance or were non-white were treated less aggressively. Medicaid and uninsured patients were also less likely to receive advanced surgical and RT technologies. These findings are difficult to explain medically and point to differences in treatment access.

Percentage of patients receiving each treatment.

		Primary Treatment			Surgical Technique			RT Technique		
		Prostatectomy	Not	p	Robotic	Not	p	Advanced	Not	p
Race	White	73	28	< .001	72	28	< .001	71	29	.002
	Black	50	50		68	32		66	34	
	Hispanic	61	39		61	39		67	33	
				p			p			p
Insurance	Private	71	29	< .001	73	27	< .001	70	31	.01
	Medicaid	38	62		54	46		61	39	
	Uninsured	44	56		51	49		68	33	

6539 Poster Session (Board #96), Mon, 1:15 PM-4:45 PM

Impact of health insurance transitions on cancer survivors and those with no cancer history. *First Author: Katherine S. Virgo, Emory University, Atlanta, GA*

Background: 15.4% of the U.S. population was uninsured in 2012. Those without coverage face limited health care access and are more likely to have poor outcomes. Cancer survivors are particularly at risk of insurance gaps due to the long-term nature of the disease. This study examines the association between cancer history and health insurance transition patterns, including insurance gain or loss, and the impact on access to care. **Methods:** Using longitudinal data from the Medical Expenditure Panel Survey (MEPS) for 2008-2012 (panels 12-16), 2386 cancer survivors and 41,211 individuals with no cancer history ages 18-63 upon MEPS survey entry during 2008-2011 were selected. Individuals were categorized as initially uninsured or insured based on first stable consecutive three-month insurance status. Multivariate logistic regressions were used to assess the association between cancer history and insurance loss or gain based on first coverage change, adjusting for the MEPS complex survey design. **Results:** Uninsured cancer survivors were more likely to gain insurance and insured cancer survivors were less likely to lose insurance than those with no cancer history (42.5% and 34.1%; 9.9% and 14.6%, respectively). In adjusted analyses, cancer history was positively associated with insurance gain and negatively associated with insurance loss; but insignificant ($p = 0.06$; $p = 0.11$, respectively). Initially uninsured, younger (18-34), non-Hispanic white, occasionally employed, risk-averse individuals were more likely to gain insurance. Initially insured, younger (18-44), low income, occasionally employed males in fair to poor health were more likely to lose insurance. Those remaining uninsured or losing insurance were more likely to experience problems accessing needed medical care and less likely to have a usual source of care. **Conclusions:** Cancer history is associated with health insurance transition patterns. Different factors impact insurance gain and loss. Cancer survivors need stable health insurance coverage, yet coverage is inconsistent. Providing incentives to those with inconsistent access, such as the young, to enroll in health insurance could decrease volatility in coverage and improve continuity of care.

6540 Poster Session (Board #97), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling of rare tumors in a dedicated community clinic. *First Author: William Jeffery Edenfield, Clinical Research Unit – ITOR Greenville Hospital System, Greenville, SC*

Comprehensive genomic profiling of rare tumors in a dedicated community clinic W. Jeffery Edenfield[1], Ryan Fields[1], Siraj M. Ali[2], W. Larry Gluck[1], Julian Chmielecki[2], Jeffrey S. Ross[2], Phillip J. Stephens[2], Vincent A. Miller[2], Ki Chung[1] [1]Greenville Health System Cancer Institute, Greenville,SC. [2]Foundation Medicine, Boston, MA **Background:** Rare tumors by European Union (EU) definition are uncommon (< 6/100,000 patients), but aggregately number more than all other solid cancers. With few prospective trials to guide treatment, therapy is based on minimum merit by case reports and small series. Comprehensive genomic profiling (CGP) may provide insight into tumor biology and identify rational therapeutic choice. **Methods:** In March 2014, the rare tumor clinic began evaluating 4-6 patients/month using CGP. DNA was extracted from 40 micron FFPE sections from 39 patients. All classes of genomic alterations were evaluated. Important alterations identified links to marketed drugs available or agents under evaluation in mechanism driven trials. **Results:** Patients were diverse. Of the 39, 6 each of biliary origin or sarcomas, 5 each neuroendocrine or glandular head and neck, and 3 mixed mullerian tumors. Nearly half had commercial drug options (18/39); 15/39 had available trial choices matched to their alteration. 61% of patients derived actionable information. 9 patients had both off-label and trial options. Marked clinical response to pazopanib in a patient with metastatic hemangioendothelioma and VHL mutation as well as a novel melanoma *ALK-OTAF* fusion will be reported separately. 3 potential germ line mutations were identified. **Conclusions:** CGP of tumors from 39 patients with rare cancers provided relevant information in the majority of cases. Although outcomes data are premature, this approach represents a reasonable standard for patients with rare cancers. The potential discovery of germline associated malignancy identifies the need for genetic consultation.

6541 Poster Session (Board #98), Mon, 1:15 PM-4:45 PM

Precision oncology: molecular testing and targeted treatment beyond indication. *First Author: Josh John Carlson, University of Washington, Seattle, WA*

Background: Advances in cancer research indicate that successful treatment may depend more on genomic alterations in the tumor rather than the organ of origin. However, data on the use of off-label molecular testing and targeted treatment is lacking. Our objective was to evaluate off-label testing and targeted treatment in a commercially insured population. **Methods:** We analyzed data from the MarketScan databases, a large employer-based claims repository, from 2011-2013 on the use of off-label molecular tests and targeted drugs for the top 10 incident cancers. We limited the analysis to the metastatic setting using a previously validated algorithm. We defined off-label use as using the test or agent in a tumor type not included in an FDA-approved medication label. **Results:** Test use was limited overall, but rose considerably in 2013 with the most use in lung, colon, and breast cancers. There was also limited though non-negligible use of targeted agents with the most common being erlotinib, imatinib, trastuzumab, vemerafinib, and dasatinib. Drug use rates remained relatively constant over the three-year period. Off-label treatment was most common in breast, lung, and colon cancers. **Conclusions:** There is limited but non-negligible use of off-label molecular testing and targeted treatment in the top 10 incident cancers. Further work will explore predictors of off-label use and patient outcomes.

6542 Poster Session (Board #99), Mon, 1:15 PM-4:45 PM

Social-ecological perspectives on breast cancer care seeking patterns in Karnataka, India. *First Author: Arun S. Shet, University of Minnesota, Minneapolis, MN*

Background: India bears approximately ten percent of the global burden of breast cancer but has lower survival rates than developed countries possibly due to delays in diagnosis and treatment. Early recognition and diagnosis of breast cancer potentially offers the opportunity for treating the early stage disease and potentially improve treatment outcomes. The underlying factors responsible for delays in access to treatment are not well-defined. There are few published studies that attempt to understand the factors that facilitate or impede care-seeking and timely diagnosis and treatment of breast cancer in the Indian context. **Methods:** Using the social-ecological theory of behaviour, we conducted semi-structured in-depth interviews with 27 breast cancer patients and 22 primary caregivers receiving care at a non-profit tertiary care hospital in Bengaluru, India to understand how care-seeking and the timing of diagnosis and treatment were influenced by multilevel factors, including knowledge and awareness of breast cancer, family and community reactions to symptoms and diagnosis, and availability and access to different types of clinical services. **Results:** Factors that impeded timely diagnosis and treatment were women's lack of awareness about the signs and symptoms and the need for timely care-seeking, competing family/household priorities, fear of a cancer diagnosis, inconsistent pathways through the healthcare system for diagnosis and treatment, financial constraints, and fear and stigma related to cancer.The main facilitators in care seeking included hope of getting cured, financial and social support from the family. **Conclusions:** A range of multilevel factors seem to be associated with women's breast cancer care trajectories. Qualitative findings suggest that multifaceted interventions that address knowledge, fear and stigma among individuals, families and communities and that improve access to health care through financial protection may be needed to downstage breast cancer in India.These emerging findings from our qualitative research are being used to develop a quantitative instrument to further study this issue using a more representative sample.

6543 Poster Session (Board #100), Mon, 1:15 PM-4:45 PM

Medical Oncologists' and Surgeons' approaches to communication of breast cancer recurrence risk. *First Author: Aaron Sabolch, Department of Radiation Oncology, University of Michigan, Ann Arbor, MI*

Background: Risk of breast cancer recurrence can be estimated with tools such as Adjuvant! Online, but little is known about how medical oncologists and surgeons use such tools or communicate risk information to patients. **Methods:** In 2012, we surveyed 750 medical oncologists and 750 surgeons identified using the AMA Physician Masterfile (a comprehensive physician list not limited to AMA members). Using a vignette, we evaluated risk communication practices (discussing risk using descriptive words, discussing risk using numbers, using online calculators, providing copy of risk estimates) and analyzed correlates of specific approaches in a logistic regression model that included physician (e.g., gender, specialty) and practice characteristics (number of breast cancer patients seen in past year, multidisciplinarity [i..e., offering same-day multi-specialty appointments]). **Results:** 498 surgeons and 398 medical oncologists responded (60.5% response rate). We excluded 130 who did not see breast cancer pts. Respondents averaged 19 years in practice, 79% were male, 74% saw > 10 breast cancer pts/yr, and 45% offered same-day multi-specialty appointments. 84% of medical oncologists and 85% of surgeons reported discussing recurrence risk using terms such as "high risk." Medical oncologists were much more likely than surgeons to use an online risk calculator (76 vs 24%, $p < .001$), provide numerical risk estimates (88 vs 47%, $p < .001$), and provide a copy of risk estimates (71 vs 17%, $p < .001$). Specialty ($p < .01$) and multidisciplinarity ($p < .01$) were the only significant independent correlates of communication practices. After controlling for specialty, clinicians offering same-day multi-specialty appointments were more likely to use online calculators (OR 1.6, 95% CI 1.1 - 2.3) and discuss numerical risk estimates (OR 1.8, 95% CI 1.2 - 2.5). **Conclusions:** Most medical oncologists use online calculators and numerical estimates to communicate recurrence risk to breast cancer patients; fewer surgeons do so. Patients who do not see a medical oncologist until after surgery may make critical treatment decisions (including whether to remove the contralateral breast) without full understanding of relevant risk information.

6544 Poster Session (Board #101), Mon, 1:15 PM-4:45 PM

A systematic approach to smoking cessation in Ontario's Regional Cancer Programs. *First Author: William K. Evans, McMaster University, Hamilton, ON, Canada*

Background: Smoking cessation (SC) is rarely undertaken in busy cancer centres but potential health benefits in cancer patients include improved general health, improved all-cause and cancer-specific mortality, reduced toxicity, greater response to treatment, decreased risk of disease recurrence and of second primaries. Based on this evidence, Cancer Care Ontario (CCO) undertook a SC initiative for new ambulatory cancer patients in its Regional Cancer Programs (RCPs). **Methods:** A steering committee recommended a framework for SC in RCPs in 2012, based on the Ottawa Model for Smoking Cessation. The initiative was piloted in all 14 provincial health regions in 2014. Regional SC "champions" participated in monthly web meetings, data calls and in-person meetings led by a secretariat at CCO. Presentations on the health benefits of SC were made to physicians and other health care providers in the RCPs. New ambulatory cancer patients are screened, advised and referred to internal or external SC services dependent on regional resources. CCO's data collection processes capture performance metrics. Patient data are aggregated at the RCP-level and provincial performance indicators reported quarterly. A standardized cancer patient resource on SC will be available in both French and English in a print-ready format and adapted for the Aboriginal population by March 2015. **Results:** During Q1 and Q2 of the 2014/15 fiscal year, 56.0% (Q1) and 51.5% (Q2) of new ambulatory cancer cases were screened for their smoking status: 25% of those screened were current or recent smokers (within last 6 months); 75% of these were advised of the benefits of cessation; nearly 50% were recommended a referral for cessation services, and about 67% of those referred accepted a referral. **Conclusions:** CCO's approach has led to province-wide implementation of a standardized intervention in a relatively short timeframe despite limited financial resources. Despite oncologist resistance and limited regional resources, there has been substantial progress. Framing SC as a quality of care issue has been critical to the success to date. Sustainability of the initiative will be dependent on funding for dedicated SC counselors and evidence of program cost-effectiveness.

6545 Poster Session (Board #102), Mon, 1:15 PM-4:45 PM

The impact of chemotherapy on hospitalizations and emergency care in older adults with advanced cancer. *First Author: Elena B. Elkin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The benefits of systemic chemotherapy for metastatic disease vary by tumor type and must be weighed against potential side effects. In patients receiving chemotherapy for advanced cancer, toxicity-related hospitalizations and emergency room (ER) visits may reduce the quality of an already limited life expectancy, particularly in the face of modest or uncertain expected benefit. **Methods:** In the population-based SEER-Medicare dataset, we identified patients 66 years or older diagnosed in 2001-2009 with metastatic cancer originating in one of 10 disease sites. The cohort was limited to patients who died by December 31, 2010. Chemotherapy recipients were matched to non-recipients by age, sex, race, geographic region, comorbidity and survival duration. The impact of chemotherapy on toxicity-related and any-cause hospitalizations and ER visits were estimated by cancer site in multivariable regression models, controlling for additional demographic characteristics. **Results:** Of 18,486 patients who received systemic chemotherapy for metastatic cancer, 92% had a hospitalization and 83% had an ER visit. Among their matched peers who did not receive chemotherapy, rates of hospitalization and ER visit were 83% and 72%, respectively. Controlling for patient and disease characteristics, chemotherapy was associated with a significantly increased risk of toxicity-related hospitalization in all 10 cancers: bladder, breast, prostate, colorectal, esophageal, pancreatic, stomach, ovarian, small cell and non-small cell lung cancers [adjusted odds ratios from 1.40 (95% CI 1.19-1.65) in prostate cancer to 3.16 (95% CI 2.79-3.57) in small-cell lung cancer] and similarly increased risks of toxicity-related ER visit in all 10 cancers [adjusted odds ratios from 1.26 (95% CI 1.10-1.53) in prostate cancer to 2.84 (95% CI 2.51-3.22) in small-cell lung cancer]. **Conclusions:** Hospitalizations and ER visits are common in patients with incurable advanced malignancies, and more likely among those who receive chemotherapy. Understanding common causes of these events may help reduce adverse effects of chemotherapy for metastatic cancer, and help patients and their families make informed treatment decisions.

6546 Poster Session (Board #103), Mon, 1:15 PM-4:45 PM

Wealth, health expenditure, and cancer: A national perspective. *First Author: Jad Chahoud, The University of Texas Health Science Center, Houston, TX*

Background: The healthcare system in the United States (US) is characterized by high expenditures with penultimate health outcomes. Socioeconomic status is a strong determinant of general population health. Our study evaluates the associations between (1) wealth and cancer outcomes, and (2) health expenditure and cancer outcomes at the State level. **Methods:** We used publicly available data from the Bureau of Economic Analysis, the Centers for Medicare and Medicaid Services and the United States Cancer Statistics. We employed GDP per capita and Health expenditure per capita as indicators for wealth and health expenditure respectively. As for cancer outcomes, we used incidence and mortality rates as well as mortality/incidence (M/I) ratios. We constructed scatter plots to illustrate these associations and used the Spearman's rank correlation coefficient to determine their strength, directionality and significance. **Results:** GDP per capita was significantly correlated with lower M/I ratios for all cancers (rho = -0.4406; p = 0.0017), breast cancer (rho = -0.3605; p = 0.0118) and colorectal cancer (CRC) (rho = -0.3612; p = 0.0117). As for health expenditure per capita, a preliminary descriptive analysis highlighted a rift between the Northeastern and the Southern States. This wide gap in health expenditure translated into worse all-cancer and breast cancer outcomes in Southern states. Further analysis showed that higher health expenditure was significantly correlated with decreased breast cancer M/I ratio (rho = -0.4237; p = 0.0027). However, CRC outcomes were not significantly affected by high health expenditure (rho = -0.1634; p = 0.2670), neither were all-cancer outcomes (rho = -0.2458; p = 0.0922). **Conclusions:** Cancer outcomes are strongly correlated with wealth as both breast cancer and CRC had significantly better outcomes in states with higher GDP per capita. However, only breast cancer outcomes were significantly correlated with higher health expenditure. CRC outcomes were not associated with higher health expenditure. This highlights a need for future research assessing the optimization of resource allocation in the States' efforts against CRC.

6547 Poster Session (Board #104), Mon, 1:15 PM-4:45 PM

How TNM stage affects surveillance intensity after treatment for breast cancer. *First Author: Daniel Wu, Saint Louis University School of Medicine, Saint Louis, MO*

Background: The mean lifetime cost of surveillance for a woman diagnosed with breast cancer at age 45 is estimated to be > $35,000. Based on trials comparing low and high intensity surveillance, ASCO and NCCN have published recommendations encouraging low intensity strategies. We aimed to determine whether ASCO experts carry out surveillance differently for patients with breast cancer of varying TNM stages. **Methods:** We created a web-based survey instrument with 4 idealized patient vignettes depicting patients with TNM stages 0 to IIIA. Respondents were asked how often they would recommend 12 specific diagnostic modalities for each vignette during post-treatment years 1-5. The survey was e-mailed to the 3245 ASCO members who had identified breast cancer as their major clinical focus. We used repeated measures ANOVA for analysis. **Results:** 1,012 (31%) of the 3245 ASCO members surveyed responded. There were 915 (90%) evaluable responses. Office visit was most frequently recommended. Responders also commonly recommended complete blood count (CBC), liver function tests (LFTs), and mammogram. There was statistically significant variation in recommended surveillance intensity for all 12 modalities according to TNM stage. **Conclusions:** We have demonstrated significant variability in surveillance after curative-intent treatment. Modalities not recommended by ASCO guidelines, such as CBC and LFTs, are frequently recommended by physicians. The frequency of recommended modalities varied depending on the TNM stage of the described patients, but ASCO guidelines do not stratify according to TNM stage. Our results suggest both overuse and underuse of surveillance modalities. Innovative solutions to promote physician and patient education can help physicians follow evidence-based surveillance guidelines and help patients to participate in these decisions. There is a need for new randomized controlled trials to evaluate newer surveillance modalities to guide clinical practice.

Frequency of recommended use of office visits: mean ± SD.

Year	TisN0M0	T2N0M0	T1N1M0	T3N2M0
1	2.8 ± 1.2	3.3 ± 1.3	3.3 ± 1.2	4.1 ± 2.2
2	2.5 ± 1.2	3.0 ± 1.1	3.0 ± 1.1	3.3 ± 1.2
3	2.1 ± 1.3	2.4 ± 1.1	2.5 ± 1.2	2.7 ± 1.3

5	1.9 ± 1.5	2.1 ± 1.3	2.2 ± 1.3	2.4 ± 1.3

6548 Poster Session (Board #105), Mon, 1:15 PM-4:45 PM

Racial differences in 20-year cardiovascular outcomes among childhood and young adult cancer survivors. *First Author: Amy M Berkman, University of Vermont, Burlington, VT*

Background: Individuals diagnosed with childhood (0-14 years) or young adulthood (15-34 years) cancers are at higher risk of cardiovascular disease (CVD) death compared to those without a history of cancer. No study has investigated whether CVD risk differs as a function of race and primary cancer type. **Methods:** Case data from the years 1973-2011 were analyzed using the 2013 Surveillance, Epidemiology and End Reports (SEER) registries. We categorized cases according to ICD-0-3 / WHO 2008 Adolescent and Young Adult classification. CVD death was based on ICD-10 codes for: diseases of the heart, atherosclerosis, cerebrovascular diseases or other diseases of the arteries. Hazard ratios were calculated using Fine & Gray methodology for competing risks (all-cause, cancer and CVD mortality) and relative risk ratios were calculated to compare risk of CVD death by race (black : white). **Results:** A total of 164,316 cases of childhood and young adult primary cancers were identified, of which 16,060 cases were black (10%), 133,932 cases (82%) were white, and 14,314 (8%) were other or unknown. There were a total of 1,584 CVD deaths. Overall, blacks had a higher risk of CVD death compared to whites at 5-years (RR 2.15, 95% CI: 1.65-2.80), 10-years (RR 2.23, 95% CI: 1.80-2.76), and 20-years (RR 1.83, 95% CI: 1.54-2.17) from the date of cancer diagnosis. The relative risk for CVD death between blacks and whites varied by cancer type, with the largest black:white difference among those diagnosed with CNS neoplasms at 10-years (HR 3.02, 95% CI: 1.47-6.18) and melanoma at 5-years (HR 26.9, 95% CI: 3.40-212.08). **Conclusions:** Black individuals diagnosed with cancer in childhood or young adulthood have a higher risk of CVD at 5-, 10-, and 20-years compared to whites. The risk of CVD mortality among blacks and whites varied by cancer type and time from cancer diagnosis. Further study is needed to understand the etiology of racial differences in this population.

6549 Poster Session (Board #106), Mon, 1:15 PM-4:45 PM

Factors associated with the large disparities in *BRCA* testing among high risk Black women. *First Author: Tuya Pal, H Lee Moffitt Cancer Ctr and Rsrch Inst, Tampa, FL*

Background: Concerns about genomic advances to increase health disparities have been raised. We sought to explore factors associated with receipt of *BRCA1* and *BRCA2* (*BRCA)* testing and assess for racial disparities through a population-based sample of young breast cancer survivors. **Methods:** Women diagnosed with invasive breast cancer at or below age 50 in 2009-2012 were recruited through the Florida State Cancer Registry with oversampling of Blacks compared to non-Hispanic Whites (NHW). Participants were asked to complete a baseline questionnaire and a medical records release for verification of genetic test results. Summary statistics, Pearson Chi-square tests and multivariable logistic regression were used to examine associations between dichotomous demographic and clinical variables and access to *BRCA* testing rates prior to enrollment. **Results:** Of the 877 participants included in this analysis, 36.7% (165/450) of Blacks versus 67.7% (289/427) of NHW had *BRCA* testing ($p < 0.001$). Medical record verification of the *BRCA* test result was achieved in over 75% of the sample. In the final logistic regression model, controlling for educational attainment and household income age at breast cancer diagnosis and triple negative status, NHW race remained the strongest predictor for having had *BRCA* testing with an odds ratio (OR) of 4.2 (95% Confidence Interval: 3.0-6.1). Other highly significant predictors of having *BRCA* testing included: 1) breast cancer diagnosis at or below age 40 (OR: 3.4); 2) annual income of $25,000 or greater (OR: 2.6); 3) triple negative disease (OR: 1.9); and 4) college education or higher (OR: 1.7) (all p-values < 0.005). Variables not significantly associated with having *BRCA* testing included having private insurance at the time of diagnosis and having children. **Conclusions:** Our results demonstrate the enormous disparity in *BRCA* testing among high risk Black women compared to NHW, which is not explained by socioeconomic factors. The rapid diffusion of gene-based care to refine cancer prevention and treatment and ultimately improve patient outcomes underscores the need to systematically understand and address these disparities so all populations may benefit from these scientific advances.

6550 Poster Session (Board #107), Mon, 1:15 PM-4:45 PM

Perceptions of clinical trial participation in African American cancer patients. *First Author: Daniel M. Geynisman, Fox Chase Cancer Center, Philadelphia, PA*

Background: African Americans (AA) participate in oncologic clinical trials (CT) at lower rates than Caucasians, despite a disproportionally high rate of cancer. While general barriers to participation in CT among AA have been explored, little is known in regard to specific differences of perspectives in those who do or do not participate. Based on an initial and separate qualitative analysis of 16 patients, a perceptual mapping survey was developed to explore barriers and facilitators to participation in CT amongst AA. **Methods:** We surveyed AA adult cancer patients at two cancer centers about demographics and knowledge, beliefs, attitudes and perceptions in regard to CT. We asked them to report how much they agreed or disagreed on a 0-10 scale (0 = strongly disagree, 10 = strongly agree) with statements regarding clinical trials' helpfulness, benefits, barriers, and value, support from those around them, and beliefs about healthcare providers. We used descriptive statistics and t-tests to assess for differences between those willing to and unwilling to participate in CT. **Results:** Of 41 patients recruited, 54% have not participated in a CT within the last 9 months. Mean age was 60 years (27-78), 51% were female, 39% completed high school and 71% had private insurance. CT participants more strongly agreed that their doctor had given them enough information to make a decision about being part of a CT ($p < 0.001$). Agreement that the benefits of being in a CT outweigh the possible side effects ($p = .016$) and that being in a CT offers the best treatment available for cancer ($p = .015$) were also stronger among CT participants. Non-CT participants more strongly believed that being in a clinical trial would make them sicker ($p = .019$), that important information would be withheld from them if they were in a clinical trial ($p = .008$) and that no one talked to them about being part of a CT ($p < 0.001$). **Conclusions:** Significant perceptual differences between AA cancer patients who have and have not participated in a CT were noted. Greater attention needs to be given to addressing negative perceptions of CT, as well as ensuring that all AA cancer patients receive clear and sufficient information regarding CT participation in order to make an informed decision about their care.

6551 Poster Session (Board #108), Mon, 1:15 PM-4:45 PM

Racial disparities in attrition among oncology clinical trial participants. *First Author: Leo Chen, University of British Columbia, Surrey, BC, Canada*

Background: Studies indicate that racial minorities are underrepresented in clinical trials. The outcomes of these minority groups following study enrollment are less clear. Our aims were to compare outcomes between White and non-White patients (pts) enrolled in oncology clinical trials and to determine if there are persistent racial disparities among study participants. **Methods:** All pts who participated in phase III breast, lung, gastrointestinal (GI) and genitourinary (GU) cancer clinical trials from 1999 to 2013 at any of the regional cancer centers in British Columbia were included. We conducted time-to-event analyses with attrition as the main outcome, defined as the time interval from study randomization to when a participant was removed from study due to 1) a primary disease-related endpoint being reached (e.g. recurrence, progression, or death) or 2) a non-cancer related cause (e.g. treatment toxicity). Multivariate Cox regression models were constructed to examine the impact of race on attrition, while adjusting for age, gender, ECOG, tumor site, and cancer stage. **Results:** We identified 780 pts with known racial status: 564 (72%) White and 216 (28%) non-White. Median age was 58 years, 70% female, 54%/35% ECOG 0/1, 43% stage IV disease, and 55%/20%/15%,10% enrolled in breast, lung, GI and GU trials, respectively. Attrition occurred in 364 (47%) pts of whom 146 (40%) were due to a primary study endpoint and 218 (60%) were attributable to non-cancer related factors, such as toxicity. Compared to White pts, non-White pts experienced higher overall (43% vs 57%, $p = 0.0004$) and cause-specific attrition (18 vs 22% and 25 vs 35% for cancer and non-cancer causes, respectively). Multivariate adjusted analysis continued to show that non-White pts faced greater likelihood of attrition due to cancer (HR 1.45, $p = 0.012$) as well as non-cancer related factors (HR 1.43, $p = 0.050$). Increased age, poor ECOG, and advanced disease were also associated with worse trial outcomes (all $p < 0.05$). **Conclusions:** In addition to underrepresentation in clinical trials, racial minorities were more likely to face attrition during study participation, potentially further hindering the generalizability of study findings in the real world population.

6552 Poster Session (Board #109), Mon, 1:15 PM-4:45 PM

Evaluation of hematology/oncology patient and physician expectations for integrative oncology in an ethnically diverse population. *First Author: Damien Mikael Hansra, Oncology and Radiation Associates, Miami, FL*

Background: Many integrative modalities are recommended in NCCN guidelines & evidence shows increased patient (pt) utilization.We aim to compare how integrative services are valued between hematology/oncology physicians (MD) & pts. **Methods:** Pts & MDs at an academic tertiary care medical center were enrolled to complete a survey. Demographics include: age, gender, race, & ethnicity. Clinical info include: cancer subtype & treating MD. Survey consisted of 7 questions assessing opinions on integrative care asking: "In addition to standard care, it is important to incorporate/provide" nutrition services, exercise therapy, spiritual/religious counseling, supplement/herbal advice, support groups, music therapy, or other complimentary medicine services (acupuncture, massage, relaxation therapy). Answers recorded on a 5 point scale (1 = highly disagree, 2 = disagree, 3 = neutral, 4 = agree, 5 = highly agree) & converted into 2 categories (1,2,3 = neutral/disagree vs. 4,5 = agree). Fisher's exact test with 2 sided p-value used to compare significance between MD & pt responses. **Results:** 909 pts and 55 MDs enrolled from June 2013 to January 2015. Pt mean age 55, range 18-88 with 47% male & 53% female. 65% of pts were Hispanic vs. 35% not Hispanic. 81% white, 12% black/African American, 2% Asian/Pacific Islander, & 5% other. 15% of pts had hematologic disorders (93% malignant 7% benign) vs. 85% of pts had solid malignancies. Significance disparities were demonstrated: 82% of pts agree that nutritional advice is important vs. 67% of MDs, $p = 0.01$, exercise therapy (86% vs. 73%, $p = 0.02$), spiritual/religious (68% vs. 50%, $p = 0.01$), supplement/herbal therapies (85% vs. 56%, $p < 0.0001$), music (64% vs. 30%, $p < 0.0001$), &"other complementary services" (75% vs. 45%, $p < 0.0001$). Non statistical favoring of support groups by pts observed (71% vs. 68% respectively, $p = 0.64$). **Conclusions:** With with exception of support groups, pts value integrative modalities more than MDs. It is expected that increased availability & utilization of integrative oncology modalities at tertiary hospital sites could improve pt satisfaction, quality of life, & other clinical endpoints.

6553 Poster Session (Board #110), Mon, 1:15 PM-4:45 PM

Genomic landscape of primary breast cancer in black vs. white women and association with tumor recurrence. *First Author: Tanya Keenan, Massachusetts General Hospital, Boston, MA*

Background: Black Americans are much more likely to die from breast cancer (BC) than white Americans. While socioeconomic issues contribute to this disparity, the influence of genomics is unclear. We aimed to determine key genomic traits and their effect on BC recurrence. **Methods**: Whole exome sequencing and gene expression data collected between 2010 and 2014 on primary breast tumors were obtained from The Cancer Genome Atlas. Genomic profiles, including intratumor genetic heterogeneity measured by the mutant-allele tumor heterogeneity (MATH) algorithm, were compared by race with logistic regression models. Cox proportional hazard models evaluated the association of race, triple negative breast cancer (TNBC), mutations, MATH, and PAM50 subtype with risk of tumor recurrence. **Results**: A total of 609 white Americans and 102 black Americans were analyzed. Black Americans had significantly more TNBC than white Americans. Black Americans compared to white Americans had more TP53 mutations (43.1% vs 27.3%, $p = 0.002$) and fewer PIK3CA mutations (20.6% vs 34.0%, $p = 0.01$). MATH was greater (5.3 units, 95% CI 2.6 to 8.0, $p < 0.001$) in black Americans than in white Americans. Black Americans had a greater prevalence of the PAM50 basal subtype (40.2% vs 18.6%, $p < 0.001$) and a lower prevalence of the PAM50 luminal A subtype (10.8% vs 35.0%, $p < 0.001$) than white Americans. By Lehmann TNBC subtype, black Americans had more basal-like 1 tumors (25.9% vs 9.8%, $p < 0.001$). Of the 506 white Americans and 89 black Americans with follow up data, black Americans also had a higher risk of tumor recurrence than white Americans (Table). Separate adjustment for TP53 mutation, PAM50 subtype, and TNBC but not MATH decreased the magnitude and significance of the racial association with tumor recurrence. **Conclusions**: Besides having a higher prevalence of TNBC, BC in black American women had significantly greater TP53 mutations, intratumor genetic heterogeneity, PAM50 basal tumors, and TNBC basal-like 1 tumors, all of which are associated with more aggressive tumor biology. These genomic differences could contribute to racial disparities in BC outcomes.

	Hazard Ratio for Tumor Recurrence	95% CI	p
Black race (adjusted for age, stage)	2.22	(1.05, 4.67)	0.04
Black race additionally adjusted for MATH	2.19	(1.03, 4.64)	0.04
TP53 mutation	1.99	(0.94, 4.21)	0.07
TNBC	1.57	(0.72, 3.44)	0.26
PAM50 subtype	1.41	(0.64, 3.09)	0.39

Treatment and characteristics of stage II colon cancer patients residing in CDC Specialized Registry areas. *First Author: Mary Elizabeth O'Neil, Centers for Disease Control and Prevention, Atlanta, GA*

Background: Some guidelines advise adjuvant chemotherapy be considered after surgical resection for high-risk stage II colon cancer patients; however, high-risk criteria are ill-defined and the long term benefits debated. This study documents patterns of care by selected patient and tumor characteristics using a population-based cohort of stage II colon cancer patients diagnosed in 2011. **Methods:** We used data from 10 CDC Specialized Cancer Registries participating in the National Program for Cancer Registries' (NPCR) Enhancing Cancer Registry Data for Comparative Effectiveness Research (CER) project to describe demographic and clinical characteristics of stage II colon cancer patients treated by surgery and adjuvant chemotherapy. We evaluated factors associated with adjuvant chemotherapy by logistic regression. **Results:** Of a total of 3,999 stage II colon cancer patients, 14.0% were treated with surgery and adjuvant chemotherapy compared to 83.6% by surgery alone. The patients treated with surgery plus adjuvant chemotherapy were more likely to be white (82.3%), non-Hispanic (83.8%), and younger but there were no differences by gender or urban residence. Most patients were insured by Medicare alone (28.2%) or private insurance (includes Medicare with private supplement) (45.9%). Approximately one-third (34.6%) had a T4 extension, 13.4% had < 12 lymph nodes examined, 21.7% had lymphovascular invasion and 21.6% were Grade III. Compared to surgery alone, the four characteristics associated with adjuvant therapy were younger age (median 61 years vs. 71 years; adjusted odds ratio [aOR]: 0.94, $P < .01$); T4 invasion (aOR: 4.38, $P < .01$); lymphovascular invasion (aOR 1.83, $P < .01$) and grade (aOR comparing Grade III to I: 1.78, $P < .01$). **Conclusions:** In this population-based cohort, younger stage II colon cancer patients with T4 lesions, lymphovascular invasion and a poorly differentiated tumor were more likely to receive adjuvant chemotherapy in addition to surgery. Ongoing data collection on outcomes, both recurrence and survival, will help clarify the benefits of adjuvant treatments in stage II colon patients. Better tools for risk stratification and predicting treatment benefits are still needed.

6555 Poster Session (Board #112), Mon, 1:15 PM-4:45 PM

The impact of the National Breast and Cervical Cancer Early Detection Program (NBCCEDP) in reducing outcome disparities based on race. *First Author: Mark A Fiala, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: The NBCCEDP, created in 1990, provides breast and cervical cancer screening and diagnostic services to low-income and uninsured women. The program's effectiveness in reducing racial disparities in outcomes is unclear. Therefore, we examined the incidence of metastatic (distant) disease at diagnosis and the mortality rates of women with metastatic disease by race before and after the advent of the NBCCEDP. **Methods:** Using the SEERStat software, we extracted the case listings of all women diagnosed with breast or cervical cancer from 1981 through 2010 in Surveillance Epidemiology and End Results (SEER)-9 registries database based on the November 2013 submission. Autopsy or death certificate only cases were excluded. As the targeted ages for breast cancer screening is 50-69 years old and 16-69 years old for cervical, only cancers diagnosed during those respective ages were included. The women were divided into three cohorts based on the year of diagnosis [1981-1990; 1991-2000; 2001-2010]. Socioeconomic status was approximated by median household income of county of residence from the 2000 US census. Incidence rates of metastatic disease were compared using χ^2, and mortality rates were compared using multivariate cox regression. **Results:** 224,183 women with breast cancer and 28,532 with cervical cancer were analyzed. Black women represented 15% of the breast cancers and 9% of the cervical. The proportion of women with metastatic disease was consistently higher for black women than white women. The mortality rate of those with metastatic disease, adjusted for year of diagnosis, age, and SES, was also consistently higher for black women than white women (Table 1); neither improved during the two most recent decades. **Conclusions:** Racial disparities persist between black and white women with breast or cervical cancer despite the screening efforts of the NBCCEDP.

Religious beliefs and stage at diagnosis in a biracial sample of newly diagnosed colon cancer patients. *First Author: Blase N. Polite, The University of Chicago, Chicago, IL*

Background: Blacks are more likely to present with advanced stage colon cancer and more likely to die from this disease than Whites. Blacks are also more likely to place God in control of their health care decision-making. Limited evidence in breast cancer suggests stronger religious beliefs may lead to more delayed care and more advanced stage at diagnosis especially among Blacks. **Methods:** Newly diagnosed patients with colon cancer were recruited at 9 facilities in metropolitan Chicago (2 public and 4 private non-academic, and 3 academic institutions). Eligible patients had a diagnosis of a first primary invasive colon cancer between the ages of 30 and 79 years, and were non-Hispanic White or non-Hispanic Black. Patients were interviewed on their prior screening and the process of their diagnosis, which was augmented with detailed chart abstraction. A broad range of social and attitudinal constructs were measured including 3 well validated religiosity scales: God Locus of Health Control (GLHC), Religious Problem Solving (RPS), and Religious Coping (Brief RCOPE). The final response rate was 54% and includes 407 patients. **Results:** Median age of the sample was 60, 52% were Black, 33% had income $<$ 20K, and 13% had $<$ HS education. Cancer stage was available on 372 (91%), and 62% were late stage (stage III, IV). Blacks had significantly higher levels of GLHC than whites (mean 22 vs. 13, on a scale of 6-30, $p < 0.001$). Univariate logistic regression models for age, race, sex, income, education, and religiosity items showed that only younger age ($p = 0.01$) and higher levels of GLHC ($p = 0.016$) were associated with late stage at diagnosis. These significant associations held in the multivariate model when both were adjusted for. There was no significant interaction between race and GLHC ($p = 0.238$). **Conclusions:** In a large bi-racial sample across diverse health care systems, younger age and higher scores on the GLHC predicted late stage at diagnosis. While Blacks had significantly higher GLHC scores, race was not associated with stage at presentation. The relationship between GLHC and advanced disease stage was not limited to Blacks. Further work is ongoing to characterize the relationship between religious beliefs and health outcomes.

6557 Poster Session (Board #114), Mon, 1:15 PM-4:45 PM

Impact of racial residential segregation (RRS) on stage at diagnosis and survival after diffuse large B-cell lymphoma (DLBCL). *First Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Racial disparities in disease presentation and survival have been reported for DLCBL, which may arise from biological or socioeconomic status (SES) differences that influence treatment and outcomes. We examined the associations between RRS, stage at diagnosis, overall survival (OS) and lymphoma-related survival (LRS) for non-Hispanic Black and White patients (pts), hypothesizing that RRS is associated with advanced stage disease and inferior survival for Black pts with DLBCL. **Methods:** We merged data from the population-based California Cancer Registry for new cases of DLBCL diagnosed during 1996-2007 with 5 Census indices of segregation among Blacks relative to Whites: dissimilarity, exposure, isolation, relative centralization, and spatial proximity. We included a measure of the % of black individuals per neighborhood (%B). Controlling for demographic and clinical factors, we used multivariable logistic regression and Cox regression to examine each RRS measure, modified by %B, on stage and survival, respectively, for Blacks and Whites separately. **Results:** Among 10,505 White and 749 Black DLBCL pts, Blacks more commonly had advanced stage disease (52 vs 45%) and resided in the lowest SES neighborhoods (28 vs 7%). Among Black pts, medium to high segregation as measured by dissimilarity (HR 2.1; 95% CI 1.1-4.1) and isolation (HR 2.2; 95% CI 1.0-5.0) were associated with advanced stage; however, there were no significant association between any RRS measure and survival. Among White pts, there was no significant associations between RRS and stage; whereas low segregation measured by spatial proximity (LRS HR 1.2; 95% CI 1.2-1.1; OS HR 1.2; 95% CI 1.1-1.4), isolation (LRS HR 1.3; 95% CI 1.1-1.5; OS HR 1.3; 95% CI 1.1-1.4), and dissimilarity (LRS HR 1.2; 95% CI 1.0-1.4; OS HR 1.3; 95% CI 1.1-1.4) in neighborhoods with high %B were associated with worse OS and LRS. **Conclusions:** Despite association with stage at diagnosis for Black pts, neighborhood composition and segregation had minimal impact for White pts and no impact for Black pts on survival, suggesting that other sociological/biological factors influence racial differences in DLBCL survival.

6558 Poster Session (Board #115), Mon, 1:15 PM-4:45 PM

Effect of demographic factors and histology on stage IV non-small cell lung cancer (NSCLC): A National Cancer Database review. *First Author: Brody Slostad, Creighton University School of Medicine, Omaha, NE*

Background: Demographic characteristics, especially race and insurance status, affect the incidence of lung cancer diagnosed at Stage IV[1]. This is the largest epidemiological study to determine patient features associated with the development of Stage IV NSCLC. **Methods:** A population-based study using the National Cancer Database (2000-2012), which contains 70% of all cancer diagnoses in the U.S. from 1658 ACS Accredited-Hospitals. Demographic groups of NSCLC presenting with Stage IV were compared to the entire cohort of NSCLC patients using the Chi square test. **Results:** Of all NSCLC patients (N=2,956,237), 36% were Stage IV at presentation. Uninsured (52%), aged 40-49 (47%), Medicaid recipients (46%), aged 50-59 (42%), Hispanic (41%) and Black (41%) patients presented with more Stage IV at diagnosis. Medicare recipients (34%) presented with less Stage IV. Adenocarcinoma (AC) and Squamous Cell (SQ) presented with 43% and 25% Stage IV disease at diagnosis, respectively. Uninsured AC (60%) patients had the most frequent Stage IV disease at diagnosis. **Conclusions:** AC presents much more frequently than SQ as Stage IV. In particular, uninsured AC patients have the most frequent Stage IV presentation. Similar to a previous NCDB study, this study, which includes 5 times as many lung cancer patients as the previous study, shows uninsured, Medicaid, Hispanic and Black NSCLC patients present with more Stage IV disease (Halpern MT, et al. (2008) Association of insurance status and ethnicity with cancer stage at diagnosis for 12 cancer sites: a retrospective analysis. Lancet Oncol 9:222-232.). Conversely, Medicare patients present with less Stage IV disease.

Patient navigation as a model to increase minority participation in cancer clinical trials. *First Author: Mona Fouad, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: For ethical, social, and scientific reasons, cancer clinical trials require participation of patients from diverse population groups. Less than 10% of all patients enrolled in clinical trials are minorities. The patient navigation model has been used to assist under-resourced cancer patients to access medical care. However, the model has not been evaluated as a tool for increasing the participation of minorities in clinical trials. The project "Increasing Minority Participation in Clinical Trials" (IMPaCT) utilized patient navigation (PN) to enhance the recruitment and retention of African Americans (AA) in therapeutic cancer clinical trials in an NCI-designated comprehensive cancer center. **Methods:** Lay individuals were recruited and trained to serve as PNs for clinical trials. The training curriculum included content related to clinical trials, the navigation process, interaction with patients, the clinical environment, and case management. The training sessions were co-led by clinical research nurses, physicians, and health educators. AA patients potentially eligible for clinical trials were identified through chart review or referrals by clinic nurses, physicians, and social workers. PNs provided two levels of services to AA cancer patients who consented to receive PN support: 1) Clinic-based education about clinical trials; and 2) Tailored supportive services for patients who enrolled in clinical trials. **Results:** Two lay individuals matching the demographic characteristics of the patients were trained and hired as PNs. Between 2007 and 2014, 424 AA cancer patients were referred to IMPaCT. Of the patients eligible for a clinical trial ($N = 378$), 302 (79.9%) enrolled in a trial and 270 (71.4%) consented to receive PN support during the trial. Of those receiving PN support, 74.5% completed the trial, compared to 37.5% of those who chose not to receive PN support. The difference in the clinical trial completion rates between participants who received PN support vs. those who did not was statistically significant ($P < 0.001$; Chi-Square test). **Conclusions:** This study indicates that PN could address barriers to clinical trial participation in AA cancer patients and improve retention in clinical trials.

6560 Poster Session (Board #117), Mon, 1:15 PM-4:45 PM

Endocrine therapy adherence, side effects, and risk perception among racially diverse breast cancer patients. *First Author: Stephanie B. Wheeler, UNC Chapel Hill, Chapel Hill, NC*

Background: Differential endocrine therapy (ET) use by race may contribute to disparities in breast cancer outcomes. The goal of this study was to examine racial variation in ET adherence, side effect experiences and perceptions about recurrence risk. **Methods:** We surveyed 1,507 stage I-III breast cancer patients using a mailed, self-administered questionnaire at 18-months post-diagnosis as part of the Carolina Breast Cancer Study Phase III (CBCS-III), a population-based, prospective cohort study that recruited participants via rapid case ascertainment in 2008-2013. Non-adherence was defined as not taking ET pills every day as prescribed, discontinuing ET pills, or missing > = 3 pills in the past 14 days. Bivariable analyses identified differences in adherence, side effect experiences and risk perceptions by race. **Results:** Overall, 994 women in our sample were prescribed ET; of these, 43% were African American (AA). The mean age at diagnosis was 54, and the majority were diagnosed with stage 1 (50%) or 2 (37%) disease. Overall, 19% were classified as non-adherent; 22% of AA women were non-adherent (vs.16% of white women, p = 0.014). Compared to white women, AA women more often forgot to take ET when traveling away from home (25% vs. 16%, p = 0.035); felt sticking to their ET treatment plan was difficult (25% vs. 14%, p < 0.0001), had trouble remembering to take their ET pills (24% vs. 13%, p = 0.0001), reported cost-related non-adherence (16% vs. 7%, p = 0.0001), and experienced bothersome side effects (25% vs. 18%, p = 0.0033). AA women more often than white women reported experiencing the following side effects frequently in the past 7 days: hot flashes (55% vs. 45%, p = 0.0017), night sweats (41% vs. 30%, p = 0.0002), breast sensitivity (24% vs. 16%, p = 0.0015), and joint pain (46% vs. 38%, p = 0.011). More AA women reported believing there would be no change in their recurrence risk if they stopped ET (20% vs. 8%, p < 0.0001). **Conclusions:** These data highlight important racial differences in adherence behaviors, side effect experiences and perceptions of recurrence risk. Culturally-tailored interventions that can help women taking ET to better manage side effects and reframe risk perceptions may better motivate adherence.

6561 Poster Session (Board #118), Mon, 1:15 PM-4:45 PM

Disparities in hospice use among patients with cancer in the Deep South. *First Author: Bradford E. Jackson, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: Higher rates of hospice use are an indicator for high-quality end-of-life care for cancer patients, however disparities have been reported. Known racial disparities in hospice utilization may be explained by hospital characteristics that would affect the likelihood of referral to hospice. The purpose of this study was to explore variations in hospice use at both the patient and hospital level. **Methods:** Administrative claims were obtained forMedicare patients ≥ 65 years old diagnosed with cancer within the UAB Health System Cancer Community Network (UAB CCN) from 2008-2014. Enrollment in hospice was assessed for all deceased patients in the 90 days before death. Using logistic regressions we assessed the association between hospice use and patient-level factors (race, gender, and cancer type), as well as hospital-level factors (presence of a board certified palliative care physician and ownership of a hospice facility). Results are presented as frequencies and percentages as well as odds ratios (OR) and their corresponding 95 % confidence limits (95%CL). **Results:** Sixty-eight percent (n = 7,186) of patients enrolled on hospice in the 90 days before death. In the unadjusted analysis, females were more likely to be enrolled on hospice than males (70% vs 66%; p = 0.002), blacks less likely than whites (62% vs 69%; p = 0.002). Hospice use varied by cancer type (77% for pancreatic cancer patients and 60% for hematologic malignancies). Hospice use was not significantly different for hospitals with board certified palliative care physicians (67% vs 69%; p = 0.178) or those certified to provide (home or inpatient) hospice care (69% vs 67%; p = 0.130). In the multivariable model adjusting for patient- and hospital-level characteristics, we observed lower odds of hospice use for blacks (OR 0.67; 95%CL: 0.57, 0.80); higher odds for hospitals certified to provide hospice care (OR = 1.41; 95%CL: 1.16, 1.71) and no difference for hospitals with palliative care physicians (OR = 0.9; 95%CL: 0.79, 1.04). **Conclusions:** Disparities in hospice enrollment exist in this hospital network of the rural Deep South. Although patient characteristics may help explain variation in hospice use, our findings show mixed associations with palliative care services.

6562 Poster Session (Board #119), Mon, 1:15 PM-4:45 PM

Utility of surveillance following curative intent resection of metastases. *First Author: Richard M. Lee-Ying, BC Cancer Agency, Vancouver, BC, Canada*

Background: Surveillance is frequently conducted after the completion of curative treatment in early stage cancers to detect resectable recurrences. As more stage IV patients undergo curative resection of metastases (CRM), surveillance of such cases is increasingly performed, but its utility is unclear. Using a cohort of metastatic colorectal cancer (mCRC) patients, we aimed to 1) characterize surveillance patterns in a population-based setting and 2) examine if surveillance contributed to improved outcomes. **Methods:** Patients diagnosed with mCRC from 1995 to 2010 and referred to any 1 of 5 cancer centers in British Columbia were reviewed. Using Cox regression models that adjusted for confounders, we identified predictors of overall survival (OS) in patients who underwent CRM. Recurrences were categorized into those detected by surveillance vs symptoms and whether further attempts at CRM were feasible. **Results:** We identified 2082 mCRC patients of whom 254 proceeded to CRM. Median age was 63, 52% were men, 44% had de novo stage IV disease, 56% received perioperative chemotherapy, and 17%/66% had lung/liver metastases, respectively. Surveillance practices after CRM varied widely, but included clinical examination (85%), CEA (86%), imaging (89%) and endoscopy (28%) in the first 5 years. The median OS of CRM cases was 40.9 months, including 191 (75%) recurrences. The median time to recurrence was 10.2 months. Recurrences were detected by surveillance in 152 (80%) cases, and proceeded to a second CRM in 41 (21%). Compared to recurrences detected by symptoms, those based on surveillance were more likely to proceed to another CRM (25% vs. 11%, p < 0.001). Adjusting for confounders, surveillance (HR 0.61 95% CI 0.39-0.94, p = 0.026) and a second CRM (HR 0.53, 95% CI 0.34-0.82, p = 0.004) were independently correlated with improved OS. **Conclusions:** In this population-based cohort of mCRC patients, the majority recurred after the initial CRM, but recurrences detected by surveillance were more amenable to a subsequent CRM. While surveillance was performed in most cases, significant variations in practice were observed, underscoring the need for wider dissemination of evidence-based guidelines for the surveillance of selected metastatic disease.

6563 Poster Session (Board #120), Mon, 1:15 PM-4:45 PM

Trends in use of PET imaging in surveillance of lung and colorectal cancer. *First Author: Christine Marie Veenstra, University of Michigan, Ann Arbor, MI*

Background: Surveillance PET imaging following curative intent treatment of non-small cell lung cancer (NSCLC) or colorectal cancer (CRC) is not supported by available evidence. ASCO and ABIM's joint Choosing Wisely campaign recommends against surveillance PET, yet the frequency with which PET imaging is performed during surveillance care is unknown. **Methods:** 65,748 patients age 66+, diagnosed with stage I-IIIA NSCLC or Stage I-III CRC in 2001-2009, who underwent surgical resection were identified in SEER-Medicare data. Eligibility for surveillance started 180 days post-operatively. Use of imaging was assessed during the first year of surveillance and classified as 1) Any PET: receipt of PET or PET/CT regardless of other imaging, or 2) PET-only: receipt of PET or integrated PET/CT only, in patients who did not undergo separate dedicated CT imaging. Unadjusted proportions of patients receiving each category of surveillance were calculated by cancer type, diagnosis year, and stage. Equality of proportions was assessed between diagnosis years with ANOVA tests. **Results:** 7,393 NSCLC patients and 35,050 CRC patients met inclusion criteria. PET use more than doubled over the study period in both cohorts. 11% of all NSCLC patients diagnosed in 2001 received any PET vs. 25% diagnosed in 2009 (P < 0.001). Similarly, 4% of all CRC patients diagnosed in 2001 received any PET vs. 12% diagnosed in 2009 (P < 0.001). PET utilization was more common in higher stage NSCLC and CRC patients, and increased significantly between 2001 and 2009. In Stage IIIA NSCLC patients diagnosed in 2001, 15% received any PET compared to 42% diagnosed in 2009 (P = 0.015). In this same group of patients, 1.5% diagnosed in 2001 received PET-only, compared to 15% diagnosed in 2009. Among Stage III CRC patients any PET use increased from 9% for those diagnosed in 2001 to 27% for those diagnosed in 2009 (P < 0.001), while use of PET-only increased from 1% to 8% over the same period (P < 0.001). **Conclusions:** Although not indicated in surveillance, PET utilization has more than doubled among NSCLC and CRC survivors over the study period. While surveillance rates may be increasing generally, increased rates of PET-only imaging suggest PET is inappropriately replacing existing surveillance protocols.

6564 Poster Session (Board #121), Mon, 1:15 PM-4:45 PM

Young adult cancer survivors' expectations of physicians for follow-up and general health care: Implications for health services delivery. *First Author: Pierre Camateros, University of British Columbia, Vancouver, BC, Canada*

Background: As patients transition from cancer treatment to survivorship, the involvement of multiple physicians may lead to confusion as to who is primarily responsible for the patients' ongoing care. This is particularly concerning for young adult cancer survivors who may have specific survivorship care needs. In this study, we examined survivors' expectations of their physicians regarding cancer follow-up and general healthcare, and identified factors associated with these expectations. **Methods**: We surveyed patients aged 20 to 39 years who were diagnosed with solid tumors, evaluated at any 1 of 5 regional cancer centers in British Columbia, and alive at 2 or more years after their original diagnosis. Using multivariate regression models, we explored the relationships between patient expectations of their care and the factors associated with these expectations, while controlling for potential confounders. **Results:** With a survey response rate of 57%, a total of 447 patients were analyzed: median age was 35 years (IQR 31-38), 30% were men, 89% had ECOG 0. Tumor sites included breast (222; 50%), testicular (126; 28%), gynecological (76; 17%), and colorectal (23; 5%). For the entire cohort, the majority (67%) viewed their cancer specialist (CS) as being chiefly responsible for their care during the first 10 years of their diagnosis, but most (64%) shifted this expectation towards their primary care provider (PCP) after 10 years of follow-up ($p < 0.001$). PCPs were also viewed as more responsible for providing preventive care than CS (85% vs. 35%, $p < 0.001$). Active contact with the CS in the past year was significantly associated with higher expectations of their CS being engaged in the ongoing care of their most recent malignancy ($p < 0.001$), treatment of side effects ($p = 0.03$), and screening of future cancers ($p < 0.001$). **Conclusions:** Young patients expect involvement from their CS even years after their original cancer diagnosis. Early integration of PCPs in the cancer care trajectory may better foster a shared-care model of health services delivery and facilitate the transition of many young cancer survivors as they complete cancer treatment and enter follow-up care.

6565 Poster Session (Board #122), Mon, 1:15 PM-4:45 PM

Effect of improving guideline-based prophylactic growth factor (pGCSF) use with chemotherapy (CT) on the risk of febrile neutropenia (FN) in non-small cell lung cancer (NSCLC) patients (pts): A Cleveland Clinic Taussig Cancer Institute (TCI) Quality Improvement (QI) Project. *First Author: Lindsey Martin Goodman, Cleveland Clinic, Cleveland Heights, OH*

Background: Per accepted guidelines, pGCSF is not recommended for pts receiving CT regimens with low risk ($< 10\%$) for FN. Factors contributing to inappropriate pGCSF use include lack of provider familiarity with national guidelines as well as the presence of standing pGCSF orders in EMR CT templates. Inappropriate use of pGCSF increases pt morbidity and healthcare costs. **Methods:** A multidisciplinary team performed a QI project through the ASCO Quality Training Program. All NSCLC pts at TCI who initiated a new CT regimen from April 2013 to October 2014 were reviewed. First-cycle pGCSF use was deemed appropriate if prescribed for CT associated with high risk of FN ($> 20\%$) or intermediate risk (10-20%) if other risk factors for FN were present. Use with low-risk CT was considered inappropriate. We implemented three QI strategies: education of NSCLC providers, development of TCI Consensus Guidelines for the use of pGCSF in NSCLC, and EMR modification: labeling of CT regimens by FN risk and removal of standing pGCSF orders from low-risk CT. Follow up data were collected from January to October 2014. FN rates before and after the QI interventions were documented. **Results:** 300 NSCLC pts received a new CT regimen during the specified time period. Prior to the interventions, 34/118 pts (29%) treated with low-risk CT received pGCSF (average 2.6 doses/pt). In all other instances pGCSF use was in accordance with guidelines. Following QI interventions, 8/126 (6%) treated with low-risk CT received pGCSF. No patient treated with low-risk CT required inpatient admission for FN during post-intervention follow up. Cost analyses indicate a potential reduction of $1.9 million in charges over 1 year with guideline-based pGCSF usage with low-risk CT. **Conclusions:** Excessive pGCSF use can be improved with focused provider education and EMR modification. The lack of FN admissions in the post-intervention period validates current guidelines. Appropriate pGCSF administration in NSCLC leads to significant cost savings without increasing neutropenic complications.

6566 Poster Session (Board #123), Mon, 1:15 PM-4:45 PM

Utility of pre-operative PET/CT staging in sentinel lymph node-positive melanoma. *First Author: Benjamin Scheier, University of Michigain Health System, Ann Arbor, MI*

Background: Sentinel lymph node (SLN) mapping is an integral part of melanoma staging. If regional metastases are identified, patients often undergo lymph node dissection (LND) as definitive treatment. The National Comprehensive Cancer Network (NCCN) makes a category 2B recommendation- based on "low-level evidence" and a non-uniform consensus- that prior to LND, patients may be considered for staging by positron emission tomography with a computed tomography scan (PET/CT). PET/CT, however, lacks data supporting this use, may inconsistently impact treatment decisions and carries a risk of false positives that may detract from clinical utility. **Methods:** A retrospective evaluation of patients seen at the University of Michigan with melanoma and clinically silent regional lymph nodes between July 2013 and September 2014 was performed.We identified78 patients with positive SLN mapping, 46 of which underwent PET/CT prior to LND. Remaining patients either underwent no staging or CT with brain MRI. Outcomes measured include changes in clinical management and incidence of false positives, defined as biopsy-evaluated PET/CT findings non-diagnostic for melanoma. **Results:** Of the 46 patients who underwent PET/CT, 15 (33%) had abnormal findings distant from the primary tumor and local lymph node basin. 9 of those 15 patients (60%) had abnormalities biopsied prior to LND. Of the 46 patients assessed, only 3 (6.5%) had PET/CT findings that ultimately identified metastatic melanoma and precluded LND. This yields a false positive rate of 67% in screening for distant metastases. There was not a statistically significant association between T and N stage and whether or not patients underwent PET/CT imaging (Fisher's exact test, $p = 0.12$ and 0.85, respectively). There was a statistical association between undergoing PET/CT and ulceration status ($p = .004$). **Conclusions:** The utility of PET/CT staging following SLN mapping in melanoma is unknown, despite its recommended use by the NCCN. In our retrospective review, we found that PET/CT has a high false positive rate and a minimal effect on patient management. PET/CT staging should be reevaluated as a category 2B recommendation by the NCCN and its utility evaluated prospectively in a clinical trial.

6567 Poster Session (Board #124), Mon, 1:15 PM-4:45 PM

Developing oncology goals and objectives for medical students: A national Delphi process. *First Author: Vincent Channing Tam, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: Our previous study showed that oncology education in medical schools is currently inadequate. The purpose of this process was to develop oncology goals and objectives for medical students based on a national consensus by oncology educators. **Methods:** A comprehensive list of oncology objectives was created using existing resources. Experts in oncology education and undergraduate medical education (UME) from all 17 medical schools in Canada were asked to participate in a 3-round Delphi consensus process. For round 1, experts scored objectives on a 9-point scale according to the degree with which they agreed an objective should be taught in UME. Objectives with a mean score of ≥ 7.0 were included. Round 2 was a web meeting where objectives with a mean score of 4.0 to 6.9 were discussed. In round 3, experts voted on inclusion and exclusion of round 2 objectives. **Results:** 34 of 37 (92%) invited experts from 14 medical schools participated. Experts consisted of oncologists (medical, radiation, pediatric, surgical, gynecologic), family physicians, UME curriculum committee members, and oncology residency program directors. The comprehensive list reviewed in round 1 contained 214 objectives. 146 received a mean score ≥ 7.0 and 68 scored 4.0 to 6.9. Nine new objectives were suggested. Main themes of expert comments were to reduce the number of objectives and to aim objectives at the general knowledge level of a family physician. In round 2, 77 objectives were discussed. In round 3, $> 75\%$ of experts agreed to include 7 (9%) objectives. The final 153 objectives were divided into the following categories: Basic Science of Oncology, Public Health, Diagnosis, Treatment, Prognosis, Knowledge of Common Cancers, Psychosocial Issues, Ethics and Professionalism, Communication, and Essential Oncology Experiences. **Conclusions:** Through a systematic process we have created a comprehensive and consensus-based set of oncology goals and objectives which may be used in UME curriculum design and also by educators and medical students. The objectives will be made available online to be shared with educators and learners globally, which will hopefully facilitate improvements in oncology education and patient care.

6568 Poster Session (Board #125), Mon, 1:15 PM-4:45 PM

Quality of life EQ-5D results from the AETHERA trial: A phase III study of brentuximab vedotin consolidation following autologous stem cell transplant for HL. *First Author: Scott David Ramsey, Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The AETHERA trial demonstrated that early consolidation treatment with brentuximab vedotin (BV) post-ASCT significantly improved PFS in pts with HL. Peripheral neuropathy (PN) was the most common adverse event. Here, we report the results of the Quality of Life (QoL) component of the trial. **Methods:** After ASCT, 329 pts were randomized to BV 1.8 mg/kg q3wk or placebo for up to 16 cycles. The EQ-5D questionnaire, including the descriptive system and visual analog scale (VAS), was administered at each cycle, end of treatment (EOT), and q3 mos during follow up until 24 mos from Day 1. Utility index value scores were calculated using the time trade-off (TTO) method for US- and UK-based value sets. Differences between arms were compared to the lower bound of an estimated minimally important difference (MID) in cancer pts (Pickard et al 2007). **Results:** In both arms, EQ-5D scores declined from baseline to 24 mos. Slightly lower scores were seen with BV vs placebo from mos 9-18, but this resolved by end of follow up. In the analysis as randomized (US TTO), the difference between arms was <0.06 (MID) at all timepoints except for mos 15 and 18. Scores by cycle were similar in the 2 arms; mean differences did not reach the MID threshold. In both arms, scores for pts with PD per investigator were lower over time vs. pts with no PD. In the BV arm, scores for pts reporting PN were similar to those who did not. Similar results were obtained with US- or UK-based value sets. EQ VAS scores did not show an important difference between arms at any timepoint. **Conclusions:** As assessed using the EQ-5D questionnaire, treatment with BV did not have a sustained impact on QoL in HL pts. In both arms, decreased QoL was observed after progression. Clinical trial information: NCT01100502.

US-indexed EQ-5D TTO scores.

	BV N=165	Placebo N=164	BV-placebo
	Mean	Mean	Mean Difference (95% CI)
Baseline	0.897	0.907	-0.010 (-0.035, 0.014)
3 mos	0.869	0.884	-0.014 (-0.048, 0.019)
6 mos	0.868	0.872	-0.004 (-0.041, 0.032)
9 mos	0.816	0.860	-0.043 (-0.087, 0.001)
12 mos	0.799	0.859	-0.059 (-0.109, -0.010)
15 mos	0.782	0.852	-0.071 (-0.126, -0.015)
18 mos	0.776	0.837	-0.061 (-0.121, 0.000)

24 mos	0.757	0.787	-0.030 (-0.102, 0.042)

6569 Poster Session (Board #126), Mon, 1:15 PM-4:45 PM

Evaluation of a pharmacist-driven oral chemotherapy adherence program. *First Author: Iris Chen Zhao, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Oral anticancer drug therapy has increased: about 1/3 of new oncology drugs in development are for oral administration. The question of adherence may complicate interpretation of response and adverse events. In a study of adjuvant tamoxifen in women with breast cancer, Partridge showed a progressive decrease in adherence from 83% in the 1st year to 50% by the 4thyear of therapy. Strategies to improve adherence should optimize efficacy and minimize toxicity. We created an Oral Chemotherapy Adherence Program (OCAP), which provides education, adherence and toxicity monitoring, coverage verification, co-pay assistance, and delivery services. The purpose of this study was to assess the effect of OCAP on adherence to oral anticancer drugs. **Methods:** Patients enrolled in OCAP from October 2013 to October 2014 were ascertained. Adherence analysis was conducted for those on oral anticancer agents for 2 or more cycles both pre- and post-enrollment. Adherence rates for these patients were measured by medication possession ratio (MPR). MPR was calculated by dividing total days of drug supply by expected duration of therapy. MPR ranged from 0-1(1 = 100% adherence). High adherence was 80-100%. Pre- and post-enrollment MPR were compared using the paired t-test. **Results:** A total of 148 patients were enrolled in OCAP. Of these, 40 patients had received 2 or more cycles of therapy pre- and post-enrollment. Prior to enrollment, the mean (SD) adherence rate was 90.3% (19.9%) with 20% of patients falling into the 65-85% adherence range. 7.5% of patients fell below 40% adherence. After enrollment, the mean (SD) adherence rate was 99.3% (8.7%) with 97.5% of patients at 85% adherence or above. The lowest adherence rate post-enrollment was 68.5% in a patient with unreliable means of contact. The mean increase in adherence was 9.08% (23.2%), which was statistically significant (P = 0.02). **Conclusions:** Higher adherence rates were observed after enrollment into our oncology pharmacist-driven oral chemotherapy adherence program. Enrollment of patients into OCAP at the time of initiation of oral anticancer therapy would likely result in increased overall adherence rates. Effects of OCAP on other important outcomes, such as adverse events and costs, are ongoing.

6571 Poster Session (Board #128), Mon, 1:15 PM-4:45 PM

Impact of enhanced reimbursement on provider participation a cancer care quality program and adherence to cancer treatment pathways in a commercial health plan. *First Author: Jennifer Malin, Anthem, Inc., Woodland Hills, CA*

Background: Payment for treatment planning and care coordination for cancer care in the U.S. has been largely funded through the margin between the acquisition cost and reimbursement of cancer drugs. The Institute of Medicine has called for new payment models to align reimbursement to support patient-centered, high-quality affordable cancer care. **Methods:** In July 2014, 6 commercial HPs in the Midwest and Georgia implemented a cancer care quality program that included additional reimbursement for treatment planning and care coordination when oncologists selected regimens that were on a pathway. Cancer treatment pathways were developed using an evidence-based process with expert advisors from academic centers and community practices for breast, lung and colorectal cancer (available at www.cancercarequalityprogram.com). Practices provided clinical data on HP members starting systemic therapy through a web portal, including tumor type, stage, line of therapy, biomarkers, performance status, and planned treatment. Using program data linked with HP data, rates of participation and pathway adherence for the initial 6 months of the program were estimated. **Results:** Between July and December, 616 practices registered 5538 patients in the program, with a mean of 8.7 patients per practice (SD 23.8, range 1 to 275). The most commonly cancer types were breast and lung cancer (29% and 15%, respectively, of all registered regimens) followed by colorectal cancer (13%) and lymphoma (10%). Based on chemotherapy claims for members incurred in September and October, 64% (95% CI, 62%-65%) of members (n = 2,989) were registered with the program, ranging from 8% to 100% patients within participating practices. Among registered patients, pathway adherence was 43% for breast cancer, 65% for colorectal cancer, and 51% for non-small cell lung cancer. **Conclusions:** A new payment model that supports quality affordable cancer care through enhanced reimbursement for treatment planning and care coordination when treatment adheres to a cancer treatment pathway is feasible. Additional interventions may be needed to increase program participation and pathway adherence.

6572 Poster Session (Board #129), Mon, 1:15 PM-4:45 PM

Avoiding overtreatment in rectal cancer when the benefit of adjuvant chemotherapy is unclear. *First Author: Jonathan M. Loree, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: Adjuvant chemotherapy (AC) is intended for early stage cancers that pose a high risk of recurrence, but its use is frequently generalized to cases in which the probability of recurrence is low and absolute benefit is small. Using a cohort of stage II rectal cancer (RCa)patients (pts), we aimed to examine population-based outcomes stratified by receipt of AC and to characterize pts in whom AC provides benefit. **Methods:** Prospectively collected data from pts referred to 5 cancer centers in British Columbia for pathologic stage II RCa from 1998 to 2009 were reviewed. Overall (OS), disease-specific (DSS) and relapse-free (RFS) survival were assessed with Kaplan-Meier methods. Cox regression models that adjusted for age, ECOG, gender and high risk features were constructed. **Results:** Of 851 pts reviewed, 469 who received neoadjuvant radiotherapy were analyzed. Median age was 67, 63% were men, 73% were ECOG 0/1, 70% underwent short course radiotherapy and 43% received AC. Those treated with AC were younger ($P<0.001$), had better ECOG ($P<0.001$) and had more high risk features ($P<0.001$). In univariate analyses, AC contributed to superior OS (HR 0.46 95%CI 0.35-0.62, $P<0.001$), DSS (HR 0.63 95% CI 0.43-0.92, $P=0.02$), and a trend to improved RFS (HR 0.70 95%CI 0.49-1.01, $P=0.055$). In multivariate analyses, however, AC correlated with better OS (HR 0.61 95%CI 0.42-0.90, $P<0.001$), but not DSS ($P=0.25$) or RFS ($P=0.46$). Subgroup analysis revealed that AC correlated with improved OS (HR 0.22 95%CI 0.07-0.70, $P=0.011$), DSS (HR 0.25 95%CI 0.07-0.89, $P=0.033$) and RFS (HR 0.24 95%CI 0.07-0.85, $P=0.03$) only in selected pts who received short course radiotherapy and had ≥ 2 high risk features (n = 49, 12% of pts), such as T4 lesion, poor differentiation, inadequate lymph node sampling or obstruction/perforation. Outcomes in other subgroups were similar regardless of receipt of AC. **Conclusions:** In this population-based cohort of stage II RCa pts, the majority do not appear to benefit from AC. Risk factors conventionally used to guide AC decisions in early colon cancer should be considered in early RCa. Incorporating molecular tests into future risk stratification may further minimize unnecessary use of AC and potential over-treatment of pts.

6573 Poster Session (Board #130), Mon, 1:15 PM-4:45 PM

Can oncology readmissions be reduced? The Cleveland Clinic experience. *First Author: Alberto J. Montero, Cleveland Clinic, Cleveland, OH*

Background: Reducing 30-day readmissions is a national policy priority. Readmissions in medical oncology patients have not been extensively evaluated, and may not be reasonably preventable. We examined the impact of interventions focused on reducing oncology readmissions in the palliative medicine (PM) and general medical oncology (GMO) units. **Methods:** Baseline rates of readmissions were gathered in the period January 2013 to March 2014. Interventions were initiated in the period leading to April 1, 2014 including: (i) provider education, (ii) within 48 hours post-discharge nursing phone calls, and (iii) within-5-day post-discharge provider follow-up appointments. Calling nurses performed symptom management, education and encouraged prescription/appointment compliance. **Results:** There were a total of 3,729 combined admissions and 1,003 readmissions in the baseline period, for a readmission rate of 26% for PM and 27% for GMO units. In the 8-month intervention period (May-Dec 2014), there were 1,694 admissions, and 396 readmissions. Callbacks and 5-day appointments were monitored with a mean compliance of 77% and 70%, respectively, improving during the study period. PM readmission rates declined by 5% to 21% ($p = 0.01$, relative risk reduction 19%). GMO readmissions also decreased by 3% to 24% ($p = 0.02$, relative risk reduction 11%). The mean total cost of one readmission was $18,365, suggesting an annual potential cost savings of $2.91 million with the observed reduction in readmissions. **Conclusions:** Readmission reductions in both units were achieved through better systematic transitions to outpatient care, including follow-up calls and early provider visits; thereby leading to a reduction in utilization of inpatient resources. These data suggest that efforts focused on improving outpatient care transition are effective in reducing oncology readmissions. This is particularly relevant in the transition towards novel bundled payment models in oncology. The observed feasibility and patient/provider acceptance of these interventions suggests sustainability, and will be validated over longer time periods.

6574 Poster Session (Board #131), Mon, 1:15 PM-4:45 PM

How well do surrogate endpoints and overall survival endpoints in clinical trials predict real-world survival? *First Author: Jason Shafrin, Precision Health Economics, Los Angeles, CA*

Background: The survival of cancer patients in the real world often differs from that measured in randomized controlled trials (RCT) for reasons including differences between trial participants and real-world patients, and crossover contamination. We compare the ability of RCT overall survival (OS) and RCT surrogate endpoints -- progression-free survival (PFS) and time-to-progression (TTP) -- to predict real-world OS prognosis across five cancers. **Methods:** Using NCCN guidelines, we identified 30 drug treatments for breast, colorectal, lung, ovarian, or pancreatic cancer approved before 2009 with Phase III RCTs reporting both OS and either PFS or TTP. Median RCT survival (i.e., PFS or TTP, and OS) and inclusion criteria were identified within each treatment's relevant pivotal trial publication. We measured median real-world OS for each treatment using a Kaplan-Meier estimator applied to SEER-Medicare data (1991-2010). Accuracy of trial PFS/TTP and OS in predicting real-world OS was measured using median absolute prediction error and $R^2$from linear regressions. **Results:** Among the 49,827 patients qualifying for inclusion in the relevant RCT study population, median survival across the 30 treatments was 6.0 months for trial surrogates (i.e., PFS/TTP), 14.8 for trial OS, and 13.5 months for real-world OS. Median error from predictive models using trial surrogates was 3.55 months compared to 1.80 months for trial OS (p= 0.156; R^2: PFS/TTP = 0.382 vs. OS = 0.613). Among all patients receiving a relevant treatment (240,852 individuals), prediction error was 5.32 months for models using trial surrogate endpoints and 5.34 months for models using trial OS (p= 0.802; R^2: PFS/TTP = 0.113 vs. OS = 0.167). **Conclusions:** RCT OS tended to outperform PFS/TTP in predicting real-world OS prognosis for patients similar to trial participants. However, in the broader real-world population of treated patients, RCT PFS/TTP and OS performed similarly. Among the five cancer sites studied, trial PFS and trial OS may be equally valuable to payers and providers seeking to predict survival in broad real-world populations.

6575 Poster Session (Board #132), Mon, 1:15 PM-4:45 PM

Time to treatment (TTT) and breast cancer survival in the United States. *First Author: Richard J. Bleicher, Fox Chase Cancer Center, Philadelphia, PA*

Background: Time to initiate breast cancer treatment is increasing in the United States, but controversy surrounds the impact of TTT on survival. The impact of the interval between diagnosis and treatment is a source of concern to patients and clinicians. We investigated the relationship using separate analyses of two of the largest cancer databases in the United States. **Methods:** Patients had noninflammatory, nonmetastatic, invasive breast cancer, with surgery as initial treatment. The first study used the SEER-Medicare database (SMDB), and second, the National Cancer Database (NCDB). Each analysis assessed survival as a function of time between diagnosis and operation (≤ 30, 31-60, 61-90, 91-120, and 121-180 days [d] from diagnosis), adjusting for demographics, comorbidities, tumor-related factors, and treatment. **Results:** The SMDB cohort had 94,544 patients ≥ 66 years old, diagnosed between 1992 and 2009. With each interval delay increase, adjusted overall survival (OS) was lower for all patients (hazard ratio [HR] 1.09, $p< 0.001$), and for those having stage I (hazard ratio [HR] 1.13, $p< 0.001$) and stage II (HR 1.06, $p= 0.010$) disease. Breast cancer-specific mortality increased with each 60-d interval (subhazard ratio 1.26, $p= 0.03$). The NCDB study evaluated 115,790 patients ≥ 18 years old, diagnosed between 2003 and 2005. The adjusted overall mortality HR was 1.10 ($p< 0.001$) for each increasing interval, significant in stages I (HR 1.16, $p< 0.001$) and II (1.09, $p< 0.001$) disease. Five-year OS adjusted for demographics, comorbidities, tumor-related factors and treatment in the SMDB progressively declined from 78.1% for ≤ 30 d to 60.9% for 121-180 d and in the NCDB from 88.0% for ≤ 30 d to 80.4% for 121-180 d. **Conclusions:** Independent analyses of two national cohorts demonstrate that an increased time to initiate surgical treatment confers lower overall and disease-specific survival for patients with early stage breast cancer. A shortened delay is associated with an outcome benefit comparable in magnitude to the addition of some standard therapies. Although time is required for preoperative evaluation and consideration of options such as reconstruction, efforts to reduce TTT should be pursued where possible to enhance survival.

6576 Poster Session (Board #133), Mon, 1:15 PM-4:45 PM

Are conflict of interest (COI) slides displayed long enough to comprehend? *First Author: James Austin Talcott, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Conflicts of Interest (COI) are displayed to alert the scientific audiences to potential financial biases. At scientific meetings, COI of oral presenters are visually displayed. COI slides increase in complexity with disclosed COI categories (CC) and relationships (R), requiring more time for audience members to process the information. We reviewed the COI slides displayed at the 2014 ASCO Annual Meeting in video presentations archived for the Virtual Meeting to assess the relationship between display time (DT) and the information they contained. **Methods:** Two reviewers (AD and JS) reported the following information for each oral scientific presentation: session, role (presenter, discussant), disclosed CG and R, and COI slide display time. To estimate the required time (RT) to process the information, we measured the required time to process the content of a sample of COI slides and created a predictive model, assuming that 1 second is required to focus on COI, and CC items require more process time than R items. **Results:** Of 485 presenters, over half reported 0 (43.1%), 1 (12.8%) or 2 (10.7%) R, but up to 29 R were reported. COI slides were visible for 1-65 seconds. However, we observed no relationship between R and COI slide display time (slope: = -.055, p = 0.39). RT (in seconds) = 1 + (1 x CC) + (0.85 x R) fit the observed RT data. We found DT ^{3} calculated RT for three-fourths of presenters when reported R was 1 or 2, but < 50% if reported R^{3}3 ($P < 0.001$). **Conclusions:** At a major cancer scientific meeting, measured DT of presenter COI slides did not increase with disclosed R. Based on estimated RT to process the COI information, DT was inadequate for comprehension for most presentations if reported R exceeded 2.

R (number)	0	1	2	3-4	5-7	8-10	> 10	Total

An analysis of corrective action plans to address slow accruing NCI-held IND early phase trials. *First Author: Holly A Massett, National Cancer Institute, Bethesda, MD*

Background: In 2011, NCI began requesting Corrective Action Plans (CAP) for early phase trials accruing < 50% of their projected accrual rate after Qtr 2 for Phase 1 (Ph1) or Qtr 3 for Phase 2 (Ph2). Study PIs of low accruing trials are asked to complete and return a CAP within 2 weeks and identify reasons and possible actions to address accrual. We report findings from an analysis of CAPs received on all NCI Cancer Therapy Evaluation Program (CTEP) held IND studies active between Aug 2011 and Feb 2013 (N = 327). **Methods:** Three methods were employed: 1) content analysis of CAPs to categorize slow accrual reasons and proposed actions (3 coders, intercoder reliability = 78%; 100% after post-coding deliberation); 2) analysis of CAP trial timelines and accrual data; 3) assessment of whether closed CAP trials met their primary scientific objectives. **Results:** CTEP requested CAPs for 150 (46%) of the 327 trials; 135 were eligible for analysis with 51% Ph1 (n = 69) and 49% Ph2 trials, and 88% adult trials (n = 119). CAP trials were open a median of 30 months (14 mo pre- and 16 mo post-CAP), and 70% (n = 94) were closed to accrual at analysis. Of closed CAP trials: 68% (n = 64) met their primary objective but took 3x longer than projected; those not meeting their objective(s) were open 6x longer before closing; and 27% (n = 25) had an accrual rate increase, post-CAP, associated with a greater likelihood of meeting the objective(s). For Ph1 trials, safety delays dominated slow accrual reasons while institutional/administrative reasons were common for Ph2. Site activation delays and access to patients ranked high for both. Only 54% of proposed corrective actions matched the reasons given for slow accrual. **Conclusions:** CAP requests had a positive impact on accrual for over one-quarter of the trials analyzed; however, most trials receiving a CAP took substantially longer to complete than projected. CTEP's new Experimental Therapeutics Clinical Trial Network (ETCTN) is poised to address many concerns identified in this analysis. CAPs should be implemented prior to Q2/Q3 to identify and address slow accruing trials earlier. CTEP is standardizing the CAP data collection to develop statistical algorithms to aid decisions related to trial closure for slow accrual.

6578 Poster Session (Board #135), Mon, 1:15 PM-4:45 PM

Prevalence and prognostic impact of prior cancer in locally advanced lung cancer. *First Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Locally advanced lung cancer patients with prior cancer diagnoses are generally excluded from clinical trials. Although the impact of prior cancer on outcomes has been described for early-stage and metastatic disease, it remains largely unknown for locally advanced lung cancer. To inform future decisions about this widespread clinical trial exclusion policy, we determined the characteristics and prognostic impact of prior cancer diagnoses among patients with locally advanced lung cancer. **Methods:** We identified patients > 65 years of age with locally advanced lung cancer in the Surveillance, Epidemiology, and End Results-Medicare linked registry. Prior cancer was characterized by prevalence, type, stage, and timing. All-cause and lung cancer-specific mortality were compared between patients with and without prior cancer using propensity score-adjusted Cox regression. **Results:** Of 50,715 locally advanced lung cancer patients, 16.4% had a history of prior cancer. Prostate (24%), gastrointestinal (17%), breast (16%), and other genitourinary cancers (15%) were the most common cancer types; 69% of prior cancers were localized or in situ. The majority (57%) of prior cancers were diagnosed within 5 years of the index lung cancer diagnosis. Prior cancer did not adversely impact all-cause (HR 0.97; 95% CI, 0.95-1.00; P= 0.03) or lung cancer-specific (HR 0.84; 95% CI, 0.82-0.87; P< 0.001) mortality compared to patients with no prior cancer. Similar outcomes were seen in a simulated clinical trial eligible population (age < 75 years, no recorded co-morbidities, and received surgery and/or radiation for the locally advanced lung cancer diagnosis; N = 3,601): overall survival HR 1.07; 95% CI, 0.97-1.19; P= 0.19; lung cancer-specific survival HR 0.85; 95% CI, 0.75-0.97; P= 0.02). **Conclusions:** For locally advanced lung cancer, prior cancer does not negatively impact outcomes. Given the ongoing need for new and better treatments for this disease, locally advanced lung cancer patients with history of prior cancer should not be excluded from clinical trials. Modifying this longstanding and widespread eligibility criterion will increase trial accrual rates and improve generalizability of study results.

6579 Poster Session (Board #136), Mon, 1:15 PM-4:45 PM

Outcomes and predictors of life sustaining treatments in patients with metastatic cancer. *First Author: Kah Poh Loh, Baystate Medcl Ctr, Springfield, MA*

Background: Patients with metastatic cancer admitted to the ICU or requiring invasive mechanical ventilation (IMV) have historically had high mortality rates. However, little is known about how frequently these patients receive life-sustaining treatments (LSTs) or which characteristics are associated with receipt of LSTs. *Methods*: We used the 2010 California Healthcare Cost and Utilization Project - State Inpatient Database to identify metastatic cancer patients (≥ 18 years), focusing on patients with a medical DRGs. Using ICD-9-CM procedure codes, we examined use of LSTs. We stratified patients by the use of LSTs and cancer types and compared patient characteristics and outcomes via chi-square or Wilcoxon tests. We used multivariate logistic regression models to identify predictors for potential use of LSTs and IMV while accounting for the clustering of patients within hospitals. **Results:** We identified 68,890 admissions among metastatic cancer patients. Mean age was 65 years and 48% were male. Cancer types were divided into lung (18%), breast (8%), colorectal (8%), GU (11%) and others (29%). Approximately 8% of these received at least one LSTs, including IMV (4%), PEG (1%), acute dialysis (1%), and TPN (3%). Receipt of LSTs varied by cancer types. Compared to patients who did not receive these treatments, length of stay (LOS) was longer in patients receiving LSTs [11.0 days vs. 5.5 days; p-value < 0.001] and in-hospital mortality rate was higher (41% vs. 10%, p-value < 0.001). In multivariable models, predictors of receipt of LST included older age, non-white race and greater burden of comorbidities. Compared to lung cancer, breast (OR 0.82, 95% CI 0.71-0.88) and GU cancer (OR 0.75, 95% CI 0.66-0.80) were less likely to receive LSTs. DNR status were marginally associated with the receipt of LSTs (OR 0.95, 95% CI 0.88-0.99) and not associated with the receipt of IMV (OR 1.04, 95% CI 0.94-1.09). **Conclusions:** Nearly 8% of hospitalized metastatic cancer patients received LSTs. Patients receiving LSTs had a longer LOS and higher in-hospital mortality rates than all hospitalized metastatic cancer patients. Lung or colorectal cancers were associated with the patients receiving LSTs. DNR status was not associated with receiving IMV.

6580 Poster Session (Board #137), Mon, 1:15 PM-4:45 PM

Determinants of early mortality in 37,568 colon cancer patients participating in 25 clinical trials of the ACCENT database. *First Author: Winson Y. Cheung, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: Clinical trials are the gold standard for evaluating novel therapeutics. Accrual of patients (pts) at substantial risk of significant treatment toxicity or early mortality compromises trial integrity, may pose greater harm than benefit, and can complicate trial interpretation. We aimed to define prognostic factors that may be used to guide risk-benefit assessments among pts being considered for phase III adjuvant colon cancer (CC) studies. **Methods:** A pooled, retrospective analysis of individual level data from CC pts enrolled in randomized trials of adjuvant systemic therapy was conducted. Separate multivariate logistic regression models with different definitions of early mortality (30, 60, 90 days, and 6 months from trial randomization) as outcome variables were constructed, adjusting for clinically and statistically significant variables from univariate and interaction tests. **Results:** We included 37,568 pts from 25 trials. Median age 61 years (IQR 53-68), 54% men, 90% White, 29% and 71% stage II and III disease, and 79%, 20%, and 1% ECOG performance status (PS) 0, 1, and 2+, respectively. Rates of early mortality were low: 109 (0.3%) at 30 days, 215 (0.6%) at 60 days, 281 (0.8%) at 90 days, and 540 (1.4%) at 6 months in the pooled cohort. On univariate analyses, increasing age, male gender, poorer PS, and stage III vs. stage II disease predicted for higher likelihood of early mortality. Race, body mass index, lymph node ratio, micro-satellite status as well as study time era were not associated with worse outcomes. In multivariate models, increased age and poorer PS were associated with early mortality at all time-points (age: p < 0.0001 and PS: p = 0.05 at 6 months), with pts aged > / = 80 years having a 6 month death rate of 4.6% as compared to < 1% for the youngest and pts with PS 2+ having a 6 month death rate of 4.4% as compared to 1.7% and 1.1% for PS 1 and 0, respectively. **Conclusions:** Early mortality in adjuvant trials of CC was infrequent. However, it was more prevalent in the elderly and among individuals with PS 2+, underscoring the need for specific trial designs that can accommodate the vulnerabilities of these underrepresented subsets of the population.

6581 Poster Session (Board #138), Mon, 1:15 PM-4:45 PM

Hospital treatment patterns and survival for metastatic colorectal cancer. *First Author: Robert Wallace Krell, University of Michigain Health System, Ann Arbor, MI*

Background: Despite evidence that multimodality therapy (surgery and multi-agent chemotherapy) improves survival for patients with metastatic colorectal cancer (CRC), there is broad variation in its use across hospitals. It is unclear whether survival differences across hospitals reflect differences in hospital quality or their treatment choices. We assessed survival for patients with metastatic CRC based upon their treatment and the hospitals treating them. **Methods:** We assessed patients with metastatic CRC in the 2003-06 National Cancer Data Base (N = 53,884 patients in 1019 hospitals). We compared survival across hospitals based on their adjusted relative utilization of cancer treatments (primary and distant site surgery, chemotherapy, or palliative care). Then, to assess the influence of different treatment patterns on survival, we compared outcomes for patients who received similar treatments across hospitals. **Results:** Compared to hospitals with low multimodality treatment utilization, patients in hospitals with high utilization were more likely to receive multi-agent chemotherapy (51.0% vs 32.1%, $p < 0.001$), primary site resection (66.3% vs 62.3%, $p < 0.001$), metastatic site resection (32.0% vs 10.0%, $p < 0.001$), or palliative care (9.1% vs 6.9%, $p = 0.014$), and had longer median survival (15.2 vs 12.4 months, $p < 0.001$). The observed survival differences across hospitals were eliminated once patients were stratified by treatment modality (adjusted HR for treatment in a high-utilization hospital 1.02 [0.98-1.07]). For example, there were minimal differences in median survival between high and low utilization hospitals for patients treated with multimodality therapy (30.7 vs 29.1 months, $p = 0.31$), chemotherapy only (12.1 vs 12.6 months, $p = 0.04$) or palliative care (7.8 vs 7.8 months $p = 0.24$). **Conclusions:** There is broad variation in hospital treatment utilization for patients with metastatic CRC. Survival differences across hospitals are minimal, however, when patients receive similar treatments. Higher survival in hospitals with high treatment utilization likely reflects their willingness to utilize cancer treatments, include palliative care, rather than other features of their overall quality of care.

6582 Poster Session (Board #139), Mon, 1:15 PM-4:45 PM

Association between Oncologic Drugs Advisory Committee (ODAC) members' financial conflicts of interest (FCOIs) and recommendations for drug approval by the U.S. Food and Drug Administration (FDA). *First Author: Ariadna Tibau Martorell, Hospital de la Santa Creu i Sant Pau, Barcelona, YT, Spain*

Background: FDA advisory committees influence decisions relating to the regulatory approval of drugs in the United States. Little is known about whether ODAC members' FCOIs affect the FDA's oncologic drug approval process. **Methods:** We consulted the FDA website for transcripts from ODAC meetings between January 2000 and December 2014. We included all meetings at which drugs used for prevention, treatment, or palliation of cancer were discussed. We restricted our analysis to meetings at which yes/no votes were cast for at least one question relating to an oncologic drug. We collected data on drug name, prevalence of self-reported FCOIs of voting members, type of FCOIs (with sponsor or competitor) and the number of members recused or with waivers allowing discussion but no voting. Association between votes favoring a drug, final drug approval and FCOIs of ODAC members were explored using logistic regression. **Results:** Eighty transcripts were available for analysis. ODAC voted favouring the drug in 50% of cases. In 6% of cases, ODAC voted against a drug, but it was subsequently approved. At least one FCOI was declared for at least one voting committee member in 59% of votes. At least one member was recused or given a waiver in 14% and 6% of votes, respectively. There has been a significant reduction in the proportion of voting members with FCOIs over time (41% in 2000 vs. 0% in 2014, trend $p < 0.001$). Voting members with any FCOIs were more likely to vote in favor of a drug (OR 1.34, $p = 0.04$). There was a near-significant interaction between the presence and type of FCOIs; FCOIs with the sponsor were associated with higher odds of voting in favor of a drug compared to FCOIs with a competitor (OR 1.89 vs. 0.97, interaction $p = 0.052$). Similar results were seen for the association of ODAC members' FCOIs and final FDA approval (OR 1.42, $p = 0.03$). **Conclusions:** FCOIs among voting members of ODAC are common, but have decreased significantly over time. FCOIs, especially with the sponsor, are associated with higher odds of ODAC recommendation and of final FDA approval of oncologic drugs.

6583 Poster Session (Board #140), Mon, 1:15 PM-4:45 PM

Frequency and predictors of hospitalization during chemotherapy: a systematic review. *First Author: Rebecca M. Prince, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Hospitalization during chemotherapy is a significant event from both the patient and healthcare system perspectives but little is known about how often it occurs and in which settings. We conducted a systematic review to define the frequency of and factors associated with treatment-related hospitalization among cancer patients (pts) undergoing chemotherapy. **Methods:** A systematic search of Medline and EMBASE databases, from 1946 to September 2013, was undertaken to identify articles reporting rates of hospitalization in pts with cancer undergoing chemotherapy. Observational studies and clinical trials were eligible but results were analysed separately for each group. Summary statistics were used to describe the results and the Chi-square test was used to compare the groups. **Results:** Sixty articles met inclusion criteria: 44 observational studies comprising 189,342 pts and 16 randomized controlled trials comprising 13,086 pts. The majority of articles (80%) focused on chemotherapy given with palliative intent most commonly in breast, lung and colorectal cancers. The proportion of pts hospitalized at least once was significantly higher in observational studies at 32% (range 27-38%) compared with 21% (range 15-27%) in randomized trials (OR 2.13, 95%CI 2.03-2.23, $p < 0.0001$). A significant difference was seen in both the adjuvant and palliative settings between real life and trial pts with 42 vs 16% (OR 2.94, 95%CI 2.72-3.18, $p < 0.0001$) of adjuvant and 33 vs 23% (OR 3.24, 95%CI 3.03-3.48, $p < 0.0001$) of palliative pts being hospitalized, respectively. Factors associated with hospitalization in observational studies included higher comorbidity, type of chemotherapy and geographic location, while performance status and type of chemotherapy were significant predictors in clinical trials. Age was not a risk factor in either population. A number of methodological issues regarding reporting of hospitalization parameters were identified such as poor definitions of the at-risk period and attribution of hospitalization as treatment-related. **Conclusions:** Hospitalization during chemotherapy is common especially in unselected patient populations. However, few articles report this and often do so poorly.

6584 Poster Session (Board #141), Mon, 1:15 PM-4:45 PM

Choosing wisely: Treatment recommendations from 36 Michigan Oncology Clinical Treatment Pathways practices. *First Author: Amy Hatfield Seung, CARET, Ann Arbor, MI*

Background: ASCO identified ten low value, commonly used practices (Schnipper et al JCO 14:1715, 2012 and JCO 31:4362, 2013) as part of the "Choosing Wisely" (CW) campaign. Pathways is a statewide quality improvement program sponsored by Michigan BlueCross BlueShield. It measures and incentivizes adherence to locally defined treatment pathways (Fineberg et al JOP 8e32s, 2012). CARET^{SM}, a web-based patient registry was developed to support this program. CARET allows providers to enter treatment data and patient characteristics, and to demonstrate pathway compliance. We report preliminary data for three CW items. **Methods:** CARET includes records entered by participating providers for medical anticancer treatment regimens. Provider-reported data is matched to insurance claims data. Three CW items were easily available for analysis, avoiding: 1) chemotherapy for patients with advanced incurable cancer, 2) unnecessary myeloid growth factors, and 3) unnecessary antiemetic drugs for chemotherapy with low or moderate risk of nausea or vomiting. **Results:** A total of 1060 anticancer regimens representing 937 unique patients were initiated in 2014. 114 physicians from 36 practices were included. 690 (65.1%) regimens required prophylactic myeloid growth factor and antiemetic pathways. Results by tumor type and by CW item are shown in the table. **Conclusions:** Pathways practices appear to CW for these three treatment measures. From our initial data, we cannot discern the role of incentives for pathway adherence; the effect of real-time, registry-based, decision support tools (CARET); support from payors; or other factors in CW. We plan to explore these reasons and analyze cost savings from CW.

	Regimens (n)	Advanced disease with PS 3-4 receiving chemotherapy n (%)	Regimens with supportive care (n)	Antiemetic nonadherence n (%)	Growth factor nonadherence n (%)

6585 Poster Session (Board #142), Mon, 1:15 PM-4:45 PM

Prospective clinical study of precision oncology in solid tumors. *First Author: Davendra Sohal, Cleveland Clinic, Cleveland, OH*

Background: Advances in tumor genomic profiling offer the promise of precision oncology but a systematic prospective evaluation is lacking. We conducted a prospective cohort study of tumor genomic testing to identify prevalence of actionable alterations and their impact on management decisions. **Methods:** Patients provided written informed consent for this prospective cohort study approved by the Cleveland Clinic Institutional Review Board. Eligibility requirements included pathologic diagnosis of select solid tumor malignancies without a known curative option, age ≥ 18 years, and ECOG PS 0-2. Tumor samples were sequenced for up to 315 candidate genes using FoundationOne (Cambridge, MA). Results were reviewed at the Cleveland Clinic Genomics Tumor Board (GTB) for biologically actionable alterations, defined as those linked to an approved therapy in the solid tumor under study or another solid tumor, a clinical trial, or a contraindication to a targeted therapy. Sample size was 250 patients. Outcomes were feasibility and clinical impact of tumor sequencing. **Results:** From Aug 2013 to Oct 2014, all 250 patients were enrolled. Median age was 60 years; 128 (51%) were female; 220 (88%) were white. Colorectal (25%), breast (18%), lung (13%), pancreatobiliary (12%), and head and neck (10%) cancers were common diagnoses. Median time from consent to genomic test result was 25 days (range, 3-140), with 27 (11%) samples having insufficient tissue for analysis. Of 223 resulted samples, an alteration was found in 96% (n = 214), with a median of 4 (0-20) alterations per sample. At GTB review, a biologically actionable alteration was declared in 63% (n = 141) of cases. However, only 10% (n = 22) of patients received tumor genomics-driven targeted therapies: 12 went on clinical trials, 3 received on-label drugs, and 7 received off-label drugs. Lack of clinical trial access was the most common reason for non-recommendation/receipt of genomics-driven therapy. **Conclusions:** This prospective study shows that routine tumor genomic profiling is feasible, with almost two-thirds of resulted samples having a biologically actionable alteration, but paucity of genomics-driven clinical trials of targeted therapies is a barrier to the success of precision oncology.

6586 Poster Session (Board #143), Mon, 1:15 PM-4:45 PM

Breast cancer progression and workplace productivity. *First Author: Wesley Yin, UCLA, Los Angeles, CA*

Background: A significant fraction of women with breast cancer leave employment due to their disease. However, little is known about the effects of breast cancer progression on productivity among those who remain employed **Methods:** Linking commercial health claims to employer records on workplace productivity, we created a cohort of employed U.S. women ages 18-64 who were treated for breast cancer between 2005 and 2012. Disease stage was measured through diagnosis codes and treatments observed, to classify women into the following breast cancer groups in each 90-day quarter: local; locally advanced; other non-metastatic; metastatic, 1st line therapy; metastatic, 2nd line therapy; metastatic, ≥ 3rd line therapy; metastatic, end-of-life care. Productivity was defined as work hours missed per quarter. We performed linear regression analysis to predict hours missed as a function of disease stage, age, comorbidities, industry of occupation, region and a time trend. To explore possible selection bias, we used a Cox survival model to test whether women whose cancer progressed were more likely to exit our employment-based dataset, controlling for age, comorbidities, industry and region. **Results:** In our cohort of 19,496 women with breast cancer,stage varied as follows:23% local; 1% locally advanced; 69% other non-metastatic; 5% metastatic 1st line; 1% metastatic 2nd line; < 1% metastatic ≥ 3rd line; 1% metastatic, end-of-life care. Women treated for breast cancer missed an average of 79 hours (about 10 days) per quarter. Disease progression was associated with greater work hours missed. In adjusted analysis, hours missed varied by stage as follows: other non-metastatic, 77h; local, 81h; locally advanced, 83h; metastatic 1st line, 87h; metastatic 2nd line, 112h; metastatic ≥ 3rdline, 106h; metastatic end-of-life care, 126h. Women whose cancer progressed were more likely to exit our employment-based dataset. Thus our estimated productivity effects are likely conservative. **Conclusions:** Breast cancer progression is associated with impaired workplace productivity, with greater impairment among those with more advanced disease. Avoiding or delaying disease progression could bring productivity gains to the workplace in addition to the benefits to the patient.

6587 Poster Session (Board #144), Mon, 1:15 PM-4:45 PM

Uncontrolled chronic conditions prior to cancer diagnosis in older adults as a predictor of unplanned hospitalizations during cancer care: A Medicare claims analysis. *First Author: Noam Avraham VanderWalde, University of Tennessee West Cancer Ctr, Memphis, TN*

Background: Unplanned hospitalizations (UH) during cancer care have been identified as a poor outcome that may significantly increase costs of care. We hypothesized that poor quality of care prior to cancer diagnosis, as defined by preventable hospitalizations for Ambulatory Care Sensitive Conditions (ACSCs), predicts for UH during cancer care. **Methods:** A retrospective claims study was conducted among Medicare fee-for-service enrollees with a first time diagnosis of one of seven cancers (breast, lung, colorectal, lymphoma, melanoma, pancreatic, or thyroid) from 6 different states (TX, OH, ME, NM, GA, and FL) between 2011 and 2012. Date of diagnosis was defined as the first cancer diagnosis claim from inpatient or outpatient claims. At least nine months of pre-diagnosis claims was required to identify pre-cancer Charlson comorbidity (CCI) and ACSC hospitalizations as measured by ER and hospitalization diagnosis codes. UHs were defined as hospitalization, with admission type of urgent or emergent within 1 year from diagnosis, excluding those for cancer treatment. Multivariate logistic regression analysis was used to model UH using known patient and county level socio-demographic variables. **Results:** A total of 21,735 cancer patients were identified. The majority of patients had breast (n = 7,548), lung (n = 5,841) or colorectal cancer (n = 3,904). Median age at diagnosis was 74. Thirty four percent of patients were male. UHs were experienced by 33% of all patients during their cancer care, while 8% had pre-diagnosis ACSC hospitalizations. ACSC hospitalizations were strongly associated with UH during cancer care (OR: 1.49, 95% CI: 1.34 – 1.66, p-value: < .001). Other variables associated with higher likelihood of UH include CCI (OR: 1.22, p-value < .001) AA race (OR: 1.30 p-value < .001), and cancer type compared to breast (lung cancer OR 3.30, p-value < .001). **Conclusions:** There is a strong association between pre-diagnosis ACSC preventable hospitalizations and UHs during cancer care, even after controlling for comorbidity. Interventions that identify vulnerable older adults at diagnosis may help improve outcomes and costs of cancer related care.

6588 Poster Session (Board #145), Mon, 1:15 PM-4:45 PM

Potentially inappropriate medication use in elderly breast cancer patients. *First Author: Meghan Sri Karuturi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Screening for potentially inappropriate medication (PIM) use is recommended in elderly cancer patients receiving chemotherapy. However, few studies have examined the patterns and impact of PIM use in this population. Our objective was to determine predictors of PIM use and impact on outcomes in breast cancer patients receiving chemotherapy. **Methods:** We used data from the Surveillance, Epidemiology, and End Results database linked to Medicare claims. Our cohort included women 66 years and older with a diagnosis of Stage II/III breast cancer receiving adjuvant chemotherapy between 7/1/2007 and 12/31/2009. We used the National Center for Quality Assurance Drugs to Avoid in the Elderly list to define baseline PIM use as a dichotomous variable in the 4 months prior to diagnosis. Outcome measures included ER visits, hospitalization, or death within 6 months of diagnosis. We included age, race, stage, Charlson comorbidity, poverty level, and number of providers as covariates. We used Chi-square or Fisher's exact test to determine associations of PIMs with covariates and outcomes, and multivariable logistic regression to determine the association of PIMs with outcomes. **Results:** 1595 patients met our criteria, of whom 339 (21.3%) had PIM use at baseline. In multivariate analysis, baseline PIM was associated with higher comorbidity (OR 1.33, 95% CI 1.0-1.76 for 1; OR 1.51, 1.07-2.13, for 2+), higher poverty level (OR 2.03, 1.43-2.88 for third quartile; OR 1.44, 1. -2.07, for highest quartile), and higher number of providers (OR 1.70, 1.18-2.44 for 4+ providers). 669 (41.9%) had an ER visit, unplanned hospitalization or died within 6 months after diagnosis. Baseline PIM was not significantly associated with the composite outcome in univariate analysis (OR 1.23, 95% CI, 0.97-1.57). Associations with outcome in the multivariate analysis included advanced stage (OR 1.48, 95% CI 1.19-1.82), higher comorbidity index (OR 1.67, 95% CI 1.23-1.26 for 2+ vs. 0) and baseline ER visits/hospitalizations (OR 1.82, 95% CI 1.33-2.49). **Conclusions:** We found no significant association between overall baseline PIM use and adverse outcomes. Ongoing analyses are evaluating the association between PIM use during chemotherapy and adverse outcomes.

6589 Poster Session (Board #146), Mon, 1:15 PM-4:45 PM

Creating a national collaborative strategy to enhance trial accrual in NCI's National Clinical Trials Network (NCTN) in the era of precision medicine. *First Author: Andrea Denicoff, National Cancer Institute, Bethesda, MD*

Background: NCI launched the NCTN on March 1, 2014 to reinvigorate the publically funded cancer trials system. As precision medicine (PM) trials increasingly require screening large numbers of patients to identify a subset of patients whose tumors contain specific molecular targets, national accrual strategies are needed. We report findings from a Network-wide interactive meeting held in Dec, 2014 to explore accrual to PM and adolescent and young adult (AYA) trials. **Methods:** NCI convened a 2-day meeting of NCTN grantees and NCI staff, with 75 representatives from Groups, Patient Advocates & Lead Academic Participating Sites (LAPS), to discuss accrual in the era of PM. Accrual challenges and strategies were identified via a mixed method approach: pre-meeting worksheets, trial case studies, group and breakout sessions and a priority ranking activity. Findings were triangulated to determine next steps to maximize future accrual. **Results:** Key themes identified included the need to streamline trial communication and promotion, emphasize accrual feasibility during trial design and review, better address minority and underserved populations, increase the efficiency and clarity of regulatory processes, and incentivize and enhance participation in trials by investigators and sites. Consensus was reached on the need for a cross-NCTN forum to collaborate on accrual for specific challenging trials and address broader accrual issues. Key themes and recommendations for the forum will be elaborated on in light of PM and AYA trials. **Conclusions:** A new NCTN Accrual Core Team (ACT) will be formed to collaboratively address identified cross-cutting themes that have implications for accrual to trials. Next steps that may be addressed by ACT include identifying ways to target messaging to promote trials to key groups (including investigators, research teams, and patients), developing templates for trial education, facilitating the pooling of resources currently replicated by sites such as Medicare Coverage Analyses, standardizing trial tools and processes, and developing metrics to monitor accrual enhancement efforts.

6590 Poster Session (Board #147), Mon, 1:15 PM-4:45 PM

Does paid sick leave affect the unmeasured costs of colorectal cancer treatment? *First Author: Christine Marie Veenstra, University of Michigan, Ann Arbor, MI*

Background: For working patients, the financial impact of colorectal cancer (CRC) diagnosis and treatment can be substantial. Unmeasured costs can include unpaid time away from work and job loss. Although not a provision of the Affordable Care Act or FMLA, paid sick leave may help CRC patients retain their jobs and alleviate some financial burden. **Methods:** In 2011-13, we surveyed Stage III colorectal cancer patients from Detroit and Georgia SEER registries 4-12 months after diagnosis. The analytic sample was restricted to respondents who were working at the time of diagnosis. We assessed two outcomes, job retention and personal financial burden. We measured personal financial burden using a validated 6-item scale and categorized it as a binary measure indicating low vs. high burden. We assessed associations between 1) paid sick leave and job retention and 2) job retention and personal financial burden in separate models, using logistic regression to control for age, sex, race, education, and income. **Results:** Among 1469 patients who returned surveys (RR 68%), 38% were working for pay at the time of CRC diagnosis. Overall, 46% of patients did not retain their jobs and 32% reported high financial burden during CRC treatment. In adjusted analyses, availability of paid sick leave was significantly associated with job retention (OR 2.59, 95% CI 1.68–3.98). After adjustment, job retention was inversely associated with high personal financial burden (OR 0.25, 95% CI 0.160.38). Compared with respondents who had paid sick leave available, those without paid sick leave were more likely to be older, have a high school education or less, and have an income of under $50,000 (all $p < 0.001$). **Conclusions:** In a robust, population-based study, we found that the availability of paid sick leave during CRC treatment was positively associated with job retention. Furthermore, personal financial burden was reduced when working patients were able to retain their jobs throughout CRC treatment. Millions of working Americans do not have access to paid sick leave, but our results indicate that an investment in paid sick leave by employers and government may provide long-term societal dividends.

6591 Poster Session (Board #148), Mon, 1:15 PM-4:45 PM

Impact of maternal death from female cancers on child mortality. *First Author: Raymond Mailhot Vega, New York University School of Medicine, New York, NY*

Background: Cervical and breast cancers are the most common causes of cancer mortality in women of childbearing age. The impact of maternal mortality on child mortality remains an under-investigated area. Elevated mortality rates in offspring are significantly associated with maternal death in both Bangladeshi and Scandinavian cohorts (Ronsmans 2010, Li 2014). This effect is contextual: when a mother dies, a child in Bangladesh is 10 times more likely to die before 10, versus 1.5 times more for a Scandinavian child. By ignoring this impact disease mortality rates underrepresent life lost, and this underestimation affects appropriate resource allocation. We propose a country-specific model to allow for estimates of offspring death rates attributable to breast and cervical cancers in women of childbearing age. **Methods:** A Monte Carlo simulation model (TreeAge) analyzed a sample population of 1 million 15yo fertile girls of a specific nationality and at risk of dying from cervical and breast cancer. Information was obtained from Globocan and UN World Population Prospects. Criteria included: 1) country-specific life tables for baseline child mortality 2) child risk of dying due to maternal loss until 10 years of age; and 3) definition of a coefficient "Q" = the multiplicative contextual increase in all cause mortality. Bangladesh and Denmark served as two benchmark populations, and coefficient Q was varied. Sensitivity analyses were performed in five nations with the highest breast or cervical mortality. The outcome measurement is relative mortality increase (RMI), such that a value of 2% denotes for every 100 women succumbing to disease, 2 children die in association. **Results:** Benchmark cases illustrate RMIs of 0.83% in Bangladesh and 0.01% and in Denmark. For 19,012 estimated maternal deaths, Bangladeshi absolute mortality increase equals 154 child deaths. Sensitivity analyses in nations with high burden of disease illustrate RMIs as high as 7.2% in Nigeria and 5.6% in Malawi. **Conclusions:** Current cause-specific mortality rates ignore child deaths in association with maternal deaths and under-allocate resources due to underestimation of effect. This model serves as a means to accurately reflect disease burden and as a guide for policymakers.

6592 Poster Session (Board #149), Mon, 1:15 PM-4:45 PM

Nationwide utilization of cardiac imaging in patients undergoing cardiotoxic chemotherapy. *First Author: Michaela Ann Dinan, Duke Clinical Rsrch Inst, Durham, NC*

Background: Current guidelines recommend cardiac evaluation in patients undergoing selected cardiotoxic regimens. However, utilization of cardiac imaging and adherence to guidelines have not been previously examined in a nationally representative cancer patient population. **Methods:** Retrospective SEER-Medicare analysis of patients with incident cancer of the breast, lung, colon, prostate (metastatic), leukemia (acute) or lymphoma between 2000 and 2009. We examined claims-based receipt of chemotherapy, cardiotoxic chemotherapy (anthracycline, trastuzumab, or bevacizumab) and their association with cardiac evaluation in the year following diagnosis. **Results:** A total of 346,903 patients met study criteria (Table). Receipt of cardiotoxic chemotherapy ranged from 1% in prostate cancer to 35% in lymphoma. Overall, 43% of patients underwent cardiac evaluation (84% echo, 30% exercise EKG, 9% MUGA, 1% nuclear imaging, 0.2% cardiac PET). Among patients receiving cardiotoxic chemotherapy, 80-90% of breast, leukemia, and lymphoma patients underwent one or more cardiac studies compared to only 40-60% of patients with colorectal, lung, or prostate cancer. **Conclusions:** Cardiac evaluation appears more common in cancer populations more frequently treated with cardiotoxic chemotherapy than in cancer populations with less exposure to these agents. Increased awareness of cardio-oncologic principles may be warranted among oncologists treating cancer types for which cardiotoxicity has not historically been a concern.

Cardiac imaging utilization by receipt of systemic and cardiotoxic therapy, 2000-2009.

		Systemic Chemotherapy		Cardiac Imaging		
Cohort	Total Patients (N = 346,903)	Any†	Cardiotoxic Chemotherapy	No Chemotherapy	Any Noncardiotoxic Chemotherapy	Cardiotoxic Chemotherapy

6593 Poster Session (Board #150), Mon, 1:15 PM-4:45 PM

A prospective evaluation of radiotherapy (RT) related skin reactions in a multi-racial/ethnic population of women with newly diagnosed breast cancer (BC). *First Author: James John Urbanic, UC San Diego, Encinitas, CA*

Background: RT-related early adverse skin reactions (EASR) are common in BC patients. EASR occur during/within 2 months post-RT. Predictive biomarkers for EASR are under active investigation. Previous studies have limited sample size/lack racial/ethnic diversity. This study designed to evaluate disparities in EASR of a multi-racial/ethnic BC population. **Methods:** Stage 0-III BC patients. Inclusion criteria: RT dose $>$ 40 Gy and daily RT 1.8 to 2.7 Gy/fx. Regional nodal irradiation, mastectomy/lumpectopmy, concur/sequent boost, chemotherapy, hormonal therapy allowed. Exclusion criteria: immediate reconstruction, partial breast RT. Primary outcome: EASR (Oncology Nursing Society (ONS) acute skin toxicity (0-6 scale)) assessed during/2 months post-RT. Mixed effects repeated measures analysis of variance used to assess race/ethnicity and mastectomy/lumpectomy differences in EASR over time. **Results:** 10/2011-6/2013, 1000 patients accrued (405 non-Hispanic white (NHW), 277 non-Hispanic black (NHB), 241 Hispanic, 62 Asian/Pacific Islanders, 15 other). Both time by race/ethnicity and time by mastectomy interactions statistically significant ($p < 0.001$ & $p = 0.008$, respectively). Based on race/ethnic cohorts, significant differences in patient characteristics ($p < 0.05$) existed for age, BMI, marital status, education, health insurance, cancer stage, and medical comorbidities. Mean ONS peaked at last day of RT (2.23), higher: mastectomy vs lumpectomy (2.66 vs 2.19) not different between race/ethnic groups. NHW women greater mean ONS score at 3 weeks into RT than other groups; however, NHW had lower mean ONS at 1 and 2 months post-RT ($p < 0.01$). ONS grade 4+ skin toxicities occurred: 15% of women at the end of RT, but no difference by race/ethnic cohorts. **Conclusions:** EASR peaks at end of RT with variation in time course by race/ethnicity. High grade toxicity uncommon and not different by race/ethnicity. This is first large study of RT EASR in a multi-racial/ethnic BC population. Additional analyses: RT dosimetry, genomics, DNA damage/repair biomarkers, and late effects are forthcoming. Clinical trial information: NCT01407770.

6594 Poster Session (Board #151), Mon, 1:15 PM-4:45 PM

PROSPECT eligibility and clinical outcomes: Results from the pan-Canadian rectal cancer consortium. *First Author: Dominick Bosse, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: The current standard for locally advanced rectal cancer (LARC) is neoadjuvant chemoradiation therapy (nCRT) followed by surgery. The PROSPECT trial (N1048) is investigating neoadjuvant FOLFOX with selective use of nCRT in patients (pts) with LARC undergoing low anterior resection (LAR). We evaluated outcomes of PROSPECT eligible and ineligible pts from a retrospective multi-institution database. **Methods:** Data from pts with LARC who received nCRT and had curative intent surgery from 2005 to 2014 were collected from 5 Canadian cancer centres. PROSPECT eligible pts included: cT3N0, cT2N1 and cT3N1 rectal adenocarcinoma, ECOG performance status (PS) $\leq$ 2, hemoglobin $>$ 80 g/L, age $>$ 18 years and receipt of LAR. Overall survival (OS), disease free survival (DFS), recurrence free survival (RFS), and time to local recurrence (TLR) were estimated using Kaplan-Meier method. Cox proportional hazards regression (MVA) was used to adjust for prognostic factors including circumferential resection margin (CRM), PS, clinical stage, pathological stage (ystg) and adjuvant chemotherapy (aCT), sex, age and RT dosage. **Results:** 1531 pts were included of whom 566 (37%) were considered eligible for PROSPECT. Eligible pts were more likely to have better PS ($p = 0.0003$), RT $\geq$ 45Gy ($p = 0.001$), negative CRM ($p < 0.0001$) and distance $\geq$ 5cm from anal verge ($p < 0.0001$). PROSPECT eligibility was associated with improved DFS (HR 0.75, 95% CI: 0.61-0.91), OS (HR 0.73, 95% CI: 0.57-0.95) and RFS (HR 0.68, 95% CI: 0.54-0.86) in univariate analyses. In MVA, RFS was improved for PROSPECT eligible pts (HR 0.75, 95% CI: 0.57 – 1.00, $p = 0.0499$), but not for OS and DFS. TLR was also similar (HR 0.95, 95% CI: 0.31-3.0) adjusting for CRM, ystg and aCT. The 3-year DFS for PROSPECT eligible pts was 79.1% compared with 71.1% for ineligible pts and the rate of freedom from local recurrence at 3 years was 97.4 v 96.8%, respectively. In comparison, the PROSPECT trial has estimated a 3-year DFS of 69-74% and a 3-year freedom from local recurrence of 96%. **Conclusions:** Real world data corroborate the eligibility criteria used in the PROSPECT study, identifying a subgroup of patients in whom recurrence risk is lower and where selective use of CRT should be actively examined.

6595 Poster Session (Board #152), Mon, 1:15 PM-4:45 PM

Conflicts of interest in pharmaceutical sponsored economic studies of breast cancer therapies: An empirical study. *First Author: Jordan D. Lane, jordan_lane@hms.harvard.edu, Boston, MA*

Background: Cost-effectiveness studies are increasingly included in the regulatory decisions of many countries and in formulary decisions worldwide. In 1999, we reported that pharmaceutical company sponsorship of economic analyses of three oncology drugs (anti-emetics, granulocyte colony stimulating factors, and taxanes) was associated with reduced likelihood of reporting unfavorable results. We re-evaluate this hypothesis 15 years later, focusing only on a single diagnosis (breast cancer) and an updated review of the economic literature. **Methods:** Breast cancer was selected for analysis since it is the cancer with the largest number of cost effectiveness studies and the cost of recent drugs has caused questioning of their incremental cost effectiveness. Search of the Tufts Medical Center Cost Effectiveness Analysis Registry resulted in 105 studies published between 1991-2012 that evaluated the cost effectiveness of drugs used to prevent or treat breast cancer. Overall study conclusions regarding cost-effectiveness of the investigated drugs were evaluated using three thresholds: $50,000 per quality adjusted life-year (QALY), $100,000 per QALY, and $150,000 per QALY. A logistical regression was performed to determine how study characteristics including funding source were associated with study findings. **Results:** Overall, 65 studies were funded by industry (62%). Studies with pharmaceutical company funding were more likely than studies with other funding to report favorable cost-effectiveness estimates (75.4% vs 40.0%, OR = 4.01 CI = 1.55-10.92 at the $50,000 threshold; 80.0% vs 57.5%, OR = 3.14, CI = 1.14-9.08 at the $100,000 threshold; and 87.7% vs 67.5%, OR = 3.27, CI = 1.05-11.08 at the $150,000 threshold). **Conclusions:** Industry sponsorship continues to be associated with a higher likelihood of reporting favorable results. These findings suggest that steps are necessary to ensure that the cancer cost effectiveness literature is not biased by sponsorship. Expanding funding sources other than pharmaceutical companies for these studies or pre-registering cost effectiveness studies may help mitigate this potential source of bias.

6596 Poster Session (Board #153), Mon, 1:15 PM-4:45 PM

Cancer mortality and published research output: Is there any relationship? *First Author: Francis Patafio, Division of Cancer Care & Epidemiology, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

Background: The relative distribution of cancer research output across disease sites is not well described. Here we evaluate whether the volume of published research and clinical trials is proportional to mortality by cancer site. We also explore whether research output is proportional to research funding by cancer site. **Methods:** Statistics from the American and Canadian Cancer Societies were used to identify the top ten causes of cancer death in 2013. The OVID MEDLINE database identified all journal articles and clinical trials published in 2013 by US/Canadian authors for these cancer sites. Total research funding in Canada by cancer site was obtained from the 2011 report by Canadian Cancer Research Alliance. Descriptive statistics and Pearson correlation coefficient (r) were used to describe the relationship between research output (volume of publications and clinical trials), cancer mortality, and research funding. **Results:** We identified 19,361 publications and 2,661 clinical trials. The proportion of publications and clinical trials were substantially lower than the proportion of deaths for lung (41% deaths, 15% publications, 16% clinical trials), colorectal (14%, 7%, 6%), pancreas (10%, 7%, 5%), and gastroesophageal (7%, 5%, 3%) cancers. Conversely, research output was substantially greater than the proportional death for breast cancer (10% deaths, 29% publications, 30% clinical trials) and prostate cancer (8%, 15%, 17%). There was substantial variation in total research investment across cancer sites that was not due to differences in relative mortality. Total investment in 2013 in Canada per cancer death was $599 for bladder cancer, $1039 for lung cancer, $2197 for colorectal cancer, $9212 for prostate cancer, and $14,329 for breast cancer. There was stronger correlation between research output and funding (all publications $r = 0.8942$ $p < 0.001$; clinical trials $r = 0.9258$, $p < 0.001$), than there was between research output and cancer mortality ($r = 0.3625$, $p = 0.3033$ and $r = 0.3395$, $p = 0.3372$). **Conclusions:** Research output is not well correlated to cancer mortality but is correlated to relative level of research funding.

6597 Poster Session (Board #154), Mon, 1:15 PM-4:45 PM

Trends in the costs and utilization of targeted cancer therapies for the privately insured non-elderly: 2001-2011. *First Author: Fabrice Smieliauskas, University of Chicago, Chicago, IL*

Background: Studies documenting high costs of cancer drugs often focus on targeted therapies as a whole without differentiating between oral and intravenous agents; such distinction is important because they differ in insurance design. Our study examined recent trends on targeted oral anticancer medications (tOAMs), and targeted IV anticancer medications (tIVAMs) and explored the cost drivers. **Methods:** We classified cancer drugs as tOAMs, tIVAMs, and non-targeted agents. Using the 2002-2011 LifeLink Health Plan Claims Database, we described trends in utilization and in insurance payments and out-of-pocket (OOP) costs per patient per month (PPPM) and during the first year of systemic therapy among privately insured non-elderly cancer patients. We performed Cochran-Armitage tests and generalized linear models to test the statistical significance of utilization and cost trends, respectively, and conducted decomposition analysis to disaggregate the cost trend into the increase driven by therapeutic substitution to more expensive classes of drugs vs. increases in drug prices over time. **Results:** Targeted therapies accounted for 11% of all systemic therapy utilization and 22% of systemic therapy expenditures in 2001, increasing to 42% (28% tIVAMs and 14% tOAMs) of utilization but 63% (38% tIVAMs, 25% tOAMs) of expenditures in 2011. Insurance payments PPPM for tOAMs more than doubled in ten years, growing from $3,381 PPPM in 2001 to $7,370 in 2011 ($P < 0.001$), whereas PPPM for tIVAMs remained fairly constant (around $7,000) throughout. Decomposition analyses of two time periods (2001-2005 and 2005-2010) showed that switching to more expensive classes of drugs accounted for the large majority of cost increase. Post-launch price increases contributed a 10-11% of spend increases during the two periods, while the increase in launch price accounted for 6% and 15% of spending growth, respectively, for each period. **Conclusions:** Payers should consider more aggressive management of pharmacy benefits for tOAMs and payment reforms for injectable drugs to contain the rising costs of cancer care.

6598 Poster Session (Board #155), Mon, 1:15 PM-4:45 PM

Target wise and pound foolish: A simple technique to evaluate the trade-off between economic burden and clinical benefit of monoclonal antibodies. *First Author: Matt Christopher Brennan, Penn State Milton S. Hershey Medical Center, Hershey, PA*

Background: Monoclonal antibodies (mabs) have great clinical potential for individual patients, but also substantial cost to society. We propose a very simple, transparent calculation to frame this debate in objective terms for practicing oncologists and policy makers. We then apply this strategy to all mabs currently approved for hematology/oncology indications. **Methods:** Mabs were identified from the FDA's approved drug products list. Approved indications for each mab in the clinical practice of hematology/oncology were extracted from section 14 of the approved prescribing information. All comparative studies used to support each drug's approval for each indication were analyzed. Cost data was obtained from publically available sources. Using this data, we calculated the cost to achieve one additional good outcome as defined by each study. Overall survival was our preferred outcome measure. If not explicitly stated, OS was calculated from the Kaplan-Meier curves using pixel coordinates. If OS data was not collected, the primary endpoint used in the trial was substituted. Total cost to achieve one additional good outcome was calculated as: cost = (cost per dose)*(median number of doses)*NNT. **Results:** Forty-four mabs were identified; 19 have hematology-oncology-relevant indications. Of 66 studies listed in the prescribing information leading to FDA approval, 47 were comparative and were included. The costs for each mab to achieve one improved outcome at the study-specified time were calculated. An abbreviated table is shown in the table below. **Conclusions**: NNT provides a simple, clinically relevant, robust way of framing the critical debate between individual benefit and public health priorities. Some monoclonal antibodies for some hematology/oncology indications may not meet reasonable thresholds for widespread use.

Drug	Indication	Trial	mOS (exp/control) in months	Endpoint	NNT	Cost ($)
Ramucirumab	Gastric Cancer	RAINBOW	9.6/7.4	6 mo OS	7	1,079,568
12 mo OS	10	1,542,240				
Bevacizumab	mCRC	ECOG E3200	12.9/10.8	12mo OS	8	254,880
24mo OS	16	509,760				
Rituximab	DLBCL	GELA	Not reached	24 mo OS	8	433,126
60 mo OS	9	487,267				
Trastuzumab	Adj HER2 + breast	HERA	Not reached	24 mo OS	12	1,785,028

6599 Poster Session (Board #156), Mon, 1:15 PM-4:45 PM

Serum tumor marker utilization in patients with advanced solid tumors. *First Author: Melissa Kate Accordino, New York Presbyterian Columbia, New York, NY*

Background: Despite data on the sensitivity and specificity of serum tumor marker tests, there is no evidence to suggest that early changes in therapy related to rising tumor markers have an effect on survival. Studies have failed to show benefit of surveillance testing in patients with limited disease. We performed a retrospective analysis in patients with advanced cancer to evaluate trends in utilization of tumor marker testing and the associated costs. **Methods:** Patients at Columbia University Medical Center with advanced or metastatic cancer were identified by ICD9 codes and confirmed with tumor registry and medical record review. Between 7/1/2013-6/30/2014 for each patient, the dates each of the following tumor markers were recorded: alpha fetoprotein (AFP), CA 125, CA 15-3, CA 19-9, CA 27-29 and carcinoembryonic antigen (CEA). Subjects who had $>$ 1 of any single tumor marker over the time-frame were included. We evaluated the maximum number of tests per month and the average number of tests per-month the patient was alive. Costs of each tumor marker were determined using 60% Medicare reimbursement rates. **Results:** Over the 12 month time frame 996 patients were included in the analysis. The mean number of any individual test per-patient was 7 and the maximum was 35; and the mean number of total tests per-patient was 12 and the maximum was 70. CEA and CA-19-9 were the most commonly ordered tests with an average of 1.94 and 2.18 times per-month, per-patient. On average the number of patients that had $>$ 1 of any individual test per month was 33%. The most common tests were CA-125, CEA and CA-19-9 (25.3%, 38.2% and 45.6% respectively). Overall 21.9% of patient had $\geq$ 3 of any individual marker per-month (38% CA19-9 and 25.6% CEA). The mean per-patient annual cost of testing was $421, with a maximum $2,567. Costs per-patient were highest for those with breast cancer (mean $755, max $1,787) and pancreatic cancer (mean $643, max $2,567). **Conclusions:** Tumor marker testing is frequent, with a large number of patients being tested multiple times per month, every month. Given the rising costs of cancer care, the large number of serum tests, and the frequency of use, efforts should be made to determine the clinical utility of tumor marker testing in metastatic cancer patients.

6600 Poster Session (Board #157), Mon, 1:15 PM-4:45 PM

Assessing financial toxicity in insured patients with multiple myeloma. *First Author: Scott F. Huntington, Abramson Cancer Center, Hosp of the Univ of Pennsylvania, Philadelphia, PA*

Background: Financial toxicity is increasingly recognized for its potential to adversely impact the quality of life and health outcomes of patients undergoing treatment for cancer. Patients with multiple myeloma (MM) may be particularly vulnerable due to high utilization of novel therapeutics and extended treatment duration. **Methods:** Patients with at least 3 months of ongoing treatment for MM were invited to participate in a survey during follow up visits at our institution. The survey was derived from published instruments and included the recently developed 11-item COST measure (financial toxicity score 0 – 44). Electronic health records informed insurance and treatment data. **Results:** Of 111 patients approached for the study, 100 individuals completed the survey. The median reported annual household income was between $60,000-79,999 and all participants were insured (43% private, 49% Medicare, 8% Medicaid/dual). Median time from diagnosis was 31 months, 75% had exposure to both lenalidomide and bortezomib, and 58% had undergone autologous transplantation. The majority (59%) labelled treatment costs as higher than expected and 70% endorsed at least minor financial burden. Thirty-six patients reported applying for financial assistance, including 18% of individuals with income over $100,000. Use of savings to pay for MM treatment was common (46%), 21% borrowed money to pay for medications, and 17% reported delays in their MM treatment due to cost. COST scores were normally distributed (median 20.5, range 0-43) and correlated with patient reported incomes, use of savings, borrowing of money, and treatment delays ($p < 0.001$). After controlling for potential confounders on linear regression, time since diagnosis was directly related ($p < 0.03$), while age and income were inversely related with COST scores ($p < 0.03$; $p < 0.001$). **Conclusions:** Financial burden and request for financial assistance were common in our insured population with MM. Younger age, lower household income, and time since diagnosis were associated with higher financial toxicity as measured by the COST score. Additional attention to rising treatment costs and cost-sharing is needed to address the growing evidence of financial toxicity impacting patients with cancer.

6601 Poster Session (Board #158), Mon, 1:15 PM-4:45 PM

Impact of site of service on chemotherapy costs: Influence of geographic location and diagnosis. *First Author: Michael A. Kolodziej, Aetna, Hartford, CT*

Background: Site of service strongly influences the cost of cancer treatment. The migration of community oncology practices to the hospital based practice setting has generated considerable discussion about the cost differential between these sites. **Methods**: We examined claims paid for chemotherapy by Aetna from August 2013 through July 2014 for all malignancies as well as breast/colon/lung cancer (BCL). **Results**: Over this period of time, Aetna paid chemotherapy claims for 46,000 unique members, including 17,000 members with breast, colon and lung cancer (BCL). For all members receiving chemotherapy as well as for members with BCL, 69% received chemotherapy in the office setting (O) and 31% received chemotherapy in the hospital outpatient setting (H). Despite this patient distribution, chemotherapy allowable reimbursement share was 42% for H and 58% for O, indicating a disproportionate share of chemotherapy reimbursement to H. When considering average chemotherapy allowed per member, patients treated in H for all cancers were 59% more costly per member, while patients treated for BCL were 40% more costly per member. When examining site of service by state, considering only states with more than 100 members treated in H, there was great variation in site distribution, from a high of 79% (Massachusetts) to a low of 15% (Florida). The allowed chemotherapy costs per unique member were 229% for all malignancies and 190% for BCL in the most costly H state compared to the most costly O state. Paying H the average O allowable would generate $100 million savings. **Conclusions**: The impact of site of service on chemotherapy costs is complex. Only 30% of patients treated with chemotherapy receive treatment in H but H received a disproportionate share of reimbursement for all malignancies as well as the most common malignancies (BCL). These differences are remarkably variable from state to state both with respect to the distribution of patients by site of service as well as the cost of care by site of service. For a large commercial payer, the site of service differential increases cost of care substantially. Given the geographic variability, a simple solution is not likely.

6602 Poster Session (Board #159), Mon, 1:15 PM-4:45 PM

Quantifying the relative value of drug therapy options in HER2+, ER-/PR- breast cancer. *First Author: John Whang, Real Endpoints, LLC, Westport, CT*

Background: US health care spending continues to exceed that of other industrialized countries, in part because there is insufficient transparency as to the relative value (benefit-cost) of different treatment options. Comparing drug regimens based on their overall value would help create a common set of metrics to enable better drug therapy decision-making and help improve quality and reduce costs of care. **Methods:** We developed a methodology to review, synthesize and assess the evidence of a drug's performance across three major domains of clinical efficacy, safety & use and economics, and to combine those assessments to determine overall value of a drug regimen. We then incorporated multi-attribute decision analysis and our evidence methodology into an interactive web-based tool to compare the relative value of all relevant drug regimens in an indication. The tool uses an explicit and transparent methodology and uses a total of 30 elements within the three domains. **Results:** Using the interactive web-based tool, we compared 3 adjuvant chemotherapy regimens in HER2+, ER-/ PR- breast cancer: 1) doxorubicin + cyclophosphamide then paclitaxel (AC-T), 2) doxorubicin + cyclophosphamide then paclitaxel + trastuzumab (AC-TH), and 3) carboplatin + docetaxel + trastuzumab (TCH). We assessed the relative value of the regimens based on weighted scores within the 3 domains. Higher scores are better. In this case study, AC-TH and TCH had similar efficacy and safety scores; AC-TH scored highest overall because of better economics. (See table.) Scores can be modified by the end user to reflect patient-specific factors such as unique toxicity concerns (e.g., history of heart failure). **Conclusions:** A transparent, personalizable interactive tool created to compare the relative value of drug regimens can be used to support treatment decisions for HER2+, ER-/PR- breast cancer incorporating clinical and economic considerations. Next steps will include validation using network meta-analysis and extension to other related areas of cancer care.

Weighted domain scores by drug regimen.

DOMAIN (Weighting)	AC-T	AC-TH	TCH
Efficacy (70%)	189	320	320
Safety & Use (20%)	58.1	56.6	58.6
Economic (10%)	70.5	63.2	45.7
TOTAL SCORE	318	440	424

6603 Poster Session (Board #160), Mon, 1:15 PM-4:45 PM

Real-world treatment patterns, healthcare resource utilization (HRU), and costs of initial line of therapy (LOT1) in multiple myeloma (MM). *First Author: Stacey DaCosta Byfield, OptumInsight, Eden Prairie, MN*

Background: MM is the second most common hematologic malignancy in adults. Few studies have evaluated the economic impact associated with MM treatment. **Methods:** This retrospective study identified patients (pts) aged ≥ 18 yrs with ≥ 2 claims for MM (ICD-9 203.00) and ≥ 1 claim for anti-cancer systemic therapy (A-CST) in a large national US claims database between Jan 2008 and Aug 2013; first MM claim date was the index date. Pts required continuous enrollment (CE) in the health plan for 6 mos pre- and ≥ 6 mos post-index date (< 6 mos if due to death), and no evidence of any cancers or A-CST in the pre-index period. Treatment patterns, HRU (inpatient, office, outpatient, and ER visits), and costs (drug and medical costs) during LOT1 were examined. LOT1 started with first A-CST; regimens included all agents received in the first 30 d. LOT1 ended at the earliest of: start of a new drug, ≥ 60-d gap after run-out of initial regimen drugs, death, or end of CE/study period (these censored LOTs were included). **Results:** Of 2053 pts, median age was 67 yrs (42% ≥ 70 yrs), 55% were male, and 638 (31%) had hematopoietic cell transplant (HCT) after LOT1 start. Median length of LOT1 was 4.3 mos (mean 6 mos). During LOT1, 96%, 90%, 43%, and 38% pts had ≥ 1 office, hospital outpatient, ER visit, and inpatient stay, respectively. Most common regimens were bortezomib ± dexamethasone (V±d, 25%), lenalidomide ±d (R±d, 17%), and VR±d (14%); in HCT pts, most common regimens were VR±d (25%), V±d (25%), and R±d (16%). Unadjusted per-pt per-month (PPPM) costs in HCT pts were $24,290 (SD $16,619; range $16,401–30,929 depending on initial regimen) and in non-HCT pts were $14,610 (SD $24,875; range $10,214–24,492). Drug and administration costs accounted for 37% of LOT1 costs and varied by initial regimen. 1-year costs after LOT1 initiation were $171,513 (SD $142,511; range $97,076–259,531). Adjusted (by initial regimen, pt characteristics, HCT, and baseline comorbidities) LOT1 costs were not significantly different with V±d and R±d; VR±d costs were higher vs V±d. **Conclusions:** HRU and costs were high during LOT1. Overall healthcare costs for LOT1 ranged from $10,214 to $30,909 PPPM depending on initial regimen and receipt of HCT.

6604 Poster Session (Board #161), Mon, 1:15 PM-4:45 PM

H-TArget model: Early technology assessment for ext generation sequencing in oncology. *First Author: Valesca Retel, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Next Generation Sequencing (NGS) promises to find mutations (targets) in individual cancer patients, to subsequently prescribe targeted therapy. Currently, NGS is in development, the effects on choice of therapy and prognosis are still unclear, and the costs for targeted therapies are high. To accelerate the reimbursement process of NGS and potential new targeted therapies, and have a NGS-panel available for patients in the earliest possible stage, early Technology Assessment (TA) is performed to inform policy making around NGS in the Netherlands. One of the aims of the TA was to conduct a cost-effectiveness analysis. **Methods:** We constructed a target-based decision model (H-TArget) to estimate the cost-effectiveness of NGS versus single- and no testing. Standard- and targeted therapies in first and second line for 9 targets (BRAF, KRAS, NRAS, EGFR, ERBB/HER, MET, ROS, ALK, RET) over 3 tumor types (melanoma, non-small-cell lung cancer (NSCLC), colorectal cancer (CRC)) were incorporated. A Dutch healthcare perspective and a 5-year time horizon were adopted. Outcomes were incremental cost-effectiveness ratios (ICER) expressed in €/quality adjusted life year (QALY). The threshold for cost-effectiveness is 80k in the Netherlands, which means that the concerning technology is cost-effective if the ICER is below this threshold. Expected Value of Partial Perfect Information (EVP(P)I) was calculated to quantify the value of further research into particular subsets of uncertain parameters. **Results:** The expected ICER was €65k/QALY for melanoma, €188k/QALY for NSCLC, and €103k/QALY for CRC. As a weighted average to the three populations, the overall ICER yielded €160k/QALY. The EVPI was €25M for melanoma, the subsets of parameters to focus on in future research were: €2M together for failures, prevalence, survival, and €23M for costs. **Conclusions:** At the moment, using NGS is only cost-effective for melanoma. This is mostly due to the high costs of targeted therapies and the fact that the effects are still small. Based on our findings, industry should strive for a significant cost reduction of targeted therapies or achieve a spectacular improvement in effectiveness, which could improve the cost-effectiveness.

6605 Poster Session (Board #162), Mon, 1:15 PM-4:45 PM

Economic evaluation for the United States (US) of gemcitabine (GEM), nab-paclitaxel plus gemcitabine (NAB-P+GEM), and FOLFIRINOX as first-line treatment for metastatic pancreatic cancer (MPC). *First Author: Mahdi Gharaibeh, Center for Health Outcomes & PharmacoEconomic Research, Tucson, AZ*

Background: Both NAB-P+GEM and FOLFIRINOX have shown superior survival efficacy over GEM alone as first-line treatment for MPC. Independent cost effectiveness/utility analyses for the US of NAB-P+GEM and FOLFIRINOX have not been performed. **Methods:** AMarkov model of outcomes and total costs estimated the life years (LY) and quality-adjusted life years (QALY) gained and incremental cost-effectiveness (ICER) and cost-utility ratios (ICUR) for patients with MPC using probabilistic sensitivity analyses, discounted at 3%/year, with full lifetime horizon, from a payer perspective, and expressed in 2015 US$. Lacking 3-way head-to-head trial results, comparative efficacy and safety of NAB-P+GEM and FOLFIRINOX were estimated using Bucher indirect comparisons. Total costs included chemotherapy, administration, disease monitoring, adverse reactions and supportive care measures. **Results:** In direct comparison, NAB-P+GEM was associated with differentials of +0.27 LY and +0.16 QALY gained over GEM at an incremental total cost of $23,031; yielding ICER of $80,562/LY and ICUR of $141,338/QALY. In direct comparison, FOLFIRINOX was associated with differentials of +0.50 LY and +0.26 QALY gained over GEM at an incremental total cost of $42,846; yielding ICER of $83,978/LY and ICUR of $164,495/QALY. In indirect comparison, FOLFIRINOX was associated with differentials of +0.23 LY and +0.16 QALY gained over NAB-P+GEM at an incremental total cost of $19,815; yielding ICER of $88,031/LY and ICUR of $202,187/QALY. HR for NAB-P+GEM vs. FOLFIRINOX was 1.26 (95%CI = 0.95-1.67, p = ns) indicating no superiority in survival outcome of either regimen. **Conclusions:** In this independent economic analysis, the superior survival efficacy of both NAB-P+GEM and FOLFIRINOX over GEM in the management of MPC is associated with positive cost-effectiveness and cost-utility. With NAB-P+GEM and FOLFIRINOX not differing statistically in survival benefit, the cost differential of $-4053/LY and $-37,692/QALY gained associated with NAB-P+GEM over FOLFIRINOX renders NAB-P+GEM the most economical of both regimens as first-line treatment for MPC.

6606 Poster Session (Board #163), Mon, 1:15 PM-4:45 PM

Price migration of oncology drugs launched in the United States between 2010 and 2015. *First Author: Alex Bastian, GfK Market Access, San Francisco, CA*

Background: As discussions of value increasingly enter the oncology arena, the price, or cost, of drugs is becoming increasingly relevant. Here, we have reviewed new cancer drugs launches in the USA to characterize the level, nature, and extent of price migrations taken by manufacturers **Methods:** FDA approvals (N = 158) between 2010 and 2015 were obtained from the FDA website, from which all non-oncology drugs (n = 119) were excluded. The remaining list (n = 39) included only oncology drugs. The Wholesale Acquisition Cost (WAC) prices at launch, and subsequent price increases, for these products were then extracted from AnalySource, a web-based analytical drug pricing database. We evaluated compound annual growth rate (CAGR), interval periods, and frequency of price increases of these agents. Further analysis identified potential distinctions across tumor types, route of administration (ROA), and other related features **Results:** The mean CAGR was 5.9%, ranging from 0% to 33.7%. Price increases occurred an average of 2.3 times at a mean interval of 11.1 months, ranging from 7 to 27 months. Notably, twelve of drugs did not increase in price. Only three drugs increased their price within 6 months of market entry, and 50% did so by month 23. Solid tumor price migration was higher than for hematologic malignancies (6.6% vs. 4.7%, respectively). The highest increase was seen within lung cancer (13.3%), with gastric and ovarian cancer showing no increase. ROA also had an important impact, with oral drugs demonstrating higher price migrations than injectable drugs (8.3% vs. 3.4%) **Conclusions:** The results of our analysis show important differences in the magnitude and frequency of price increases taken by oncology drug manufacturers. Differences are seen by tumor type and by ROA. Further inquiry may be useful to determine the structural and strategic factors driving these differences.

CAGR (%)	Injectable	Oral	All
Solid Tumors	4.4%	8.5%	6.6%
Lung		13.3%	13.3%
Prostate	12.4%	7.8%	10.6%
Thyroid		7.5%	7.5%
Colorectal	5.1%		5.1%
Skin	0.6%	6.8%	4.2%
Breast	1.1%		1.1%
Other	0.0%	3.6%	2.4%
Hematological	1.7%	8.1%	4.7%
CLL	0.0%	17.6%	8.8%
Lymphoma	3.3%	5.6%	4.1%
CML	0.0%	6.1%	4.0%
MM	1.7%	4.5%	3.1%
Other	1.9%	8.7%	4.1%
All	3.4%	8.3%	5.9%

6607 Poster Session (Board #164), Mon, 1:15 PM-4:45 PM

Patient-reported symptoms and Canadian Health Utility scores in esophageal cancer patients. *First Author: Mark Doherty, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Health utility scores (HUS) are an increasingly important tool to help determine the cost-effectiveness of therapies worldwide. The EQ-5D-3L is a validated tool for deriving HUS, with reference data in numerous populations, but there is limited information on the role that individual symptom complexes (SC) play in determining HUS in Esophageal cancer (EC) patients. **Methods:** A cross-sectional survey of EC patients at Princess Margaret Cancer Centre (2012-2014) assessed EQ-5D-3L and FACT-E. EQ-5D scores were converted to HUS using Canadian references. SC were developed: domains from FACT-E were identified and grouped to represent symptoms such as pain, dysphagia, fatigue, dyspnea, nausea and loss of appetite. Multivariable regression analysis was performed to assess associations between SC and HUS, adjusting for age, sex, and stage of disease. **Results:** Of 197 patients, median age was 67 (range 32-93) years, 76% were male, with stage I/II-IVA/IVB (6%/66%/28%) disease. Mean (SE) HUS were 0.90(0.05), 0.82(0.01), and 0.73(0.03) for stage I/II-IVA/IVB disease. Correlations between HUS and symptom scores are summarised in the table below. SC constructed for appetite, pain, nausea and fatigue showed significant association with HUS. **Conclusions:** A number of prevalent and important symptoms and SC correlated well with EQ5D-derived HUS, particularly appetite, pain, nausea, and fatigue. The strongest association was seen with pain. These relationships provide additional support for using these HUS in health-economic models.

Mutivariable regression model results.

Parameter	β	Standard Error	p
Appetite	-0.012	0.004	0.0013
Dysphagia	0.005	0.003	0.11
Pain	-0.023	0.005	<.0001
Nausea	-0.022	0.007	0.0036
Fatigue	0.088	0.026	0.0008
Dyspnea	0.034	0.042	0.43
Age	-0.002	0.001	0.0219
Sex (F vs M)	-0.006	0.022	0.81
Stage (early vs late)	0.072	0.022	0.0011

6608 Poster Session (Board #165), Mon, 1:15 PM-4:45 PM

Financial hardship associated with cancer in the United States. *First Author: K Robin Yabroff, National Cancer Institute, Rockville, MD*

Background: Expenditures associated with cancer, its treatment, and lasting effects of treatment are increasing in the US. The purpose of this study is to estimate the prevalence of financial hardship associated with cancer and identify characteristics of cancer survivors associated with financial hardship. **Methods:** We identified 1,202 cancer survivors ages ≥ 18 years from the 2011 Medical Expenditure Panel Survey (MEPS) *Experiences with Cancer* survey. Material financial hardship was measured by ever 1) borrowing money or going into debt, 2) filing for bankruptcy, 3) being unable to cover their share of medical care costs, or 4) making other financial sacrifices due to cancer, its treatment or lasting effects of treatment. Psychological financial hardship was measured as worry about paying large medical bills. We examined factors associated with any material or psychological financial hardship using separate multivariable logistic regression models stratified by age group (18-64 and ≥ 65 years). **Results:** Cancer survivors ages 18-64 years were more likely to report any material financial hardship than those ages ≥ 65 years (28.4% vs 13.8%; $p < 0.05$). Worry about paying large medical bills was also more common among cancer survivors ages 18-64 years than those ages ≥ 65 years (31.9% vs 14.7%, $p < 0.05$). In adjusted analyses, cancer survivors ages 18-64 years who were younger, female, non-white, and treated more recently were significantly more likely to report any material financial hardship associated with cancer compared to those who were older, male, non-Hispanic white, and treated less recently. Those who were female, had lower family income, and treated more recently were more likely to report psychological financial hardship. Among cancer survivors ages ≥ 65 years, those who were younger and non-white were more likely to report any financial hardship (all $p < 0.05$). **Conclusions:** Cancer survivors commonly experience material and psychological financial hardship. The working age population is especially vulnerable. Efforts to characterize cancer survivors likely to experience financial hardship and improve patient-provider communication about affordability are crucial, especially with ongoing implementation of the Affordable Care Act.

6609 Poster Session (Board #166), Mon, 1:15 PM-4:45 PM

Impact of a Stage IV NSCLC care pathway on front-line (FL) and maintenance (M) chemotherapy use at the Cleveland Clinic Taussig Cancer Institute (TCI). *First Author: Marc A. Shapiro, Cleveland Clinic, Cleveland, OH*

Background: Care pathways can reduce cancer care costs and variability in NSCLC. Effective implementation requires measurable outcomes and available data in near real-time. **Methods:** Between 10/1/13 and 7/7/14, TCI developed an evidence and value-based Stage IV NSCLC pathway. For patients with non-squamous EGFR WT/ALK neg NSCLC, ECOG PS 0-2 and sufficient renal function, FL carboplatin/pemetrexed (pem) followed by M pem is recommended standard care while bevacizumab (bev) is not. The pathway recommends best supportive care for pts with ECOG PS $\geq$ 3. To test feasibility, 4 academic thoracic and 12 community oncologists implemented the pathway into their practices starting 7/7/14. This analysis studies pathway impact on FL and M treatment decisions and charges in patients with metastatic non-squamous EGFR WT/ALK negative NSCLC. 57 pts meeting pathway criteria initiated care with these oncologists from 7/7/14 to 12/31/14 (Cohort A). A retrospective cohort (Cohort B) of 181 pts meeting similar criteria initiated care from 1/1/12 to 7/1/13. Care patterns were defined by manual chart review through 1/8/15. As only 1 Cohort A pt has progressed on M therapy, charge results assume pts who have initiated M pem will receive the same average of 5.11 doses seen in Cohort B. For Cohort B, actual FL and M therapy charges are reported. 3 Cohort B pts remain on M therapy. **Results:** Care patterns in Cohorts A and B were compared. 53 (93%) vs 128 (71%) ($p = 0.0003$) pts received pathway recommended FL care respectively. 42 (74%) vs 110 (61%) received chemotherapy ($p = 0.0839$). In pts receiving FL platinum-based regimens, 2 (6%) vs 35 (39%) received bev ($p < 0.0001$) outside of pathway recommendations. In Cohort A, 6 (32%) completing FL therapy initiated M therapy vs 36 (40%) in Cohort B. In pts completing FL therapy, FL and M drug charges per pt were an estimated $107,258 vs $205,431 (48% decrease). **Conclusions:** Implementation and measurement of adherence to a stage IV NSCLC pathway is feasible at an academic oncology practice with a regional network. This implementation led to a significant improvement in care variation and nearly 50% reduction in chemotherapy charges primarily through decreased bev use.

6610 Poster Session (Board #167), Mon, 1:15 PM-4:45 PM

Cost-effectiveness of trastuzumab emtansine (T-DM1) for HER2-positive advanced breast cancer (ABC). *First Author: Quang Anh Le, Western Univ of Health Sci, Pomona, CA*

Background: The EMILIA trial demonstrated T-DM1 significantly increased in median profession-free (3.2 months) and overall (5.8 months) survival relative to combination therapy with lapatinib plus capecitabine (LC) in patients with HER2-positive ABC previously treated with trastuzumab and a taxane. We performed an economic analysis of T-DM1 compared to LC and monotherapy with capecitabine (C) from both US payer and societal perspectives. **Methods:** We developed 4 possible Markov models to compare the projected lifetime costs and outcomes of T-DM1 and LC, and C. Markov models 1 and 2 have four health states (progression-free, response to therapy, disease-progression, and death), and Markov models 3 and 4 have three health states (progression-free, disease-progression, and death). In models 1 and 3, the possibility of death can occur in any health state; while in models 2 and 4, death can only occur in disease-progressing health state. Transition probabilities were estimated from published relevant trials. Six-week cycle time was modeled to follow the assessment time interval in the trials. Direct costs of the therapies, major adverse events, laboratory tests, and disease progression, indirect costs (productivity losses due to morbidity and mortality), and health utilities were obtained from published sources. The models used 3% discount rate and reported in 2014 US dollars. One-way and probabilistic sensitivity analyses were performed in the study. **Results:** When incorporating both model structural and parameter uncertainty, the resulting incremental cost-effectiveness ratios (ICER) comparing T-DM1 to LC and T-DM1 to C were $172,152 per quality-adjusted life year (QALY) and $126,251/QALY from the US societal perspective, respectively. From the US payer perspective, the ICERs were $205,598/QALY (T-DM1 vs. LC) and $164,628/QALY (T-DM1 vs. C). (See Table) **Conclusions:** From the US societal perspective, T-DM1 may be cost-effective relative to C. However, T-DM1 is not clearly cost-effective when comparing to LC from both perspectives.

Treatment Regimen	Lifetime Direct Cost ($)	Lifetime Indirect Cost ($)	QALYs
T-DM1	270,630	27,335	2.04
LC	180,202	42,046	1.60
C	101,966	66,653	1.01

6611 Poster Session (Board #168), Mon, 1:15 PM-4:45 PM

A network meta-analysis-based cost-effectiveness analysis of systematic therapies in advanced pancreatic cancer. *First Author: Kelvin K. Chan, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: For advanced pancreatic cancer, there are new treatment options that are more effective than gemcitabine alone (G). In this analysis we utilized data from a recently published Bayesian network meta-analysis (NMA) to assess the cost effectiveness of G, G+5-fluorouracil (GF), G+capecitabine (GCap), G+cisplatin (GCisp), G+oxaliplatin, G+erlotinib, G+nab-paclitaxel (GnP) and FOLFIRINOX from a Canadian health care perspective. **Methods:** Analysis was conducted through a three-state Markov model which follows a cohort of patients with advanced pancreatic cancer until death. Analysis used data on the progression of disease with treatment from the G arms of RCTs combined with estimates from the NMA of the effect of the newer regimens on disease progression and adverse events. Estimates of heath care costs were obtained from local providers and utilities were derived from the literature. The Markov model estimated the effect of treatment regimens on costs and quality adjusted life years (QALYs) discounted at 5% per annum. Detailed sensitivity analyses were conducted. **Results:** If a decision maker was willing to pay between $15,259 and $182,723 for a QALY, GF would be the optimal treatment regimen. For a willingness to pay of greater than $182,723, FOLFIRINOX would be optimal. Based on a willingness to pay for a QALY of $50,000, the price of oxaliplatin would need to be reduced by 83.4% for FOLFIRINOX to be optimal, whilst the price of nab-paclitaxel would need to be reduced by 93.1% for GnP to be optimal. At this threshold, the probability that GF is optimal is 52.7%, compared to 26.8% for GCisp, 19.0% for GCap and 1.6% for G and 0% for all other treatment regimens. **Conclusions:** At the current time with current drug prices and from the Canadian health care perspective, GF is the optimal treatment regimen based on the criteria of cost effectiveness. The acquisition costs of oxaliplatin is expected to decrease significantly once generic, and may make FOLFIRINOX more cost effective in advanced pancreatic cancer. GnP does not appear to be cost-effective regardless of willingness to pay threshold with its current pricing.

6612 Poster Session (Board #169), Mon, 1:15 PM-4:45 PM

Costs and resource utilization associated with skeletal related events in Medicare patients with prostate cancer metastatic to bones. *First Author: Jean A. McDougall, Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Approximately 40% of men diagnosed with metastatic prostate cancer will experience $\geq$ 1 skeletal related events (SREs), defined as a pathological fracture, spinal cord compression, or the need for surgery or radiotherapy to the bone. To understand the potential value of recently approved agents for prostate cancer, that may delay or prevent SREs, accurate assessment of their costs and resource utilization is needed. **Methods**: Men $>$ 65years of age, diagnosed with prostate cancer and bone metastasis between 2004 - 2009 were identified from the Surveillance Epidemiology and End Results (SEER) registries and linked to Medicare Parts A and B claims. Propensity score matching was used to establish a cohort of SRE exposed and unexposed patients. Direct medical costs and resource utilization were estimated from Medicare claims records. Kaplan Meier Sample Average (KMSA) estimates were calculated to estimate the cost attributable to an SRE, taking into account censoring. Poisson regressions were used to estimate the incidence rate ratio comparing resource utilization by type and number of SRE to those with no SREs. **Results**: 891 patients with SREs were matched to patients without SREs. The KMSA cost of patients with SREs was $21,191 (USD 2013) higher than the costs of those patients without an SRE. Costs continued to increase linearly with cumulative numbers of SREs, with patients experiencing only one SRE accruing a total of $85,625 in direct medical costs, compared to $115,603 in patients experiencing 2 SREs and $142,547 for patients experiencing $\geq$ 3 SREs. Resource use was substantially higher in patients experiencing at least one SRE than in matched unexposed patients. Compared to unexposed patients, those with 1 or more SREs had twice as many emergency room visits and nearly 4-times as many hospitalizations. **Conclusions**: Among men with metastatic prostate cancer, experiencing an SRE may increase the cost of care by over $20,000 and is associated with substantially higher resource utilization. This cost continues to rise with recurring SREs, emphasizing the importance of therapies to prevent or treat SREs in patients with prostate cancer metastatic to the bones.

6613 Poster Session (Board #170), Mon, 1:15 PM-4:45 PM

Cost-effectiveness analysis of regorafenib for metastatic colorectal cancer. *First Author: Daniel A. Goldstein, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Regorafenib was approved by the FDA in 2012 for the management of previously treated metastatic colorectal cancer (mCRC). It is now the standard of care in the third-line setting. Compared to placebo it improves median overall survival by 1.4 months but is associated with adverse effects and additional cost. The objective of this study was to examine the cost-effectiveness of regorafenib compared to best supportive care for patients receiving 3rd-line treatment for mCRC. **Methods:** We developed a Markov model to compare the cost and effectiveness of regorafenib compared to best supportive care in the 3rd-line treatment of mCRC based on randomized data from the CORRECT trial. Weibull models were fitted to the published overall and progression-free survival curves, and were used to extrapolate the cause-specific mortality and progression risks. Costs for administration and management of adverse events were based on Medicare reimbursement rates for hospital and physician services, and drug costs based on the Medicare average wholesale prices (all in 2014 US $). Health outcomes were measured in life years (LYs) and quality-adjusted life years (QALYs). Quality of life adjustments were calculated based on health utility values in the CORRECT trial and toxicity disutilities and durations were included for the most common toxicities: hand/foot syndrome, diarrhea, and hypertension. Model robustness was addressed by univariate and probabilistic sensitivity analyses (PSA). **Results:** In the model, regorafenib provided an additional 0.04 QALYs (0.13 LYs) at a cost of $39,391. The incremental cost-effectiveness ratio (ICER) was $897,411/QALY. In all one-way sensitivity analyses, the ICER of regorafenib was > $700,000/QALY. The ICER of regorafenib was greater than $200,000/QALY in > 99% of PSAs. **Conclusions:** This is the first US-based cost-effectiveness analysis of regorafenib in mCRC and our findings show that regorafenib provides minimal incremental benefit at high incremental cost per QALY. The ICER of regorafenib could be improved by use of an effective biomarker to select patients most likely to benefit, or by a lower price for payers.

6614 Poster Session (Board #171), Mon, 1:15 PM-4:45 PM

Stage specific health utility index scores of Canadian cancer patients. *First Author: Hiten Naik, University of Toronto, Toronto, ON, Canada*

Background: In order to improve the precision of health economics analyses in oncology, reference datasets of health utility index (HUI) scores are needed from cancer patients. These data are particularly sparse among Canadian patients. Using EQ5D we generated stage-specific HUI scores for lung, breast, colorectal, prostate, head/ neck and ovarian cancer, and all-stage reference values for 21 additional cancer sites. **Methods:** 1,760 ambulatory cancer patients at the Princess Margaret completed the EQ5D instrument. HUI scores were calculated using Canadian valuations. Clinical information was abstracted from patient charts and data was analyzed using descriptive statistics and multiple regression. **Results:** Among all patients, the mean±SEM HUI score was 0.81±0.004 (Canadian algorithm). The cancer sites with the lowest mean HUI scores were acute lymphoblastic leukemia (0.70±0.03) and pancreatic (0.76±0.03); testicular (0.89±0.02) and chronic lymphocytic leukemia (0.90±0.05) had the highest scores. Scores varied by stage among lung, breast, colorectal, prostate, head and neck and ovarian cancer patients (see Table). After adjusting for age and cancer site, HUI scores were significantly higher amongst patients with a university/ college education ($p = 0.002$), those married or living with a partner ($p < 0.001$), employed ($p < 0.001$), and those with local/regional vs. distant metastatic disease ($p = 0.001$). **Conclusions:** This work represents the first reference set of stage specific HUI scores for several cancers derived using Canadian valuations. Mean HUI scores varied by basic socio-demographic and clinical parameters, including stage. Future research will incorporate these data into the economic analyses required for policy and clinical decision-making.

6615 Poster Session (Board #172), Mon, 1:15 PM-4:45 PM

Disclosure of industry payments to oncologists: Early open payments data. *First Author: Deborah Catherine Marshall, UC San Diego, Department of Radiation Medicine and Applied Sciences, La Jolla, CA*

Background: The Open Payments program discloses industry payments to identified physicians ('physician payments'). We characterize these payments by oncology specialty. **Methods:** We analyzed the December 2014 release of Open Payments data on physician payments made from August-December 2013. We characterized physician payments by type (general or research). We also evaluate physician ownership interests in reporting manufacturers. Data were aggregated by physician and oncology specialty [medical oncology (hematology/oncology, medical oncology, pediatric hematology/oncology); radiation oncology; and surgical oncology (surgical oncology, gynecologic oncology)]. We compared the number of physicians receiving payments to the total number of active physicians in each specialty in 2012 (AMA. Physician Characteristics and Distribution in the US. Chicago: AMA; 2014). **Results:** There were 82,213 payments to 9,893 oncology physicians (50% vs. 46% for all medical specialties) totaling $31 million ('M'), Table. Payments for food/beverage were most common (79%) but represent only 10% of the total value. The most common nature of payment by total value was compensation for services (excluding consulting and CME) in medical oncology (38%), consulting fees in radiation oncology (30%), and education in surgical oncology (27%). Ownership interests totaled $8M in amount invested and $12M in total value of interest. Medical oncology had the highest proportion of physicians with ownership interest (1.7%) of oncology specialties. **Conclusions:** These data can inform policy-making and advocacy efforts for oncology specialties. Partially supported by the NIH (Grant TL1TR00098).

Industry payments to oncology physicians, August-December 2013.

Specialty	Number of payments	% of physicians receiving payments	Total value: all payments	Total value: general payments	%	Total value: research payments	%
Medical oncology	74,107	54%	$26,317,128	$14,900,718	57%	$11,416,410	43%
Radiation oncology	4,612	31%	$ 3,440,178	$ 1,048,742	30%	$ 2,391,436	70%
Surgical oncology	3,494	86%	$ 1,108,222	$ 1,082,796	98%	$ 25,426	2%
All oncology	82,213	50%	$30,865,528	$17,032,256	55%	$13,833,272	45%

Improving the value of PSA prostate cancer screening with "smarter" strategies and increased use of active surveillance. *First Author: Joshua A. Roth, Fred Hutchinson Cancer Rsrch Ctr, Seattle, WA*

Background: Prostate-specific antigen (PSA) screening for prostate cancer is controversial. Epidemiological researchers and guideline groups have suggested many personalized and conservative strategies to improve benefit-risk tradeoffs.The goal of this study is to identify strategies most likely to be cost-effective, and to examine the added value of increased active surveillance (AS) for low-risk cases. **Methods:** We extended an established CISNET microsimulation model to project life years (LY), quality-adjusted life years (QALYs), and costs for cohorts of U.S. men from age 40 to death in 15 screening strategies with fixed or personalized screening ages, intervals, and PSA biopsy thresholds. We calculated the incremental cost-effectiveness ratio (ICER) for each vs. no screening under "contemporary" or "increased AS" treatment practices. "Contemporary" practices were based on age, stage, and grade-specific initial treatments in the SEER program. "Increased AS" practices immediately treated cases if Gleason sum ≥ 7 or clinical T-stage ≥ T2a and monitored all others. Analyses used a 3% annual discount rate and a willingness to pay of $150,000/QALY. **Results:** All PSA screening strategies increased LYs (range = 0.014-0.021) and costs (range = $100-900) vs. no screening and were highly cost-effective (ICER range = $25,000-43,000/LY). With "contemporary" treatments, only strategies with biopsy threshold at PSA ≥ 10 mg/L increased QALYs (range = 0.001-0.002), and only quadrennial screening of ages 50-74 was cost-effective ($150,000/QALY). With "increased AS," all strategies with biopsy threshold at PSA ≥ 10 mg/L increased QALYs (range = 0.003-0.005) and were cost-effective (ICER range = $45,000-95,000/QALY), as was quadrennial screening of ages 55-69 with biopsy threshold at PSA ≥ 3 mg/L (Inc QALYs = 0.002, Inc Cost = $130, ICER = $65,000/QALY). **Conclusions:** Personalized PSA screening strategies with conservative screening frequency and/or PSA biopsy threshold appear to be cost-effective vs. no screening, particularly when combined with increased AS for low-risk cases.

6617 Poster Session (Board #174), Mon, 1:15 PM-4:45 PM

Hepatitis B virus screening before adjuvant chemotherapy in patients with early stage breast cancer: A cost-effectiveness analysis. *First Author: William W. L. Wong, University of Toronto, Toronto, ON, Canada*

Background: The seroprevalence of Hepatitis B virus (HBV) infection among Canadian was 0.4%, and 1.6% among immigrants. Most infected individuals have clinically silent disease. Cytotoxic chemotherapy causes reactivation in 30% of the HBV infected patients. This can be severe and fatal, may also lead to interruption of chemotherapy. HBV screening before adjuvant chemotherapy (ADJ) for breast cancer (BC) seems to be a plausible strategy. Our objective is to estimate the health and economic effects of HBV screening strategies. **Methods:** We developed a state transition microsimulation model to examine the cost effectiveness of 3 strategies for 55 year old BC patients undergoing ADJ: (1) *No screen*; (2) *Screen Imm*: Screen immigrant only and treat; (3) *Screen all*: Screen all and treat; with antiviral therapies. In the model, health states were constructed to reflect the natural history of BC and HBV. Model data were obtained from published literature. We used a payer perspective, a lifetime time horizon, and used a 5% discount rate. **Results:** *Screen all* would prevent 38 severe reactivations (SR), 9 deaths from reactivation (DR), 21 chemotherapy interruptions (CI), 32 decompensated cirrhosis (DC), 38 HCCs, and 56 HBV deaths per 100,000 persons screened over the lifetime of the cohort. *Screen Imm* would prevent 29 SR, 7 DR, 16 CI, 23 DC, 27 HCCs, and 41 HBV deaths. *Screen all* was associated with an increase of at least 0.0034 quality adjusted life years (QALY) and cost C$164 more per person, translating to an incremental cost effectiveness ratio (ICER) of C$47,808-76,527/QALY gained compared with *No screen*, depends on different antiviral therapies. *Screen all* was the most cost effective, while *Screen Imm* was ruled out due to extended dominance (ED) by *No Screen* and *Screen all*. **Conclusions:** HBV screening before ADJ for BC patients would prevent a significant number of reactivations, and is likely be cost effective.

Strategy	Cost($)	QALYs	VS no screen			Sequential ICER($)
			DCost($)	DQALYs	ICER($)	
No screen	53,986	10.4345	-	-	-	-
Screen Imm	54,120-54,203	10.4361-10.4361	134-217	0.0016-0.0017	82,188-130,084	ED
Screen all	54,150-54,252	10.4379-10.4379	164-266	0.0034-0.0035	47,808-76,527	

6618 Poster Session (Board #175), Mon, 1:15 PM-4:45 PM

Grading financial toxicity based upon its impact on health-related quality of life (HRQol). *First Author: Jonas A. De Souza, University of Chicago Medicine, Chicago, IL*

Background: Financial toxicity (FT) is an important patient-centered outcome. The impact of this toxicity on patients' HRQoL is not well known. We hypothesized that FT can be graded based on statistically significant and clinically meaningful decreases in HRQoL. **Methods:** FT was assessed by the quantitative COST (COmprehensive Score for financial Toxicity). Gradations of FT's impact on HRQoL were based on established conventions for clinically meaningful small, medium and large effect sizes (e.s.) for the FACT-G HRQoL instrument. The optimal COST cutoff scores for FT grades were determined by ROC curve analyses maximizing the sum of the sensitivity and specificity in comparison with normative FACT-G values for the general adult population. Following FACIT standards, higher FT was represented by lower COST values. Demographics, tumor type, length of disease, chemotherapy use, resource utilization, HRQoL, and symptoms (EORTC QLQ-C30 symptom scales) were collected. Data were analyzed using Pearson correlations, linear regression, and chi-square tests. **Results:** A total of 233 patients who had completed at least 3 months of chemotherapy were assessed. The correlation between the COST and FACT-G was $r = 0.42$, $p < .001$. ROC curve analyses produced optimal COST FT grades (G) as follows: G0 $\geq$ 26 (n = 99 patients, 42%), G1: $\geq$ 14-25 (n = 71, 31%) and G2: $>$ 0-14 (n = 58, 25%). Five patients (2%) had scores of 0 (G3). On multivariate analyses, pts with G0 had no impact of FT in their HRQoL; G1 had a statistically significant small and meaningful e.s. difference compared to G0 (0.26, $p < .05$); G2 had a statistically significant and medium e.s. (0.47, $p < .001$); G3 had a significant and clinically meaningful large e.s. (0.99, $p < .005$). There was a significant relationship between FT (grades 1-3) and younger age ($p <$ .01), non-Caucasians ($<$ .05), less than a college degree ($<$ .01), unemployment (.001), Medicaid ($<$ .05), and lower income ($<$ .001). **Conclusions:** We developed a FT grading system based on clinically meaningful changes in HRQoL. There were 134 (58%) patients with Grades 1-3 FT. Financial distress as it relates to HRQoL is a meaningful event that can be objectively measured, and should be included in the assessment of patient-centered outcomes.

Medical expenditures and productivity loss among colorectal, breast, and prostate cancer survivors in the US. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: We examined the economic burden among survivors of the three most prevalent cancers (colorectal, female breast, and prostate) in nonelderly and elderly populations in the US. **Methods:** The 2008 to 2012 Medical Expenditure Panel Survey data was used to identity colorectal (n = 540), breast (n = 1,568), and prostate (n = 1,170) cancer survivors, and individuals without a cancer history (n = 109,423). Total economic burden was defined as the sum of medical expenditures and productivity loss (i.e. employment disability, productivity loss at work measured by missed work days, and productivity loss at home measured by additional days stayed in bed). Excess burden was measured as the difference in economic burden between cancer survivors and individuals without a cancer history. All analyses were conducted by cancer site and stratified by age (nonelderly: 18-64 vs elderly: 65+). Multivariable analyses controlled for age, sex, race/ethnicity, marital status, education, comorbidities, health insurance, and geographic region. **Results:** The total annual economic burden per nonelderly cancer survivor was $20,238 for colorectal, $14,202 for breast, and $9,278 for prostate. When compared to individuals without a cancer history, excess medical expenditures among nonelderly cancer survivors was $8,647 for colorectal, $5,119 for breast, and $3,586 for prostate (all $p < 0.01$). Moreover, nonelderly colorectal and breast cancer survivors experienced significantly greater excess employment disability (colorectal: 14%; breast: 5%) and productivity loss at work (colorectal: 7 days; breast: 3 days) and at home (colorectal: 5 days; breast: 3 days; all $p < 0.01$). Elderly cancer survivors also bear significant total economic burden (colorectal: $18,860; breast: $14,351; prostate: $16,851). However, their excess medical expenditure is much lower than nonelderly cancer survivors. Excess productivity loss among elderly cancer survivors was not significantly different from elderly individuals without a cancer history. **Conclusions:** The economic burden of cancer varies by cancer site and age group. Nonelderly cancer survivors experience greater excess economic burden than elderly cancer survivors.

6620 Poster Session (Board #177), Mon, 1:15 PM-4:45 PM

Contribution of cancer care to total spending among high-cost Medicare beneficiaries. *First Author: Miranda Kim, Harvard Rad Onc Prog, Boston, MA*

Background: Medicare spending is highly concentrated, with the top decile of Medicare patients accounting for more than half of total Medicare expenditures. Understanding the patterns of spending that contribute to these high costs may lead to important policy changes and innovative programs aimed at successfully reducing spending and potentially improving outcomes. We know little about the contribution of cancer as a diagnosis and types of cancers present among high cost Medicare beneficiaries. **Methods:** We used 20% of the 2012 Medicare data to identify fee-for-service (FFS) beneficiaries who were continuously enrolled for the year and were age 65 or older. High cost patients were defined as those in the top decile of spending in 2012 and non-high cost patients were the remaining patients. To identify patients with a cancer diagnosis, we used ICD-9 codes for the top 10 cancer killers. **Results:** Among all Medicare fee-for-service beneficiaries, 18% carried a cancer diagnosis. A cancer diagnosis was far more likely to be present among high-cost patients compared to non-high-costs patients: 26.2% versus 17.1% ($p < .001$). Cancer diagnoses found more frequently in the high-cost group as compared to the rest of Medicare beneficiaries included colorectal (32.7% vs. 24.8%, $p < .001$), head and neck (3.2% vs. 0%, $p < .001$), lymphoma (1.0 vs. 0%, $p < .001$), pancreatic (9.9 vs. 6.8%, $p < .001$) and esophageal cancer (2.7% vs. 0.8%, $p < .001$). There were significantly fewer breast (3.6% vs. 9.2%, $p = < .001$) and prostate (2.4% vs. 12.3%, $p < .001$) patients in the high-cost group. **Conclusions:** Among elderly Medicare recipients, high-cost patients are significantly more likely to carry a cancer diagnosis, suggesting that interventions aimed reducing cancer costs may be highly effective in reducing overall healthcare spending. Certain cancer diagnoses are particularly overrepresented in this cohort, pointing to a need for further studies aimed at understanding specific components driving cancer costs in this population.

6621 Poster Session (Board #178), Mon, 1:15 PM-4:45 PM

A framework to assess the cost effectiveness of predictive biomarkers in oncology: Test Incremental Cost Effectiveness Ratio (TICER). *First Author: Anton Safonov, Yale School of Medicine, New Haven, CT*

Background: Cost effectiveness of predictive biomarkers is currently assessed by Markov Chain (MC) simulations, requiring resources and expertise. Our goal was to develop a practical index to aid clinicians in biomarker cost utility estimation at an early stage of development. **Methods**: We used decision trees to derive a test incremental cost-effectiveness ratio (TICER) index that combines six parameters including biomarker prevalence, progression free survival (PFS), health-related quality of life (HRQoL), cost of testing, cost of treatment, and cost of progression. We assessed the model on existing (HER2, ALK, OncotypeDx) and emerging (PDL1 expression) predictive biomarkers. We conducted one-way and multivariate probabilistic sensitivity analyses (PSA) and generated cost-effectiveness acceptability curves (CEAC). Benefit was expressed as quality-adjusted progression-free years (QAPFY). **Results**: We used literature reported values for base case and varied the parameters over a broad range to estimate the contribution of each variable to TICER. TICER was calculated by one-way PSA for each variable as the median CEAC (cost at 50% probability of acceptance), while sampling the remaining variables from their respective distributions. The table shows the base case and range of TICER compared to literature values and the acceptance probability considering a cutoff of $200K/QAPFY, providing a relative ranking in terms of cost effectiveness. The TICER model is driven primarily by PFS and HRQoL while biomarker prevalence and test costs have a lesser effect. **Conclusions**: TICER is flexible to a variety of clinical scenarios and does not require assumptions about health states up to death like MC-based methods do. The cost effectiveness of a predictive test is driven by the efficacy and QOL associated with biomarker-directed therapy rather than marker prevalence or assay cost.

Biomarker	Base Case TICER ($K/QAPFY)	Range of TICER by PSA ($K/QAPFY)	Acceptance Probability of $200K/QAPFY	Literature Value ($K/QALY)
HER2	155.2	113 to 235	74.9%	145
ALK	258.3	206 to 433.2	18.4%	256
PD-L1	280.7	227 to 482	12.8%	N/A
OncotypeDx	-5.1 (negative indicate cost saving)	-13.2 to – 2.8	99.5%	-6.7

6622 Poster Session (Board #179), Mon, 1:15 PM-4:45 PM

Cost-sharing and financial burden for Medicare patients with newly diagnosed cancer. *First Author: Amol Narang, Department of Radiation Oncology and Molecular Sciences, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Proposals for reducing Medicare spending include measures that increase beneficiary cost-sharing by regulating the extent of supplemental insurance. However, the financial burden on patients of such policies is unclear, particularly for health shocks such as cancer. To address this question, we used the Health and Retirement Study (HRS) to characterize the out-of-pocket (OOP) cost burden of newly diagnosed cancer and its relation with supplemental insurance. **Methods:** Medicare-eligible, community-dwelling HRS participants who did (N = 1409) or did not (N = 16,757) report a new cancer diagnosis from 2002-2012 were identified. Supplemental insurance was classified in order of increased cost-sharing as public (dual-eligible/VA), private (employer-sponsored/Medigap), or none (Medicare alone). OOP costs included hospital stays, doctor visits, outpatient surgery, prescription drugs, home health, dental, and special facilities. Financial burden was defined as OOP costs over per-capita household income. Multivariable quantile regression was used to assess the median and 90thpercentile (p90) of OOP costs and financial burden. **Results:** Newly diagnosed cancer patients experienced increased annual OOP costs (median: $2222 vs. $1791, $p < 0.001$; p90: $10,420 vs. $7807, $p < 0.001$) and financial burden (median: 9.0% of household income vs. 7.4%, $p < 0.001$; p90: 51.0% vs. 42.4%, $p < 0.001$). Supplemental insurance significantly affected cancer patients' median financial burden (public: 3.3%, private: 9.9%, none: 16.6%, $p < 0.001$), which was magnified at the 90th percentile (public: 31.8%, private: 48.3%, none: 106.2%, $p < 0.001$). Importantly, financial burden at the 90thpercentile did not increase following a new cancer diagnosis for patients with public or private supplemental insurance, but significantly increased for patients with Medicare alone (p90: 106.2% vs. 58.1%, $p < 0.001$). **Conclusions:** More than 10% of newly diagnosed cancer patients with Medicare alone faced OOP costs greater than their income. Proposals to increase cost-sharing in the Medicare population should include provisions that protect patients from health shocks such as cancer, potentially though OOP cost limits or value-based exceptions.

6623 Poster Session (Board #180), Mon, 1:15 PM-4:45 PM

Out-of-pocket cost trends for Medicare patients with newly diagnosed cancer. *First Author: Amol Narang, Department of Radiation Oncology and Molecular Sciences, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: While rising cancer care costs have been well-documented, the extent to which these costs have translated into increased patient financial burden is unclear. To address this question, we used a nationally, representative panel survey to characterize trends over time in the out-of-pocket (OOP) costs of newly diagnosed cancer patients. **Methods:** Medicare-eligible, community-dwelling participants in the biennial Health and Retirement Study who reported a new cancer diagnosis between 2002-2012 were identified (N = 1409). Respondent-reported OOP costs included the following categories: hospital stays, doctor visits, outpatient surgery, prescription drugs, home health, dental care, and special facilities. A multivariate generalized linear model and quantile regression were used to assess the mean, median, and 90thpercentile of OOP costs. Adjusted levels of OOP costs were compared over time using a contrast test. **Results:** Mean annual OOP costs decreased from $7868 (95% CI: $6477 - $9259) for patients with a new cancer diagnosis at the 2002 survey to $4242 (95% CI: $2642 - $5841) for patients with a new cancer diagnosis at the 2012 survey, a decline of $3626 (95% CI: $1508 - $5745, $p = 0.001$). Median annual OOP costs declined by $580 (95% CI: $66 - $1095, $p = 0.03$). The steepest decline in OOP costs occurred between 2004 and 2008 (mean: $5070, 95% CI: $2944 - $7195, $p < 0.001$; median: $1031, 95% CI: $515 - $1547, $p < 0.001$), while OOP costs did not significantly change between 2008 and 2012 (mean: $779, 95% CI: -1411 – 2969, $p = 0.486$; median: $17, 95% CI: -515 – 549, $p = 0.949$). The 90th percentile of annual OOP costs similarly declined over the study period from $13,203 (95% CI: $11,403 - $15,002) to $8063 (95% CI: $5,995 - $10,131), a decline of $5,140 (95% CI: $2,340 - $7,880, $p < 0.001$). **Conclusions:** Despite the growing costs of cancer care,Medicare patients with newly diagnosed cancer were increasingly shielded from high OOP costs over the study period, with a sharp decline between 2004 and 2008 which may be attributable to the introduction of Medicare part D. Given the more recent plateau in OOP costs and proposals to increase cost-sharing in this population, close monitoring of OOP cost trends will be important for avoiding excessive financial burden.

TPS6624 Poster Session (Board #181a), Mon, 1:15 PM-4:45 PM

Patients' competence in oral cancer therapies. *First Author: Christoph Riese, Scientific Institute of Office-based Hematologists and Oncologists -WINHO, Cologne, Germany*

Background: Oral agents for cancer treatment are increasingly prescribed. Regardless the benefits of oral agents, oral cancer medications have a considerable potential for side-effects, toxicity and drug interactions. Inadequate use of medication therefore leads to ineffectiveness of medication and in some cases to early breakup of therapy. This type of therapy requires a high level of self-management competence of the patient and her/his social setting. A standardized recurring patient education program by oncology nurses may influence the handling of the oral agents in a positive way. We evaluated whether providing adequate information on the clinical picture, treatment options, side effects, and the proper handling of medication influences therapy adherence, self-management ability, and eventually therapeutic success. **Methods:** The cluster randomized controlled study was conducted from March until December 2014. This trial took part in total 28 office based oncology practices all over Germany. The oncology nurses for the intervention group were specially trained for the education program in techniques of motivational communication and the usage of oral agents. The intervention (n = 17 practices) was conducted in addition to the counselling for therapy, by the oncologist. The control group received only the oncologists counseling. Primary endpoint was the patient's competence measured by a combination of the tools: self-efficacy, quality of life and therapy related knowledge. Secondary endpoints are side-effects, health related stress, overall dose and break up rate. The analysis of the data is still ongoing and will be finished in April 2015. Clinical trial information: VfD_PACOCT_12_003487.

TPS6625 Poster Session (Board #181b), Mon, 1:15 PM-4:45 PM

Health and economic outcomes of two different follow up strategies in effectively cured advanced head and neck cancer patients. *First Author: Lisa F. Licitra, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: optimal timing and type of examinations for the follow up (FUP) of head and neck squamous cell cancer (HNSCC) survivors have not been established yet. There is also a need to find out which is the most cost-effective FUP program in this population. The present trial aims at comparing a more intensive radiologic FUP approach with a less intensive one, also evaluating its economical impact on healthcare system. **Methods:** this is a randomized, phase II, multicenter trial conducted in 15 Centers throughout Italy and Switzerland. Patients with stage III-IV SCC of oral cavity, oropharynx, larynx or hypopharynx having already received radiation therapy as part of their curative treatment and in complete remission at six months are randomized in two arms according to different FUP approaches. A non intensive FUP approach (ARM A) foresees only a radiologic evaluation (locoregional CT scan or MRI) within 6 months since treatment end and subsequently only at signs or symptoms occurrence (according to NCCN guidelines). An intensive FUP approach (ARM B) consists of scheduled radiologic evaluations (CT scan or MRI of head and neck) 2 times/year in the first 2 years and 1 time/year in the third and fourth year; PET scans are requested yearly in the first 3 years for patients with smoking history. FUP visits consist of physical and fiberoptic endoscopic examinations of head and neck district, laboratory tests, quality of life questionnaires and evaluation of out-of-pocket costs and productivity losses; timing of FUP visits is the same in both arms. An estimated 330 patients (randomized 1:1) are being enrolled over the first year; health outcomes and costs will be assessed over the next two years. The percentage of potentially salvageable recurrences or second primaries, as well as the cause-specific survival and the overall survival of recurring patients will be evaluated in both groups. Incremental cost-effectiveness ratio (cost/life year gained) and cost-utility ratios (cost/QALY) will be calculated referring to WHO thresholds of 1-3 times per capita gross domestic product. ClinicalTrials.gov Identifier: NCT02262221. The trial is funded by a grant from the Swiss Bridge Foundation. Clinical trial information: NCT02262221.

7000 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Correlation of acute myeloid leukemia (AML) stem cell phenotype with cytogenetic/molecular features and prognosis. *First Author: Jonathan Michael Gerber, Levine Cancer Institute, Charlotte, NC*

Background: Emerging evidence supports the clinical significance of leukemia stem cells (LSCs).We previously found that patients with AML exhibited 1 of 3 distinct LSC phenotypes based on CD34, CD38, and aldehyde dehydrogenase (ALDH): 1. $CD34^-$, 2. $CD34^+CD38^-ALDH^{intermediate}$ ($ALDH^{int}$), or 3. $CD34^+CD38^-ALDH^{high}$ ($ALDH^{high}$) [Gerber, et al. *Blood*, 2012]. We hypothesized that LSC phenotypes might correlate with cytogenetic/molecular features and treatment outcomes. **Methods:** Diagnostic samples from 98 patients with newly diagnosed normal or unfavorable cytogenetic AML, enrolled on clinical protocol NCT01413880, were analyzed by FACS. Sorted cell populations were assayed by FISH and/or PCR for leukemia-specific abnormalities. Fisher's exact and Mantel-Haenszel tests were used to analyze differences in risk factors and outcomes by LSC phenotype. **Results:** LSCs were $CD34^-$ in 21 cases; $ALDH^{int}$ in 44; and $ALDH^{high}$ in the remaining 33. Poor risk cytogenetics and/or FLT3-ITD mutations were uncommon in the $CD34^-$ (4/21 = 19%) and $ALDH^{int}$ (17/44 = 39%) cases, but were frequent in the $ALDH^{high}$ cases (28/33 = 85%, $p < 0.001$). NPM1 mutations were detected in 14/21 (67%) of the $CD34^-$ LSC patients vs. just 8/77 (10%) of the patients with $CD34^+$ LSCs ($p < 0.001$). Both patients with t(9;11) had $CD34^-$ LSCs ($p < 0.001$), while antecedent MDS or MPN ($p = 0.04$) were more common in patients with $ALDH^{high}$ LSCs. Only 15/33 patients (45%) with $ALDH^{high}$ LSCs achieved complete remission, compared to 29/43 patients (69%) with $ALDH^{int}$ LSCs and 19/22 patients (86%) with $CD34^-$ LSCs ($p < 0.01$). Among patients who did not undergo allogeneic stem cell transplant, long term disease-free survival was 0% (0/6) in patients with $ALDH^{high}$ LSCs vs. 31% (4/13) with $ALDH^{int}$ and 62% (8/13) with $CD34^-$ LSCs ($p = 0.04$). **Conclusions:** LSC phenotype correlates with cytogenetic/molecular risk factors and response, permitting rapid risk-stratification of AML patients. This may be of particular use for patients with $ALDH^{high}$ LSCs, who appear to be at high risk – more likely to harbor adverse cytogenetic/molecular features and prove refractory to chemotherapy. Earlier identification would facilitate access to clinical trials of novel induction approaches.

7001 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Association between KIR genes and risk of MDS. *First Author: May Daher, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Myelodysplastic syndrome (MDS) represents a spectrum of clonal hematopoietic disorders affecting the myeloid lineage, characterized by cytopenias and dysplastic features. MDS is risk-stratified according to International Prognostic Scoring System (IPSS) scores. The major clinical complication in these disorders, especially in the high-risk group, is the potential to evolve into acute myeloid leukemia (AML). Evidence is accumulating that genetic factors play an important role in conferring susceptibility/resistance to MDS. In this regard, activating killer-cell immunoglobulin-like receptor (KIR) genes expressed in natural killer cells (NK cells) are of particular interest. Humans may inherit different numbers of the six distinct activating KIR genes. Little is known about the impact of this genetic variation on the innate susceptibility or resistance of humans to develop MDS. **Methods:** We addressed this issue by performing a case-control study involving 180 MDS patients (120 with high IPSS, 60 with low IPSS) and 117 healthy donors. DNA samples were collected in both cases and controls and analysis of activating KIR genes was performed using PCR. **Results:** Our results showed that patients with high-risk MDS had significantly lower numbers of activating KIR genes compared to patients with low-risk MDS (P = 0.009) and compared to healthy controls (P = 0.00001). Patients with low-risk MDS also had fewer activating KIR genes when compared to controls (P = 0.04). Importantly, inheritance of each additional activating KIR gene had a protective effect against development of high risk MDS (RR 0.7, P < 0.001). **Conclusions:** These results suggest that inheritance of a higher number of activating KIR genes is protective against MDS, and that once the disease develops, harboring a lower number of KIR genes is associated with higher risk disease. Hence, our study provides novel insights concerning the pathogenesis of MDS in adults and has implications for the development of new immunotherapies using NK cells with potential of controlling the disease and preventing progression to high risk disease and eventually to AML.

7002 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

The international Prognostic Index for patients with CLL (CLL-IPI): An international meta-analysis. *First Author: Nadine Kutsch, Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital Cologne, Cologne, Germany*

Background: In the era of more effective treatments for CLL, the established clinical staging systems [Rai/Binet] do not accurately discriminate between prognostic groups. There are several new prognostic markers, but no system integrates the major clinical, biological and genetic variables into one widely accepted score. Therefore we performed a comprehensive analysis of 26 prognostic factors to develop an internationally applicable prognostic index for CLL patients (pts) [CLL-IPI]. **Methods:** Our full analysis set (FAS) was collected from 8 phase 3 trials from France, Germany, UK, USA and Poland [3472 pts at early & advanced stage; median age 61 years (yr) (range 27 - 86); median observation time (OT) 80 months (ms)]. The FAS was randomly divided into training and internal validation datasets [TD, 2308 (67%); IVD, 1164 (33%)]. Methods of multivariable statistics were applied and the main end point was overall survival (OS). Handling of missing data was performed by complete case analysis. The model was externally validated in a third dataset comprised of 845 newly diagnosed CLL pts from Mayo Clinic [median age 62 yr (range 25 - 89); median OT 63 ms]. **Results:** Based on 1192 (52%) pts from the TD, 5 independent predictors for OS were identified: age, clinical stage, del(17p) and/or *TP53* mutation, *IGHV* mutation status and β_2-microglobulin (B2M) level. Using weighted grading, a prognostic index was derived separating 4 different pt groups: low (score 0-1), intermediate (score 2-3), high (score 4-6) and very high risk (score 7-10) with significantly different OS [93%, 79%, 64% and 23% OS at 5 yr for the low to very high risk group respectively, $p < 0.001$; *C*-statistic c = 0.72 (95% CI, 0.69-0.76)]. This multivariable model was confirmed on the IVD [575 (49%) pts; c = 0.777 (0.73-0.82)] and the 4 risk groups were reproduced with 97%, 91%, 68% and 21% 5-yr OS [($p < 0.001$), c = 0.79 (0.74-0.85)] on the Mayo set. **Conclusions:** The resulting CLL-IPI combines the most important genetic risk factors (*IGHV*, del(17p)/*TP53* mutation) with clinical stage, age, and B2M into an easily applicable prognostic score for CLL pts. Moreover, it both discriminates between prognostic groups and is informative regarding current treatment recommendations.

7003 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Results of a first-in-human, phase I/II trial of ASP2215, a selective, potent inhibitor of FLT3/Axl in patients with relapsed or refractory (R/R) acute myeloid leukemia (AML). *First Author: Mark J. Levis, Sidney Kimmel Comp Cancer Ctr at Johns Hopkins, Baltimore, MD*

Background: FLT3 Internal tandem duplication (ITD) and tyrosine kinase domain (TKD) mutations are seen in 30% of AML patients (pts) and are associated with poor survival. Secondary FLT3-TKD mutations are associated with treatment failure with tyrosine kinase inhibitors. ASP2215 is a potent inhibitor of FLT3 and Axl with activity against FLT3-ITD and FLT3-TKD. **Methods:** A phase I/II trial was conducted to investigate safety and efficacy in pts with R/R AML. The dose escalation followed a 3+3 design and evaluated doses from 20 to 450 mg once daily. A parallel multi-dose expansion cohort was initiated based on the efficacy seen in dose escalation. **Results:** 166 pts have enrolled between October 2013, and December 2014, 25 in the dose escalation and 141 in the dose expansion cohorts. At the 450 mg dose, 2 pts had a DLT (grade 3 diarrhea and ALT/AST elevation), and the maximum tolerated dose was determined to be 300 mg. Common possibly or probably drug related treatment emergent adverse events of any grade include fatigue (13%), constipation (10%), anemia (8%), nausea (8%), diarrhea (7%), thrombocytopenia (6%), decreased platelet count (6%), vomiting (6%), dizziness (6%), peripheral edema (5%), increased transaminases (5%) and hypomagnesemia (5%). 120 pts are evaluable for response. Overall response rate (ORR) was 57% in 82 pts with FLT3 mutations, and 63% in 68 pts in the 80 mg and higher dose levels. A plasma inhibitory activity assay confirmed effective, sustained in vivo FLT3 inhibition consistently in pts receiving doses of 80 mg and above. **Conclusions:** ASP2215, a potent inhibitor of FLT3/Axl, is well tolerated in patients with R/R AML and results in a high degree of clinical activity. Randomized phase III trials of ASP 2215 at 200 mg per day in newly diagnosed and R/R AML are planned. Clinical trial information: NCT02014558.

	FLT3 mutated		
Response	20-300 mg n (%) (82 pts)	≥ 80 mg n (%) (65 pts)	FLT3 wild type n (%) (38 pts)
Complete Remission (CR)	4 (5%)	3 (5%)	0
CR, incomplete platelet recovery (CRp)	4 (5%)	4 (6%)	0
CR, incomplete hematologic recovery (CRi)	27 (33%)	25 (38%)	3 (8%)
Partial Remission (PR)	12 (15%)	10 (15%)	1 (3%)
Composite CR (CR+CRp+CRi)	35 (43%)	32 (49%)	3 (8%)
ORR (CRc+PR)	47 (57%)	42 (65%)	4 (11%)

7004 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Clinical activity of ERY001 (erythrocyte encapsulated l-asparaginase) and native l-asparaginase (L-ASP) in combination with COOPRALL regimen in phase III randomized trial in patients with relapsed acute lymphoblastic leukemia (ALL). *First Author: Yves Bertrand, Institut d'Hémato-Oncologie Pédiatrique, Hospices Civils de Lyon, Lyon, France*

Background: Asparaginase is a cornerstone in the treatment of ALL, but its utility is limited by toxicities including hypersensitivity. Clinical allergy is associated with inactivation of asparaginase by antibodies (A-Abs), which can also neutralize asparaginase without any clinical signs of hypersensitivity (silent inactivation). ERY001 improves pharmacokinetics, tolerability and maintain circulating asparaginase (ASPA) activity due to the protective barrier of the erythrocyte membrane. **Methods:** This open, randomized international Phase 3 study enrolled pts with relapsed ALL. The co-primary endpoints were the duration of ASPA activity $>$ 100IU/L and the incidence of ASPA hypersensitivity during induction. Key secondary endpoints were complete remission (CR), minimal residual disease (MRD), event free survival (EFS) and overall survival (OS).The study was powered to detect 3-fold difference in the incidence of allergic reactions between treatments. Pts (n = 80), aged 1-55 years were randomized to ERY001 (150 IU/kg, n = 26 or L-ASP (10,000 IU/m^2, n = 28), or to ERY001-exp (prior allergy, n = 26). **Results:** In the non-allergic pts, ERY001 significantly reduced the incidence of ASPA hypersensitivity (0% vs 43%; $p < 0.001$). ASPA activity $>$ 100 IU/l was 21 $\pm$5 vs 9$\pm$ 8 days in ERY001 and L-ASP, respectively ($p < 0.001$). The CR rate: ERY001 (65%, 95% CI: [51.6:89.8]) vs L-ASP (39%, 95% CI: [23.3:63.1]; p = 0.026). Allograft was successfully performed in 65% of ERY001 vs. 46% of L-ASP. The proportion of patients who achieved MRD $< 10^{-3}$ in F1-F2/VANDA was 35% and 25% in ERY001, and L-ASP arms, respectively. At 12 mo, EFS rate was 65% and 49% in ERY001 and L-ASP arm, respectively. Treatment with ERY001 was well tolerated **Conclusions:** ERY001 provides an alternative option for patients with relapsed ALL, which is well tolerated and efficacious. Clinical trial information: NCT 01518517.

7007 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Long-term follow-up of patients with acute myelogenous leukemia receiving an autologous telomerase-based dendritic cell vaccine. *First Author: Hanna Jean Khoury, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: A phase II clinical trial was conducted in which subjects with AML were administered a telomerase-based dendritic cell immunotherapy (AST-VAC1; hTERT-DCs). The hTERT-DCs were prepared from leukapheresis collections from 33 subjects and were transfected with an mRNA encoding telomerase (hTERT) and the lysosomal sorting signal, LAMP-1, which enhances immunostimulatory activity. hTERT is essential for maintaining the proliferative capacity of tumor cells. **Methods:** AML patients were eligible to receive hTERT-DCs if they were in CR1 or CR2 with intermediate or high risk cytogenetics or if they were in early relapse with $<$ 20% marrow blasts. The hTERT-DCs were prepared after induction therapy and before or after completion of consolidation cycles. The hTERT-DCs were administered as 6 weekly followed by 6 biweekly intradermal injections. **Results:** Twenty-one patients (median age: 55) in complete remission (16 CR1 and 3 CR2) and or early relapse (2) received at least 3 injections of the hTERT-DCs. Only one grade 3 or 4 adverse event, (idiopathic thrombocytopenia), possibly related to the immunotherapy was observed during the first year. The two patients who were vaccinated during early relapse progressed rapidly and did not receive the full dosing regimen of hTERT-DCs. Of the 19 patients that were in CR, 14 received all 12 doses of hTERT-DCs. Fifty-eight percent (11/19) developed cellular immune responses to hTERT as assessed by peptide ELISpot analysis. Eleven of 19 patients (median follow-up 52 mos.) are still in remission as of last follow-up; seven developed detectable cellular immune responses to hTERT. Of the 19 CR patients, 7 were $\geq$ 60 yo at the time of hTERT-DC immunotherapy. Four of 7 patients $\geq$ 60 yo remain relapse free 52-59 months post DC-hTERT immunotherapy with all four developing immune responses to hTERT. The three patients that received DC-hTERT while in CR2 were in remission as of their last follow-up of 24, 50 and 59 months with two having hTERT immune responses. **Conclusions:** The results suggest that immunotherapy with hTERT-DCs is safe, can stimulate an immune response to telomerase, and may provide anti-tumor immune responses even in high risk patients with AML Clinical trial information: NCT00510133.

7008 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Allogeneic transplantation for myelofibrosis: Final analysis of a prospective study after a median follow up of 5 years. *First Author: Uday R. Popat, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We report final results of a prospective phase II clinical trial of busulfan(bu) and fludarabine(flu) conditioning in patients with myelofibrosis(MF). After observing a higher relapse rate in the initial cohort, we increased the intensity of conditioning regimen for subsequent patients. Here we report updated mature results with a median follow up of 5 years. **Methods:** Patients with advanced MF were eligible if they had adequate organ function and at least 9/10 HLA matched related or unrelated donor. Of the 46 patients, first 15 (bu low group) received IV busulfan 130 mg/m^2/day x 2 (day -3,-2). Of the remaining 31 (bu high group), 27 received IV busulfan dose to a target daily AUC of 4000 μmol.min x 4 (day -5 to -2) and 4 patients received a fixed dose of 100 mg/m^2/day x 4 (days -5 to -2). All patients received fludarabine 40mg/m^{2}x 4 (day -5 to -2). **Results:** 23 males and 23 females with a median age of 58 years (27-74) had intermediate (28) or high-risk (18) disease as per DIPSS plus criteria. Donors were matched sibs (19), matched unrelated (23), or mismatched unrelated (4). All patients engrafted with a median time to neutrophil engraftment of 13 (0-27) days and a median time to platelet engraftment of 24 (0-268) days. Cumulative incidence (CI) of grade II-IV, grade III, IV acute GVHD, and Chronic GVHD w 22%, 7%, and 40%, respectively. With a median follow up of surviving patients of 5.1 years (range 1-8.3 years), 3 year overall survival (OS), event-free survival (EFS), cumulative incidence (CI) of non-relapse mortality (NRM), and CI of relapse were 69%, 48%, 13%, and 39%, respectively. Multivariate analysis showed that Bu-high dose (HR 0.44; p = 0.07) was associated with lower relapse rate. Bu-high dose (HR 0.5; p = 0.09), DIPSS plus high (HR 2.69; P = 0.02) and Age (HR 1.05; P = 0.08) were predictors of EFS. DIPSS plus high (HR 5.99; P = 0.001) and Age (HR 1.07; P = 0.03) were adverse predictors of OS. **Conclusions:** Allogeneic transplantation results in long-term survival in patients with myelofibrosis with better outcome seen in earlier phase of the disease. PK guided myeloablative busulfan (AUC 16,000 μmol.min) appears promising in reducing relapse rate without increasing non-relapse mortality.

7009 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Association of reduced intensity conditioning (RIC) allograft (alloHCT) as first transplant approach in relapsed/refractory grade 3(G-3) follicular lymphoma (FL) with improved outcomes in long-term survivors. *First Author: Evgeny Klyuchnikov, Department for Stem Cell Transplantation, University Cancer Center, Hamburg, Germany*

Background: No studies to date have evaluated the role of RIC alloHCT compared to autologous (auto) HCT in pts with G-3 FL, in the rituximab-era. **Methods**: Adult pts with relapsed/refractory G-3 FL undergoing first RIC alloHCT or first autoHCT and reported to CIBMTR during 2000-12 were eligible. Pts with large cell transformation and those not receiving rituximab before HCT were excluded. **Results**: Characteristics of 197 pts included in this analysis are shown in the table below. AlloHCT pts were younger, more heavily pretreated, and had longer interval between diagnosis and HCT. The 5-yr adjusted probabilities of non-relapse mortality (NRM), relapse, progression-free survival (PFS) and overall survival (OS) of autoHCT vs. alloHCT groups were 4% vs. 27% (p < 0.0001); 61% vs. 20% (p < 0.0001); 36% vs. 51% (p = 0.06) and 59% vs. 54% (p = 0.7) respectively. 5-year incidence of second malignancies was similar (alloHCT = 8%; autoHCT = 9%). On multivariate analysis autoHCT was associated with reduced NRM (RR = 0.20; p = 0.001). Within the first 11 months post HCT, auto- and alloHCT were similar in terms of relapse and PFS. Beyond 11 months post HCT, autoHCT was associated with higher relapse (RR = 21.8; p = 0.003) and worse PFS (RR = 3.2; p = 0.005). In the first 24 months post HCT, autoHCT was associated with improved OS (RR = 0.42; p = 0.005), but beyond 24 months it was associated with lower OS (RR = 3.6; p = 0.04). **Conclusions**: RIC alloHCT as first transplant approach can provide better long-term survival outcomes for G-3 FL.

Table	AlloHCT (%)	AutoHCT (%)	P-value
	61	136	
Median age, years	53 (36-64)	57 (27-76)	0.01
KPS ≥ 90	42 (69)	86 (63)	0.21
Stage III-IV at diagnosis	52 (85)	105 (77)	0.11
Prior rituximab-resistance	30 (49)	84 (62)	0.12
Median lines of therapy	3 (1-5)	3 (1-5)	0.01
Duration of first response			0.31
< 1 year	22 (36)	44 (32)	
≥ 1 year	34 (56)	87 (64)	
Time from diagnosis to HCT, months	32 (5-159)	24 (6-224)	0.02
Type of donor			
Matched sibling	36 (59)		
8/8 MUD	23 (38)		
7/8 MUD	2 (3)		
PB graft	58 (95)	135 (99)	0.05
TBI in conditioning	9 (15)	8 (6)	0.04

Median follow up	57 (5-132)	59 (3-145)	

7010 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

Efficacy and safety of CD19-targeted 19-28z CAR modified T cells in adult patients with relapsed or refractory B-ALL. *First Author: Jae Hong Park, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Adult patients (pts) with relapsed or refractory (R/R) acute lymphoblastic leukemia (ALL) have dismal prognosis. We previously reported high anti-tumor activity of autologous T cells genetically modified to express 19-28z chimeric antigen receptor (CAR) targeting CD19 in adult pts with ALL. Herein, we report the long-term outcome of our phase I trial in adults with R/R ALL (NCT01044069). **Methods:** Adult pts with R/R B-ALL underwent leukapheresis, and T cells were transduced with a gammaretroviral vector encoding a CAR construct composed of anti-CD19 scFv linked to CD28 and CD3ζ signaling domains (19-28z). All pts received conditioning chemotherapy followed by 1–3x10^6 19-28z CAR T cells/kg. **Results:** 33 pts have been treated, and 32 pts are evaluable for response. The median age was 54 years (range, 22-74). 12 pts (36%) had Ph+ ALL, 11 pts (33%) had prior allogeneic stem cell transplant (allo-SCT), and 14 pts (42%) had ≥ 3 prior lines of therapy. At the time of CAR T cell infusion, 16 had morphologic disease (> 5% blasts in BM) and the remaining 16 pts had minimal residual disease (MRD). 13/16 pts with morphologic disease (81%) and 16/16 pts with MRD (100%) were in complete remission (CR) after 19-28z CAR T cell infusion, yielding an overall CR rate of 91% (29/32). Of the 28 MRD evaluable patients, MRD negative CR rate was 82%. 11 pts underwent allo-SCT following the CAR T cells. As of 1/25/15, the median follow-up was 5.1 months (range, 1.0-37.6+), with 14 pts having ≥ 6 months of follow-up. 6-month overall survival (OS) rate of all patients was 58% (95% CI: 36-74). Among the pts who achieved CR, OS rate at 6 months for pts who had allo-SCT vs. no allo-SCT following CAR T cells was 70% (95% CI: 33-89) vs. 61% (95% CI: 29-82; p = 0.30). Severe cytokine release syndrome (sCRS) requiring vasopressors or mechanical ventilation for hypoxia was observed in 7 patients, effectively managed with IL-6R inhibitor and/or corticosteroids. **Conclusions:** 19-28z CAR T cells can induce a high CR rate of 91% in adult patients with R/R ALL. The risk of sCRS correlates with disease burden and can be effectively managed. These findings strongly support the use of 19-28z CAR T cells in adults with R/R ALL and warrants investigation in a phase II trial. Clinical trial information: NCT01044069.

7011 Poster Discussion Session; Displayed in Poster Session (Board #1), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Long-term follow-up of a phase Ib trial of idelalisib (IDELA) in combination with chemoimmunotherapy (CIT) in patients (pts) with relapsed/refractory (R/R) CLL including pts with del17p/*TP53* mutation. *First Author: Jacqueline Claudia Barrientos, Hofstra North Shore - LIJ School of Medicine, New Hyde Park, NY*

Background: IDELA is a first-in-class PI3Kδ inhibitor approved in combination with rituximab for pts with relapsed CLL. **Methods**: Pts with R/R CLL were treated continuously with 150 mg BID oral IDELA and a limited # of cycles (C) of CIT to evaluate safety and efficacy of combination regimens. Pts could enroll in extension study after 48 wks. Responses were evaluated by published criteria (Hallek 2008; Cheson 2012). **Results**: 114 pts (37F/77M) median (med) age 65 (range 41-87) yrs enrolled with: extensive prior therapies (med 3, range 1-9), refractory disease (51%), high risk Rai (60%), del17p/*TP53* mutation (29%), del11q (13%), unmutated *IGHV* (79%). Med exposure was 14.6 (range 0-49) mos. 61 pts (54%) enrolled in extension study. 21 (34%) were continuing on study. Most common and select AEs independent of causality (any Grade/Gr ≥ 3): diarrhea/colitis (52%/19%), pyrexia (45%/4%), cough (37%/1%), nausea (29%/1%), fatigue (32%/4%), pneumonia (23%/15%), dyspnea (22%/3%), rash (21%/4%), pneumonitis (4%/4%). AST/ALT elevation Gr ≥ 3 was seen in 12%. Most common reasons for discontinuation were AEs (25%) or PD (25%). 2 pts discontinued due to AST/ALT elevation, 1 due to Richter's transformation. 20 (18%) deaths were reported on study; 6 pts experienced PD before death. ORR was 82.5% in all pts, 70% in pts with del17p/*TP53* mut, and 87% among pts without. SD/PD was reported in 10%/3%. Med overall PFS was 26.1 mos, 20.3 mos for pts with del17p/*TP53* mut, and 36.8 mos for pts without. Med OS for all pts or pts with del17p/*TP53* mut was not reached. Estimated OS at 36 mos was 73.1% for all pts, 57.3% for pts with del17p/*TP53*, and 78.3% for pts without. **Conclusions**: IDELA in combination with CIT shows a manageable safety profile without increased toxicities and has substantial clinical activity in heavily pretreated, refractory, and high-risk CLL including presence of del17p/*TP53*mutation. Phase 3 trials of IDELA with O or BR in pts with R/R CLL are ongoing (NCT01659021, NCT01732926). Clinical trial information: NCT01088048.

Dose adherence and baseline exposure analysis of the ibrutinib 420 mg dose administered to patients with previously treated chronic lymphocytic leukemia (CLL). *First Author: Paul M. Barr, Wilmot Cancer Institute, University of Rochester, Rochester, NY*

Background: Ibrutinib (ibr), a first-in-class, once-daily, oral, covalent inhibitor of Bruton's tyrosine kinase (BTK), is rapidly eliminated from plasma after oral administration (Advani, JCO 2013). Complete or near complete BTK active site occupancy (median > 90%) is achieved at 4 hours and maintained at 24 hours with ibr 420 mg once-daily (O'Brien, Lancet Oncology 2013). At 140 or 280 mg doses, fewer patients (pts) attained complete BTK occupancy (Poggesi, AACR 2014). This analysis evaluated the effect of the ibr 420 mg once-daily dose on IRC-assessed progression-free survival (PFS) in pts with previously treated CLLfrom thephase 3 RESONATE trial. **Methods**: Dose intensity (DI) was defined as the proportion of actually administered vs planned doses of 420 mg. DI was also defined in first 8 weeks to compare statistically with post-week 8 PFS. Steady-state AUC/C_{max} was estimated per NONMEM modeling using 2 timepoint samples (weeks 1 and 4). Missed doses had to be consecutive. **Results**: Ibr-treated pts (n = 195) had a mean DI of 95% (median 100%) with 8.3 months of treatment. The majority of dose interruptions restarted at 420 mg; 3.6% of pts had 1 and 0.5% had 2 dose reductions due to AEs. Pts with higher DI experienced longer PFS (median NR) compared to lower DI (11 months). Using an adjusted mean DI of 96% in first 8 weeks and post week-8 PFS, this trend was confirmed with HR = 0.4 (P= 0.0127). Pts with higher DI had a lower rate of progression regardless of del17p, p53 mutation, or del11q CLL. In 179 pts receiving ibr 420 mg with PK assessment at weeks 1 and 4, no difference was seen in median PFS with lower vs higher ibr exposure (AUC or C_{max}). There were fewer PFS events in pts not missing (n = 136) vs those missing (n = 59) ibr doses for ≥ 8 consecutive days (13% vs 31%, respectively), with median PFS of NR vs 11 months, respectively. The mean duration of these missed doses was 26 days. **Conclusions**: A higher mean dose intensity of ibr is associated with improved PFS, with patients missing more than 1 week of treatment experiencing more PFS events. These results, and the established clinical profile, support the clinical utility of sustained adherence to the once-daily 420 mg dose of ibr in patients with previously treated CLL. Clinical trial information: NCT01578707.

Prognostic testing patterns in CLL pts treated in U.S. practices from the Connect CLL registry. *First Author: Anthony Mato, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Genetic aberrations detected by fluorescence in situ hybridization (FISH) and cytogenetic (CG) testing provide prognostic information for CLL pts. The identification of genetic abnormalities has particular relevance in choosing immunochemo- or kinase inhibitor therapies, SCT or clinical trial. Here, we analyze factors influencing decisions to perform FISH or CG testing. **Methods:** Connect CLL is a large, prospective, longitudinal, multicenter, observational registry of 1494 CLL pts at 179 community (n=1,311), 17 academic (n=155), and 3 government (n=28) sites. Pts were enrolled within 2 months of initiating any line of therapy (LOT). Univariate (UV) and multivariate (MV) logistic regression analyses were conducted to identify characteristics associated with a decision to perform genetic testing at LOT1 and at LOT≥2. **Results:** FISH or CG was performed at study enrollment in 861/1,494 (58%) pts (36% CG, 49% FISH, 28% both). 65% of 889 pts were tested for FISH/CG prior to LOT1, 50% of 260 in LOT2, 45% of 345 in LOT>3. Of 861 pts tested at enrollment, 29% had FISH/CG retested with a subsequent LOT. In UV analyses (14 predictors), FISH/CG were more often performed at academic sites (p .005), in pts age ≤75 (p .0002), at enrollment at LOT1 vs. LOT ≥2 (p < .0001), in private insurance pts (p .002) and Rai stage ≥2 (p<.0001). Table 1 describes independent predictors of performing genetic testing stratified by LOT and practice setting. **Conclusions:** Our results indicate that only a fraction of CLL pts are tested/re-tested for genetic alterations by FISH/CG. Given the significance of identifying del17p or complex CG in selecting each LOT, these results indicate a need for increased awareness of the importance of this testing.

MV analysis: Predictors of FISH/CG.

Time point/Practice setting	Covariate	OR 95% CI
LOT1/All sites	Academic vs community-govt site	1.76 1.03-2.99
	White vs other	1.90 1.13-3.17
	Private insurance	1.44 1.08-1.92
LOT1/Community-Govt sites	White vs other	2.40 1.26-4.58
	Age≤75 vs. < 75	1.44 1.01-2.05
	RAI stage ≥2 vs. 1	1.52 1.07-2.14
LOT≥2:/All sites		
	White vs other	0.34 0.17-0.68
	Age≤75	1.45 1.01-2.07
LOT≥2/Community-Govt sites	White vs other	0.41 0.16-1.04
	Age≤75	1.65 1.05-2.61

Association of relapse of FLT3-ITD AML with normal karyotype with internal tandem duplication allelic burden, base-pair insertion length, and NPM1 status. *First Author: Sarah L Sammons, Division of Hematology/Oncology, Department of Medicine, University of Maryland Greenebaum Cancer Center, Baltimore, MD*

Background: FMS-like tyrosine kinase internal tandem duplication (FLT3-ITD) mutation in normal karyotype AML (NK-AML) is a poor prognostic feature. The prognostic significance of the mutant to wild type allelic ratio and base pair insertion length (bpInsLng) of FLT3-ITD with or without Nucleophosmin (NPM1) mutation remains controversial in this population. **Methods:** The medical records of 149 patients with NK-AML were reviewed (2007-2014) including subject and disease characteristics, and treatment outcomes. Patients with any cytogenetic abnormality were excluded. Treatment failure was defined as relapsed or refractory disease after chemotherapy regardless of transplant. Death of any causes was considered an event. A FLT3-ITD mutation was detected as the presence of a migrating PCR product larger than the wild-type product (330-bp). ITD allelic burden (AB) was calculated as the ratio of ITD to wild type allele expressed as a percentage. Time to failure was analyzed using the Kaplan-Meier estimate and the Mantel-Cox logrank test. Patients who were alive with no evidence of disease at the last follow-up were treated as censored observations. The protocol was approved by the IRB. **Results:** The mean age of patients was 58±14 years (range 22-88). FLT3 mutation status was available in 139 cases; 45 (30.2%) carried FLT3-ITD with assessment of AB and bpInsLng available in 29. The median ITD AB was 33% (range 3-433). For the time to failure analysis patients were classified as low or high allelic burden using the median value as the cut point. The median length of the mutant fragment was 372-bp (range 345-500). NPM1 mutation was detected in 38 (26%) patients. In FLT3-ITD population regardless of NPM1 status, patients with AB higher than median value (33%) had significantly higher hazard rate of treatment failure than those with low AB (hazard ratio = 5.4, 95% CI: 1.5-19.5, p = 0.004). ITD bpInsLng lower or higher than the population median value did not predict treatment failure rate (p = 0.6). **Conclusions:** In patients with FLT3-ITD NK-AML, ITD AB > 33% can significantly predict higher relapse rate irrespective of mutant bpInsLng and NPM1 status.

Activity of the mitochondrial metabolism inhibitor cpi-613 in combination with high dose Ara-C (HDAC) and mitoxantrone in high risk relapsed or refractory acute myeloid leukemia (AML). *First Author: Timothy S. Pardee, Comprehensive Cancer Center of Wake Forest University, Winston-Salem, NC*

Background: CPI-613 is a novel agent that targets mitochondrial metabolism. It inhibits mitochondrial respiration in AML cells and in a single agent phase I study was active for several patients with myeloid malignancies-.This trial was designed to determine the maximum tolerated dose (MTD) and efficacy of CPI-613 in combination with HDAC and mitoxantrone in relapsed or refractory AML. **Methods:** CPI-613 was given daily on days 1 through 5 starting at a dose of 500 mg/m^2. Beginning on day 3, HDAC (3,000 mg/m^2 or 1,500 mg/m^2 for age ≥ 60) was given every 12 hours for 5 doses and mitoxantrone at 6 mg/m^2 was given daily for 3 doses. If residual disease was present on day 14, a second cycle could be given. Patients who achieved a complete remission with or without complete count recovery (CR or CRi) could receive additional cycles with the goal of stem cell transplantation when possible. **Results:** A total of 48 patients are evaluable. The median age is 60 (range 21-79). Fourteen patients had refractory disease and 11 received one or more previous lines of salvage therapy. Cytogenetics were poor risk in 23, intermediate in 20, good in 4 and one patient had CML blast crisis. The overall response rate was 48% (19CR+4CRi). Three of five patients with FLT3 mutations achieved a CR/CRi (60%). Patients age ≥ 60 had a CR/CRi rate of 46% (12/26). Surprisingly, patients with poor-risk cytogenetics had a CR/CRi rate of 48% (11/23). In a historical cohort of poor-risk patients treated with HDAC, mitoxantrone and asparaginase, only 25% responded. Median survival for the entire cohort is 6.4 months. Six patients (12.5%) died on or before day 30. The CPI-613 dose has been escalated to 2750 mg/m^2 with the MTD not yet determined. Stem cell transplantation was performed on 23% (11/48) of patients. Samples from patients before and after CPI-613 showed induction of phosphorylation of the E1α subunit of pyruvate dehydrogenase and AMPK consistent with the proposed mechanism of action. **Conclusions:** CPI-613 in combination with HiDAC and mitoxantrone is a promising salvage regimen and these data support additional studies especially in older patients and those with high-risk disease. Clinical trial information: NCT01768897.

Safety and tolerability of the combination of ATRA + arsenic trioxide (ATO) + gemtuzumab ozogamicin (GO) in high-risk acute promyelocytic leukemia (APL): Initial report of the SWOG/Alliance/ECOG S0535 trial. *First Author: Jeffrey E. Lancet, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: High-risk APL remains a therapeutic challenge, with significant rates of early mortality and relapse. Recent evidence confirmed excellent outcomes in low-risk APL with the combination of ATO and ATRA (Lo-Coco, NEJM 2013), and a previous pilot study indicated the efficacy of a combination of ATO + ATRA + GO in a subset of high-risk APL (Ravandi, JCO 2009). SWOG designed a larger phase 2 study to confirm the safety and efficacy of this combination in high-risk APL. **Primary Objectives**: 1) assessment of early (6 week) death rate; 2) assessment of 3-year continuous complete remission (CCR) **Methods:** Adult patients with newly diagnosed high-risk APL (WBC $\geq$ 10k/uL) were eligible. Induction therapy consisted of: ATRA (45 mg/m^2/day) - day 1 until CR; ATO (0.15 mg/kg/day) – day 10 until CR; GO 9 mg/m^2- day 1. Patients in CR received consolidation with ATO x 2 cycles, followed by ATRA + daunorubicin x 2 cycles, followed by GO x 2 cycles. Subsequent maintenance therapy consisted of ATRA + 6-MP + methotrexate for up to 1 year. **Results:** From 2008 to 2013, 73 patients were enrolled and evaluable for toxicity. Median age was 46.5 years, with 52% females and 48% males. Sixty-two (85%) patients completed induction therapy as planned, and 48 patients (66%) completed all planned consolidation. Six of 73 patients (11%) died within 6 weeks of treatment initiation (95% confidence interval 6-21%), supporting rejection of the null hypothesis (30% early death rate). The most common treatment-emergent grade 3-4 adverse events (AE) during induction included: febrile neutropenia (33%), AST/ALT elevation (12%), hypoxia/differentiation syndrome (11%), hyperglycemia (11%), headache (11%), prolonged QTc (11%). Amongst 59 patients receiving consolidation, the most common treatment-emergent grade 3-4 AEs included: febrile neutropenia (52%), headache (14%), fatigue (14%), and nausea (12%). The efficacy analysis of CCR is ongoing. **Conclusions:** The combination of ATO + ATRA + GO appears safe and well-tolerated in patients with high-risk APL, with an acceptable early mortality rate. 3-year CCR assessment is not yet mature. Clinical trial information: NCT00551460.

Correlation of overall survival (OS) with bone marrow blast (BMBL) response in patients (pts) with myelodysplastic syndrome. *First Author: Lewis R. Silverman, Mount Sinai Medical Center, New York, NY*

Background: BMBL % is the prognostic variable with the greatest impact on outcome in MDS patients at diagnosis and subsequent time points. Current composite response criteria (IWG, Cheson 2006) do not consistently correlate with OS. Treatment impact of BMBL as an independent response criterion has not been adequately evaluated. **Methods:** We evaluated the correlation between OS and BMBL in pts with higher-risk (HR) MDS from 4 datasets from 7 studies with 887 pts: ONTIME, a Phase III randomized study of 2nd-line rigosertib (RIG) vs best supportive care (BSC) (N = 299; Silverman, ASH 2014); 4 Phase I/II studies of RIG in pts with MDS/AML (N = 39; Silverman, Hematol Oncol 2014); AZA-001, a Phase III study of azacitidine (AZA) vs 3 conventional care regimens (N = 358; Fenaux, Lancet Oncol 2009; Gore, Haematologica 2013); Cancer & Leukemia Group B (CALGB) Study 9221, a Phase II, randomized trial of 1st-line AZA vs BSC (N = 191; Silverman, J Clin Oncol 2002). Change in blasts was defined similarly: BM complete response is BMBL $\leq$ 5% and $\geq$ 50% decrease from baseline; BM partial response is $\geq$ 50% decrease from baseline, but BMBL still $>$ 5%; stable disease is $<$ 50% decrease or increase from baseline. **Results:** In ONTIME, landmark time-dependent analyses showed correlation of BMBL response/stabilization with OS at 4 wks (P= 0.011) and 12 wks ($P<$ 0.001). In the 4 Phase I/II studies, BMBL response/stabilization at 4–8 weeks was associated with a quadrupling of median OS ($P<$ 0.001). In Study AZA-001, time-dependent analysis of BMBL stabilization was associated with a significantly reduced risk of death in both treatment cohorts ($P<$ 0.001). In Study 9221, landmark analysis of BMBL response/stabilization showed a 6-fold improvement in OS ($P<$ 0.001). **Conclusions:** These studies, spanning more than a decade with different therapeutic agents and settings, demonstrate a consistent positive correlation between BMBL response and OS in pts with HR-MDS, including pts on supportive care. This suggests that use of reduction/stabilization in BMBL can serve as a new early response parameter, as an intermediate clinical endpoint for evaluation of new agents, and as a biomarker for disease progression in HR-MDS itself.

Effect of long noncoding RNA *RUNXOR* on the epigenetic regulation of *RUNX1* in acute myelocytic leukemia. *First Author: Hong Wang, Cancer Center, First Hosipital of Jilin University, Changchun, China*

Background: *RUNX1*, a master regulator of hematopoiesis, is the most commonly perturbed target of chromosomal abnormalities in hematopoietic malignancies. About 30%–40% of acute myeloid leukemia (AML) patients carry the t(8;21) translocation. However, little is known regarding the molecular mechanisms underlying *RUNX1*-associated translocation. Long non-coding RNAs (lncRNAs) have been implicated in a variety of important biological processes by epigenetic mechanisms. **Methods:** Using a novel R3C (**R**NA-guided **C**hromatin **C**onformation **C**apture) method developed in our lab, we identified lncRNAs that participate in the regulation of *RUNX1 in AML*. Full length of lncRNAs was characterized by Marathon cDNA Amplification Kit. Expression of lncRNAs in AML was quantitated by qPCR. Reverse transcription-associated trap (RAT) and chromatin conformation capture (3C) assays were used to map DNA/RNA interaction. The protocol of AML patients bone marrow and peripheral blood cell samples was approved by the Human Medical Ethical Review Committee from Jilin University First Hospital and informed consent was obtained from each AML patient and normal donor. **Results:** 1)We discovered a novel intragenic 216 kb long noncoding RNA within the *RUNX1* locus, named *RUNXOR* (***RUNX1*** **o**verlapping **p**romoter-derived **n**oncoding **R**NA). *RUNXOR* was transcribed from an upstream promoter that overlaps all of the *RUNX1* gene's exons and introns. 2) *RUNXOR*lncRNA was overexpressed both in AML cell lines and AML patients' bone marrow, and was upregulated by Chemotherapeutic drug Ara-C. 3) *RUNXOR* lncRNA interacted with the promoter and enhancer of *RUNX1*. By recruiting histone methyltransferase EZH2, it induced H3K27 modification and epigenetically regulated *RUNX1*. 4) Using the 3C assay, we showed that *RUNXOR* interacted with the most frequent translocation break regions in translocation related genes, including *EVI1, ETO, TEL*, and *CBFA2T3*. **Conclusions:** This study identifies *RUNXOR* as a novel lncRNA involved in long range DNA interaction of *RUNX1 in AML*. The lncRNA may function as a putative tumor suppressor by epigenetically regulates *RUNX1* and scaffolds the translocation associated DNA in AML.

NFAT2 to regulate anergy induction in CLL through Lck. *First Author: Melanie Maerklin, Department of Hematology, Oncology and Immunology, University of Tuebingen, Tuebingen, Germany*

Background: NFAT2 is a highly phosphorylated transcription factor which regulates developmental and activation programs in diverse cell types. CLL constitutes a heterogeneous disease with some patients exhibiting an indolent course for many years and others progressing rapidly and requiring early treatment. A defined subgroup of patients shows enhanced responsiveness to stimulation of the B cell receptor (BCR) complex and more aggressive disease. In contrast, another subset of CLL patients with more indolent course is characterized by an anergic B cell phenotype referring to B cell unresponsiveness to IgM ligation. Here, we analyzed the role of NFAT2 in the pathogenesis of CLL and in anergy induction in CLL cells. **Methods:** We crossed conditional CD19-Cre NFAT2 knock out mice with the Eμ-TCL1 transgenic mice, which develop a human-like CLL. We analyzed TCL1+NFAT2 ko mice and TCL1 mice without a NFAT2 deletion served as controls. We performed a comparative gene expression analysis, Ca^{2+}mobilization assays and Western Blots for multiple downstream signaling molecules on both CLL cells. **Results:** Mice with NFAT2 ko exhibited a significantly more aggressive disease course with accelerated accumulation of CLL cells and a dramatically reduced life expectancy. We detected a substantially altered expression profile of genes associated with B cell anergy in the TCL1+NFAT2 ko mice. The vast majority of these genes was expressed significantly less in the absence of NFAT2 with Lck, Pacsin1 and Cbl representing the biggest hits. While anergic CLL cells from TCL1 mice exhibited an unresponsive phenotype with respect to Ca^{2+} flux upon IgM ligation, TCL1+NFAT2 ko mice showed a normal capacity to mobilize $Ca^{2+}$and a normal activation of the downstream signaling. IgM stimulation did not activate normal phosphotyrosine induction in TCL1 mice. However TCL1 mice showed a strong activation of the anergy regulator Lck. **Conclusions:** Genetic loss NFAT2 leads aggressive disease and controls the expression of several important anergy-associated genes. We identified Lck as a critical target of NFAT2 in this context. Taken together, our data demonstrate that the NFAT2-Lck axis plays an essential role in the pathogenesis of CLL and implicate it as a potential target in its treatment.

7020 Poster Discussion Session; Displayed in Poster Session (Board #10), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

GATA-1, FOG-1, and FLI-1 regulation in essential thrombocythemia independently from JAK2 and CALR mutations. *First Author: Ciro Roberto Rinaldi, University of Lincoln, Lincoln, United Kingdom*

Background: GATA-1 is the founding member of the GATA transcription factor family and it is essential for cell maturation and differentiation within the erythroid and megakaryocytic lineages. We and others have demonstrated that elevated GATA-1 expression is found in the bone marrow of Essential Thrombocythemia (ET) patients, independent of *JAK2V617F* and *CALR* mutations. GATA-1 is able to coordinate lineage specification through its ability to bind both DNA and protein partners that include; Friend of GATA (FOG-1) and the Friend leukemia integration 1 (FLI-1) transcription factors. FOG–1 is vital for megakaryocyte and erythroid–lineage commitment and its expression largely overlaps spatiotemporally with that of GATA-1. FLI-1 is an ETS family member that is expressed at high levels in megakaryocytic progenitors. In conjunction with GATA-1, FLI-1 targets those genes responsible for megakaryopoiesis. **Methods:** Following on from our earlier work we analyzed the expression levels of GATA-1 in relation to its interacting transcription factors, FOG-1 and FLI-1 in megakaryocyte development. Peripheral blood specimens were collected from 36 patients diagnosed with ET, 17 JAK2 mutated (47%), 4 CALR (11%) mutated, 1 MPL mutated (3%) and 14 with no molecular abnormalities, and compared with a cohort of healthy volunteers. Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analyzed by Real Time PCR for GATA-1, FOG-1 and FLI-1 expression relative to the housekeeping gene GAPDH using the $2^{-\Delta\Delta CT}$ method. **Results:** We confirmed the data obtained in bone marrow demonstrating that GATA-1 is significantly up-regulated in ET patients and that GATA-1 overexpression is independent from *JAK2V617F* and *CALR* mutations. However, the transcription factors FOG-1 and FLI-1 do not appear to be subject to the same regulatory control in ET as that of GATA-1. **Conclusions:** These results suggest that GATA-1 is specifically deregulated in essential thrombocythemia.

A multi-institution phase I trial of ruxolitinib in chronic myelomonocytic leukemia (CMML). *First Author: Eric Padron, Moffitt Cancer Center, Tampa, FL*

Background: CMML is a lethal myelodysplastic/myeloproliferative neoplasm (MDS/MPN) characterized by peripheral monocytosis and bone marrow (BM) dysplasia with limited therapeutic options. Preclinical studies have identified the JAK2 inhibitors as therapeutic candidates. We conducted the first phase 1 clinical trial exploring the safety and efficacy of ruxolitinib, an FDA approved JAK1/2 inhibitor, in patients with CMML. **Methods:** All CMML WHO subtypes were included without regard to previous therapy. Key exclusion criteria included an ANC $< 0.25x10^3$ c/dL and a platelet count $< 35x10^3$c/dL. The use of GM-CSF analogs was prohibited. Four cohorts were enrolled using a "rolling six" study design, with doses ranging from 5mg BID to 20mg BID in 5mg dose escalations. Descriptive statistics were used to report baseline characteristics and response rates. The study was registered at clinicaltrials.gov NCT01776723 **Results:** Between March 2013 and January 2015, 19 patients (pts) were enrolled and treated with ruxolitinib. The Median age was 71 years and all pts had CMML-1. MPN-CMML by FAB criteria constituted 67% of pts and 47% had higher-risk disease by the Global MD Anderson Scoring System. Eleven pts (58%) received prior therapy and 8 pts (42%) received a prior hypomethylating agent. No dose limiting toxicities for ruxolitinib were identified. One subject had Grade (G)3 thrombocytopenia with no other drug-associated G3 or G4 adverse events. The mean duration of therapy was 122 days (range, 28-409 days). Of 15 pts evaluable for response, 3 had hematologic improvement and one pt had a partial response per 2006 IWG criteria. Six of 9 pts with splenomegaly had a $> 50\%$ reduction in spleen size. Fourteen of 15 pts with reported B-symptoms had clinically meaningful or complete resolution on ruxolitinib. There was no change in allelic burden of somatic mutations in responders; broad spectrum cytokine profiling will be available at the time of presentation. **Conclusions:** The recommended phase 2 dose of ruxolitinib is 20mg BID. We demonstrate that ruxolitinib has promising activity in CMML with particular benefit in those with disease related B-symptoms. A phase 2 study is planned to further test the efficacy of ruxolitinib in CMML. Clinical trial information: NCT01776723.

Propensity score analysis: Frontline therapy with high-dose (HD) imatinib vs. 2nd generation tyrosine kinase inhibitors in patients with chronic myeloid leukemia in chronic phase. *First Author: Koji Sasaki, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The clinical efficacy of the second generation of tyrosine kinase inhibitors (TKI) has not been compared to that of HD imatinib in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP). **Methods:** Response and survival for 374 pts with newly diagnosed CML-CP enrolled in four consecutive or parallel prospective clinical trials of imatinib 800 mg daily, dasatinib, or nilotinib were analyzed. Logistic regression was used for propensity score (PS) calculation from baseline pt characteristics including age at diagnosis, gender, race, Sokal scores, white blood cell, hemoglobin, platelet, blasts in peripheral blood and bone marrow, albumin, urea nitrogen, creatinine, lactate dehydrogenase, total bilirubin, the proportion of Philadelphia chromosome by conventional karyotype and fluorescence in situ hybridization, the presence of clonal evolution, the type of BCR-ABL transcript, and time from diagnosis to therapy. PS analysis with 1:1 matching was performed with the nearest matching method. The Kaplan-Meier method was used to calculate OS, EFS, TFS, and FFS. **Results:** Of the 374 pts analyzed, 158 were treated with HD imatinib, 109 with nilotinib, and 107 with dasatinib. The median follow-up was 124 months, 49 months, and 54 months, respectively. PS matching identified 81 pts in imatinib vs. dasatinib and 84 pts in imatinib vs. nilotinib, respectively. The cumulative best response, five-year OS, EFS, TFS, and FFS are summarized in the table below. **Conclusions:** High-dose imatinib may have similar efficacy compared to second generation TKIs without clear difference in response or long-term survival endpoints.

Main outcomes after PS matching.

	IM800 [n = 84]	Nilotinib [n = 84]	P	IM800 [n = 81]	Dasatinib [n = 81]	P

7023 Poster Session (Board #), Sun, 8:00 AM-11:30 AM

Results of a phase III randomized, controlled study evaluating the efficacy and safety of idelalisib (IDELA) in combination with ofatumumab (OFA) for previously treated chronic lymphocytic leukemia (CLL). *First Author: Jeffrey Alan Jones, Ohio State University, Columbus, OH*

Background: IDELA (Zydelig) is a selective oral PI3Kδ inhibitor approved in combination with rituximab for previously treated pts with CLL. This open-label study (NCT01659021) compared IDELA + OFA v OFA in pts with relapsed CLL. **Methods**: Pts with CLL progressing ≤ 24 mo from last therapy, who had received ≥ 2 cycles of a purine analogue or bendamustine, were randomized 2:1 to either Arm A (IDELA 150 mg BID continuously plus OFA, 300 mg IV wk 1, then 1 gm IV wkly x 7 and q 4 wk x 4) or Arm B (OFA, same as Arm A except 2 gm was substituted for 1 gm dosing). Stratification was performed for relapsed v refractory, del17p and/or TP53 mutation, and *IGHV* mutation. IRC-assessed response and PD based on imaging using modified IWCLL 2008 criteria. The 1° endpoint was PFS and 2° endpoints were confirmed ORR, lymph node response (LNR), OS, PFS in pts with del(17p) and/or TP53 mutation, and CR rate. Results are from the final analysis. **Results:** Pt attributes were balanced in the 2 arms: Med age 67; Rai II/III/IV 18/13/51%, med no. prior regimens 3, refractory 49%, del17p/TP53mut 40%, *IGHV* unmut 78%. Exposure, disposition, and efficacy are shown in Table. Results were consistent across risk groups. Gr ≥ 3 AEs in Arm A included diarrhea/colitis (20.2%), pneumonia (12.7%), and febrile neutropenia (11.6%). **Conclusion:** IDELA + OFA yielded superior PFS, ORR, and LNR compared to OFA in relapsed CLL, including within high-risk subgroups. Safety was manageable with a profile similar to that previously observed in CLL trials. The open label design may have led to an imbalance in dropout, with a higher rate in Arm B. Clinical trial information: NCT01659021.

A multicenter open-label phase 1b/2 study of ibrutinib in steroid dependent or refractory chronic graft versus host disease (cGVHD). *First Author: David Bernard Miklos, Stanford University, Stanford, CA*

Background: Chronic GVHD (cGVHD) is a common and serious complication after allogeneic stem cell transplantation (SCT). Both B and T cell-mediated mechanisms have been implicated in the pathophysiology of cGVHD. There are no approved therapies for cGVHD. In murine models, ibrutinib (ibr) reduces the severity of cGVHD (Dubovksy JCI 2014). In humans, ibr was tolerable in post-SCT patients (pts) and may improve donor chimerism and/or graft-vs-leukemia effects while reducing cGVHD (Miklos ASH 2014, Coutre ASH 2014). **Methods**: This ongoing phase 1b/2 study was designed to evaluate the safety and efficacy of ibr in pts with steroid-dependent/refractory cGVHD. Eligible pts had to have $\leq$ 3 prior regimens for cGVHD and either $>$ 25% BSA erythema or an NIH mouth score $>$ 4. Phase 1b was designed to determine the recommended phase 2 dose (RP2D) with the initial being 420 mg. Response was assessed every 3 months using the NIH consensus cGVHD Activity Assessment. **Results**: 6 pts (median age, 56 yrs, mean Karnofsky score, 85) were enrolled in phase 1b. Median time from transplant was 23 mo. Median time on ibr was 19.3 wks. Ibr dose was reduced to 280 mg in 1 pt due to recurrent stomatitis. Most common treatment-emergent AEs included fatigue (n = 5), diarrhea (n = 4), ecchymosis/bruising (n = 3) and stomatitis (n = 2), all grade 1/2. SAEs (all grade 3) occurred in 2 pts including one pt with pneumonia and another with pyrexia and fungal brain abscess. The latter was the only event leading to discontinuation of ibr (at 10.9 weeks). Preliminary analysis of efficacy for pts receiving at least 3 months of treatment indicated that all 5 evaluable pts achieved PR. The 2 pts evaluable at 6 months remain in PR. Improvements in clinician assessed GVHD-score, skin erythema and mouth score were observed in pts at these early time points. RP2D was determined to be 420 mg. **Conclusions**: Ibrutinib given for steroid-dependent/refractory cGVHD was well tolerated; AEs were consistent with the known safety profile for ibrutinib. The efficacy data observed at this early time point is preliminary and needs confirmation in a larger number of pts for longer duration. Phase 2 enrollment is ongoing. Clinical trial information: NCT02195869.

7025 Poster Session (Board #14), Sun, 8:00 AM-11:30 AM

Symptomatic BK virus as a significant independent predictor of immune suppression and poor overall survival in allogeneic hematopoietic stem cell recipients. *First Author: Ala Abudayyeh, The University of Texas MD Anderson Cancer Center, Division of Internal Medicine, Section of Nephrology, Houston, TX*

Symptomatic BK virus as a Significant Independent Predictor of Immune Suppression and Poor Overall Survival in Allogeneic Hematopoietic Stem Cell Recipients **Background:** BK virus (BKV) infections are known indicators of immune suppression in hematopoietic stem cell transplant (HSCT) recipients; they can lead to hemorrhagic cystitis, ureteral stenosis, renal dysfunction and prolonged hospital stays. In this study we looked at all transplant associated variables and the patient's immune status to evaluate what factors predicted for the risk of BKV viuria. We hypothesized that BKV infection is a marker of poor immune recovery and survival outcomes in HSCT recipients. **Methods:** We analyzed all engrafted patients undergoing first allogeneic HSCT at MD Anderson Cancer Center between January 2004 and December 2012. We evaluated their immune panels and their transplant associated factors. BKV positivity was defined as BKV detection in urine by PCR testing. Overall survival outcome was defined as the time from the day of stem cell infusion to the day of death. **Results:** We identified a total of 2477 patients with a median age of 52 years. BK viruria was manifest in 25% (n = 629) of the patients. The median time from transplantation to BK viruria development was 42 days. On multivariate analysis, age; female sex; acute GVHD; chronic GVHD; myeloablative conditioning regimen; cord blood transplantation; low CD3, CD4, CD8, and CD56 levels; and a low platelet count were significantly associated with BKV infection with mostly p values of ($P < 0.001$). In addition, BKV infection was associated with a lower overall survival duration ($P < 0.001$). Patients with BKV infections were more likely to be immunosuppressed for the first 3 years after transplantation than were patients without BKV infections. **Conclusions:** This study for the first time reports a significant association between BKV reactivation following allogeneic HSCT and decreased overall survival. In addition, this study provides valuable information on the immune status of HSCT recipients with BKV infections to help us formulate plans for more effective prevention and treatment of this infection.

7026 Poster Session (Board #15), Sun, 8:00 AM-11:30 AM

The relationship between *HIF* family gene expression in allogeneic T-cell products and acute graft-versus-host disease. *First Author: Joseph Rimando, National Institutes of Health, Bethesda, MD*

Background: Allogeneic hematopoietic cell transplantation (HCT) provides beneficial graft-versus-tumor effects (GVT) but is limited by graft-versus-host-disease (GVHD). In murine models and clinical trials, our group has shown that *ex vivo*-manufactured rapamycin-resistant donor T cells (T-rapa cells) provide a favorable balance of GVT and GVHD effects. Recently, T cells cultured in rapamycin for 6 days (TR_6) were found to mediate increased GVHD relative to T cells cultured for 12 days (TR_{12}); specifically, TR_6 recipients had approximately 40% acute GVHD whereas TR_{12} recipients had approximately 10% acute GVHD. The *HIF* gene family allows T cells to survive at hypoxic sites including potential GVHD target sites. We thus hypothesized that the increased GVHD mediated by the TR_6 cells relative to the TR_{12} cells might be due in part to differences in *HIF* family gene expression. **Methods:** We used microarray gene expression analysis (Agilent Platform) to find differences in *HIF* gene family expression (94 genes) between the TR_6 and TR_{12} clinical products (n = 40 products evaluated for each condition). To assess the impact of culture interval and rapamycin on *HIF* expression, we used western blotting to measure *HIF1/2* expression (see Table). **Results:** On gene expression analysis, the *HIF1/2* gene family was greatly upregulated in each TR_6 cell product relative to the TR_{12} cell products. When compared with T cells at culture initiation, T-rapa cells had decreased *HIF* family gene expression at day 3, increased expression at day 6, and decreased expression again at day 12. These RNA-based results were confirmed at the protein level with western blotting. **Conclusions:** Relative to TR_{12} cells, TR_6 cells have increased *HIF* family expression at both the RNA and protein level. Further studies will address our hypothesis that increased *HIF* expression in the TR_6 cells contributes to their increased GVHD potential.

Experimental design.

Experimental Cohort[1]	T Cell Culture[2]	Culture Duration
1	X	Initiation
2A/2B	X	4 hours
3A/3B	X	24 hours
4A/4B	X	3 days
5A/B	X	6 days
6A/B	X	12 days

[1]Cohorts A and B were without or with rapamycin (1 uM), respectively. [2]CD4+ T cells were cultured with anti-CD3/CD28 co-stimulatory beads, IL-2, and IL-4.

7027 Poster Session (Board #16), Sun, 8:00 AM-11:30 AM

Physical activity as a predictor of outcomes in hematopoietic stem cell transplantation (HSCT) recipients. *First Author: Asmita Mishra, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Prior analyses in cancer patients demonstrated lower mortality associated with greater physical activity. The association of recreational physical activity and mortality in patients receiving HSCT remains unclear. The aim of this retrospective study is to analyze the relationship between pre-HSCT self-reported physical activity by the IPAQ short form and post-HSCT outcomes. **Methods:** Data were collected from the Moffitt Cancer Center Health Research Informatics and transplant databases. Between 01/01/2011 and 11/19/2013, 238 consecutive and unique patients received either an autologous (auto) (n = 152) or allogeneic (allo) (n = 86) HSCT. IPAQ scoring algorithm was used to ascertain metabolic equivalent of task-hours (MET-hrs) per week. Based on MET-hrs/wk aggregate score, patients were subsequently divided into three activity categories: low (n = 61), moderate (n = 70), and vigorous (n = 107). **Results:** Median follow-up for survivors was 7.1 months (range 2.9-11.1 months). There was no significant difference in age, gender, KPS, CIBMTR disease risk, HCT-CI, conditioning intensity, number of prior chemotherapy regimens, and pulmonary function among the three categories (p = NS). For alloHSCT, six month overall survival differed significantly between the three groups [Low: 73% (95% CI: 50 – 87%); Moderate: 81% (59 – 91%); Vigorous: 91% (76 – 97%) P =0.0033] (Fig. 1). In univariate analysis, vigorous activity was associated with decreased risk non-relapse mortality compared to low activity (HR: 0.07 (95% CI: 0.01-0.56) P =0.0127). After adjusting for disease risk and KPS, alloHSCT recipients reporting vigorous activity had a lower mortality than those who reported low physical activity in multivariate analysis (HR: 0.189 (95% CI:0.063-0.567) P =0.0029). Self-reported physical activity is not associated with mortality, relapse-free survival, or non-relapse mortality in autoHSCT recipients (p = NS). **Conclusions:** Vigorous activity for patients undergoing HSCT is an independent predictor of survival after alloHSCT. Further studies are warranted to evaluate impact of physical activity on HSCT outcomes. An ongoing prospective single center trial assessing this is nearly complete.

7028 Poster Session (Board #17), Sun, 8:00 AM-11:30 AM

Association of higher total nucleated cell dose with improved survival in patients receiving donor lymphocyte infusion after allogeneic stem cell transplantation. *First Author: Nathan Singh, University of Pennsylvania, Philadelphia, PA*

Background: Donor lymphocyte infusion (DLI) after allogeneic stem cell transplant is an established therapy for disease relapse. Long-term survival after DLI remains poor, and identification of factors associated with improved outcomes is of significant interest. **Methods:** We retrospectively analyzed the total nucleated cell (TNC) dose of DLIs in 79 patients (pts) who received un-manipulated DLI at the University of Pennsylvania between 2000-2014. We included pts who received DLI for relapse or falling chimerism, but excluded those who received low dose ($\leq 0.5x10^8$TNC/kg) for stable mixed chimerism. Multivariable regression analyses were used to evaluate associations between cell dose, survival, best response and GVHD. Classification and Regression Tree (CART) analysis was used to identify optimal cutoff in the TNC dose. **Results:** Pts received DLI from sibling (61%) or unrelated (39%) donors, and 10% were HLA-mismatched. Median follow-up was 68 months (range 0.33-156.2). Median age was 53 years (21-75), and diseases included AML (47), MDS (15), NHL (8), ALL (2), CML (2), Hodgkin (2), myelofibrosis (2) and myeloma (1). Six pts received DLI for falling chimerism without overt relapse. The best response to DLI was complete response (CR) in 27 of 70 evaluable pts. Any GVHD and severe GVHD developed in 24 of 61 and 15 of 59 evaluable pts, respectively. We found that pts receiving $\geq 1.6x10^8$ TNC/kg had improved six-month (adjusted OR = 0.25, 95% CI [0.07-0.89], p = 0.03), one-year (aOR = 0.16, [0.04-0.77], p = 0.02), and overall survival (aHR = 0.47, [0.27-0.82], p = 0.01). A survival advantage for a higher TNC dose was also significant in the subset of AML and MDS pts (aHR = 0.41, [0.22-0.76], p = 0.005). Higher TNC dose did not correlate with development of any GVHD (aOR = 0.67, [0.22-2.06], p = 0.48) or grade III-IV GVHD (aOR = 0.51, [0.10-2.68], p = 0.43). There were also no significant differences in achieving a CR (aOR = 1.56, [0.40-6.10], p = 0.52). **Conclusions:** TNC dose of $\geq 1.6x10^8$ TNC/kg correlated with improved survival without an increased risk of developing GVHD, and thus higher target TNC doses should be considered in pts receiving DLI.

7029 Poster Session (Board #18), Sun, 8:00 AM-11:30 AM

A randomized controlled trial of ibandronate for the prevention of bone loss following allogeneic stem cell transplantation. *First Author: Xerxes Pundole, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Bone mineral density (BMD) loss occurs rapidly within the first year following allogeneic hematopoietic stem cell transplantation (alloHCT), which can lead to fractures. Nonpharmacologic prophylaxis measures are inadequate in preventing bone loss following alloHCT and the effect of ibandronate has not been evaluated. **Methods:** We performed a phase 3 single-center open-label randomized controlled trial of intravenous ibandronate to prevent BMD loss in adult recipients of alloHCT at The University of Texas MD Anderson Cancer Center. The treatment group received 3 mg of intravenous ibandronate over 15–30 seconds starting within 45 days of alloHCT and at 3, 6, and 9 months after alloHCT. All patients received daily calcium (500 mg) and daily vitamin D (400 IU) oral supplements twice daily for 12 months. We compared changes in BMD in the lumbar spine, femoral neck, and total hip at 6 and 12 months following alloHCT relative to baseline between treatment and control groups. **Results:** Of 414 patients screened, 78 were enrolled in the trial, 39 randomized to the ibandronate group and 39 to the control group. Baseline age, sex, race, underlying disease, donor type, stem cell origin, hormonal status, and baseline BMD did not differ significantly between the 2 groups. The treatment group had less BMD loss in the lumbar spine at 6 and 12 months than the control group ($P \leq 0.03$). Both groups lost more BMD in the femoral neck and total hip than in the lumbar spine at 6 and 12 months, and changes in BMD in the femoral neck and total hip at 6 months ($P = 0.33$ & $P = 0.10$ respectively) and 12 months ($P = 0.81$ & $P = 0.44$ respectively) did not differ significantly between groups. Both glucocorticoids and tacrolimus reduced BMD in the lumbar spine, but ibandronate had a significant protective effect and prevented this loss. **Conclusions:** Ibandronate prevents bone loss in the lumbar spine in patients who undergo alloHCT, particularly those who received high doses of glucocorticoids or tacrolimus. However, ibandronate does not completely prevent bone loss at the femoral neck and total hip. Pharmacologic agents with different mechanisms of action should be evaluated in this population for better prevention of bone loss. Clinical trial information: NCT00824993.

7030 Poster Session (Board #19), Sun, 8:00 AM-11:30 AM

Outcomes of hematopoietic stem cell transplant (HSCT) in HIV patients in HAART era. *First Author: Kathan Mehta, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Prior studies have shown that outcomes of HSCT in HIV patients are similar to non-HIV patients since effective implementation of HAART by 1998; but they are limited by small sample size or non-inclusion of recent data. **Methods:** We queried National Inpatient Sample, a largest inpatient dataset in US, from 1998 to 2012 for HSCT using ICD9 procedure code 41.0. HIV patients were identified by ICD9 diagnostic code of 042, 043, 044, V08 and 079.53. Primary outcome was in-hospital mortality and secondary outcomes were in-hospital complications of HSCT. **Results:** 39,517 Patients who underwent HSCT were identified (weighted N = 192,562). Among these 108 patients had HIV (weighted N = 520). There was no difference in in-hospital mortality, intubation, sepsis, bacteremia, or graft vs host disease (GVHD) between HIV and non-HIV patients after HSCT. In allogeneic HSCT, HIV patients had significantly higher incidence of non-tuberculous mycobacteria (NTM), cytomegalovirus (CMV) and fungal infections as compared to non-HIV patients. Incidence of stomatitis was lower in HIV patients after allogeneic HSCT. In autologous HSCT, herpes simplex virus (HSV) infection was more common in HIV patients (Table). **Conclusions:** While HIV patients are not at higher risk of serious in-hospital complications of HSCT, they are at higher risk of opportunistic infections (OI's). Further research is needed to prevent OI's in HIV patients after HSCT.

Outcomes of HSCT in USA.

	Autologous HSCT (weighted N = 112,365)			Allogeneic HSCT (weighted N = 80,198)

Post-transplantation long-term events in a cohort of HIV-positive patients affected by relapsed/refractory lymphoma. *First Author: Ernesto Zanet, National Cancer Institute CRO Aviano, Aviano, Italy*

Background: The advent of highly active antiretroviral therapy (HAART) allowed to extend autologous stem cell transplantation (ASCT) to the HIV-positive population. In the literature data are scarce concerning the long-term events in this population. **Methods:** We treated consecutively 36 HIV-positive patients (pts) affected by relapsed/refractory lymphomas with ASCT. Ten pts died during or early after ASCT due to progressive disease (4 pts), chemotherapy toxicity (1 pt) and infection (5 pts). We analyzed the post-ASCT long-term data of 26 pts, reaching a complete response after ASCT. All patients received HAART concomitantly to chemotherapy. **Results:** Two pts experienced a lymphoma relapse, after 4.27 and 3.08 years from ASCT, respectively. Five patients presented with a secondary malignancy (1 patient an anal squamous cell cancer, 1 patient a squamous cell carcinoma of the larynx and 1 patient a cervical intraepithelial neoplasia (CIN) grade 2, 1 patient a melanoma of the skin, 1 patient a HL developed in a patient primarily affected by NHL, respectively), with a median time of 3.01 years from ASCT. Nine patients had OI: 3 patients developed a Pneumocystis Carinii pneumonia, 1 patient a Cytomegalovirus pneumonia, 1 patient a Mycobacterium Avium Complex pneumonia, 1 patient a Herpes Simplex Chronic Ulcer, 3 patients cutaneous relapsing Herpes Zoster, respectively. The median time of OI appearance was 0.25 years (IQR: 0.11-2.33). Two pts died: one of lymphoma relapse, the other of car accident.With a median of 6-years follow up (IQR: 4.55-9.87) the OS and PFS of the entire sample of pts were 91% and 36% at 10 years, respectively. **Conclusions:** 24 out of 26 pts are still alive and in long-term complete remission after ASCT. These data confirm the long-term efficacy of ASCT. The appearance of OI is earlier than that of second malignancies after ASCT. The secondary malignancies developed by our pts are non-AIDS-defining cancers and at least three cases are linked to a viral pathogenesis (HPV for both anal cancer and cervical cancer precursor lesion; EBV for HL). Both OI and second malignancies were successfully managed and cured and the only long-term death occurred due to lymphoma relapse.

7032 Poster Session (Board #21), Sun, 8:00 AM-11:30 AM

Ratio of total leucocyte count to C-reactive protein: Does it help differentiate engraftment fever from infective fever in patients undergoing autologous stem cell transplant? *First Author: Sachin Punatar, Tata Memorial Centre, Mumbai, India*

Background: Engraftment fever (EF) is common in 2nd week post autologous hematopoietic stem cell transplant (auto HSCT). It is difficult to differentiate from infective fever (IF). This leads to unnecessary use and cost of antibiotics. Also timely treatment of EF may prevent progression to full blown engraftment syndrome (ES). We studied the role of total leucocyte count (TLC) to C-reactive protein (CRP) ratio in differentiating EF from IF. **Methods:** Consecutive patients with breakthrough fever (BF) from d+7 to d+15 post auto HSCT, from March 2011 to August 2013, were included in this retrospective analysis. BF was defined as new onset fever preceded by an afebrile period of at least 48 hours. BF episodes were classified as IF or EF. Fever was classified as IF if blood culture was positive, or there were radiological signs of infection or if fever subsided within 48 hours of change of antibiotics. EF was defined as fever associated with rising counts without any identifiable infective focus responding to steroids. Antibiotics were added at the onset of BF. If fever persisted beyond 48 hours and no infective cause was identified, systemic steroids were started. Daily morning TLC and CRP values were obtained from patients' records. TLC:CRP ratio was calculated from day of admission to day of discharge. Optimal cut-off value of the ratio on the day of BF was obtained by plotting a receiver operating curve. Sensitivity and specificity were calculated. **Results:** Seventy patients had BF of 110 auto HSCT patients. Nineteen had multiple myeloma, 50 had lymphoma and 1 neuroblastoma. Median day of neutrophil and platelet engraftment was 10 and 13 respectively. The median day of BF was 9. Sixty two patients had EF, among whom 15 had ES. We found an optimal value of 0.056 for differentiating between IF and EF. Using a ratio $>$ 0.056 for diagnosing EF, sensitivity and specificity were 63% (95% CI – 50 – 75%) and 100% (95% CI – 63 – 100%) respectively. **Conclusions:** In 2nd week post auto HSCT, a value of the ratio of TLC:CRP $>$ 0.056 on the day of BF is highly specific for EF. Prospective studies are warranted to confirm the results. This could help reduce unnecessary use and cost of antibiotics.

7033 Poster Session (Board #22), Sun, 8:00 AM-11:30 AM

Chemomobilization with (R)-ICE (rituximab, ifosfamide, carboplatin, etoposide) compared to G-CSF and plerixafor (G+P) mobilization in lymphoid malignancies. *First Author: Lauren Westfall Veltri, West Virginia Univ, Morgantown, WV*

Background: No studies have compared the efficacy and safety of chemomobilization with (R)-ICE against G+P mobilization in patients with lymphoid malignancies. **Methods:** We analyzed 126 consecutive patients with lymphoid malignancies undergoing chemomobilization with (R)-ICE (n = 63) or G + P (n = 63), in two different institutions. **Results:** Baseline characteristics are shown in Table 1. (R)-ICE mobilization provided a significantly higher total CD34+ cell yield (median 5.5×10^6 vs. 3.4×10^6 cells/kg, $P < 0.001$), day 1 CD34+ cell yield (2.4×10^6 vs. 1.7×10^6 cells/kg, $P = 0.009$) and CD34+ cell dose given at transplant (4.9×10^6 vs. 3.4×10^6 cells/kg, $P < 0.001$). The median number of apheresis sessions required was two in each group. Neutrophil engraftment was faster with (R)-ICE mobilization (median 10 days vs. 11 days, $P < 0.001$). Similarly platelet count recovery was faster with (R)-ICE (12 days vs. 16 days, $P < 0.001$). The transfusion of packed red blood cells was significantly higher in the (R)-ICE group. Plerixafor as a rescue was used in the (R)-ICE group if day 1 cell yield was $<1.0 \times 10^6$ cells/kg (n = 12). There were no mobilization failures (failure to collect a minimum of 2.0×10^6cells/kg) in the (R)-ICE group, while four patients in the G + P group had unsuccessful collection. **Conclusions:** Our analysis demonstrates that chemomobilization with (R)-ICE, allowing for plerixafor rescue on day 1 leads to better resource utilization with only 20% needing plerixafor and resulted in a higher total CD34+ cell yield with faster engraftment and minimal toxicities.

	Mobilization Strategy

The impact of HBO on early ALC recovery following high-dose therapy and autologous transplantation. *First Author: Omar Salah Aljitawi, University of Kansas Medical Center, Overland Park, KS*

Background: Historically, early absolute lymphocyte count (ALC) recovery (defined as ALC of 500 cells/microL day 15 of transplant) is seen in around 50% of patients receiving autologous stem cell transplantation (ASCT) and is associated with improved survival. Early ALC recovery is related to recovery of natural killer (NK) cells mediated by interluken-15 (IL-15). We are currently conducting a pilot study primarily investigating hyperbaric oxygen (HBO) as a modality to facilitate blood count recovery in ASCT setting. By lowering erythropoietin (EPO) at time of hematopoietic stem cell (HSC)/progenitor cell infusion, HBO appears to facilitate bone marrow homing of HSC/progenitors with retained multi-lineage potential. Accordingly, we hypothesized that HBO pre-treatment might facilitate early ALC recovery. **Methods:** Patients treated on the ongoing pilot study were evaluated for ALC recovery, as previously defined. Blood samples were collected at baseline (prior to high-dose chemotherapy), day 0 (prior to HBO and 6 hours later), 24- and 48-hours following HBO therapy, and on the third day of neutrophil engraftment. Plasma IL-15 was measured by ELISA. **Results:** Of the twenty patients who were treated on study, one patient did not tolerate HBO therapy and 2 patients were released to their oncologist prior to day 15 post-ASCT, accordingly 17 patients were assessable for ALC recovery. 13 out of the 17 patients (76%) achieved ALC 500 prior to day 15, and all achieved ALC 500 by day 18 post-ASCT. In our cohort, the median time to achievement of ALC 500 was 12 (8-18) days. To date, twelve patients had IL-15 levels measured in pg/ml for all time points except baseline level which was measured in 5 patients. Average IL-15 level was higher on day 0 prior to HBO therapy compared to baseline level (22.83 +/- 3.20 vs 4.94+/-1.38) and third day of neutrophil engraftment IL-15 level was higher than baseline level (13.1 +/- 1.7 vs 4.94 +/-1.38). IL-15 level peaked 48-hours following HBO therapy (31.9 +/-3.67). **Conclusions:** Compared to historic data, the rate of early ALC recovery in our HBO pilot study appears to be encouraging. HBO effects on post-ASCT ALC recovery and IL-15 warrant further evaluation. Clinical trial information: NCT02087657.

7035 Poster Session (Board #24), Sun, 8:00 AM-11:30 AM

Outcomes of ASCT for cardiac AL-amyloidosis and cardiac light chain deposition disease. *First Author: Al-Ola A. Abdallah, University of Arkansas for Medical Sciences Myeloma Institute for Research and Therapy, Little Rock, AR*

Background: Melphalan based autologous stem cell transplant (ASCT) can reverse the progression of systemic amyloidosis and light chain deposition disease (LCDD) in selected patients. However, role of ASCT in patients with cardiac involvement due to amyloidosis and LCDD is still unclear **Methods:** Our database at Myeloma Institute for Research and Therapy identified 53 patients, with biopsy proven cardiac amyloidosis and cardiac LCDD between January 2004 and December 2012. A retrospective analysis was performed to identify difference in outcomes between the patients who received ASCT or chemotherapy (CTX). **Results:** Out of these 53 patients, 5 patients were excluded because they did not receive treatment for plasma cell dyscrasia. 37 patients received ASCT and 11 patients received CTX, such as bortezomib, lenalidomide, low dose melphalan, interferon, and cyclophosphamide 66% (n = 32) patients had elevated Brain natriuretic peptide $>$ 500 Pg/ml, 40% (n = 19) had elevated lactate dehydrogenase $>$ 190, 15% (n = 7) had elevated levels of beta-2-microglobulin $>$ 3.5 mg/dl, 44% (n = 21) had elevated creatinine $>$ 1.5 mg/dl at the time of diagnosis. Echocardiogram showed speckled appearance in 19% (n = 9) patients, diastolic dysfunction was present in 58% (n = 28), systolic dysfunction was present in 27% (n = 13), 62% (n = 30) had increase diastolic intra-ventricular septum (IVSD) thickness measuring $>$ 1.3 cm. On a long term follow up, the group of patients with CA who received ASCT had median survival of 4.53 year compared to median survival of 1.85 years for those who received CTX (p = 0.69). 35% (n = 13) patients had life threatening events including severe congestive heart failure, arrhythmias and severe infections in the first 12 months of treatment with ASCT **Conclusions:** CA is aggressive disease with median survival of 8 months. Eligibility for ASCT in CA varies across institutions. Our single institution experience shows that patients with CA might benefit from ASCT with improvement in median survival as compared to those who received CTX. However ASCT should be further investigated with focused evaluation prior treatment, supportive care during and after treatment to decrease the risk of life threatening events.

7036 Poster Session (Board #25), Sun, 8:00 AM-11:30 AM

Long-term outcomes of rituximab use prior to autologous stem cell transplant (ASCT) in low-grade follicular lymphoma (FL) at the time of first progression. *First Author: Roberto Antonio Ferro, University of Nebraska Medical Center, Omaha, NE*

Background: Some studies suggest that prior use of rituximab is associated with poor outcomes following ASCT in relapsed diffuse large B-cell lymphoma (DLBCL). The effects of rituximab use prior to ASCT on long-term outcomes of FL are unclear. Rituximab in addition to ASCT has been associated with an increased risk of secondary primary malignancy (SPM) especially of solid tumors; however, this study included all lymphoma subtypes (J Clin Oncol 29:814-824, 2011). **Methods:** This is a retrospective study of 84 low grade FL patients treated by the Nebraska Lymphoma Study Groupbetween 1987-2013. We used the Chi-square or Fisher's exact tests to compare characteristics of patients who did vs. did not receive rituximab before ASCT. The Kaplan-Meier method was used to estimate overall survival (OS) and event-free survival (EFS). **Results:** 34 patients (40%) received rituximab prior to ASCT. Rituximab vs. no-rituximab groups were similar in sex distribution (males 74% vs. 54%, $p = 0.07$), more likely to be older (mean age of 51 vs. 44 years, $p = 0.0004$), have received 3 or more prior chemotherapy regimens (53% vs. 24%, $p = 0.004$) and less likely to have received total body irradiation (TBI) (3% vs. 74%, $p < 0.0001$). Rituximab group was more likely to be at second complete remission (53% vs. 14%, $p = 0.0004$) prior to ASCT. At a median follow-up of 10.2 years, 41 patients (49%) died. The 10-year EFS was similar (49% vs. 32%, $p = 0.10$) but the 10-year OS was better in the rituximab group (74% vs. 46%, $p = 0.009$). The risk of SPM (excluding non-melanoma skin cancers) was similar in the groups with or without rituximab (18% vs. 12%, $p = 0.21$). **Conclusions:** Within the limitations of this study, rituximab use prior to ASCT resulted in similar EFS but improved OS. In addition, we did not find an increased risk of SPM with rituximab use prior to ASCT. Patients who received rituximab prior to ASCT (performed at the time of first progression) have an OS of 74% at 10 years post-ASCT. Rituximab use prior to ASCT does not influence outcomes of subsequent ASCT in FL as it appears to do in DLBCL. The current study confirms that ASCT remains an excellent salvage option for patients previously treated with immunochemotherapy.

7037 Poster Session (Board #26), Sun, 8:00 AM-11:30 AM

Overall survival and treatment response in patients with myelodysplastic syndrome and acute myeloid leukemia treated with DNA methyl-transferase inhibitors vs. conventional care regimens: A meta-analysis of 5 randomized trials. *First Author: Seongseok Yun, University of Arizona, Tucson, AZ*

Background: Acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are two of the most common myeloid neoplastic disorders that are characterized by genetic instability and ineffective hematopoiesis. DNA methyl-transferase inhibitors (DMTI) have been widely used for elderly MDS and AML patients who are not qualified for stem cell transplantation (SCT), however the outcomes from previous trials were inconsistent. The purpose of current meta-analysis is to assess the efficacy of DMTI compared to conventional care regimens (CCRs) in patients with high risk MDS or AML. **Methods:** Relevant articles were searched in PubMed, EMBASE and Cochrane database. Eligible studies were limited to randomized trials comparing DMTI (azacitidine or decitabine) and CCRs (best supportive care, low dose cytarabine or intensive chemotherapy) in adult patients with MDS or AML. Cochrane's Q statistic was used for the calculation of the statistical heterogeneity. Relative risks and 95% CI were calculated using random effect model and RevMan 5.3 software. **Results:** Significant OS benefit was associated with DMTI treatment compared to CCR with OS of 33.2% vs. 21.4% (RR 0.83, 95% CI, 0.71 to 0.98, $P = 0.03$). CR/PR rate was also significantly higher in DMTI group with a response rate of 23.7% vs. 13.4% (RR 0.87, 95% CI, 0.81 to 0.93). In a subgroup analysis, only azacitidine treatment showed OS improvement (RR 0.75, 95% CI, 0.67 to 0.85), but not in decitabine (RR 0.96, 95% CI, 0.92 to 1.01). Additional subgroup analysis according to cytogenetic risk and BM blast counts did not show significant RR difference. **Conclusions:** In a meta-analysis of randomized trials in patients with MDS or AML, DMTI treatment was associated with treatment response and survival benefit, although the initial treatment response failed to translate into survival benefit in patients treated with decitabine. Collectively, these results suggest that azacitidine may be the best therapeutic option in high risk MDS or AML patients who are not eligible for allogeneic SCT regardless of cytogenetic risk or degree of bone marrow involvement.

7038 Poster Session (Board #27), Sun, 8:00 AM-11:30 AM

Exosome transcriptome analysis to provide novel tools for CLL patient stratification. *First Author: Raffaele Calogero, University of Torino, Torino, Italy*

Background: Routine diagnostic techniques can detect very low levels of CLL phenotype cells. Monoclonal B-cell lymphocytosis (MBL) is a diagnostic category encapsulating individuals with an abnormal B-cell population but not meeting the diagnostic criteria for a B-cell malignancy. MBL and CLL show similar karyotypes and mRNA/miRNA expression data were shown not to be suitable for a molecular discrimination between the two diseases. Exosomes are vesicles secreted into the extracellular environment. A growing body of evidence suggests that exosome-contained coding and non-coding RNAs may be used as biomarkers for the diagnosis and prognosis of malignant tumors. **Methods:** We analyzed the exosome transcriptome of 14 CLL patients and 13 MBL patients, characterized by similar karyotypes. We collected data for coding genes, fusion transcripts, long non-coding RNAs, snRNA, snoRNA, miRNA precursors and mature transcripts, using whole-transcriptome and small RNA sequencing analyses. **Results:** A subset of 8 CLL patients was characterized by a reduced expression of four miRNAs (miR-146a-5p, miR-151a-3p, miR-22-3p, miR-584-5p), which act as tumor suppressors in various solid cancers. Six of the above mentioned patients were also characterized by an up-modulation of TPT1, which is a predictor of poor prognosis in breast cancer. It is notable that TPT1 is located on q13-14.11, however, six out of eight samples with high TPT1 expression are characterized by 63% to 95% deletion of the long arm of chromosome 13, which suggests that TPT1 exosome expression is associated to the sub-population of CLL still retaining at least part of the long arm of chromosome 13. Furthermore, using a signature based on miR-6813 and two snRNA U2 pseudogenes we managed to stratify CLL patients in 4 groups, which are independent by the patient karyotype. MBL patients clustered all in the same group together with 3 CLL patients (21%). **Conclusions:** Our work describes an exhaustive analysis of the transcriptome of exosomes circulating in the peripheral blood of CLL/MBL patients. Our data suggest that the exosome transcriptome of CLL and MBL patients carries an important amount of non-coding RNAs, which might be instrumental for CLL patients' stratification.

7039 Poster Session (Board #28), Sun, 8:00 AM-11:30 AM

Cellular immunotherapy for refractory hematological malignancies. *First Author: John Leonard Reagan, Brown University Oncology Research Group, Providence, RI*

Background: Allogeneic cellular infusion is a potent immune stimulus. We present data from our FDA approved IND Phase II clinical trial (BrUOG 273) where allogeneic haploidentical lymphocytes are infused without prior chemotherapy or radiation to create a rejection response that hypothetically breaks host tumor tolerance. **Methods:** Eligible patients have relapsed or refractory acute leukemia. HLA haplo donors undergo leukapheresis without G-CSF priming. 1-2x10^8CD3+ cells/kg were infused unprocessed immediately after collection. Peripheral blood collected 1-4, 8-24, 34-48, 72-96 and 168-192 hours post infusion were examined for effector cell populations, stimulatory/inhibitory signals, and cytokine release profiles. Wilcoxon rank sum tests were used for statistical analysis. **Results:** Five patients were infused haplo donor cells. Four developed hyperpyrexia post infusion that lasted 24-48 hours (median T 0-4 hours post infusion 98°F, median Tmax 8-192 hours post infusion 102.4°F, $p = 0.009$). Host CD8 T cells demonstrated decreased perforin expression post compared to pre-infusion (median pre 77.6%, median post 61%, $p = 0.03$) with no changes in granzyme A/B, LAMP1, or FasL expression. Rapid up-regulation of PD-1 on host CD8 T cells (median pre 5.6, median post 49.7, $p = 0.005$) was present. Non-statistically significant upregulation of PD-1 ligands occurred on leukemic blasts from 0-4 to 34-48 hours post infusion. Cytokine release profiles post infusion showed high IL-10 (median 86pg/mL) with low IFNg (median < 1pg/mL) and IL-6 (median 7.47pg/mL) levels. One of five patients demonstrated a decrease in marrow blast counts post therapy (43% pre to 21% 4 weeks post infusion). No dose limiting toxicities or durable chimerism was seen. **Conclusions:** Haplo cellular infusions are well tolerated and show biological activity in relapsed AML. One of five patients had a reduction in marrow blasts with haplo infusion alone. Host CD8 T cells were less activated post infusion compared to pre-infusion and increased inhibitory PD-1 expression post infusion. Cytokine release profiles were more anti-inflammatory than those previously described. Greater initial CD8 T cell activation +/- immune checkpoint inhibitory blockade may improve efficacy. Clinical trial information: NCT01685606.

7040 Poster Session (Board #29), Sun, 8:00 AM-11:30 AM

A meta-analysis of randomized clinical trials in acute promyelocytic leukemia (APL). *First Author: Francesco Lo-Coco, University of Rome Tor Vergata, Rome, Italy*

Background: All-trans retinoic acid (ATRA) and arsenic trioxide (ATO) have dramatically improved treatment outcomes in Acute Promyelocytic Leukemia (APL). To address the question regarding the most effective and safe regimen for 1st-line APL, a meta-analysis was performed following a systematic review of the clinical literature in APL. **Methods:** A systematic literature review on all published randomized controlled trials (RCT) in APL identified 17 papers. One additional publication was included following discussions with a clinical expert. Comparable RCTs were grouped into networks based on similar induction and consolidation regimens, resulting in three networks for meta-analysis. Network 1 consisted of RCTs with ATRA, anthracycline (AraC), and chemotherapy (Chemo) regimens. Three trials with arsenic + ATRA arms made up Network 2; observation maintenance arms from 3 studies commprised Network 3. **Results:** In Network 1, ATRA + AraC + Chemo + ATO was associated with superior event-free survival (EFS) at 4 years (yrs) vs. ATRA + Chemo and ATRA followed by Chemo + AraC. The mean odds ratios (OR) were 4.45 (CI: 2.11-9.40, p = 0.00018) and 4.73 (CI: 2.44-9.16, p = 0.00001), respectively. Relative risks (RR) were not statistically significant. Mean results showed that EFS at 7 yrs for ATRA + AraC + Chemo + ATO was likely to be higher. Other outcomes did not demonstrate a statistically significant difference in treatment arms. In Network 2, ATRA + Realgar-Indigo naturalis formula (RIF, an oral arsenic derivative) in induction was associated with a higher disease-free survival (DFS) at 2 yrs compared to ATRA or ATO monotherapy. The RRs were 49.35 (CI: 1.66-1466.53, p = 0.01) and 15.53 (CI: .46-525.2, p = 0.04), respectively. Other outcomes included 2-yr DFS for monotherapy regimens of ATRA vs. ATO, complete remission rate, and liver-related adverse events, none of which had statistically significant results. In Network 3, no in DFS at 5 yrs were observed between treatment arms. **Conclusions:** Results suggest that regimens containing ATO or RIF appear to be associated with improved outcomes compared to those which include ATRA plus Chemo without ATO. Furthermore, the regimens which included ATO or RIF were not associated with increased toxicities.

7041 Poster Session (Board #30), Sun, 8:00 AM-11:30 AM

Impact of unbalanced karyotypes at diagnosis on prognosis of CML. *First Author: Ruediger Hehlmann, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany*

Background: Major route additional cytogenetic aberrations (ACA) at diagnosis of chronic myeloid leukemia (CML) indicate an increased risk of progression and shorter survival. Since all major route ACA are unbalanced it is unclear whether other unbalanced ACA at diagnosis also confer an unfavourable prognosis. **Methods:** On the basis of 1348 Philadelphia chromosome positive chronic phase patients of the randomized CML-study IV we examined the impact of unbalanced minor route ACA at diagnosis in comparison to major route ACA on prognosis. **Results:** At diagnosis, 1175 patients (87%) had a translocation t(9;22)(q34;q11) and 74 (5.5%) a variant translocation t(v;22) only, while a loss of the Y-chromosome (-Y) was present in addition in 44 (3.3%), balanced or unbalanced minor route ACA each in 17 (1.3% each) cases and major route ACA in 21 (1.6%) cases. Patients with unbalanced minor route ACA achieved complete cytogenetic remission, major molecular remission, progression-free survival (PFS) and overall survival (OS) at similar rates as did patients with t(9;22), t(v;22), -Y, and balanced minor route karyotypes. In contrast, patients with major route ACA had a shorter OS and PFS than all other groups ($p < 0.005$ for all pairwise comparisons with major route). Five year survival probabilities were for t(9;22): 91.4% (95% CI 89.5 – 93.1), t(v;22): 87% (77.2 – 94.3), - Y: 89.0% (76.7 – 97.0), balanced: 100%, unbalanced minor route: 92.3% (72.4 – 100), major route: 52.2% (28.2 – 75.5). **Conclusions:** We conclude that only major route, but not unbalanced minor route ACA at diagnosis have a negative impact on prognosis of CML. This observation of the prognostic relevance of specific cytogenetic aberrations for a given malignancy may be of importance also to other cancers. Clinical trial information: NCT00055874.

7042 Poster Session (Board #31), Sun, 8:00 AM-11:30 AM

Fludarabine, cyclophosphamide, and multiple-dose rituximab as frontline therapy for chronic lymphocytic leukemia. *First Author: Nicholas James Short, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: FCR results in durable responses in patients with previously untreated CLL. Previous reports suggest that dose-intensified rituximab increases response rates compared to standard-dose rituximab in patients with relapsed CLL. The effect of rituximab intensification of FCR in patients with previously untreated CLL is unknown. **Methods:** We evaluated the safety and efficacy of a modified FCR regimen with multiple-dose rituximab (FCR3) in 65 patients with previously untreated CLL. The FCR3 regimen consisted of six 28-day cycles of IV fludarabine (25 mg/m^2/d) and cyclophosphamide (250 mg/m^2/d) over 3 days. For cycle 1, rituximab was given at 375 mg/m^2 on day 1 and at 500 mg/m^2 on days 2-3. For cycles 2-6, rituximab was given at 500 mg/m^2 on days 1-3. Results were compared to a historical cohort treated with FCR. **Results:** The overall response rate to FCR3 was 97%. Forty-eight patients (75%) achieved CR, 10 (16%) achieved nPR, 4 (6%) achieved PR, and 2 (3%) did not respond to FCR3. Response rates were not significantly different from the historical FCR cohort. The median time to progression (TTP) for patients achieving CR, nPR and PR was 86 months, 49 months and not evaluable, respectively (P = 0.14 for CR vs. nPR). MRD negativity by flow cytometry was achieved in 62% of patients. Median TTP was 81 months, which was similar to the median TTP of 84 months with FCR (P = 0.63). Median OS was not reached, with 58% of patients still alive at a median survivor follow-up of 9.7 years (P = 0.58 compared to FCR). Thirty-one (65%) of those patients who achieved CR, 6 patients (60%) who achieved nPR and 1 patient (25%) who achieved PR are still alive. Grade 3-4 neutropenia, grade 3-4 thrombocytopenia and major infection were observed with 45%, 5% and 1.9% of FCR3 courses (not significant compared to FCR). Therapy-related MDS or AML developed in 7 patients (11%) (P < 0.01 compared to FCR) at a median of 32 months and accounted for 26% of all deaths. **Conclusions:** In patients with previously untreated CLL, FCR3 resulted in similar response rates, TTP and OS compared to a historical cohort of patients treated with FCR. FCR3 was associated with a significantly increased incidence of therapy-related MDS/AML, which warrants further evaluation. Clinical trial information: NCT00794820.

7043 Poster Session (Board #32), Sun, 8:00 AM-11:30 AM

Safety and activity of blinatumomab for older patients (pts) with relapsed/refractory (R/R) B-precursor acute lymphoblastic leukemia (ALL) in two phase 2 studies. *First Author: Hagop M. Kantarjian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment options for older pts with R/R ALL are limited. Blinatumomab is a bispecific T-cell engager (BiTE) antibody construct that directs cytotoxic T cells to CD19-expressing B cells, and is approved in the US for treatment of Ph- R/R ALL. In two phase 2 adult studies of blinatumomab (Topp MS, et al. *J Clin Oncol*. 2014;32:4134-40; Topp MS, et al. *Lancet Oncol*. 2015;16:57-66), 69% and 43%, respectively, achieved complete response (CR) or CR with partial hematologic recovery (CRh*). We report pooled data for the combined subsets of older pts (≥ 65 yrs). **Methods:** Pts with R/R B-precursor ALL received open-label blinatumomab by continuous IV infusion (4 weeks on/2 weeks off). Pts achieving CR or CRh* after two cycles could receive three consolidation cycles. Response was assessed by bone marrow aspiration. CR required blasts < 5%, ANC > 1000/μL and platelets > 100,000/μL. CRh* required blasts < 5%, ANC > 500/μL and platelets > 50,000/μL. Minimal residual disease (MRD) was detected by ASO-PCR of Ig heavy chain loci. **Results:** 36 older pts (median age 70 yrs, range 65-79) received blinatumomab for a median (range) of 2 (1-6) cycles. 20 (56%) pts achieved best response of CR/CRh* within two cycles, including 14 (39%) CR and 6 (17%) CRh*. Among responders, 12 (60%) had complete MRD response and 4 other pts had detectable MRD but < 10^{-4}. With median follow-up of 18.2 months, median (range) relapse-free survival for responders was 7.4 (1.0-34.0) months. With median follow-up of 29.4 months, overall survival was 5.5 (0.3-41.9) months. 10 (28%) pts were alive at last follow up; 6 in remission. 2 (10%) responders underwent allogeneic HSCT after blinatumomab. Treatment-emergent adverse events (AE) CTCAE grade ≥ 3 were reported for 31 (86%) pts, most commonly febrile neutropenia (22%) and neutropenia (19%). Neurologic AE occurred in 26 (72%) pts, including grade ≥ 3 events for 28%. 1 (3%) pt had grade ≥ 3 cytokine release syndrome. Of 7 fatal AEs, none were considered related to treatment. **Conclusions:** Older pts (≥ 65 yrs) with R/R ALL in two phase 2 studies of open-label blinatumomab had similar treatment responses and tolerability as pts in the overall study populations. Clinical trial information: NCT01209286 and NCT01466179.

7044 Poster Session (Board #33), Sun, 8:00 AM-11:30 AM

Phase 1 study of CWP232291 in relapsed/refractory acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CWP232291, a novel peptidomimetic small molecule identified via a phenotypic drug discovery screen, shows selective inhibitory activity at submicromolar levels on a Wnt gene reporter and decreases expression of the β-catenin target genes, cyclin D1 and survivin. It has broad anti-cancer efficacy in vitro, with significant preclinical tumor regression outperforming standard cytotoxic AML drugs. **Methods:** Subjects with relapsed AML or MDS were infused CWP232291 iv over 5 -30 minutes for 7 days in 21-day cycles until disease progression in a first in human, 3+3 dose-escalation, Phase 1 design. **Results:** Results to January 27, 2015 over a dose range of 4 – 257 mg/m^2 in 56 patients (53 AML; 3 MDS) are reported. Common (≥ 10% patients) drug-related adverse events (AEs) included nausea (43%), infusion-related reaction (36%), vomiting (29%), diarrhea (16%), and anorexia (11%). Toxicity was mostly ≤ grade 2 (91%), grade 3/4 events comprised 9%, observed similarly across all dose cohorts. Related serious AEs comprised fever, nausea, and anaphylactic reaction, at 19, 54 and 198 mg/m^2, respectively. Dose-limiting toxicity included nausea, rash and anaphylactic reaction (54, 153 and 198 mg/m^2, respectively). Toxicity was managed effectively with standard-of-care medications and, in the event of recurrence, could be mitigated with prophylaxis in subsequent cycles. Within 30 minutes CWP232291 was completely converted to its active metabolite, CWP232204. CWP232204 maximum plasma concentration (C_{max}) and area under the time-concentration curve (AUC) values were dose proportional. At the highest dose with data (153 mg/m^2; n = 6), the mean terminal elimination half-life (t½) was 6.3 hrs, mean C_{max} was 9922 ng/mL, and AUC was 6797 ng●hr/mL. A complete remission was seen in one AML patient after 2 cycles at 153/118 mg/m^2, with normalization of neutrophil and platelet counts; maximum reduction from baseline in β-catenin and survivin expression were > 90% and 77%. No other objective responses were seen but higher doses showed significant reductions in these biomarkers. **Conclusions:** CWP232291 single agent efficacy was observed in AML. MTD has not been defined; accrual is ongoing. Clinical trial information: NCT01398462.

7045 Poster Session (Board #34), Sun, 8:00 AM-11:30 AM

Impact of nilotinib treatment on subclinical cardiovascular biomakers. *First Author: Martine Gardembas, Hospital University Center of Angers, Angers, France*

Background: Nilotinib is a tyrosine kinase inhibitor targeting the BCR-ABL1 oncoprotein. It has been approved for the treatment of chronic myeloid leukemia-CP. Recently, a higher rate of cardiovascular events (CVE) have been reported as part of the non hematological nilotinib related adverse events. Although the CVE events may be influenced by several factors including pro-atherogenic and anti-angiogenic properties of nilotinib, the contribution in the atherosclerotic process still remains unclear. The purpose of this cross-sectional study was to determine the impact of nilotinib treatment on subclinical atherosclerotic biomarkers. **Methods:** 15 patients (mean 44 yrs ±14 yrs, 8 men) treated with nilotinib (Nilo) were compared to 30 age- and gender-matched patients with metabolic syndrom (MS) and 30 healthy controls. Subclinical atherosclerosis was assessed by the presence of carotid, aortic and femoral plaques, intima media thickness (IMT), arterial stiffness (Beta index), ankle brachial pressure index (ABI), and brachial arterial pressure (BAP). The overall cardiovascular risk (CVR) was determined according the 10 years-Framingham CV score. Statistical differences ($p < 0.05$) between the groups were determined by Chi2 and Kruskal-Wallis or ANOVA statistics as appropriate (Stata 12.1). **Results:** Median duration exposure to nilotinib was 1299 days (range 252-2196). Plaques were significantly more frequent ($p = 0.007$) in the Nilo group (53%) than in healthy controls (13 %,) but no difference between Nilo and MS group (63%, $p = 0.371$). There were no statistically significant differences in IMT ($p = 0.271$), Beta stiffness index ($p = 0.428$), ABI and BAP. The CVR score in Nilo group was similar than in the control group ($p = 0,136$). **Conclusions:** Patients treated with nilotinib exhibited a higher amount of plaques although at a lower CVR score. These data would suggest that patients treated with nilotinib, likely develop focal lesions rather than a systemic arteriosclerotic process. Subclinical cardiovascular biomarkers could provide more targeting options for the personalized follow-up of patients treated with nilotinib. However, these preliminary data need to be confirmed in a larger longitudinal study. Clinical trial information: NCT02161978.

7046 Poster Session (Board #35), Sun, 8:00 AM-11:30 AM

Survival of de novo and secondary acute promyelocytic leukemia: A propensity matched analysis of the Surveillance, Epidemiology and End Results database. *First Author: Ranjan Pathak, Reading Health System, Wyomissing, PA*

Background: Secondary acute promyelocytic leukemia (sAPL) is an uncommon entity with no prior large population-based studies. It is unclear whether there is any difference in the overall survival (OS) of sAPL and *de novo* APL. **Methods:** We used the Surveillance, Epidemiology, and End Results (SEER) 13 database and appropriate International Classification of Disease (ICD-O-3) histology codes to identify adult patients with sAPL and *de novo* APL diagnosed between 1992 and 2011. Propensity matching was performed using the MatchIt package of R v2.15.2 to create a matched dataset of sAPL and *de novo*APL. Kaplan Meier survival and multivariate analysis (Cox proportional hazard regression model) was performed using SPSS v22.0. **Results:** sAPL (n = 109) accounted for 5.5% of all APL cases (n = 1964). Crude incidence of sAPL was 0.85 per 10,000 primary malignancies. Patients with sAPL, compared to *de novo* APL, were more likely to be older (65 vs. 44 years, $p < 0.001$), White (85% vs. 79%, $p = 0.003$) and diagnosed after year 2005 (53% vs. 40%, $p = 0.008$). The two subgroups did not differ by gender ($p = 0.665$) and marital status ($p = 0.745$). Mortality rate within 1 month of diagnosis was similar between sAPL and de novo APL (28.9% vs. 23.0%, $p = 0.20$). One-year (55% vs. 57%, $p = 0.70$), two-year (51% vs. 54%, $p = 0.79$) and five-year (42% vs. 50%, $p = 0.24$) OS rates were similar. In a multivariate analysis, sAPL was not associated with a significantly worsened OS as compared to *de novo*APL (HR 1.11; 95% CI 0.78-1.58; $p = 0.546$). OS was worse with older age at diagnosis but better in more recent years. Compared to patients < 55 years, patients 55-70 years (HR 1.86, 95% CI 1.02-3.41, $p = 0.043$) and > 70 years (HR 4.64, 95% CI 2.54-8.46, $p < 0.001$) were more likely to have worse OS. Compared to patients diagnosed before 1995, OS was better among patients diagnosed in the recent years (HR after 2005, 0.37, 95% CI 0.17-0.80, $p = 0.012$). **Conclusions:** This is the largest population-based study utilizing propensity matched analysis that demonstrates similar OS in sAPL and *de novo* APL. This indicates that the patients with sAPL can be managed very similarly to *de novo* APL and do not need to be excluded from clinical trials of APL.

7047 Poster Session (Board #36), Sun, 8:00 AM-11:30 AM

Four-year minimum follow-up of ongoing patients (pts) with chronic-phase chronic myeloid leukemia (CP-CML) in a phase 1 trial of ponatinib (PON). *First Author: Moshe Talpaz, University of Michigan, Ann Arbor, MI*

Background: PON, an approved oral tyrosine kinase inhibitor (TKI), has potent activity against native BCR-ABL and resistant mutants, including T315I. A phase 1 trial evaluated PON safety and antileukemic activity; this analysis includes 4-year minimum follow-up of ongoing pts, the longest follow-up of PON-treated pts to date. **Methods:** Pts (N = 81) with resistant/refractory hematologic malignancies received PON (2–60 mg qd) in this ongoing, open-label, dose-escalation trial (NCT00660920; enrollment 2008–2010; data cutoff, 26 Sept 2014). The median follow-up for 43 CP-CML pts was 49.9 (1.7–69.9) mo; minimum follow-up for 22 ongoing CP-CML pts was 50.2 mo. **Results:** Data are reported for CP-CML pts. Median age was 55 years; time since diagnosis 6.6 years. 60% of pts had received ≥ 3 TKIs; 63% had BCR-ABL mutations (28% T315I). At time of analysis, 51% remained on study. Most common reasons for discontinuation: adverse events (AEs) 26%; progression 9%. By intention-to-treat analysis: major cytogenetic response (MCyR) was 72%; complete cytogenetic response (CCyR), 65%; major molecular response (MMR), 56%; MR4, 42%; and MR4.5, 28%; responses are durable (**Table**). Median durations of MCyR, CCyR, and MMR were not reached. Of 22 ongoing pts at data cutoff, 18 (82%) were in CCyR; 17 (77%) had MMR or better (MMR n = 6; MR4 n = 1; MR4.5 n = 10). Most common treatment-emergent AEs were rash 65%, fatigue 60%, abdominal pain 58%, headache 58%, and arthralgia 53%. Arterial occlusive event (AE/serious AE) rates were 40%/30%, including cardiovascular (30%/21%), cerebrovascular (9%/7%), and peripheral vascular (14%/9%); venous thromboembolic event rates were 5%/0%. **Conclusions:** These data represent the longest follow-up with PON. With 4-year minimum follow-up for ongoing pts, PON continues to provide benefit to ongoing CP-CML pts with prior TKI failure. Risks and benefits should be evaluated when using PON. Clinical trial information: NCT00660920.

Stability of Response in CP-CML Pts Treated With PON.

	Responders, n	Lost Response, n[a]	Maintain Response at 4 Years, % (95% CI)[b]
MCyR	31	8	68 (44–84)
CCyR	28	8	70 (48–84)

Safety and feasibility of anticoagulation prophylaxis with enoxaparin in acute lymphoblastic leukemia during asparaginase-based intensification therapy. *First Author: Hassan Abdulmaoula Sibai, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Venous thromboembolism (VTE) is a well-known complication in adults receiving asparaginase (ASP) for acute lymphoblastic leukemia (ALL). We previously reported 27.3% VTE rate in patients (pts) receiving a modified Dana Farber Cancer Institute (DFCI) intensification phase. Low-dose enoxaparin (ENOX) was not associated with lower rate of VTE. We describe escalated dose of ENOX in adults treated with this protocol. **Methods:** 38 pts with ALL treated with a weekly ASP-based modified DFCI intensification for 21-30 weeks, received ENOX 1 mg/kg subcutaneously daily (**adjusted-dose group**).The result was compared with a similar group of 41 pts receiving ENOX 40 mg for pts weighing $<$ 80 kg, or 60 mg for pts $\geq$ 80 kg (**low-dose group**), and to a historical cohort of 99 pts treated with the same protocol, without prophylaxis. **Results:** There was no significant difference among groups with respect to median age, weight and number of cycles. The actual mean dose of ENOX in the low-dose group was 0.62 mg/kg, as compared to 0.84 mg/kg in the adjusted-dose group. No major bleeding complications were observed. Minor bleeding rate was 5%.VTE rate in the entire cohort was 22.7%.VTE rate in pts receiving adjusted dose ENOX was 18%, as compared to 26.8% in the low-dose group. There was no significant difference in the VTE rate according to age or gender. Sites of VTE in the prophylaxis groups included lower extremity (9), sagittal sinus (3), central line related (5) and pulmonary embolism (8); some pts had $>$ 1 site. **Conclusions:** Prophylactic ENOX during intensification in adults with ALL was safe: despite dose increase to 1 mg/kg, no increase in bleeding events was observed. There was trend toward a lower rate of VTE with 1 mg/kg ENOX, particularly in patients weighing $\geq$ 80 kg; however, a larger cohort is needed to determine if the difference is significant.

	No Prophylaxis n = 99	ENOX low-dose n = 41	ENOX adjusted-dose n = 38	P-value*
Rate of VTE	27/99 (27.3%)	11/41 (26.8%)	7/38(18%)	0.42
Weight < 80 kg	18/67 (26.9 %)	4/26 (15.3%)	5/29 (17.2%)	1
Weight > 80 kg	9/32 (28.1%)	7/15 (46.7%)	2/9 (22%)	0.38

7049 Poster Session (Board #38), Sun, 8:00 AM-11:30 AM

Elevated blood pressure (BP) and adverse events (AEs) of hypertension (HTN) in ponatinib (PON) leukemia trials. *First Author: Hanna Jean Khoury, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: PON is a potent, multitargeted tyrosine kinase inhibitor with proven efficacy in resistant Ph+ leukemia. This analysis reports elevated BP and AEs of HTN in PON leukemia trials. **Methods:** PON safety and efficacy were evaluated in patients (pts) with relapsed/refractory hematologic malignancies in the ongoing phase (ph) 1 trial, in heavily pretreated CML/Ph+ ALL pts in the ongoing PACE (ph 2) trial, and in newly diagnosed CP-CML pts in the terminated EPIC (ph 3) trial vs imatinib (IM). Ph 1 and EPIC, but not PACE, excluded pts with uncontrolled HTN (untreated systolic/diastolic $>$150/$>$100 mm Hg in ph 1, $>$ 140/$>$ 90 mm Hg in EPIC). Elevated BP was defined by single highest measurement (systolic/diastolic): grade (G) 1/pre-HTN 120–139/80–89, G2 140–159/90–99, G3 $\geq$ 160/$\geq$ 100 mm Hg. HTN AEs were reported by investigators. **Results:** Elevated BP was frequent at trial entry; G1/G2–3 rates: 44%/42% in ph 1; 37%/47% in PACE; 51%/19% PON vs 52%/12% IM in EPIC. Any increase in BP grade from baseline was also frequent: 74% in ph 1; 68% in PACE; 68% PON vs 51% IM in EPIC. In PACE, estimated systolic/diastolic BP increases over time were low: 2.3/0.7 mm Hg/year. HTN AEs were reported in 38%, 28%, 18%, and 2% of ph 1, PACE, EPIC-PON, and EPIC-IM pts, respectively. Hypertensive crisis was reported in 2 PACE and 2 EPIC-PON pts. HTN AEs did not lead to discontinuation or death. Few pts had dose modifications for HTN AEs (0% ph1; 5% PACE; 3% EPIC-PON; 0% EPIC-IM). A retrospective multivariate analysis of pooled pts showed HTN AEs were significantly associated with PON dose intensity. **Conclusions:** Increase in BP was frequently observed in PON trials, including in pts on IM. Rates of HTN AEs were relatively lower and seen primarily with PON. While associated with PON dose intensity, HTN AEs rarely led to change in therapy. Given BP variability, AE reporting may be a more reliable indicator of clinically meaningful HTN. Clinical trial information: NCT00660920; NCT01207440; NCT01650805.

Phase I trial of α-particle therapy with actinium-225 (^{225}Ac)-lintuzumab (anti-CD33) and low-dose cytarabine (LDAC) in older patients with untreated acute myeloid leukemia (AML). *First Author: Joseph G. Jurcic, Columbia University Medical Center, New York, NY*

Background: ^{225}Ac-lintuzumab consists of a radiometal that emits 4 α-particles linked to an anti-CD33 antibody. A phase I trial showed safety and efficacy of ^{225}Ac-lintuzumab in relapsed AML. We are conducting a multicenter, phase I trial to determine the maximum tolerated dose (MTD), toxicity, and activity of fractionated-dose ^{225}Ac-lintuzumab combined with LDAC. **Methods:** Patients $\geq$ 60 yrs with untreated AML not suitable for standard induction were eligible. Patients received LDAC 20 mg BID for 10 d every 4-6 wks for up to 12 cycles. During Cycle 1, 2 doses of ^{225}Ac-lintuzumab were given one week apart, 4-7 d following LDAC. ^{225}Ac doses were escalated using a 3+3 design. **Results:** Twelve patients (median age, 77 yrs; range, 68-87 yrs) were treated. Eight (67%) had prior myelodysplastic syndrome, for which 6 (75%) received hypomethylating agents (n = 5) or allogeneic stem cell transplant (n = 1). One (8%) had chronic myeloid leukemia in molecular remission prior to AML. Nine patients (75%) had intermediate-risk and 3 (25%) had poor-risk AML. Median CD33 expression was 74% (range, 45-100%). ^{225}Ac-lintuzumab was given at 0.5 (n = 3), 1 (n = 6), or 1.5 (n = 3) μCi/kg/fraction. Up to 4 cycles were given, and 2 patients remain on therapy. DLT was seen in one patient at 1 μCi/kg/fraction who had grade 4 thrombocytopenia and marrow aplasia $>$ 6 wks after therapy. Grade 3/4 toxicities included neutropenia (n = 2), thrombocytopenia (n = 3), febrile neutropenia (n = 6), pneumonia (n = 3), bacteremia (n = 1), cellulitis (n = 1), transient creatinine increase (n = 1), hypokalemia (n = 1), rectal hemorrhage (n = 1), and generalized weakness (n = 1). Six of 8 patients (75%) evaluated after Cycle 1 had bone marrow blast reductions (mean reduction, 68%; range, 34-100%). Five patients (63%) had blast reductions of $\geq$ 50%, but no remissions were observed to date. Median progression-free survival (PFS) was 2.4 mos (range, 1.3+-16.9 mos). **Conclusions:** Fractionated-dose ^{225}Ac-linutuzmab can be combined safely with LDAC and has antileukemic activity. Accrual continues to define the MTD. Additional patients will be treated at the MTD to determine response rate, PFS, and OS. Clinical trial information: NCI-2014-01360, NCT01756677.

7051 Poster Session (Board #40), Sun, 8:00 AM-11:30 AM

Re-exposure to blinatumomab after CD19-positive relapse: Experience from three trials in patients (pts) with relapsed/refractory B-precursor acute lymphoblastic leukemia (R/R ALL). *First Author: Max S. Topp, Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, Germany*

Background: Blinatumomab is a bispecific T-cell engager antibody construct designed to link cytotoxic T cells and CD19-positive B cells, inducing tumor cell lysis. In this combined analysis, we evaluated outcomes for patients with R/R ALL enrolled in 3 open-label phase 2 studies (NCT01471782 [study 205], NCT01209286 [study 206], NCT01466179 [study 211]) who received retreatment with blinatumomab following hematologic relapse after initial blinatumomab response. **Methods:** Patients were $<$ 18 (205) or $\geq$ 18 (206 and 211) years of age with Ph- R/R B-precursor ALL. Blinatumomab was dosed by continuous IV infusion. A cycle was 4 weeks on, 2 weeks off. The primary endpoint was hematological remission within 2 cycles. Patients with relapse following a response of $\geq$ 3 months duration could receive up to 3 cycles of retreatment; patients with GVHD or CNS involvement were ineligible. **Results:** Eleven patients received retreatment with blinatumomab (205, n = 2; 206, n = 5; 211, n = 4). Seven (64%) were male; mean (range) age was 31 (4, 77). At the time of initial treatment, 9 (81%) had $\geq$ 1 line of prior salvage chemotherapy; 7 (64%) had prior HSCT. Among 10 patients who achieved hematological remission during the 2 cycles of initial treatment, the median (range) duration of response prior to relapse was 9 (3-11) mo. Five (45%) patients had HSCT between first blinatumomab response and relapse. Outcomes during retreatment are shown in the table. One patient was retreated a second time and obtained a CR. **Conclusions:** Four (36%) patients with R/R ALL who relapsed following initial response responded to retreatment with blinatumomab. Overall, rates of adverse events occurring during retreatment were similar to those observed in the full studies. Clinical trial information: NCT01471782, NCT01209286, and NCT01466179.

	Retreated Patients (n = 11)

7052 Poster Session (Board #41), Sun, 8:00 AM-11:30 AM

***RAS* mutation acquisition at transformation from myelodysplastic syndrome to acute myeloid leukemia to predict poor outcome.** *First Author: Talha Badar, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although *RAS* mutation (m) in de novo MDS has not shown to influence outcome but it does have prognostic value when acquire later in disease course (Takahashi et al. Leukemia. 2013; 27 (10): 2081-3). We sought to further characterize the acquisition of *RAS*m at the time of transformation to AML in a large group of MDS patients and assessed its prognostic impact. **Methods:** We retrospectively analyzed 289 MDS patients who had wild type (wt) *RAS* at the time of MDS diagnosis and were referred to our institution between 2002 and 2013. Ninety eight (34%) patients had repeat mutation testing at the time of transformation to AML, and we evaluated these patients for the frequency of *RAS*m acquisition and its clinical implications. **Results:** Twenty two (22%) patients acquired *RAS*m at the time of transformation to AML. At the time of diagnosis of MDS, the median age was 65 years (range 26-83). Five percent, 14%, 22%, 25%, and 32% patients had R-IPSS very low, low, intermediate, high, and very high-risk disease, respectively. The median number of therapies patients received for MDS was 1 (range 0-4), and 8 patients had stem cell transplants (SCT). At the time of transformation to AML, the median age was 59 years (range, 27-86). In 22 (22%) patients who had poor-risk cytogenetics (complex, -7/7q-, -5/5q-, or inv 3), 14 (14%) acquired *RAS*m versus 8 (8%) who had wt *RAS* ($p = 0.33$). Most patients received either cytarabine- or hypomethylating agent-based induction regimens. Overall, 25% (12% with *RAS*m and 13% with wt *RAS*) achieved CR/CRi ($p = 0.17$), and 15 (15%) patients had SCT. The median survival after leukemia transformation in *RAS*m patients was 3.6 months compared to 7.5 months in *RAS* wt patients ($p = 0.0002$). When we excluded patients with poor risk cytogenetics, median survival was 3.9 months for *RAS*m patients versus 9.3 months for *RAS*wt ($p < 0.001$). In a multivariate analysis, *RAS*m (hazard ratio [HR] = 2.9, $p < 0.0001$) and t-MDS/AML (HR = 2.0, $p < 0.01$) were associated with poor prognosis, and SCT was associated with a favorable outcome (HR = 0.30, $p < 0.001$). **Conclusions:** Acquisition of *RAS*m at the time of transformation to AML is associated with poor outcome and it may provide opportunities for targeted therapy.

7053 Poster Session (Board #42), Sun, 8:00 AM-11:30 AM

O-desulfated heparin and chemotherapy for the treatment of AML. *First Author: Tibor Kovacsovics, Huntsman Cancer Institute-University of Utah, Salt Lake City, UT*

Background: Acute myeloid leukemia (AML) therapy is associated with pancytopenia and a high failure rate due to resistant leukemia stem cells that use CXCL12/CXCR4 to home to marrow niches. Platelet factor 4 (PF4) negatively regulates megakaryopoiesis. O-desulfated heparin (ODSH), a low anticoagulant heparin derivative, inhibits PF4 and like other heparins, may inhibit CXCL12/CXCR4. This study combined ODSH with chemotherapy for the treatment of AML. **Methods:** Adults with newly diagnosed non-APL AML were enrolled. Induction consisted of cytarabine and idarubicin (7+3). Following a bolus, ODSH was given as a continuous infusion on days 1 – 7. Patients younger than 60 received consolidation therapy with high dose cytarabine along with ODSH. Growth factors were not used during induction. Primary endpoints were safety and tolerability of ODSH, and its effect on platelet count recovery. Secondary endpoints included the effect of ODSH on complete remission (CR) rate. The effect of ODSH on CXCL12/CXCR4 was studied using an ELISA assay. **Results:** Twelve patients were enrolled (median age 56, range 22 – 74, 3 women). Three, 5, and 4 patients had good, intermediate, and poor risk disease, respectively. Two patients did not finish induction due to events unrelated to ODSH. Day 14 bone marrows were available on 11 patients and were aplastic in all without detectable leukemia. Eleven patients had a morphologic CR after 1 induction (2 with minimal residual disease). Ten patients remain in CR1. One elderly patient relapsed 6 months after completing consolidation therapy off study. Four patients received an allogeneic stem cell transplant in CR1. All patients who received a full induction were evaluable for platelet recovery and had a median day to an untransfused platelet count $\geq$ 20,000/μl of 22 (range 18 – 23). Six patients who received a full induction were evaluable for neutrophil recovery and had a median day to a neutrophil count $\geq$ 500/μL of 23 (range 20 – 27). No ODSH-associated adverse events occurred. ODSH inhibited the CXCL12/CXCR4 axis *in vitro* at concentrations achievable *in vivo*. **Conclusions:** ODSH is well tolerated when combined with intensive therapy for AML. It may enhance count recovery and treatment efficacy. Further study of this strategy is justified. Clinical trial information: NCT02056782.

7054 Poster Session (Board #43), Sun, 8:00 AM-11:30 AM

A multidrug resistant engineered CAR T cell for allogeneic combination immunotherapy. *First Author: Julien Valton, Cellectis SA, Paris, France*

Background: the adoptive transfer of CAR T cell represents a highly promising strategy to fight against multiple cancers. The clinical outcome of such therapies is intimately linked to the ability of effector cells to engraft, proliferate and specifically kill tumor cells within patients. When allogeneic CAR T cell infusion is considered, host versus graft and graft versus host reactions must be avoided to prevent rejection of adoptively transferred cells, host tissue damages and to elicit significant antitumoral outcome. This work proposes to address these three requirements through the development of multidrug resistant TCR$\alpha\beta$-deficient CAR T cells. **Methods:** Primary T cells were successfully engineered using the TALEN technology **Results:** we demonstrate that these engineered T cells displayed efficient antitumor activity and proliferated in the presence of drugs, currently used in clinic as preconditioning lymphodepleting regimens. The absence of TCR$\alpha\beta$ at their cell surface along with their drug-resistance properties could prevent their alloreactivity and enable them to resist to lymphodepleting regimens that may be required to avoid their ablation via HvG reaction. **Conclusions:** by providing a basic frame work to develop a universal T cell compatible with allogeneic adoptive transfer, this work is laying the foundation stone of the large scale utilization of CAR T cell immunotherapies.

7055 Poster Session (Board #44), Sun, 8:00 AM-11:30 AM

Allogeneic hematopoietic cell transplant (HCT) in patients (pts) $\geq$ 60 years of age with first relapsed or refractory acute myeloid leukemia (R/R AML) after treatment with vosaroxin plus cytarabine (vos/cyt) vs placebo plus cytarabine (pla/cyt): Results from VALOR. *First Author: Gary J. Schiller, UCLA, Los Angeles, CA*

Background: Increasing numbers of older pts with AML receive HCT due to wider donor availability and improvements in supportive care that reduce transplant-related morbidity/mortality. VALOR, a large phase 3 trial of vos/cyt vs pla/cyt in pts with R/R AML [NCT01191801], provided the opportunity to assess outcomes of HCT in pts $\geq$ 60 y/o with R/R AML. **Methods:** Pts were randomized 1:1 to receive cyt (1 g/m^2 IV over 2 hr, d 1-5) plus either vos (90 mg/m^2 IV over 10 min, d 1 and 4; 70 mg/m^2 in subsequent cycles) or placebo. In this posthoc subgroup analysis, we assessed complete remission (CR) rates prior to HCT, posttreatment HCT rates, HCT outcomes, and overall survival (OS) by treatment arm in R/R AML pts $\geq$ 60 y/o. **Results:** Overall, 451 pts $\geq$ 60 y/o received vos/cyt (n = 226) or pla/cyt (n = 225). Posttreatment HCTs were performed in 47 (20.8%) pts on vos/cyt and 44 (19.6%) pts on pla/cyt. Of the 91 HCT pts, 27 had achieved CR after vos/cyt vs 16 after pla/cyt. An additional 7 pts (vos/cyt) and 6 pts (pla/cyt) received subsequent therapy and went on to achieve CR, resulting in totals of 34 vos/cyt vs 22 pla/cyt pts who achieved CR prior to transplant. Median OS for pts who underwent posttreatment HCT on the vos/cyt arm was 20.2 mo vs 12.2 mo on the pla/cyt arm (HR 0.699; one sided P = 0.088). There were no clinically meaningful differences between treatment arms with respect to transplantation type, complications associated with HCT (including graft-vs-host and veno-occlusive disease), 100-day mortality, or achievement of engraftment. **Conclusions:** While HCT rates were comparable between treatment arms in this older R/R AML population, higher pre-transplant CR rates in the vos/cyt arm enabled more pts $\geq$ 60 y/o to undergo transplant while in CR as compared to the pla/cyt arm. With median OS lengthened by 8 months, a trend toward an OS benefit was observed for vos/cyt-treated pts. Additional follow-up is being conducted to further assess the impact of vos/cyt treatment on posttreatment HCT. Clinical trial information: NCT01191801.

7056 Poster Session (Board #45), Sun, 8:00 AM-11:30 AM

Cardiovascular events in patients with chronic myelogenous leukemia treated with tyrosine kinase inhibitors: A systematic review and meta-analysis. *First Author: Chatree Chai-Adisaksopha, McMaster University, Hamilton, ON, Canada*

Background: Tyrosine kinase inhibitors (TKIs) have dramatically improved survival for patients with chronic myelogenous leukemia (CML). However, there are growing evidences that TKIs may be associated with an increased risk of cardiovascular events. **Methods:** We searched MEDLINE, EMBASE and the Cochrane Central Register of Controlled Trials (CENTRAL) databases. Included studies were: (1) randomized controlled trials or cohort studies of adult patients (≥ 18 years) treated with TKIs for chronic phase or accelerated phase CML, (2) studies that reported at least one cardiovascular outcome (peripheral arterial occlusive disease (PAOD), ischemic heart disease or stroke/TIA). The primary outcome of this review were a composite of major cardiovascular events. The pooled incidences of cardiovascular events with corresponding 95% confidence intervals [CI] were performed using a single-proportion random-effects model. The pooled risk ratio (RR) with 95% CIs was calculated using a Mantel-Haenszel random-effects model to compare the effect between nilotinib and imatinib. **Results:** We identified 32 studies enrolling 16,218 patients (20 studies investigated nilotinib, 12 imatinib, 4 ponatinib, 1 dasatinib and 1 bosutinib). The pooled incidence rates (95% CI) of cardiovascular events were 8% (6-10%) for nilotinib, 1% (0-1%) for imatinib, 2% (1-2%) for dasatinib, 10% (5-16%) for ponatinib and 13% (11-16%) for bosutinib and 6% (3-10%) for non-TKI studies. The direct comparison between nilotinib and imatinib suggested that nilotinib treatment was associated with a significantly increased risk of the cardiovascular events (RR 1.6; 95%CI 1.4-1.8). **Conclusions:** Here, we evaluated the pooled estimates of the incidence of cardiovascular events in CML patients treated with TKIs. The pool proportions suggested that, when compared to non-TKI treated patients, patients who received imatinib and dasatinib had lesser cardiovascular events, whereas the incidence was greater among patients receiving nilotinib, ponatinib and bosutinib.

7057 Poster Session (Board #46), Sun, 8:00 AM-11:30 AM

Factors influencing outcomes in patients (Pts) with relapsed/refractory b-precursor acute lymphoblastic leukemia (r/r ALL) treated with blinatumomab in a phase 2 study. *First Author: Hagop Kantarjian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Blinatumomab, a bispecific T-cell engager (BiTE) antibody construct, showed efficacy in r/r ALL in a large phase 2 study (Topp et al. *Lancet Oncol* 2015;16:57). We evaluated associations of baseline characteristics with outcomes. **Methods:** Pts (≥18 y) had Ph-negative r/r ALL (1st relapse <12 mo; relapse <12 mo of HSCT; ≥2ndsalvage; refractory). Blinatumomab was given by continuous IV infusion (4 wk/2 wk off) for ≤5 cycles (cycle 1: 9 μg/d days 1–7; then 28 μg/d; subsequent cycles: 28 μg/d). The primary endpoint was complete remission (CR) or CR with partial hematologic recovery (CRh) within 2 cycles. Associations of baseline factors (platelets, prior salvage, bone marrow blasts [BMB], disease stage, age, region, prior HSCT, prior relapse, LDH) with CR/CRh and overall survival (OS) were assessed (Cochran-Mantel-Haenszel test, uni- and multivariate logistic regression). **Results:** 81 (43%) of 189 pts treated achieved CR/CRh within 2 cycles. Median (95% CI) RFS was 5.9 (4.8–8.3) mo; median OS was 6.1 (4.2–7.5) mo. CR/CRh was seen in all groups, including pts ≥65 yrs (44%), with/without prior HSCT (45%/42%), and pts with ≥3 prior salvages (34%). Pts with ≥50% BMB at baseline had 29% CR/CRh vs 73% in pts with <50% BMB, similar to the 78% minimal residual disease (MRD) response rate in pts with MRD+ ALL in the BLAST study (Goekbuget et al. *Blood* 2014;124:379), suggesting low biologic resistance to blinatumomab. In multivariate analyses, lower BMB and higher platelet count were associated with CR/CRh; higher platelet count and lower LDH were associated with longer OS (Table). **Conclusions:** Blinatumomab has antileukemia activity in pts with r/r ALL, including pts with poor prognostic factors. Low baseline BMB count had the strongest association with response, supporting early blinatumomab administration. For pts with higher tumor burden, cytoreduction/higher doses may be options. Clinical trial information: NCT01466179.

	Odds Ratio for CR/CRh (95% CI)	P	Hazard ratio for OS (95% CI)	P
BMB				
<50% vs ≥50%	5.1 (2.5–10.5)	<0.0001		ns
Platelet count (10^9/L)		0.0341		<0.0001
<50 vs ≥100	0.3 (0.1–0.8)		4.2 (2.3–7.8)	
50 to <100 vs ≥100	0.3 (0.1–1.0)		2.6 (1.3–5.4)

7058 Poster Session (Board #47), Sun, 8:00 AM-11:30 AM

Performance status and comorbidities on outcome of hypomethylating therapy in older adults (≥60 years old) with acute myeloid leukemia. *First Author: Anju Chana, Department of Medicine, SUNY-UB School of Medicine, Buffalo, NY*

Background: Outcomes of standard induction chemotherapy in older patients (pts) ≥ 60 years old with acute myeloid leukemia (AML) are significantly affected by medical co-morbidities and performance status. We asked whether these same factors impact the outcome of upfront hypomethylating therapy. **Methods:** We retrospectively reviewed 83 consecutive pts ≥ 60 yrs old with newly diagnosed AML who underwent induction therapy with hypomethylating agents at our institute between 2008-13. Sixty-nine patients received decitabine (20 mg/m^2 daily for 5-10 days) and 14 received azacitidine (75 mg/m^2 daily for 7 days). Number of underlying co-morbidities, Charlson Co-morbidity Index (CCI), Hematopoietic Cell Transplant- Comorbidity Index (HCT-CI), Eastern Cooperative Oncology Group (ECOG) performance status (PS), and overall survival (OS) were assessed. **Results:** Median age was 75.5 (range 60-92) years. Three-quarters (63) were male. Median white blood cell count was 5 x 10^9/L (range 0-121). Over half (46, 55%) the pts had secondary AML, and 31 (40%) had adverse cytogenetics. Six pts (7%) had *FLT-3* mutant and 8 (10%) had *NPM-1* mutant AML. ECOG PS was assessed as 0 (13 pts, 16%), 1 (55 pts, 66%), 2 (12 pts, 14%), and ≥ 3 (3 pts, 4%). Co-morbidities were measured as 0 (19 pts, 23%), 1 (28 pts, 34%), 2 (19 pts, 23%) or ≥ 3 (17 pts, 20%). CCI was 2-3 (6 pts), 4-5 (39 pts), 6-7 (28 pts), and ≥ 8 (10 pts). Sixteen pts (20%) achieved a complete response with an overall response date of 28%. Median OS of all pts was 9.1 (95% CI 4.5-12.4) months. ECOG was significantly associated with OS (p = 0.039) with median durations of 12.6 (PS 0), 11.3 (PS 1), 3.5 (PS 2) and 0.5 (PS ≥ 3), months, respectively. Co-morbidities, CCI, or HCT-CI were not significantly associated with survival (p = NS). **Conclusions:** Our results suggest that PS, not co-morbidities, predicts outcomes in older AML pts receiving upfront decitabine/ azacitidine. These data contrast with prior studies showing that co-morbidities, CI, HCT-CI, and PS all significantly impact outcomes of intensive induction. Prospective studies of the potential benefit of hypomethylating therapy in older AML patients with multiple co-morbidities are warranted.

7059 Poster Session (Board #48), Sun, 8:00 AM-11:30 AM

Efficacy and safety of an anti-FLT3 antibody (LY3012218) in patients with relapsed acute myeloid leukemia. *First Author: David Sanford, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LY3012218 (IMC-EB10) is a monoclonal antibody that binds FLT3 with high affinity and prevents binding of the FLT3-ligand and downstream signaling. Preclinical data using LY301228 demonstrates anti-leukemia activity which appears to be mediated via antibody dependent cell-mediated cytotoxicity (ADCC). **Methods:** We conducted a phase 1 trial to determine the safety, pharmacokinetics, and preliminary efficacy of LY3012218 in patients with relapsed/refractory acute myeloid leukemia (AML). Patients were eligible if they were ≥ 18 years, had a performance status < 3, adequate organ function, a life expectancy of > 3 months, and were not candidates for higher intensity therapy. Exclusion criteria included stem cell transplant within < 3 months, central nervous system leukemia or isolated extramedullary disease. Patients were treated in 4 dose cohorts (5 mg/kg (n = 3), 10 mg/kg (n = 13), 20 mg/kg (n = 3), 30 mg/kg (n = 5)) and received the drug intravenously weekly on days 1, 8, and 15 for cycle 1 and days 1, 8, 15, and 22 for subsequent cycles. **Results:** 31 patients were screened and 24 patients were treated. 14 patients were male (58.3%), the median age was 70.3 years (range 26-82), the median number of prior therapies was 2 (range 1-6) and 26% had a baseline FLT3 mutation. 12 patients reported 20 serious AEs with the most frequent including: pneumonia (n = 6, 25%), neutropenia (n = 3, 12.5%) and sepsis (n = 2, 8.3%). Dose limiting toxicities of infection, vomiting (10 mg/kg), and increased transaminases (30 mg/kg) were observed, although these were not clearly related to LY3012218. No MTD was defined. The serum trough concentrations for 5 to 30 mg/kg treatments (mean of Cmin: 41.9 to 739 μg/mL) following the third infusion were above the target trough concentration (33 μg/mL) associated with antitumor activity in preclinical models. Twenty one patients were evaluated for response and all were classified as treatment failures. **Conclusions:** Treatment with LY3012218 appears safe but did not demonstrate clinical activity as a single agent in relapsed/refractory AML. The lack of efficacy may be due to an absence of ADCC with LY3012218 or the presence of ligand-independent activation of signaling pathways down-stream of FLT3. Clinical trial information: NCT00887926.

7060 Poster Session (Board #49), Sun, 8:00 AM-11:30 AM

Association between early promoter methylation changes and outcome in older acute myeloid leukemia patients treated on SWOG S0703 (NCT0065884). *First Author: Sucha Nand, Loyola Univ Cancer Ctr, Maywood, IL*

Background: Treatment of acute myeloid leukemia (AML) in older patients remains a therapeutic challenge. Current treatment options range from supportive care alone to full-dose chemotherapy. Identifying factors that predict response to therapy may help increase efficacy and avoid toxicity. **Methods**: The phase II SWOG S0703 study investigated the use of hydroxyurea and azacitidine with gentuzumab ozogamicin in the elderly AML population. This regimen appeared to have efficacy similar to the standard AML regimens, with less toxicity in the poor risk population. Here we report the laboratory findings of samples accrued as part of this study. Global DNA methylation, promoter DNA methylation of six candidate genes (*CDKN2A*, *CDKN2B*, *HIC1*, *RARB*, *CDH1* and *APAF1*), and expression analysis of these same genes were determined at several time points before and during therapy. **Results**: The goal of this study was to investigate whether DNA methylation or gene expression changes predict clinical response. Global DNA methylation was not associated with a clinical response. Samples from days 3 or 4 of treatment showed significantly decreased *CDKN2A* promoter DNA methylation in patients achieving complete remission (CR) compared to those who failed to achieve CR. Samples from day 7 of treatment showed significantly decreased *RARB*, *CDKN2B* and *CDH1* promoter DNA methylation in patients achieving CR and/or complete remission with incomplete blood count recovery (CRi) compared to those who failed to achieve CR. Of the genes assessed in this study, there was a significant negative correlation (R^2= -0.47) between *APAF1* promoter methylation and *APAF1* gene expression between pre-study and day 3 or 4 samples among patients who later went on to achieve CR. **Conclusions**: These findings offer a potentially important early insight that may inform clinicians about the likelihood of success with demethylating agents in the treatment of older patients with AML. Such information may help to decrease toxicity and improve therapeutic efficacy in these patients. Support: NIH/NCI/NCTN CA180888, CA180819 and in part by Celgene Corporation and Pfizer, Inc.

7061 Poster Session (Board #50), Sun, 8:00 AM-11:30 AM

Azacitidine in older patients with acute myeloid leukemia (AML). Results from the ALMA study according to the MRC risk index score. *First Author: Jose F Falantes, Hospital Universitario Virgen del Rocio, Seville, Spain*

Background: Treatment of patients (pts) >60y with AML remains challenging. The MRC and LRF validated a 1y survival risk index score in 2843 older AML pts treated with intensive (IC) and non-intensive (NI) chemotherapy, identifying 3 groups with different risk estimates[1]. Azacitidine (AZA) prolonged OS in older AML pts vs. conventional care (AZA-AML-001 trial)[2]. Nevertheless, comparison between AZA and IC was jeopardized by the low number of subjects randomized to AZA or IC. Aim: To assess the impact of AZA in a retrospective cohort of older AML pts, unfit for IC, stratified by the MRC/LRF risk score. **Methods:** The ALMA cohort accrued 110 unfit AML pts who received compassionate front-line AZA before 2011 in 22 Spanish sites (Ramos F et al, Leuk Res. 2014). Cytogenetic, age, white blood count (WBC), PS and AML type categorized pts as good, standard and poor-risk, as stated by Wheatley's score. **Results:** Characteristics of the ALMA cohort and distribution across MRC/LRF risk categories are shown in Table 1. After accounting for the above 5 parameters, the ALMA cohort included more poor-risk pts than the MRC/LRF series (63% vs. 31%/37% in the AML11/AML14 trials, respectively). After 28 months median follow-up, 1y survival of ALMA cohort was 66%, 40% and 31%, respectively, for the good, standard and poor-risk groups. Comparison of these estimates with those of MRC/LRF trials are also shown in Table 1. Potentially relevant clinical differences are apparent in the poor-risk group when comparing AZA to either approach. **Conclusions:** Although retrospective and non-matched, AML pts unfit for IC seemed to benefit from AZA to a similar extent to IC. Moreover, in the poor-risk subset (n=70), 1y survival with AZA was equivalent and likely superior to previous AML/MRC strategies.

7062 Poster Session (Board #51), Sun, 8:00 AM-11:30 AM

An alvocidib-containing regimen is highly effective in AML patients through a mechanism dependent on MCL1 expression and function. *First Author: B. Douglas Smith, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Through multiple Phase I/II studies, alvocidib (flavopiridol) has proven to be highly effective in both frontline and relapsed/refractory AML when sequentially administered before ara-C and mitoxantrone (FLAM). In frontline patients, FLAM resulted in a complete remission (CR) rate of 70% versus 46% CR with ara-C and daunorubicin (7+3). Among patients with secondary (s)AML, FLAM produced 60% CR versus 35% CR with 7+3. The clinical activity of alvocidib in AML strongly correlates with inhibition of cyclin-dependent kinase-9 (CDK9) and disruption of super enhancer mediated transcription. The myeloid leukemia cell 1 (MCL1) gene is critically regulated by CDK9 activity under SE-mediated transcriptional control. **Methods:** Studies with AML cell lines were conducted to model the sequential treatment of the FLAM regimen. MCL1 expression and apoptosis were monitored in these nonclinical experiments. To further substantiate this mechanism clinically, mitochondrial profiling was conducted on 63 archived FLAM-treated samples. **Results:** Treatment with alvocidib results in a rapid downregulation of MCL1. In AML cell lines, we observe a two-fold decrease in MCL1 following alvocidib treatment that is associated with increased sensitivity to subsequent treatment with ara-C and mitoxantrone and enhanced apoptosis. Analysis of the BH3 priming states in AML clinical samples revealed NOXA priming was significantly higher in CR bone marrow samples (44.5% primed) compared with samples from non-responders (NR) (5.2% primed) ($p = 0.006$). NOXA is known to interact most directly with MCL1, suggesting that the AML samples that are most responsive to FLAM treatment may have a high survival dependence on MCL1. Interestingly, combining NOXA priming data with cytogenetic risk factors in pts with sAML, increased the predictive power of the assay as evident by a receiver operating characteristic (ROC) analysis yielding an AUC of 0.92 with $p = 0.0002$. Importantly, the correlation between NOXA and FLAM response is distinct from priming states predicting response to other ara-C regimens. **Conclusions:** This work reveals a potential biomarker for identification of patients likely to respond to FLAM.

7063 Poster Session (Board #52), Sun, 8:00 AM-11:30 AM

Ethnic differences in survival of elderly chronic myeloid leukemia patients in pre- and post-imatinib era in the United States. *First Author: Dipesh Uprety, Abington Memorial Hospital, Abington, PA*

Background: Survival of chronic myeloid leukemia (CML) has improved since FDA approval of imatinib in May 2001. However, there is limited data on survival pattern of elderly patients. We conducted this study to evaluate ethnic differences in survival of elderly CML patients. **Methods:** We selected elderly CML patients ($\geq$ 65 years) from the Surveillance, Epidemiology, and End Results (SEER) 18 database. We analyzed one- and five-year relative survival (RS) rates of CML patients by ethnicity during pre-imatinib (1990-2000) and post-imatinib (2001-2006) time periods. We used Z-test to compare survival rates. **Results:** The database comprised of 5,802 patients. Among them, 3,183 were males and 2,619 were females. Likewise, 5,073 were Caucasians and 394 were African Americans. The median age at diagnosis was 76 years. The median follow up period was 18 months (range: 1 to 60 months). The RS of the patients improved significantly in post-imatinib era as compared to pre-imatinib era (1 year: 65.6 $\pm$ 0.9 vs 59.2 $\pm$ 1.0, Z score = 4.93; 5 year: 34.6 $\pm$ 1.1 vs 22.2 $\pm$ 0. 9, Z score = 8.45). Survival rates of Caucasians improved significantly (1 year: 59.2 $\pm$ 1.1 vs 65.6 $\pm$ 1.0, Z score = 4.49; 5 year: 22.3 $\pm$ 1.0 vs 34.3 $\pm$ 1.1, Z score = 7.59) but there was no significant improvement in survival for African Americans (1 year: 58.8 $\pm$ 3.8 vs 61.1 $\pm$ 3.7, Z score = 0.49; 5 year: 21.1 $\pm$ 3.5 vs 31.1 $\pm$ 4.0, Z score = 1.61). There was no difference in survival rates of African Americans compared to Caucasians in pre-imatinib era. **Conclusions:** Survival rates of elderly CML patients have improved significantly in post-imatinib era. This improvement in survival rates is limited to Caucasians.

7064 Poster Session (Board #53), Sun, 8:00 AM-11:30 AM

The prognostic impact of combined NPM1+/FLT3- mutational status in newly diagnosed acute myeloid leukemia (AML) patients with intermediate risk cytogenetics according to age and treatment modality. *First Author: Mehrdad Hefazi, Mayo Clinic, Rochester, MN*

Background: Combined NPM1+/FLT3- is associated with a favorable prognosis in adults with AML, treated with standard chemotherapy. The impact of this on outcome is however not well defined according to age and different treatment modalities, including chemotherapy with or without hematopoietic cell transplantation (HCT), and hypomethylating agents (HMA). **Methods:** Out of 620 newly diagnosed AML pts treated between 2007 and 2014, 169 with intermediate risk cytogenetics and known NPM1/FLT3 were analyzed. **Results:** Estimated 3-yr overall survival (OS) according to age, NPM1/FLT3 status, and treatments are shown in the table. Among adults and elderly treated with chemotherapy alone, those with NPM1+/FLT3- had a superior OS compared to those without this mutational status (P=0.004 and 0.0008, respectively). Adults without NPM1+/FLT3- had a significantly improved OS when treated with HCT in addition to chemotherapy (P<0.0001), and a comparable OS to those with NPM1+/FLT3- (P=0.43), when treated with chemotherapy alone. Similarly, elderly without NPM1+/FLT3- had a superior OS when treated with chemotherapy followed by HCT (P=0.028), and a comparable OS to those with NPM1+/FLT3- (P=0.83), when treated with chemotherapy alone. Among elderly pts without NPM1+/FLT3-, those treated with HMA alone (n=12) had a similar OS to those treated with chemotherapy without HCT (P=0.86). **Conclusions:** Combined NPM1+/FLT3- is associated with a favorable prognosis, irrespective of age, in newly diagnosed AML pts with intermediate risk cytogenetics, treated with chemotherapy. In pts without NPM1+/FLT3-, the OS improves with the addition of HCT to standard chemotherapy, irrespective of age. HMA seems to be comparable to chemotherapy alone in elderly pts without NPM1+/FLT3-.

Elderly (>60 yrs.) N=84*				Adults (18-60 yrs.) N=85

Infectious complications in AML patients treated with induction vs. hypomethylating therapy. *First Author: Marla M Jalbut, Massachusetts General Hospital, Boston, MA*

Background: Infectious complications are common during AML treatment, partly related to cytopenias during standard induction. It is less clear whether the same degree of infectious complications occur with hypomethylating agents (HMAs), especially early in therapy. We compared incident infectious events, as well as death due to infection, among AML patients treated with HMAs vs. induction chemotherapy. **Methods:** We evaluated consecutive cases of newly diagnosed AML at Massachusetts General Hospital from 2010-2014, and identified 47 patients given upfront therapy with HMAs, and 126 given induction, typically "7+3." The cumulative incidence of infectious events, including related death, was calculated by the method of Fine and Gray, with death/non-infectious death as a competing risk, as appropriate. Incidence rate ratios were calculated between groups. Survival was compared by the method of Kaplan and Meier and log-rank test. **Results:** Median follow-up was 596 days. Induction patients were younger (62 vs 76 y.o., $p < 0.0001$), and fewer had secondary AML (33% vs. 62%, $p = 0.001$). Patients given induction had improved CR/CRi rates (83% vs. 38%) and 1-year OS (64.2% vs. 35.3%) compared to HMAs. The 30-day cumulative incidence of febrile neutropenia (82.5% vs. 34.4%, $p < 0.0001$), bacteremia (23% vs. 8.6%, $p = 0.0021$), and colitis (18.3% vs. 4.4%, $p = 0.0028$) was higher with induction vs. HMA therapy, while incident cellulitis was lower (4.8% vs. 17.2%, $p = 0.028$). Induction patients also had an increased incidence rate of febrile neutropenia (IRR 7.07, $p < 0.0001$), and lower rate of cellulitis and UTI (IRR 0.26, $p = 0.0006$, and IRR 0.30, $p = 0.0020$, respectively). There was no significant difference in fungemia, pneumonia, non-invasive candida infection, nor the cumulative incidence of death due to infection at 120 days (4.0% induction vs. 4.3% HMA, $p = 0.57$). **Conclusions:** AML patients treated with induction had greater rates of febrile neutropenia, bacteremia, and colitis compared to those treated with HMA therapy, but lower rates of cellulitis and UTI. In spite of the marked increase in early infectious events during induction vs. HMA therapy, there was no significant difference in the cumulative incidence of death due to infection.

Digital *Fusion-Gene* expression profiling in acute leukemia (AL): Clinical validation of throughput molecular technology in laboratory medicine. *First Author: Ariz Akhter, University of Calgary, Calgary, AB, Canada*

Background: AL is a heterogenous and aggressive disease with dismal prognosis. Chromosomal translocations constitute the basis of current WHO classification and are central to AL pathogenesis. FISH technique is utilized to detect variable translocations for patient prognosis and therapy selection. It is a labor intensive and expensive technique, which may not support rapidly expanding scope of additional translocations of clinical importance in AL patients. Hence, throughput automated technologies may play a critical in the management of AL patients. **Methods:** Nanostring platform utilizes a novel digital color-coded automated technology that is based on direct multiplexed measurement of gene expression. The "*nCounter Leukemia Fusion Gene Expression Assay Kit"* allows profiling a comprehensive set of 25 fusion genes that result from balanced translocations in AL. It also includes probes for 12 clinically proven AL-related biomarkers. RNA extracted from FFPE tissue from 50 AL patients with known balanced chromosomal translocations and validated the fusion gene expression on this platform. **Results:** We observed highly significant concordance between Nanostring fusion gene results with FISH data in various translocation such as t(9;22) (BCR-ABL); t(15;17) PML-RARA; t(8;21) (AML-ETO); t(4;11) (MLL-AF4) and Inv(16) (CBFB-MYH11) ($P < 0.05$). Nanostring technology failed to validate fusion gene transcript in patients with t(12;21) (TEL-AML). High expression of BAALC, a prognostic biomarker associated with poor outcome in AL patients was noted in t(9;22) (58%), t(15;17) (12%), t(4;11) (50%), t(12, 21) (20%), t(8;21) (20%) and Inv(16) (63%). **Conclusions:** We have validated the application of automated throughput technology for AL patients in a clinical laboratory. Our study provides an efficient, viable and economical solution for the rapidly expanding molecular repertoire of laboratory testing for AL patients, which is critical to determine prognosis and select effective therapy. This approach also provides a promise to seamlessly incorporate newly discovered (up to 800) targets of diagnostic and prognostic importance on this digital platform.

7067 Poster Session (Board #56), Sun, 8:00 AM-11:30 AM

Construction and characterization of novel CD33/CD3 tandem diabodies (TandAbs) for the treatment of acute myeloid leukemia (AML). *First Author: Uwe Reusch, Affimed GmbH, Heidelberg, Germany*

Background: CD33 had been validated as an AML target in randomized studies of the antibody-drug conjugate, gemtuzumab ozogamicin (GO) in a subset of patients, but currently explored CD33-targeted therapeutics are ineffective in many patients. Here, we explored the potential therapeutic activity in AML of a series of novel CD33/CD3-directed tandem diabodies (TandAbs). These tetravalent bispecific antibodies comprised of single chain antibody variable fragments (scFv) have avidity due to two binding sites for each antigen and attractive pharmacokinetics due to a molecular size that is larger than the renal clearance threshold. **Methods:** CD33/CD3 TandAbs were generated from humananti-CD33 and anti-CD3 scFv domains and expressed in CHO cells. Binding affinities of purified TandAbs were determined via flow cytometry. T-cell activation was assessed via quantitation of CD25 and CD69 on T-cells. Cytotoxic properties of TandAbs against CD33+ AML cell lines and primary specimens from adults with AML, selected across the entire cytogenetic/molecular disease spectrum, were determined in 48-hour assays in the presence of healthy donor T-cells. **Results:** Our studies demonstrated that CD33/CD3 TandAbs induced potent cytolysis of CD33+ AML cell lines and patient-derived AML specimens at pM concentrations. Their cytotoxic effect required the presence of T-cells and was quantitatively dependent on the concentration of the TandAb as well as the effector-to-target (E:T) cell ratio. In a series of 29 primary AML specimens, high-affinity CD33/CD3-directed TandAbs were broadly active *in vitro*, even in leukemias with low CD33 expression, with similar activity profiles in specimens from patients with newly diagnosed AML and those with relapsed or refractory disease. **Conclusions:** CD33/CD3 TandAbs have potent and selective cytotoxicity for CD33+ AML cells that is independent of disease stage. Our findings identified several TandAbs that merit further study as targeted AML therapeutics.

7068 Poster Session (Board #57), Sun, 8:00 AM-11:30 AM

Long-term bosutinib (BOS) for Philadelphia Chromosome–Positive (Ph+) advanced (ADV) chronic myeloid leukemia (CML) after prior tyrosine kinase inhibitor (TKI) failure. *First Author: Carlo Gambacorti-Passerini, University of Milano-Bicocca, Monza, Italy*

Background: ADV Ph+ CML pts have worse outcomes vs chronic CML pts. In this first report of BOS activity in this cohort as fully enrolled, we evaluate long-term efficacy and safety of BOS in ADV pts ≥4 vs ≥1 y from last enrolled pt. **Methods:** Ongoing phase 1/2 BOS study in 79 accelerated (AP) and 64 blast phase (BP) pts with prior TKI failure **Results:** For AP and BP pts, 18% and 3% remained on BOS at 4 y (vs 48%; 13% at 1 y; 1 y = 48 wk); 57% and 28% newly attained or maintained baseline overall hematologic response (OHR) by 4 y (most by 12 mo); 40% and 37% attained/maintained major cytogenetic response (MCyR) by 4 y (most by 12 mo). Kaplan-Meier (KM) probabilities of maintaining OHR in responders at 4 vs 1 y were 49% vs 78% (AP) and 19% vs 28% (BP); KM MCyR probabilities at 4 vs 1 y were 49% vs 65% (AP) and 21% vs 21% (BP). AP and BP pts were treated for median 10.2 (range, 0.1–88.6); 2.8 (0.03–55.9) mo. Most common AEs were gastrointestinal (AP, 96%; BP, 83%), primarily diarrhea (85%; 64%), which was typically low grade (grade 1/2: 96%; 93%), transient (median duration/any grade AE: 2 [range, 1–910] d; 2 [1–211] d); no pt discontinued due to this AE. Newly occurring AEs arose mostly in y1; new cardiac/vascular AEs occurring in y4 were pericardial effusion, sinus bradycardia/1st degree atrioventricular block (same pt), and hypertension (all n=1); those in y1 (>2 pts either cohort) were pericardial effusion (AP, n=4; BP, n=1), tachycardia (n=2; n=4), hypertension (n=3; n=2; Table). Serious AEs occurred in 56% AP and 58% BP pts, most commonly pneumonia (n=9; n=5). 11 AP and 13 BP pts died within 30 d of last dose; 2 BOS-related (AP). Treatment discontinuations were mostly due to PD (AP, ≤1/>1 y, n=10/13; BP, n=29/3) and AEs in AP (n=16/5); death (n=6/0) and symptomatic deterioration (n=6/0) in BP. **Conclusions:** Durable response was seen in ~50% AP responders (~25% BP responders at y1, for whom BOS may be bridge to transplant); toxicity was manageable with long-term treatment. Clinical trial information: NCT00261846.

7069 Poster Session (Board #58), Sun, 8:00 AM-11:30 AM

Clinical activity, safety profile, and hepatotoxicity of TGR-1202, a novel once daily PI3Kδ inhibitor, in patients with CLL and B-cell lymphoma. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: TGR-1202 is a novel, next generation PI3Kδ inhibitor which lacks the hepatotoxicity associated with other PI3Kδ inhibitors and is active in patients (pts) with advanced heme malignancies (ASH 2014). Herein we present updated safety and efficacy results from a Ph I study of TGR-1202 in pts with rel/ref CLL and B-cell lymphoma. **Methods**: TGR-1202 is administered orally once-daily following a 3+3 dose escalation design. Eligible pts have rel/ref B-cell non-Hodgkin lymphoma (NHL), chronic lymphocytic leukemia (CLL), or other B-cell malignancy and an ECOG PS ≤ 2. Endpoints: safety, PK/PD, and efficacy. **Results**: As of Feb 2015, 58 pts evaluable for safety including CLL, FL, Hodgkin's (HL), DLBCL, MCL, and MZL. Median age 63 yo (range: 22-85), 72% male, ECOG 0/1/2: 19/38/1, median prior Tx: 3 (range: 1-14), 48% refractory to prior Tx. Safety: The only Gr ≥ 3 AE in ≥ 10% of pts was neutropenia (10%). AEs (all grades, all causality) in > 20% of pts were limited to diarrhea (34%), fatigue (31%), nausea (29%), and cough (26%). All diarrhea events Gr1/2, except one Gr3 event occurring in a pt in Cyc 1, which persisted for 2 days and resolved without dose interruption. Notably, in contrast to similar agents, no drug-related hepatotoxicity or colitis has been observed to date (ave time on study 7 Cyc). 2 episodes of Gr3 fatigue at 1800 mg of a new micronized formulation met the criteria for DLT. Expansion cohorts are open at 800 mg (CLL) and 1200 mg (NHL). Efficacy: A strong exposure-response relationship has been observed. Of 14 evaluable CLL pts, 13 (93%) achieved a nodal PR (median nodal ↓ of 76%), of which 7 (50%) achieved a PR per Hallek 2008 criteria. Responses have been limited in pts with aggressive lymphoma and HL. Of the 12 evaluable FL pts, 8 (67%) remain on study progression-free (range 7 - 99+ weeks), with 3 achieving a PR, notably being the 3 pts exhibiting the highest TGR-1202 plasma concentrations. **Conclusions**: TGR-1202 is well tolerated in pts with rel/ref heme malignancies with no reported hepatotoxicity or colitis (41% of pts on study 6+ Cyc) and promising activity in CLL and NHL. Enrollment continues in expansion cohorts. Clinical trial information: 01767766.

7070 Poster Session (Board #59), Sun, 8:00 AM-11:30 AM

A phase I trial of the human double minute 2 inhibitor (MK-8242) in patients with refractory/recurrent acute myelogenous leukemia (AML). *First Author: Farhad Ravandi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Human double minute 2 (HDM2) binds to and inhibits wild-type (WT) p53, thereby promoting oncogenesis. MK-8242 is a potent, orally bioavailable, small-molecule inhibitor of the HDM2:p53 protein-protein interaction being developed as a novel cancer therapy. **Methods:** This multi-center, non-randomized, open-label, 2-arm (A/monotherapy and B/combination therapy), 2-part (dose escalation and confirmation) study was designed to evaluate the safety/tolerability, pharmacokinetics (PK) and recommended phase 2 dose (RP2D) of MK-8242 +/- cytarabine in p53 WT patients (pts) with refractory/recurrent AML. The study was terminated for reasons unrelated to safety; only the monotherapy dose-escalation phase was completed. In Arm A, MK-8242 was initially dosed p.o. either QD (30 mg-250 mg) or BID (120 mg-250 mg) for 7 days on/7 days off (7on/7off) in a 28-day cycle The dosing schedule was later modified to 7on/14off in a 21-day cycle (210 mg or 300 mg BID) to improve the safety profile of the drug. **Results:** 26 pts enrolled (24 evaluable for response). Median age was 66 yrs (range: 29-81). All pts had ≥ 1 AE with 5 (19%) discontinuing due to AEs. There were 7 deaths (3 pneumonia-related; 2 AML progression; 1 sepsis; 1 respiratory failure); only 1 death (fungal pneumonia due to marrow aplasia) was deemed drug-related. With the initial 7on/7off regimen, DLTs occurred only in the 250 mg BID group in 2 pts (bone marrow failure, G1 and G4). After switching to the 7on/14off schedule, no DLTs were observed for the 210 mg BID or 300 mg BID groups (doses above 300 mg not tested). Across all dosing schedules, best responses were: 1/24 PR observed after 11 wks (120 mg QD, 7on/7off); 1/24 CRi observed after 2 wks (210 mg BID, 7on/14off); and 1/24 morphologic leukemia-free state after 4 wks (250 mg BID, 7on/7off). Plasma PK analysis on day 7 at the 210 mg BID dose revealed $AUC_{0\text{-}12hr}$ of 8.7 μM*hr, C_{max} of 1.5 μM (n = 5, T_{max}, 2-6 hr) and $T_{1/2}$ of 7.9 hr. **Conclusions:** The modified 7on/14off regimen showed a more favorable safety profile than the 7on/7off schedule, and a MTD for this regimen was not established. Clinical activity was seen at 210 mg BID (7on/14off), providing impetus for further study of HDM2 inhibitors in pts with AML. Clinical trial information: NCT01451437.

7071 Poster Session (Board #60), Sun, 8:00 AM-11:30 AM

Development of a bispecific tetravalent CD33/CD3 TandAb for the treatment of AML. *First Author: Uwe Reusch, Affimed GmbH, Heidelberg, Germany*

Background: Acute Myeloid Leukemia (AML) is a hematologic malignancy with dire prognosis; immunotherapy may offer a much needed alternative to cytotoxic chemotherapy. TandAbs are tetravalent, bispecific diabodies that exceed renal clearance limits, providing both avidity and pharmacokinetic advantages over monovalent bispecific constructs. To identify a potential immunotherapeutic for AML and other $CD33^+$ hematologic malignancies, fully human T-cell recruiting, CD33-directed bispecific TandAbs were constructed and profiled for manufacturability, stability and pharmacologic activity. **Methods:** Anti-CD33 scFv with high affinity to both human and cynomolgus CD33 were selected from fully human scFv libraries using phage display. Stable anti-CD33 scFv were formatted into TandAbs; linker length and domain order/topology were also varied. Expression levels in stably transfected CHO cells, purification properties, and stability were evaluated. Mechanism-based functional assays measured CD33/CD3 TandAb-mediated cytotoxicity towards CD33+ target cells. T cell activation and proliferation in the presence and absence of target cells were also studied. *In vitro* safety assessments of specificity and cytokine release from T cells without target cells were performed. CD33/CD3 TandAbs were studied in prophylactic and established HL-60 xenograft models. **Results:** CD33/CD3 TandAbs with excellent production and stability profiles also had potent cytotoxic activity towards CD33+ target cells (EC50 < 10 pM). TandAbs demonstrated equivalent binding affinity and potency for human and cyno antigens, facilitating toxicity studies. T cell activation, proliferation and cytotoxicity were strictly linked to the presence of CD33+ target cells. CD33/CD3 TandAbs did not elicit cytokine release from T cells without target cells. Potent anti-tumor activity of CD33/CD3 TandAbs was observed *in vivo*. **Conclusions:** A human CD33/CD3 TandAb therapeutic candidate with a promising activity and safety profile to date warrants clinical development as a potential treatment for AML. Preclinical development is ongoing.

7072 Poster Session (Board #61), Sun, 8:00 AM-11:30 AM

Serum chemokines and cytokines in CLL patients treated with duvelisib, a PI3K-δ,γ inhibitor. *First Author: Mark Douglas, Infinity Pharmaceuticals, Cambridge, MA*

Background: PI3K-δ and PI3K-γ play complementary roles in malignant B-cells and the tumor microenvironment (TME). Inhibition of PI3K-δ blocks cytokine-mediated CLL proliferation, while inhibition of PI3K-γ blocks M2 macrophage polarization and T-cell migration in vitro. Duvelisib, an oral PI3K-δ,γ inhibitor, has shown clinical activity in a phase 1 study in patients (pts) with advanced hematologic malignancies (Study IPI-145-02), including pts with relapsed/refractory (R/R) CLL (O'Brien, ASH 2014). **Methods:** Serum from 52 pts with R/R CLL and 30 healthy subjects (HS) was analyzed for 72 analytes (cytokines, chemokines, and matrix metalloproteinases) using Luminex xMAP technology at baseline, Cycle 1 Day 8 (C1D8), C2D1, and C3D1. Median change from baseline was analyzed for statistical significance using a paired t-test with Bonferroni correction for multiple hypotheses; threshold for reduction was ≤ 50% of baseline and for increase was ≥ 150% of baseline. Comparison between CLL and HS utilized a 2-sample t-test with Bonferroni correction. **Results:** Following treatment with duvelisib, the median serum levels of 12 analytes decreased to ≤ 50% of baseline ($p < 0.0002$) by C1D8. These included CCL1, CCL3, CCL4, CCL17, CCL22, CXCL10, CXCL13, IL-6, IL-10, IL-12p40, MMP-9 & TNFα. All of these were significantly elevated ($p < 0.0042$) at baseline in CLL pts compared to HS and reduced towards normal range following duvelisib treatment. In addition, MMP1 was the only analyte for which median serum levels increased above the threshold of ≥ 150% of baseline ($p < 0.0002$). Together, these 13 analytes were further explored for potential associations with clinical efficacy. TNFα was significantly elevated ($p < 0.0013$) at C2D1 & C3D1 in pts who did not exhibit a nodal response. **Conclusions:** Most of the analytes reduced following duvelisib treatment are known to be involved in the communication between CLL cells and the TME. Furthermore, one of these analytes (TNFα) exhibited elevated levels at C2D1 and C3D1 in pts who did not achieve a nodal response. Together, these data indicate that modulation of the TME via PI3K-δ,γ inhibition may be an important mechanism of action in supporting clinical activity of duvelisib in patients with CLL. Clinical trial information: NCT01476657.

7073 Poster Session (Board #62), Sun, 8:00 AM-11:30 AM

The dual SRC-ABL inhibitors in Ph+ acute lymphoblastic leukemia to enhance synergy between targeted BCR-ABL and BCL-2 inhibitors. *First Author: Jessica Taft Leonard, Oregon Health and Sci Univ, Portland, OR*

Background: Outcomes in adult Philadelphia Chromosome Positive Acute Lymphoblastic Leukemia (Ph^+ALL) remain poor with a 5 year overall survival of less than 40%. Addition of the targeted BCR-ABL inhibitors (TKI) to standard cytotoxic therapy has greatly improved upfront treatment, yet relapse remains common with a median survival of just 4.5 months. Therefore identification of targeted agents that could enhance the activity of TKIs is urgently needed. ABT 199 is a BCL-2 inhibitor which has shown pre-clinical activity against a variety of B cell malignancies. Here we evaluate the combination of ABT199 across a panel of TKIs to explore potential mechanisms of synergy in hopes to better define the optimal combination for future clinical studies. **Methods:** Drug efficacy *in vitro* was determined using the Ph^+ALL cell line SupB15. Cells were incubated with varying concentrations of dasatinib, imatinib, nilotinib or ponatinib in combination with ABT199 for 72 hours. Cell viability was assessed using a colorimetric MTS assay, and cell apoptosis was assessed with annexin V staining. Combination effects were calculated using Calculsyn software. Standard immunoblots were used to assess inhibition of downstream pathways. **Results:** The combination index (CI) values for each of the TKIs with ABT199 ranged between 0.13 – 1.4 for Imatinib, 0.4 – 1.05 for Nilotinib, 0.06 – 0.33 for Ponatinib, and 0.07 – 0.64 for Dasatinib, where $CI < 1$ predicted synergy. As a single agent, ABT199 induced the highest degree of apoptosis, enhanced preferentially by dasatinib and ponatinib. Evaluation of key phosphorylated kinases showed that all four TKIs effectively inhibited the downstream ABL1 target pCRKL. In addition, both dasatinib and ponatinib inhibited pLYN while dasatinib also inhibited pBTK. **Conclusions:** Combination of BCL-2 and BCR-ABL targeting in Ph^+ALL is synergistic *in vitro*. The enhanced synergy seen with dasatinib and ponatinib may be due to the ability of these agents to target additional pathways active in leukemic cells. The addition of ABT-199 as part of TKI therapy for adult Ph^+ALL warrants further clinical investigation, particularly in patients with relapsed or refractory disease.

7074 Poster Session (Board #63), Sun, 8:00 AM-11:30 AM

Early clinical activity and pharmacodynamic effects of duvelisib, a PI3K-δ,γ inhibitor, in patients with treatment-naïve CLL. *First Author: Manish R. Patel, Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, FL*

Background: Signaling via PI3K-δ and PI3K-γ has distinct and complementary effects on malignant B-cells and nonmalignant immune cells in chronic lymphocytic leukemia (CLL). Duvelisib, an oral PI3K-δ,γ inhibitor, has shown clinical activity in a phase 1 study, IPI-145-02. The activity of duvelisib monotherapy in pts with treatment-naïve (TN) CLL from this study are reported here. **Methods:** Following dose escalation, an expansion cohort of TN CLL pts was enrolled ($n = 18$). Response was based on iwCLL (2008) criteria. Safety included AEs and laboratory assessments. Pharmacodynamic assessments included peripheral blood (PB) flow cytometry for phospho-S473 AKT (pAKT) and Ki67, and measurement of serum chemokines and cytokines. Numbers of PB T-cell subsets were also monitored. **Results:** As of Oct 2014, 18 TN CLL pts received duvelisib 25 mg BID. The best ORR per iwCLL was 82% (PRs in 14/17 evaluable pts) with a median time on treatment of 53 weeks (range 8-69). Ten pts remain on treatment, while 8 discontinued, including 6 pts due to AEs. AEs overall were mostly Gr. 1 or 2. The most common ≥ Gr. 3 AEs were neutropenia (7/18) and ALT/AST increase (3/18). Inhibition of pAKT in CLL cells was rapid following a single dose and sustained through Cycle 2 Day 1 (C2D1). A reduction in the Ki67 proliferative fraction in both CLL and T-cells was also observed. The overall number of T-cells and T-cell subsets (CD4, CD8, memory cells) did not decrease through C3D1. Duvelisib also resulted in reductions in the median serum levels of CCL3, CCL4, CCL17, CCL22, CXCL10, CXCL13, IL-10, IL-12p40, MMP-9, IL-16, and TNFα to ≤ 50% of baseline at C1D8 and/or C2D1 ($p < 0.01$). **Conclusions:** Duvelisib 25 mg BID shows clinical activity in TN CLL pts.The inhibition of pAKT and Ki67 in CLL cells suggests duvelisib inhibits the PI3K pathway and suppresses malignant cell proliferation in TN CLL pts. In addition, the effect of duvelisib on serum chemokines, cytokines, and T-cell proliferation suggests that modulation of the tumor microenvironment may contribute to the observed early clinical activity of duvelisib in pts with TN CLL. These data support the further development of duvelisib in TN CLL, including combinations with other targeted therapies. Clinical trial information: NCT01476657.

7075 Poster Session (Board #64), Sun, 8:00 AM-11:30 AM

CDA status as predictive marker of aplasia duration and clinical outcome in AML patients receiving cytarabine based chemotherapy. *First Author: Cedric Mercier, La Conception University Hospital of Marseille, Marseille, France*

Background: Cytarabine is mainstays for treating hematological malignancies. As most nucleosidic analogs, cytarabine is metabolized in the liver by an exclusive enzymatic pathway driven by cytidine deaminase (CDA). CDA is highly polymorphic and dysregulations have been repeatedly associated with poor clinical outcome in patients treated with gemcitabine. **Methods:** We have used a test to determine, on a phenotype basis, CDA status in patients. This test was used in a subset of 42 adult patients (18F, 24M, mean age 60 years), all treated with a cytarabine-containing regimen. Response and treatment-related toxicities were monitored following current standards (CTC). This was a retrospective and prospective observational single-center study. All patients requiring a first induction chemotherapy for AML (AML de novo or secondary to myelodysplastic syndrome) and consolidation phase. The objective was to determine the relationship between the CDA status and clinical outcome. **Results:** In patients, mean CDA activity was 2.85 U/mg (min: 1, max: 14.8 U/mg). Ten out of 41 patients (i.e., 24%) showed low CDA activities and were considered as poor metabolizer (PM). Conversely, 4 patients (i.e., 9.75%) displayed particularly elevated (i.e., > 6U/mg) CDA activities and were considered as ultra-rapid metabolizer (UM). During first induction chemotherapy, the duration of aplasia was 30 days vs 22 days in low CDA activities group and normal or elevated CDA activities respectively ($p < 0.05$). During consolidation chemotherapy, the duration of aplasia was 21 days vs 9 days in low CDA activities group and normal or elevated CDA activities respectively ($p < 0.001$). Of note, PM patients all showed severe toxicities, including three toxic-deaths. Conversely, UM patients showed little efficacy. **Conclusions**: Overall this study strongly suggests that CDA status could be a relevant marker for predicting clinical outcome in patients treated with cytarabine. CDA status is significantly related with duration of aplasia, it could be further used as a covariate to tailor drug dosage so as to ensure an optimal efficacy/toxicity balance in patients with hematological malignancies.

7076 Poster Session (Board #65), Sun, 8:00 AM-11:30 AM

Long-term bosutinib (BOS) in patients (pt) with chronic phase (CP) chronic myeloid leukemia (CML) after prior imatinib (IM) failure. *First Author: Jeffrey Howard Lipton, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: BOS is a Src/Abl tyrosine kinase inhibitor for adults with Ph+ CML resistant/intolerant to prior therapy. We assess long-term efficacy/tolerability of BOS after ≥5 y vs ≥2 y follow-up from last enrolled pt. **Methods:** Data were from an ongoing phase 1/2 study in CP CML pts on 2nd-line BOS (500 mg/d start dose) after IM failure (n = 284). **Results:** 41% of pts remained on BOS at 5 y vs 54% at 2 y (1 y = 48 wk); 60% and 50% had newly attained or maintained baseline major cytogenetic response (MCyR) or complete cytogenetic response (CCyR) (most in ≤2 y). Kaplan-Meier (KM) probability of maintaining MCyR or CCyR in responders was similar at 5 y (71%, 71%) and 2 y (76%, 79%); 6 and 7 pts lost response > 2 y. Cumulative incidence of on-treatment transformation to AP/BP CML at 5 y was 4%; 55% discontinued without transformation < y5. 1/153 pts on-treatment > 2 y transformed to AP in y3–5. KM overall survival was 84% at 5 y vs 91% at 2 y (40% censored < y5). Median treatment duration was 25.6 (range 0.2–94.9) mo; follow-up: 51.4 (0.6–96.3) mo. 37 pts discontinued BOS y3-5 (vs 131 ≤2 y), mostly for disease progression (n = 11), AE (n = 7, y3: coronary artery disease, scleroderma, renal failure; y4: ascites and serositis [same pt], blood creatinine increased, pulmonary hypertension; y5: thrombocytopenia), and unsatisfactory efficacy (n = 7). Common newly occurring AEs (in > 5 pts) in y3 were cough (n = 7), blood creatinine increased (n = 7), pyrexia (n = 6), and blood creatine phosphokinase increased (n = 6); y4: blood creatinine increased (n = 6), pleural effusion (n = 6); y5, none in > 5 pts. Newly occurring AEs of interest (**Table**) were most common in y1–2; vascular AEs > y2 were primarily hypertension (y3, n = 5; y4, n = 3; y5, n = 2). 4 on-treatment deaths occurred y3–5, none BOS-related. **Conclusions:** BOS showed durable efficacy and manageable toxicity; a large proportion of CP CML pts with prior IM failure remained successfully treated at 5 y. Clinical trial information: NCT00261846.

7077 Poster Session (Board #66), Sun, 8:00 AM-11:30 AM

First report of a phase I/II study of DFP-10917, a nucleoside analog, given by continuous infusion (CI) in patients (pts) with relapsed or refractory acute leukemia. *First Author: Hagop M. Kantarjian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: DFP-10917 has a unique mechanism of action upon prolonged administration at a low dose. Under such administration, DFP-10917 is converted to its nucleotide form and then incorporated into DNA in tumors to cause DNA strand breaks resulting in G2/M phase-arrest by cell-checkpoint regulators and ultimately the apoptosis of tumor cells. **Methods:** In phase I, DFP-10917 was administered by 7-day CI followed by 21 days rest (stage 1) or 14-day CI followed by 14 days rest (stage 2) in pts with relapsed or refractory acute leukemia in order to determine the maximum tolerated dose (MTD), recommended phase II dose (RP2D) and dose-limiting toxicity (DLT) of CI DFP-10917. **Results:** In stage 1, 27 pts received a 7-day CI of DFP-10917 at 8 escalating doses ranging from 4 to 35 mg/m^2/day. At the 35 mg/m^2 dose level, one patient experienced a DLT of grade 3 diarrhea during cycle 1. Two other pts treated at the 35 mg/m^2 dose level completed cycle 1 study treatment without DLT. The starting dose for stage 2 was calculated as 2/3rds the cumulative 7-day DFP-10917 dose at the MTD of 30 mg/m^2/day divided by 14-day resulting in a dose of 10 mg/m^2/day x 14 days. In stage 2 of phase I, 4 pts received 10 mg/m^2/day x 14-day CI DFP-10917 with DLTs of prolonged hypo-cellularity in 2 pts. At the 6 mg/m^2/day x 14-day dose level, 1 of 6 evaluable pts in a cohort experienced a DLT of prolonged hypo-cellularity, and the MTD/RD was defined as 6 mg/m^2/day x 14-day CI. Initial efficacy assessments include leukemia responses observed in 7 of 10 pts (70%) receiving the 14-day DFP-10917 CI; three were bone marrow complete responses, and four were partial response. Patients have received up to 7 cycles of DFP-10917 CI to date with ongoing responses. **Conclusions:** The MTD/RP2D of DFP-10917 in relapsed AML was established for 14-day CI at 6 mg/m^2/day, and the phase II study was initiated based on an acceptable safety profile. In phase II, the therapeutic efficacy of the DFP-10917 will be evaluated in relapsed or refractory acute myeloid leukemia (AML), or pts aged ≥ 60 years with newly diagnosed AML. Enrollment of the phase II study is ongoing.Clinical trial information: NCT01702155. Clinical trial information: NCT01702155.

7078 Poster Session (Board #67), Sun, 8:00 AM-11:30 AM

A phase (Ph) 1/2 trial of rituximab (RX), imprime PGG (IP), and alemtuzumab (AL) in the early treatment of patients (Pts) with high risk chronic lymphocytic leukemia (CLL). *First Author: Nandita Bose, Biothera, Inc., Eagan, MN*

Background: IP, a beta 1,3/1,6 glucan, can prime innate immune cells via complement receptors to kill antibody (Ab)-targeted, complement-opsonized tumor cells. Endogenous anti-beta glucan Abs (ABA) are required for IP binding and activation of innate immune cells. In stage IV NSCLC, serum ABA levels correlate with response to IP-containing therapy. Results from the Ph 1 portion of this study showed that IP in combination with RX and AL was well tolerated and associated with 73% complete response (CR) rate (Blood 120: abstr 1792, 2013). Here, we report clinical and translational results at the end of Ph 2. **Methods:** Primary endpoint of Ph 2 was % pts with CR 3 mos after completing 5 wks of IP + RX + AL. Eligible pts (n = 14) had CLL (per standard IWCLL criteria), high risk molecular features, no prior treatment, no standard indication for treatment initiation, adequate performance status and organ function. Planned enrollment was up to 39 pts. The study was terminated early due to slow accrual. Translational studies evaluated baseline serum ABA levels and in vitro IP binding to healthy donor whole blood immune cell subsets. **Results:** Among 14 pts enrolled, 6 (43%), 5 (36%) and 3 (21%) had Rai Stage 0, 1 and 2, respectively. CLL risk factors were 17p13- (21%), 11q22- (36%), and unmutated IGHV or VH3-21 use with ZAP70 and/or CD38 (43%). Grade 3/4 AEs were diarrhea, transaminase increase, dehydration, gastritis, hypertension, hyponatremia, neutropenia and febrile neutropenia. 13 (93%) pts responded to therapy (7 CR, 2 CR w/incomplete marrow recovery, 1 nodular PR and 3 PR by IWCLL-NCI 2008 criteria). As of 9/23/14 cutoff, median (med) f/u was 18.0 mo (range 9.5 - 28.0). Overall med duration of response was not reached: only 5/13 responders had progressed (med 5.6 mo; range 2.9 - 8.5); 8 are progression-free after med 10.2 mo (range 5.8 - 21.0). There were no deaths. ABA correlated with IP binding to neutrophils, monocytes and B-cells but not clinical response. Macrophage Ab-dependent cellular phagocytosis was enhanced *in vitro*and may contribute to anti-tumor mechanisms. **Conclusions:** IP in combination with RX and AL was safe and well tolerated, with high response rates. Clinical trial information: NCT01269385.

7079 Poster Session (Board #68), Sun, 8:00 AM-11:30 AM

Moxetumomab pasudotox and minimal residual disease in hairy cell leukemia. *First Author: Robert J. Kreitman, Laboratory of Molecular Biology, NCI, NIH, Bethesda, MD*

Background: Moxetumomab pasudotox is a recombinant immunotoxin containing truncated Pseudomonas exotoxin fused to an anti-CD22 Fv, reported to achieve 46% complete remissions in 28 relapsed/refractory hairy cell leukemia (HCL) patients treated with 5-50 ug/Kg every other day for 3 doses (QOD x3) per cycle. As a secondary endpoint of this phase I study, minimal residual disease (MRD) was studied in the original cohort and in an additional 21 patients enrolled at the highest dose level, amounting to 33 patients at 50 ug/Kg QOD x3. **Methods:** MRD studies included immunohistochemistry (IHC) of bone marrow biopsy (BMBx) and flow cytometry (FC) of blood and bone marrow aspirate (BMA). Real-time quantitative (RQ)-PCR, previously reported to detect 1 HCL cell in 10^6normal, used immunoglobulin rearrangement (IgH)-specific primers, when patient HCL IgH sequencing was possible. **Results:** Elimination of MRD by BMA FC, BMBx IHC and blood FC was achieved in 13 of 46 evaluable patients, 12 (36%) of 33 at 50 ug/Kg x3 and 1 (33%) of 3 at 40 ug/Kg QOD x3, vs 0 of 10 at lower doses (p = 0.04). Of 36 patients at 40-50 ug/Kg, those MRD-negative included 5 by blood FC, 1 by BMBx IHC, 5 by both blood FC and BMBx IHC, and 13 by all 3 studies. The median time to resolution of MRD in these 13 patients was 84 days, just prior to cycle 4. Of these 13 MRD-free patients, 11 (85%) remain MRD-free for 28-72 (median 45) months, and all 13 remain MRD-free in blood. In contrast, 7 of 10 patients MRD-free by blood but not BMA FC eventually became MRD+ in blood (p = 0.0005). RQ-PCR was more sensitive than BMA FC; of 19 patients evaluable for RQ-PCR, 5 of 6 MRD-free by BMA FC were also MRD-free by BMA RQ-PCR. **Conclusions:** Moxetumomab pasudotox can eradicate MRD in multiply relapsed HCL patients. We are aware of no other non-chemotherapy option with documented multi-year MRD-free BMA FC in a significant fraction of HCL patients. BMA MRD eradication is associated with lack of HCL progression in blood. Additional testing with RQ-PCR will determine if this more sensitive test is associated with outcome and can be used to help determine the optimal number of cycles. This study of investigator reported data was sponsored by MedImmune and supported by NCI's Intramural Research Program and the Hairy Cell Leukemia Foundation. Clinical trial information: NCT00462189.

7080 Poster Session (Board #69), Sun, 8:00 AM-11:30 AM

Correlation of genomic analysis by MyAML with chemotherapy drug sensitivity. *First Author: Pamela S. Becker, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Whole genome sequencing has demonstrated tremendous heterogeneity in the mutations and chromosomal translocations associated with acute myeloid leukemia (AML), yet we remain quite limited in our ability to predict outcomes of treatment. Most patients with AML cannot be cured with chemotherapy, and the overall survival remains poor. Thus, new approaches are needed to better tailor treatment for individual patients. **Methods:** MyAML uses next generation sequencing to analyze the coding regions and gene fusion genomic breakpoints of 194 genes associated with AML. Fragmented genomic DNA is captured with a customized probe design, and sequenced with 300bp paired end reads on an Illumina MiSeq instrument to an average depth of coverage $>$ 1000x. Using a custom bioinformatics pipeline, MyInformatics, single nucleotide variants (SNVs), indels, inversions and translocations are identified and annotated. High throughput drug sensitivity testing was performed against a panel of 160 drugs, of which 56 are FDA approved. De-identified samples from 12 patients with de novo AML and 12 patients with relapsed AML were analyzed. For 2 patient samples, Duplex Sequencing was also performed to detect sub-clonal mutations below the detection limit of conventional next-generation sequencing. Pearson's correlation was used to examine all possible pairs of missense mutations and the in vitro cytotoxicity response across the sample set. **Results:** From the 24 patient samples analyzed to date, an average of 129 missense mutations were identified in each sample with an allelic frequency $>$ 5%. These samples also contained an average of over 12 coding indels (~5 frameshift and 7 inframe indels) per sample. In addition, MyAML identified 3 samples with inv(16) and 6 samples with translocations, including the cryptic *NUP98-NSD1*t(5;11) that were not detected by karyotyping. For 2 of the samples, Duplex Sequencing was performed at a depth of $>$ 6000x. The FLT3 D835 tyrosine kinase domain (TKD) was identified in 2 patients not previously known to have this mutation. **Conclusions:** Data from disease focused genomics and in vitro chemotherapy sensitivity testing of individual patient samples will likely lead to innovations in treatment and improved outcomes in AML.

7081 Poster Session (Board #70), Sun, 8:00 AM-11:30 AM

Phase II trial of the combination of subcutaneous bortezomib (Bortez) and pegylated liposomal doxorubicin (PLD) for the treatment of patients with acute myelogenous leukemia (AML). *First Author: Ben Kent Tomlinson, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: The proteasome inhibitor Bortez has activity in AML, both as a single agent and in combination with standard induction. Bortez inhibits NF-κB signaling, and NF-κB activity promotes anthracycline resistance. The combination of Bortez and PLD was well tolerated in trials for multiple myeloma. **Methods:** We performed a phase II trial of Bortez and PLD in subjects at least 18 years old with relapsed/refractory AML or treatment naïve AML unfit for or who refused standard therapy. Bortez 1.5mg/m^2 was given subcutaneously on days 1, 4, 8, and 11, and PLD 40mg/m^{2}was given IV on day 4. Cycles were 21 days long. The primary endpoint was objective response rate (ORR), defined as complete remission (CR) plus partial remission (PR). **Results:** Fifteen subjects (53% male) were enrolled. Median age was 70 years (range 32-83). Four had relapsed, five had refractory, and six had untreated AML. Subjects had a median of two prior lines of therapy (range 0-7), including two with prior allogeneic transplantation. No subjects achieved a CR and three achieved a PR for an ORR of 20%. Two of the subjects achieving PR were treatment naïve. There were 12 patients that did not meet response criteria, and all three subjects with a PR progressed after cycle 2. The median number of completed cycles was 1 (range 0-2). Of 14 subjects with circulating blasts, eleven (79%) had a decrease in circulating blasts after the first cycle. Four subjects died from disease-related complications during cycle 1. The most common grade 3-4 adverse events were hematologic and infectious, occurring in 93% and 60% of subjects respectively. Two subjects (13%) had grade 3 peripheral sensory neuropathy. **Conclusions:** The combination of Bortez and PLD demonstrates modest anti-AML activity in a cohort of AML patients that includes heavily pretreated patients. The combination was well tolerated. Given the modest response rate and short duration of response, outcomes could be improved with modification of the current dosing schedule and/or inclusion of additional agent(s). Responses seen in older treatment naïve subjects suggest that this regimen should be studied further in this patient population. Clinical trial information: NCT01736943.

7082 Poster Session (Board #71), Sun, 8:00 AM-11:30 AM

Lenalidomide added to bendamustine-rituximab for untreated chronic lymphocytic leukemia (CLL): A phase 1 study. *First Author: Jeremy S. Abramson, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Lenalidomide is an immunomodulator with activity in CLL. Bendamustine-rituximab (BR) is a widely used upfront regimen. We conducted a phase I trial combining lenalidomide (len) with BR. **Methods:** Patients had untreated CLL with an indication for therapy; ANC $\geq$ 1000, platelets $\geq$ 50000; and adequate organ function. A 3+3 design was used with 10 additional patients at the MTD. Escalating doses of len were added to standard dose BR, with bendamustine dosed at 90mg/m^2. Len was given on d8-22 in c1, and d1-21 in subsequent cycles. The starting dose level for len was 2.5mg. Level 2 was 2.5mg for c1 and escalated to 5mg with c2. Level 3 was 5mg for c1, then 10mg with c2. Patients could receive up to 6 cycles. All patients received allopurinol, aspirin and pegfilgrastim support. DLT was assessed during c1 of dose level 1, and c1-2 of subsequent dose levels. **Results:** Twenty-three patients were accrued. Median age was 64 (range 43-85). Thirty-five percent of patients had Rai stage 3/4, 52% had unmutated *IGHV*, and 26% had 11q deletion. Dose level 2 had one DLT of pulmonary embolism (PE). Dose level 3 was declared the MTD. Eleven subjects completed 6 cycles; median number of cycles was 5 ($<$ 1-6). Reasons for discontinuation were neutropenia (3), PE (2), rash (2), zoster (1), thrombocytopenia (1), Hodgkin lymphoma transformation(1), withdrawal of consent (1), and physician decision (1). Most common toxicities of any grade were rash (n = 14), fatigue (13), nausea (11), fever (10), anemia (9), thrombocytopenia (6), cough (5), and diarrhea (5). Five patients were suspected of tumor flare, 4 of whom were treated with steroids and the other spontaneously remitted. No tumor lysis syndrome was seen. Grade 3-4 toxicities occurring in $>$ 1 patient were rash (6), neutropenia (4), febrile neutropenia (3), anemia (2), and pneumonitis (2). One subject developed CMV reactivation. Dose reductions were required in 9/13 subjects at the MTD due to neutropenia (6), rash (3) and anemia (1). The ORR was 87% and CRR was 39%. **Conclusions:** Len-BR results in increased toxicity compared to what would be expected from BR alone, though efficacy was high. Given the rate of toxicities after the DLT assessment period, the 10mg len dose may be too high for most patients. Clinical trial information: NCT01400685.

7083 Poster Session (Board #72), Sun, 8:00 AM-11:30 AM

Clinical outcome of adult acute lymphoblastic leukemia based on Philadelphia chromosome status and socioeconomic status. *First Author: Bao Duy Dao, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Adult patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) often relapse with chemotherapy alone. Many undergo allogeneic stem cell transplant (alloSCT) in first complete remission (CR1). Use of tyrosine kinase inhibitors (TKI) with chemotherapy improves outcomes although the standard of care for Ph+ALL remains undefined. **Methods:** 105 consecutive adult patients with ALL were treated at UT Southwestern Medical Center and its county affiliate Parkland Hospital from 2004-2014. Associations between alloSCT, socioeconomic status, and overall survival (OS) were evaluated using Cox regression methods and Kaplan-Meier analysis. **Results:** 34 patients had Ph+ALL. Median age was 49 years. 26 patients received chemotherapy + TKI alone. 8 patients underwent alloSCT after initial chemotherapy + TKI. 82.4% of Ph+ALL patients achieved CR1. At median follow up of 18 months, 61.5% of Ph+ALL patients who did not undergo alloSCT were alive compared to 50.0% of patients who did. AlloSCT was not significantly associated with OS (p = 0.74). Survival was not significantly differed between Ph+ALL and Ph-ALL (p = 0.58). Impact of socioeconomic status on OS within the Ph+ALL group was limited by small sample size. Within the entire cohort of ALL patients, about half of patients had an indigent care plan and were treated at the county hospital. These patients had an OS of 15.5 months compared to 49 months among privately insured patients (p = 0.008). OS improved from 17.9 months for patients treated at the county hospital to 78 months for individuals treated at our university facility (p = 0.0052). In univariate analysis, OS was significantly associated with insurance type (HR = 2.09; 95% CI 1.20-3.64) and treating facility (HR 2.24; 95% CI 1.25-4.00). In multivariate analysis, this association was no longer significant. **Conclusions:** In the advent of TKI, alloSCT did not significantly influence OS in Ph+ALL patients. Administration of chemotherapy + TKI alone may be a viable alternative given the increased morbidity associated with alloSCT. Socioeconomically disadvantaged patients appear to have inferior survival, but this needs further investigation in a larger cohort.

7084 Poster Session (Board #73), Sun, 8:00 AM-11:30 AM

Prognostic impact of renal insufficiency (RI) at diagnosis in patients with chronic lymphocytic leukemia (CLL). *First Author: Paolo Strati, Mayo Clinic, Rochester, MN*

Background: Renal function has a well-established prognostic role in patients with some hematological malignancies, such as multiple myeloma. However, its impact on survival in patients with CLL hasn't been explored. **Methods:** We used the Mayo Clinic CLL database to identify all patients diagnosed with CLL between 01/1995 and 11/2014 using the 2009 iwCLL criteria and seen at our center prior to treatment. Patients for whom we could not calculate a baseline creatinine clearance (Cr-Cl) due to missing creatinine/weight or who were missing baseline complete blood count (CBC) (n = 466) were excluded from final analysis. Renal insufficiency (RI) was defined as Cr-Cl < 45 mL/min calculated with the Cockroft-Gault equation. Logistic regression was used to determine which factors predicted RI. Fisher's exact test was used to compare treatment types by RI. The Kaplan-Meier method was used for the survival analyses. **Results:** The final analysis included 1268 patients. Of these, 87 (7%) had RI at diagnosis. Factors significantly associated with RI on univariate analysis (UVA) were age > 65 years, female sex, hypertension (HTN), hemoglobin < 11 g/dL, and Rai stage III-IV. Factors associated with RI on multivariate analysis (MVA) were age > 65 years, female sex, HTN, and advanced Rai stage. Of the 506 patients who required treatment, 25 had RI. Type of first treatment differed between patients with and without RI ($p < 0.001$); patients with RI were more likely to receive alkylator-based therapy (48% vs 15%) and less likely to receive purine analogue-based CIT (8% vs 44%). Median overall survival (OS) was 124 months, 59 months for those with RI, 132 months for those without RI ($p < 0.001$). Baseline characteristics (age, sex, HTN, diabetes, CBC, CD49d, CD38, ZAP70, *IGHV* mutation status and FISH) as well as RI were associated with OS on UVA. **Conclusions:** RI is relatively frequent at time of CLL diagnosis (7% of cases) and has a profound influence on therapy selection among patients requiring treatment. RI at time of CLL diagnosis is associated with overall survival.

7085 Poster Session (Board #74), Sun, 8:00 AM-11:30 AM

Effect of grade (G) 3 fibrosis on clinical outcome of patients (Pts) with myelodysplastic syndromes (MDS): Mayo Clinic Experience. *First Author: Naveed Cheema, Mayo Clinic, Rochester, MN*

Background: There have been renewed attempts at characterizing the clinicopathological findings of MDS with fibrosis (MDS-F) in order to determine if it warrants a distinct entity. Most of these studies were small while few studied clinical outcome of MDS-F. **Aim:** To studyclinical outcomes of patients with MDS-F. **Methods:** A retrospective, single-institution study of MDS cases per WHO classification from 1993-2014 was done. Bone marrow biopsy (BMB) fibrosis was identified as G 1, 2, or 3 on reticulin stain. Wilcoxon, Pearson tests, Kaplan Meier, multivariant analysis were done via JMP. **Results:** Initial screen of our database revealed 108 (13%) of 835 pts with MDS as MDS-F. On follow up, 49/108 (45%) had subsequent BMB. In 33/49 (67%) pts, diagnosis changed (median time 7 months, m) into AML,RAEB,RCMD in 17 (52%), 10 (30%), and 2 (6%) pts. A second change was in 5/14 pts. Final diagnoses in 49 pts were AML/RAEB/RCMD in 18 (37%), 15 (31%), and 8 (17%) (rest were atypical/ CMML/MDS MPN/RARS/MDS-F). Comparison between fibrosis (n = 108) and non-fibrosis groups (n = 727) showed no statistically significant difference in survival or time to AML. Statistically significant variables between the groups were age ($p = 0.0002$), platelet ($p < 0.0001$), multilineage dysplasia ($p < 0.0001$), dysmegakaryopoiesis ($p < 0.0001$), peripheral blasts ($p = 0.01$), cellularity ($p < 0.0001$) and IPSS-R group ($p = 0.01$). There was a statistically significant difference in mOS across all grades of fibrosis (33 in G1, 39 in G2, 8 m in G3, $p = 0.001$). Pts with G3 fibrosis vs all others had a statistically significant lower mOS of 8 vs 29 m ($p < 0.0001$). In multivariate analysis, only age ($p < 0.0001$), IPSS-R ($p < 0.0001$) and G3 fibrosis ($p = 0.018$) were found to have a statistically significant effect on mOS (but not blast or gender). JAK2 status and CD34 clustering had no significance on survival amongst the fibrosis group. **Conclusions:** MDS-F is a small entity with distinct lab and BMB findings. Only G3 fibrosis had a significant negative impact on mOS. On follow up, 55% progressed into AML or RAEB. Age, IPSS-R and G3 fibrosis were the only significant contributors to mOS. Our finding needs to be further investigated within larger sets of MDS pts.

7086 Poster Session (Board #75), Sun, 8:00 AM-11:30 AM

Up-regulation of CALR in patients with essential thrombocythemia independent from CALR mutations. *First Author: Ciro Roberto Rinaldi, University of Lincoln, Lincoln, United Kingdom*

Background: Somatic mutations in the exon 9 of calreticulin (CALR) gene were recently discovered in patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF) lacking JAK2 and MPL mutations, and absent in patient with polycythemia vera (PV). Among patients with ET or PMF with un-mutated JAK2 or MPL, CALR mutations were detected in 67% of those with ET and 88% of those with primary PMF. Over expression of the most frequent CALR deletion caused cytokine-independent growth in vitro owing to the activation of signal transducer and activator of transcription 5 (STAT5) by means of an unknown mechanism. Patients with myeloproliferative neoplasms carrying CALR mutations presented with higher platelet counts and lower hemoglobin levels than patients with mutated JAK2, but also a lower risk of thrombosis and longer overall survival than patients with mutated JAK2. **Methods:** We analyzed by Real Time PCR, CALR expression in peripheral blood (PB) of 38 patients affected by ET, 17 JAK2 mutated (45 %), 4 CALR (10.5%) mutated, 1 MPL mutated (3%) and 14 with no molecular abnormalities, and compared with a cohort of healthy volunteers. **Results:** We found a significant over expression of CALR (median 5.15; range 1.13-270.08) comparing with controls (median 0.38, range 0.18-1).No significant difference was found comparing CALR expression in CALR mutated (median 4.9, range 1.51-37.14) and CALR/JAK2 un-mutated patients (4.68, range 1.51-28.71). CALR up-regulation is not mutually exclusive with JAK2 mutations, there was, in fact, no difference in CALR mRNA between JAK2 mutated (median 5.09, range 1.13-270) and wild type ET patients (median 5.08, range 1.51-37). There was no significant difference when we correlated CALR expression with PLT counts, spleen size or type of cytoreductive therapy. **Conclusions:** CALR mRNA expression is independent from the CALR mutational status and more interestingly is up-regulated also in JAK2 mutated patients. A larger cohort of patients is required to confirm these preliminary findings.

7087 Poster Session (Board #76), Sun, 8:00 AM-11:30 AM

Ruxolitinib in polycythemia vera: Follow-up from the RESPONSE trial. *First Author: Srdan Verstovsek, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The RESPONSE trial is a multicenter, open-label phase 3 study evaluating the efficacy and safety of ruxolitinib (Rux) compared with best available therapy (BAT) in patients (pts) with polycythemia vera resistant to or intolerant of hydroxyurea. Results from the primary analysis, 48 wks from last pt first treatment (LPFT), were published (Vannucchi, NEJM 2015). **Methods:** This was a second preplanned analysis 80 wks after LPFT. The primary response was defined as achieving both hematocrit (HCT) control without phlebotomy (PBT) through wk 32 and a ≥ 35% reduction in spleen volume (SV) by imaging at wk 32. Durability of the primary response, HCT control, spleen volume reduction, and complete hematologic remission (CHR), as well as long-term safety, were evaluated. **Results:** At data cutoff, 91 (82.7%) pts randomized to Rux (Rux arm) were receiving treatment (median exposure, 111 wks), compared to 93 (84.5%) at the wk 48 analysis (median exposure, 81 wks). No pts remained on BAT, compared to 3 pts at the wk 48 analysis. Of the 23 (21%) pts in the Rux arm who achieved the primary response at wk 32, only 1 lost this response. For the 60% of pts in the Rux arm who achieved HCT control at wk 32, the probability of maintaining this response for 80 wks from time of initial response was 89%. Of the 98 pts on Rux at wk 32, 90% did not have a PBT from wk 32 to 80. A ≥ 35% SV reduction at wk 32 was achieved in 38% of Rux pts; all maintained their response. CHR at wk 32 was achieved in 24% of Rux pts; the probability of maintaining CHR for 80 wks was 69%. The Pruritus Symptoms Impact Scale was "very much improved" for 5 of 10 pts in the Rux arm at their end of study visit. The most common nonhematologic adverse events in the Rux arm were headache (21.8% at the wk 80 analysis [ie, entire follow-up] vs 20.9% at the wk 48 analysis), diarrhea (20.0% vs 19.1%), pruritus (20.0% vs 17.3%), and fatigue (17.3% vs 17.3%); most were grade 1 or 2. Grade 3 or 4 anemia and thrombocytopenia occurred in 1.8% and 5.5% of pts, respectively (no increase from wk 48 analysis). The rate of treatment discontinuation in the Rux arm due to adverse events remained low (4.5%). **Conclusions:** In RESPONSE, Rux responses were durable and treatment remained generally well tolerated, with 83% still receiving Rux at a median exposure of 111 wks. Clinical trial information: NCT01243944.

7088 Poster Session (Board #77), Sun, 8:00 AM-11:30 AM

Case series of hypomethylating agents (HMA) effect on myelodysplastic/myeloproliferative neoplasm unclassified (MDS/MPN-U): Mayo Clinic experience. *First Author: Ahmed K. Abou Hussein, Mayo Clinic, Rochester, MN*

Background: MDS/MPN-U is a rare myeloid disorder that has both dysplastic and proliferative features, but cannot be parsimoniously classified as either MDS or MPN. There is currently no standard treatment algorithm for MDS/MPN-U and is either based on MPN or MDS best available therapies. **Methods:** A retrospective, single-institution study between 1993-2014 of WHO-defined MDS/MPN-U cases was carried after getting appropriate IRB approval. Patients with diagnosis of chronic myelomonocytic leukemia and refractory anemia with ring sideroblasts were excluded. Wilcoxon, Pearson tests, Kaplan Meier, multivariant analysis were done via JMP 10. **Results:** A total of 63 patients with MDS/MPN-U were identified, 10 of whom were treated with HMA. The indication for treatment was thrombocytopenia in 50%, anemia in 30%, and symptomatic splenomegaly in 20%. Median age was 67.5 years (56-82), with 80% of the patients were males. Median platelet count was 101 $x10^9$ (14-184), hemoglobin (Hg) of 9.4 g/dL (6.9-16.3), white blood cell (WBC) count of 8.3 $x10^9$(1.8-90.7), peripheral blood blasts of 1% (0-6); bone marrow blasts of 5% (3-20). Cytogenetics were diploid in 70%, while splenomegaly was found in 30%. Two HMAs were used, with decitabine in 60% and azacitidine in the other 40%. There was no statistical significance on overall survival (OS) between the two HMAs ($p = 0.2$). The median number of treatment cycles was 5 (1-20), with achievement of complete response (CR) in 20%, partial response (PR) in 10%, stable disease in 40%, and progressive disease in 30%. Transformation to AML was seen in 40%, with a median time of 372 days (248-929). Bone marrow transplant was performed in one patient. Median OS was 15 months. Multivariate analysis revealed bone marrow blasts ($p = 0.01$) as the only statistically significant factor on OS (but not WBC, Hg or platelets). **Conclusions:** MDS/MPN-U is a rare entity with no standard treatment algorithm available at present. HMAs yielded an overall response (CR+PR) of 30%, with a median OS of 15 months. On a multivariate analysis only bone marrow blasts had an impact on mOS. Larger studies are needed to confirm our findings in this rare disease.

7089 Poster Session (Board #78), Sun, 8:00 AM-11:30 AM

Outpatient allogeneic hematopoietic cell transplant following alemtuzumab based reduced intensity conditioning in patients with advanced mycosis fungoides/Sezary syndrome. *First Author: Enkhtsetseg Purev, National Institutes of Health, Bethesda, MD*

Background: Advanced mycosis fungoides/Sezari syndrome (MF/SS) is associated with poor prognosis and is incurable with conventional chemotherapeutic approaches. We describe a novel transplant approach that enables outpatient administration and monitoring, provides a measure of disease control prior to engraftment, and reduces the incidence of GHVD. **Methods:** Subjects with advanced MF received a G-CSF mobilized PBSC allograft from an HLA identical sibling following alemtuzumab, and fludarabine conditioning regimen. CSA was used as GVHD prophylaxis to supplement alemtuzumab-induced *in-vivo* T-cell depletion. Donor lymphocyte infusions (DLI) were used as required to promote transition to full donor chimerism and/or promote a graft-vs-tumor effect. Conditioning and as well as stem cell infusions were carried out largely in an outpatient setting. **Results:** 5 subjects with stage IIb-IV MF/SS were enrolled. The conditioning was well tolerated with no serious adverse events. None of the subjects had profound and prolonged neutropenia and thrombocytopenia. Median time to calculated donor neutrophil recovery was 45 d (range 15 d to 6 mo). 4/5 subjects achieved full and sustained donor T-cell and myeloid chimerism, which occurred at a median 9 mo and 6 mo post-transplant, respectively. Among those at risk, 2/4 developed CMV reactivation. None of the subjects developed PTLD. At a median follow-up of 3 yrs, 1 subject developed aGVHD and 1 subject developed cGVHD. 3 subjects achieved complete remission at a median of 7 mo post-transplant mediated by a potent graft-versus-tumor effect. 3 subjects are alive at 10 yrs, 8 yrs, and 6 mo after transplant. 1 subject died 3 yrs post-transplant from a second malignancy while SS was in complete remission, 1 subject died 6 mo post-transplant from grade IV GI GVHD. **Conclusions:** The outpatient based reduced intensity transplant approach described here is well tolerated and associated with prolonged, GVT-induced complete remissions in patients with advanced stage MF/SS. The trial is ongoing and efforts are underway to permit enrollment of patients with available HLA-matched unrelated donors. Clinical trial information: NCT00047060.

7090 Poster Session (Board #79), Sun, 8:00 AM-11:30 AM

Hepatitis C virus infection in patients undergoing hematopoietic cell transplantation in the era of direct-acting antiviral agents. *First Author: Andreas Kyvernitakis, Department of Infectious Diseases, Infection Control, and Employee Health, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There is paucity of literature regarding hepatitis C virus (HCV) infection in hematopoietic cell transplant (HCT) recipients. In the study described herein, we aimed to evaluate several aspects of HCV infection in HCT recipients, including the yield of HCV antibody testing, impact of this infection on cancer status, morbidity and mortality, along with the role of antiviral treatment (AVT). **Methods:** The medical records of cancer patients with chronic HCV infection seen at MD Anderson Cancer Center from 8/2009-12/2014 were reviewed. Those seen from 8/2009-10/2012, were reviewed retrospectively, whereas those seen from 11/2012-12/2014, were analyzed prospectively in an observational study. Diffuse large B-cell, mantle cell and follicular lymphomas were considered HCV-associated non-Hodgkin lymphomas (NHLs), as reported previously. We treated patients with different AVT regimens, including pegylated IFN, pegylated IFN plus ribavirin (PR), sofosbuvir plus PR, sofosbuvir plus ribavirin, and sofosbuvir plus simeprevir. **Results:** Of 434 HCV-infected cancer patients evaluated, 59 underwent 64 HCTs. The majority (80%) underwent autologous transplantation. Thirteen percent of them became HCV-seronegative post-HCT. Acute exacerbation and reactivation occurred in 28% and 10% of HCTs, respectively. Compared to patients who did not receive AVT, treated patients had fewer relapses of HCV-associated NHL (83% versus 20%; P = .04), slower progression to cirrhosis (323 days versus 2242 days; P = .05), and a higher 5-year survival rate (50% versus 82%; P = .01). AVT discontinuation rates post-HCT were 71% in those receiving IFN-containing regimens versus none in those receiving IFN-free regimens (P = .02). AVT was effective in 28% of those given IFN-containing treatment and 100% of those given direct-acting antivirals. **Conclusions:** HCV seropositivity can be lost post-HCT, posing a diagnostic challenge. HCV treatment should be offered to all HCT recipients, as it improves both hepatic but also oncologic outcomes. HCV infection in HCT recipients can be successfully treated with selected direct-acting antivirals.

7091 Poster Session (Board #80), Sun, 8:00 AM-11:30 AM

Influence of variant allele frequency (VAF) on the phenotypic penetrance of TP53 mutations in myeloid malignancies. *First Author: David Andrew Sallman, Moffitt Cancer Center, Tampa, FL*

Background: The clinical implementation of next generation sequencing (NGS) has allowed for the quantitative detection of clinically significant somatic mutations in myeloid malignancies. However, the clinical relevance of the VAF in these mutations is unknown. Here we investigate the role of *TP53* VAF in MDS and AML which is a recognized adverse prognostic feature associated with a complex karyotype. **Methods***:* A training set of NGS profiled MDS or AML cases were retrospectively identified from the Moffitt Cancer Center MDS database. A validation set was obtained from WHO defined MDS cases profiled at Genoptix. Clinical variables and outcomes of MDS patients were characterized at the time of sample procurement. Fisher's exact and t-tests were used for comparative analyses. Kaplan-Meier estimates were used to estimate overall survival and analyzed from the date of mutation identification. **Results***:* From May 2013 to October 2014, 43 patients of 252 screened cases were identified in our training set with a *TP53* mutation. The mean VAF across duplicate libraries was 39.8%. As previously reported, *TP53* mutation was strongly associated with complex karyotype (70% vs 6%, $p < .0001$). When parsed by VAF, 100% of *TP53* mutated patients with a VAF $> 40\%$ had complex cytogenetics in comparison to 50% of patients with a VAF $< 20\%$ ($p = .0016$). Further, patients with complex cytogenetics had a significantly increased VAF (median 49% vs 18%, $p = .0009$). MDS patients with a *TP53* VAF $> 40\%$ had a median overall survival (OS) of 102 days versus an OS that was not reached in patients with lower VAF ($p = .04$). The validation set ($n = 150$) confirmed the training set findings ($p < .0001$). Additionally, *RUNX1*mutations were associated with thrombocytopenia ($p < .0001$) and VAF more strongly predicted the presence of thrombocytopenia ($p = .04$), suggesting that allelic burden influences phenotype penetration across multiple genes. **Conclusions***:* Consideration of *TP53* VAF improves prognostic precision compared to binary mutational analysis alone. This study supports inclusion of VAF at point of care for *TP53* and other recurrent mutations.

7092 Poster Session (Board #81), Sun, 8:00 AM-11:30 AM

Prognostic and predictive value of IPSS-R in assessing overall survival (OS) in a phase III study of rigosertib in second-line higher-risk (HR) MDS patients. *First Author: Lewis R. Silverman, Mount Sinai Medical Center, New York, NY*

Background: ONTIME was a randomized (2:1) study of rigosertib (RIG) vs best supportive care (BSC) in 299 pts with HR-MDS who had relapsed after, failed to respond to, or progressed during hypomethylating agents (HMAs). This study showed a trend favoring RIG in the overall ITT analysis and a significant effect of RIG in the subgroup of patients with very high risk (VHR) per the IPSS-R. **Methods:** We examined the utility of the IPSS-R and the correlation between baseline disease characteristics and OS in 93 RIG and 41 BSC pts with IPSS-R VHR. Results*:* This first clinical study using IPSS-R in 2nd-line HR-MDS pts showed an effect ($p < 0.001$) of RIG on median OS vs BSC in not only the overall group of pts with IPSS-R VHR, but also in several subgroups defined by baseline disease characteristics (see table). Overall, adverse events (AEs) were reported in 100% of RIG pts and 95% of BSC pts with IPSS-R VHR. AEs ≥ Grade 3 in ≥ 10% of pts were: anaemia (RIG 24%, BSC 11%), thrombocytopenia (21%, 11%), febrile neutropenia (17%, 11%), neutropenia (15%, 13%), pneumonia (12%, 13%). Conclusions*:* IPSS-R is a useful prognostic tool for 2nd-line MDS pts. After HMA failure, MDS pts with IPSS-R VHR and certain subgroups identified by baseline disease characteristics showed an OS advantage when treated with RIG compared to BSC. Such characteristics should be considered in the design of future 2nd-line studies in MDS patients with IPSS-R VHR. Clinical trial information: NCT01241500.

Median (months) OS by baseline disease characteristics in pts with IPSS-R VHR.

7093 Poster Session (Board #82), Sun, 8:00 AM-11:30 AM

Use of dual donor T-cell chimerism to predict prognosis after double cord blood allogeneic transplantation. *First Author: Muhamed Baljevic, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Double cord blood transplantation (dCBT) is an important strategy to overcome dose limitation of single CBT. By day 21, over 80% of patients (pts) have single unit dominance maintaining long-term hematopoiesis. However, outcomes of pts who have persistence of both CB units after dCBT is unknown. **Methods:** We retrospectively analyzed 105 pts who engrafted after dCBT between 2003 through 2014 and had donor T cell chimerism (TCC) of at least 10% from each CB unit at day 100 +/- 30 after transplant (dCTT). Pts alive and free of disease progression at day 100 were evaluable. **Results:** Of 105 pts, 10 (9.5%) had dTCC. Median age was 43 (range; 1-73). Disease diagnosis was AML in 57.1% and ALL in 21.9%. Disease status at dCBT was 1st or 2nd complete remission in 67.6% and active disease in 32.4%. Conditioning was myeloablative in 73.3% and reduced intensity in 26.7%. Immunosuppressive therapy included mycophenolate mofetil and tacrolimus; all pts received anti-thymocyte globulin. One of the CB units were manipulated by ex-vivo expansion in mesenchymal stem cell co-culture in 72.4% of the pts. The median dose of $CD34^+$ and total nucleated cells infused was $0.36x10^6$/kg (0.12-5.35) and $0.51x10^7$/kg (0.3-1.29), respectively. Singe TCC (sTCC) and dTCC pts were comparable except for more frequent ≥ 4/6 HLA matching between 2 CB units (66.3% vs. 90%, $p = 0.1$), and less use of CB manipulation in dTCCC (74.7% vs. 50%, $p = 0.1$). Transplant outcomes were similar between groups with 3-year (yr) overall survival and progression free survival of 40% vs. 41.4% and 40% vs. 32.3%, respectively. Seven of 10 pts with dTCC were evaluable for long-term assessment [> 6 months (mo)]: 1 pt had autologous recovery with progression after 6 mo of dCBT. Unit dominance was observed in 4 pts, within 4 to 20 mo after dCBT; 1 of them progressed 5 mo after unit dominance and another died of fungal infection at 15 mo. Two AML pts had long-term dTCC with units contributing 58%/42% and 84%/16% at 4 and 3.2 yrs after dCBT. Both were alive in remission at last follow-up. **Conclusions:** The unique situation of TCC from both CB units around day 100 is not associated with worse transplant outcomes in pts receiving dCBT. These provocative results need to be confirmed in larger studies.

TPS7094 Poster Session (Board #83a), Sun, 8:00 AM-11:30 AM

A phase II, randomized trial of standard of care with or without midostaurin to prevent relapse following allogeneic stem cell transplantation in patients with FLT3-ITD mutated acute myeloid leukemia. *First Author: Richard T. Maziarz, Oregon Health and Sci Univ, Portland, OR*

Background: Midostaurin, an orally administered multitarget kinase inhibitor, potently inhibits the FLT3 and c-Kit tyrosine kinases. Prior phase 1/2 and 1b clinical trials of the drug have demonstrated tolerable safety profiles and clinical activity in pts with AML (Fischer, *J Clin Oncol*, 2010; Stone, *Leukemia*, 2012), and it is currently in development in advanced mastocytosis (phase 2; Gotlib, ASH 2014) and AML (phase 3; Stone, ASCO 2011). In the phase 3 randomized trial in pts with newly diagnosed, *FLT3*-mutated AML aged < 60 years, midostaurin 50 mg BID or placebo was administered sequentially with standard induction and consolidation therapy, followed by 1 year of maintenance. Results are pending from this primary therapy trial (RATIFY; NCT00651261). Overall, pts with *FLT3*-ITD–mutated AML have a poor prognosis and are generally considered for curative alloHSCT in first clinical remission (CR1). However, an EBMT retrospective analysis of outcomes for pts who underwent alloHSCT in CR1 demonstrated a high rate of early relapse, with very poor long-term survival (Brunet, *J Clin Oncol*, 2012). There is interest in the use of post-transplant adjuvant maintenance therapy with hypomethylating agents or TKIs in pts with high-risk AML to potentially increase long-term relapse-free and overall survival (OS). **Methods:** This randomized, open-label phase 2 study is investigating the efficacy and safety of midostaurin 50 mg BID in pts with *FLT3*-ITD–mutated AML who underwent alloHSCT in CR1 to determine whether the addition of study drug will reduce relapse at 18 mo post-HSCT. Secondary endpoints are disease-free survival, nonrelapse mortality, OS, safety, and pharmacokinetics. Key inclusion criteria include a documented *FLT3*-ITD mutation, age 18 to 60 years, 8/8 or single-allele mismatch 7/8 donor, and CR1 status. Pts may enroll after the date of engraftment and hematologic recovery to an ANC > 1000/μL and platelets ≥ 20,000/μL without platelet transfusion. **Status:** The trial is open at 18 centers, and 22 of the planned 60 pts have been enrolled. ClinicalTrials.gov no. NCT01883362. Clinical trial information: NCT01883362.

TPS7095 Poster Session (Board #83b), Sun, 8:00 AM-11:30 AM

Randomized, multicenter, open-label, phase 3 study of the BTK inhibitor ibrutinib in combination with obinutuzumab vs. chlorambucil in combination with obinutuzumab in patients with treatment-naïve CLL/SLL (PCYC-1130): iLLUMINATE. *First Author: Ian Flinn, Sarah Cannon Research Institute, Nashville, TN*

Background: There are limited safe and effective first-line options for CLL patients (pts) who have comorbidities, are older, and are not candidates for fludarabine-based regimens. The combination of chlorambucil with obinutuzumab is a recently approved treatment option for these pts. In a recent trial in treatment-naïve (TN) pts with CLL (median age 71 y), single-agent ibrutinib resulted in an ORR of 71% (CR, 13%), PR with lymphocytosis of 13%, and an estimated 22-month PFS of 96% and OS of 96% (O'Brien, 2014). Ibrutinib was effective even in pts with poor prognostic factors. This randomized, multicenter, open-label, phase 3 trial compares the chemotherapy-free combination of ibrutinib and obinutuzumab to chlorambucil/obinutuzumab, in TN pts with CLL not appropriate for fludarabine-based chemoimmunotherapy due to comorbidity, age, or presence of del17p. **Methods**: In iLLUMINATE, an ongoing trial of TN pts who have active disease requiring therapy, approximately 212 TN CLL/SLL pts will be randomized if they meet 1 of the following criteria: CIRS > 6, estimated CrCL ≥ 30 but < 70 mL/min, del17p or TP53 mutation, or are ≥ 65 years of age. Pts will be randomized to ibrutinib (420 mg per day continuously) or oral chlorambucil (0.5 mg/kg D1 and D15 of each 28-day cycle for 6 cycles). All pts will be given 6 cycles of IV obinutuzumab according to the product label. Key exclusion criteria include any prior treatment for CLL, evidence of CNS involvement, or Richter's transformation. Treatment will be administered up to the specified maximum number of cycles, or until PD or unacceptable toxicity. The primary endpoint is PFS, assessed by Independent Review Committee (IRC). Secondary endpoints include ORR, MRD-negative response rate, OS, hematologic improvement, patient-reported outcomes, safety, and tolerability. Pts on the chlorambucil/obinutuzumab arm may cross over to ibrutinib after IRC-confirmed PD if they meet treatment criteria. Enrollment has initiated and is planned in approximately 16 countries including the US, EU, and Australia (NCT02264574). Clinical trial information: NCT02264574.

TPS7096 **Poster Session (Board #84a), Sun, 8:00 AM-11:30 AM**

A multicenter, open-label phase 2a study of ibrutinib with or without cytarabine in patients with acute myeloid leukemia (PCYC-1131). *First Author: Jorge E. Cortes, Department of Leukemia, MD Anderson Cancer Center, Houston, TX*

Background: Therapeutic options in patients with acute myeloid leukemia (AML) who are elderly, unfit, or who relapse after induction therapy remain an unmet need. Studies with primary AML samples and cell lines suggest a role for Bruton's tyrosine kinase (BTK) as a therapeutic target in AML (Rushworth, 2014). Expression and increased phosphorylation of BTK were detected in AML cells, and treatment with ibrutinib (an oral, covalent inhibitor of BTK) resulted in down-regulation of cell growth, decreased adhesion to the bone marrow stromal cells and cell migration induced by a CXCR4 ligand, SDF1 (Zeitseva, 2014). As such, ibrutinib may have a dual anti-AML effect by (1) a direct anti-proliferative/cytotoxic activity and (2) mobilizing cells from the protective bone marrow microenvironment. In addition, ibrutinib augmented the cytotoxicity of cytarabine and daunorubicin in patient derived AML cells. **Methods**: PCYC-1131 (NCT02351037) is a phase 2, open-label, non-randomized study of ibrutinib ± low-dose cytarabine (LD-AraC) in patients with AML. The study will enroll approximately 67 patients with pathologically documented AML that has failed standard treatment, or patients without prior therapy who declined standard treatment. Initially, the safety of the combination will be assessed in 6–9 patients receiving oral ibrutinib 560 mg once daily continuously + LD-AraC at 20 mg twice daily subcutaneously for 10 days per 28-day cycle. Dose limiting toxicities (DLTs) will be assessed during the first treatment cycle. If less than 33% of patients experience DLTs, additional patients will be assigned at investigator discretion to receive ibrutinib monotherapy (n = 33), or ibrutinib + LD-AraC (n = 34). Patients on ibrutinib monotherapy who experience treatment-failure or relapse will be permitted to add LD-AraC. The primary endpoints are overall remission rate, safety, and tolerability. Additional endpoints include relapse-free survival, event-free survival, overall survival, clinical benefit rate, pharmacokinetics of ibrutinib ± LD-AraC, and evaluation of prognostic and predictive biomarkers. Safety data will be summarized descriptively. Clinical trial information: NCT02351037.

TPS7097 **Poster Session (Board #84b), Sun, 8:00 AM-11:30 AM**

An international phase 3 randomized, placebo-controlled study of CC-486 (oral azacitidine) maintenance therapy in patients with acute myeloid leukemia (AML) in complete remission (CR): The Quazar AML maintenance trial. *First Author: Gail J. Roboz, Weill Medical College of Cornell University and the New York Presbyterian Hospital, New York, NY*

Background: Few inroads have been made in the past 30 years to improve overall survival (OS) in older patients (pts) with AML. While induction chemotherapy (IC) can induce CR in 40-50% of older pts, most relapse within 3-18 months. Post-remission therapy (Tx) is required to prevent relapse. Parenteral azacitidine (AZA) prolonged OS in older pts with AML vs conventional care regimens (10.4 vs 6.5 months, *P*= 0.1009) (Dombret, *Haematologica*, 2014:LB2433). CC-486 is an oral formulation of AZA in development for use in hematologic malignancies. An oral formulation allows delivery of AZA at lower systemic doses over a more prolonged schedule than is practical with SC AZA. CC-486 taken at home is convenient for pts, eliminates injection- and catheter-site reactions, and avoids resource utilization costs of hospital/clinic visits. Thus, CC-486 may offer a relapse-free survival (RFS) advantage and improve quality of life. The Quazar phase 3 AML Maintenance trial (clinicaltrials.gov NCT01757535) is designed to assess whether CC-486 is an effective low-intensity maintenance Tx that can extend OS in older pts with AML. **Methods:** Pts aged ≥ 55 yrs with *de novo* AML or AML secondary to MDS in first CR or CRi (IWG 2003) after IC, with or without consolidation, are randomized 1:1 to 300 mg QD CC-486 or placebo for 14 days of 28-day treatment cycles. Randomization is stratified by age (55-64 / ≥ 65 yrs) and cytogenetic risk (Intermediate / Poor) at induction, prior MDS, and post-remission consolidation Tx. All pts can receive supportive care. The primary endpoint is OS. Secondary endpoints include RFS, time to relapse, time to discontinuation, and safety. Exploratory analyses assess molecular and cellular markers of minimal residual disease during maintenance Tx that may be predictive of clinical outcomes. Enrollment began in May 2013, with a target of 460 pts from 150 global sites. Accrual is designed to allow enough events for ≥ 90% power to detect a statistically significant treatment effect on OS (n = 330 deaths; expected duration 60 months). By Jan 2015, 168 pts had been randomized. Study enrollment continues through 2016. Clinical trial information: NCT01757535.

TPS7098 **Poster Session (Board #85a), Sun, 8:00 AM-11:30 AM**

First-in-human study of FLX925, an orally administered FLT3/CDK4/CDK6 inhibitor, in subjects with relapsed or refractory acute myeloid leukemia (AML). *First Author: Naval Guastad Daver, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Acquired mutations in oncogenic kinases remains an obstacle between valid therapeutic hypotheses and meaningful patient benefit. The inhibition of FLT3 can be efficacious in AML patients, particularly in FLT3-ITD mutated cancers. However, relapse is common and frequently associated with the acquisition of secondary resistance mutations in FLT3. FLX925 is a next-generation kinase inhibitor that was prospectively designed to address or avoid common mechanisms of resistance to earlier FLT3 inhibitors, with its unique binding mode and potent activity against CDK4/CDK6 (Keegan et al, Mol Cancer Ther, 2014). FLX925 retains its cellular potency against clinically relevant secondary resistance mutations in FLT3 that occur with quizartinib or sorafenib treatment. In addition, FLX925 potently inhibits CDK4/CDK6, central components of the cell cycle machinery. This unique profile may reduce the emergence of resistant clones and extend the therapeutic potential of FLX925 to other malignancies dependent on these pathways (e.g., MCL). These data suggest the unique profile of FLX925 makes it an ideal inhibitor for the treatment of cancers driven by FLT3 signaling, such as AML. **Methods:** This open label, sequential-group, dose escalation and cohort expansion study includes adult patients diagnosed with relapsed or refractory AML. Eligible patients need to have failed prior induction therapy or relapsed within 12 months of prior therapy. During cohort expansion, at the RP2D, patients will be enrolled into 3 cohorts: subjects with a FLT3 ITD or kinase domain mutation with (Cohort A) or without (Cohort B) prior FLT3 inhibitor treatment, or patients without a FLT3 mutation at screening (Cohort C). The primary objectives of the study are to characterize the safety and tolerability of twice-daily, oral FLX925. Key secondary objectives are to evaluate the pharmacokinetic (PK) profile, pharmacodynamics (PD) effects, and the magnitude and duration of antitumor activity with FLX925, using standard criteria. A Simon 2-stage mini-max approach will be used to test the null hypothesis based on the CRc rate. This trial (NCT02335814) is currently enrolling patients. Clinical trial information: NCT02335814.

TPS7099 **Poster Session (Board #85b), Sun, 8:00 AM-11:30 AM**

GRASPA-AML 2012-01 study (NCT01810705): A multicenter, open, randomized phase 2b trial evaluating ERY001 (L-asparaginase encapsulated in red blood cells) plus low-dose cytarabine vs low-dose cytarabine alone, in treatment of newly diagnosed acute myeloid leukemia (AML) elderly patients, unfit for intensive chemotherapy. *First Author: Xavier G. Thomas, Centre Hospitalier Lyon Sud, Cedex, France*

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder of hematopoietic progenitor cells and the most common malignant myeloid disorder in adults, with a median age of 65 years at diagnosis. There is unmet medical need for elderly patient with AML unfit for intensive chemotherapy. L-asparaginase (L-ASP) plays a key role in all treatment phases for Acute Lymphoblastic Leukemia (ALL). Some leukemic cells, with asparagine synthetase deficiency, need plasmatic L-asparagine for protein synthesis. L-ASP hydrolyses L-asparagine leading to depletion of this amino acid. Normal cells are resistant to L-asparaginase because they can synthesize asparagine using asparagine synthetase. Several clinical studies and case reports showed a potential benefit of L-ASP in certain AML cell lines or mixed lineage leukemia. ERY001 is a novel platform of RBC encapsulation of L-asparaginase. Antitumor activity of ERY001 as well as any L-ASP is based on depletion in plasmatic asparagine, which is an essential amino acid for cells survival in almost all lymphoblastic cells. **Methods:** GRASPA-AML 2012-01 is an international multicenter, open label, randomized, phase 2b trial evaluating clinical activity and tolerability of ERY001 plus low-dose cytarabine (LDAC) vs LDAC alone, in treatment of elderly patients (65-85 years), with newly diagnosed AML and who are unfit for intensive chemotherapy. The primary objective is progression free survival (PFS). The key secondary objectives are: response to treatment, event free survival, overall survival, quality of life, pharmacokinetic and pharmacodynamics profiles, and immunogenicity. Patients are randomized 2:1 to: Arm A: LDAC only (40 mg daily for 10 consecutive days, every 28 days); Arm B, ERY001 (100 IU/kg) in combination with subcutaneous LDAC, for up to 24 months. Patients are assessed every 4-5 days during each cycle. The study is currently in recruiting phase. Seventy-three patients were recruited to date. Clinical trial information: NCT01810705.

TPS7100 Poster Session (Board #86a), Sun, 8:00 AM-11:30 AM

A phase 1b trial of duvelisib, a PI3K-δ,γ inhibitor, in combination with obinutuzumab in patients with CLL/SLL previously treated with a Bruton's tyrosine kinase inhibitor (BTKi). *First Author: James Stewart Blachly, Ohio State University Medical Center, Columbus, OH*

Background: Abrogating B-cell receptor pathway signaling through BTK inhibition is an effective treatment strategy for CLL. However, some patients (pts) do not respond, or progress despite BTK inhibitor (BTKi) treatment. Duvelisib, an oral inhibitor of PI3K-δ and PI3K-γ, can reduce downstream PI3K signaling even in the setting of BTK C481S mutation, thus providing an alternative for attenuating CLL growth and survival signaling. Early clinical activity observed in a Phase 1 study of duvelisib monotherapy in a subset of pts previously treated with a BTKi, suggest further evaluation is warranted (Porcu, ASH 2014). Combining duvelisib with obinutuzumab may augment clinical benefit through both cell intrinsic and extrinsic mechanisms. This study (IPI-145-18; ClinicalTrials.gov: NCT02292225) was designed to identify a tolerable dose of duvelisib combined with obinutuzumab, and to evaluate the safety and efficacy of the combination in relapsed/refractory CLL/SLL pts previously treated with a BTKi. **Methods:** This is a Phase 1b, open-label, dose escalation, safety and tolerability study of duvelisib in combination with obinutuzumab in pts with CLL/SLL whose disease is refractory to or has relapsed while receiving a BTKi therapy. Dose escalation (DE) Cohort 1 will receive duvelisib 25 mg BID in combination with obinutuzumab at its approved dose and schedule. Dose escalation of duvelisib to 50 mg BID or 75 mg BID may occur based on evaluation of dose limiting toxicities. Sequenced administration may be explored if the DE of duvelisib cannot progress when treatments are administered concurrently. An expansion phase is planned to explore the optimal dosing regimen of duvelisib in combination with obinutuzumab. Approximately 64 pts will be enrolled at 5-6 US sites. The primary endpoints are dose-limiting toxicities (DE phase only), AEs, and safety laboratory changes. Secondary endpoints are overall response rate, duration of response, progression-free survival, overall survival, BTK mutation status, and pharmacokinetics. Response will be evaluated according to the modified IWCLL 2008 response criteria. Clinical trial information: NCT02292225.

TPS7101 Poster Session (Board #86b), Sun, 8:00 AM-11:30 AM

Phase III randomized, double-blind, active-controlled study of momelotinib versus ruxolitinib in patients with myelofibrosis. *First Author: Elliott F. Winton, Emory Univ School of Medcn, Atlanta, GA*

Background: Momelotinib (MMB) is a JAK1/2 inhibitor that displays potent *in vitro* inhibitory activity against cells dependent on JAK2, including cells with the JAK2V617F mutation. In a completed phase I/II study of MMB which enrolled 166 subjects with myelofibrosis (MF) (CCLO9101), the rate of spleen response was 39%, and the rate of anemia response was 53% (Pardanani et al, Blood 2013). Assessment at 3 months showed improvement of constitutional symptoms. Most common treatment-related adverse events were thrombocytopenia (46%), peripheral neuropathy (44%), diarrhea (25%), dizziness (24%), and nausea (22%). Dizziness is believed to be part of the first-dose effect of MMB. **Methods:** 420 subjects with primary (PMF), post-polycythemia vera (PPV-MF), or post-essential thrombocythemia MF (PET-MF) will be randomized in a 1:1 manner to receive either MMB plus ruxolitinib (RUX) placebo, or RUX plus MMB placebo in this double-blind, active-controlled study for 24 weeks, with the option for eligible subjects to subsequently continue open-label MMB treatment for up to an additional 168 weeks. Key inclusion criteria include palpable splenomegaly $\geq$ 5 cm, high risk or intermediate-2 risk MF, or intermediate-1 risk MF with symptoms, and platelet count $\geq 50 \times 10^9$/L. Prior use of a JAK inhibitor is not allowed. The primary endpoint is Splenic Response Rate at Week 24, defined as the proportion of subjects achieving $\geq$ 35% reduction in spleen volume at Week 24 as measured by MRI or CT scan. Secondary endpoints include Response Rate in Total Symptom Score at Week 24 defined as the proportion of subjects who achieves $\geq$ 50% reduction from baseline in total symptom score to Week 24 as measured by the modified MPNSAF TSS diary. The Data Monitoring Committee last reviewed the trial in November 2014 and recommended that the trial continue as planned. Clinical trial registry number: NCT01969838. Clinical trial information: NCT01969838.

TPS7102 Poster Session (Board #87a), Sun, 8:00 AM-11:30 AM

Phase III randomized, open-label, active-controlled study of momelotinib versus best available therapy in ruxolitinib-treated patients with myelofibrosis. *First Author: Vikas Gupta, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: Momelotinib (MMB) is a JAK1/2 inhibitor, and displays potent *in vitro* inhibitory activity against cells dependent on JAK2 including cells with the JAK2V617F mutation. Dosing of ruxolitinib (RUX), the first JAK inhibitor approved for myelofibrosis (MF), is based on platelet count, with dose reduction indicated for various degrees of hematologic toxicity. In the phase III study of RUX versus placebo (PBO) in MF (COMFORT-1), 70% of subjects in the RUX arm experienced thrombocytopenia of any grade compared to 31% of subjects in the PBO arm, with rates of Grade 3 and 4 thrombocytopenia of 13% and 1% on the RUX and PBO arms, respectively. Grade 3 and 4 anemia rates were 45% and 19% for the RUX and PBO arms, respectively (Verstovsek et al, NEJM 2012). For those patients who experience significant hematologic toxicities while on RUX, no approved alternative JAK inhibitor therapy is currently available. **Methods:** 150 subjects with primary, post-polycythemia vera, or post-essential thrombocythemia MF will be randomized in a 2:1 manner to receive either MMB or best available therapy (BAT) for 24 weeks, with the option for eligible subjects to continue open-label MMB in an extended treatment phase for up to an additional 168 weeks. Treatment on the BAT arm may include RUX. Key inclusion criteria are palpable splenomegaly $\geq$ 5 cm, currently or previously treated with RUX and characterized by either requirement for red blood cell transfusion while on RUX, or dose adjustment of RUX to $<$ 20 mg twice daily at start of or during RUX treatment plus either $\geq$ Grade 3 thrombocytopenia, $\geq$ Grade 3 anemia, and/or $\geq$ Grade 3 hemorrhage. The primary endpoint is Splenic Response Rate at Week 24, defined as the proportion of subjects who achieve $\geq$ 35% reduction in spleen volume from baseline at Week 24, as measured by MRI or CT scan. Secondary endpoints include Response Rate in Total Symptom Score, defined as the proportion of subjects who achieve $\geq$ 50% reduction in total symptom score from baseline to Week 24 as measured by the modified MPNSAF TSS diary. The DMC last reviewed the trial in Nov 2014 and recommended that the trial continue as planned. Clinical trial registry number: NCT02101268. Clinical trial information: NCT02101268.

TPS7103 Poster Session (Board #87b), Sun, 8:00 AM-11:30 AM

Phase 1 study to evaluate the safety and tolerability of MEDI4736, an anti-programmed cell death ligand-1 (PD-L1) antibody, in myelodysplastic syndrome (MDS) after treatment with hypomethylating agents. *First Author: Guillermo Garcia-Manero, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Myelodysplastic syndrome (MDS) is a group of clonal bone marrow disorders associated with an increased risk of transformation to acute myeloid leukemia (AML). Despite recent progress in the treatment of MDS, therapeutic options are still limited, particularly for patients who fail to respond or relapse during treatment with hypomethylating agents and thus have poor survival rates. The programmed cell death-1 (PD-1)/programmed cell death ligand-1 (PD-L1) pathway is an important checkpoint used by tumor cells to block antitumor responses. PD-L1 is present on myeloblasts during progression from MDS to AML, and its expression is enhanced by hypomethylating agents, providing the rationale for targeting PD-L1 in MDS. MEDI4736 is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity. **Methods:** This Phase 1, multicenter, open-label, dose-escalation, and dose-expansion study (NCT02117219) evaluates the safety/tolerability of IV MEDI4736 in patients with pathologically confirmed MDS and Eastern Cooperative Oncology Group performance status of 0-2 who failed to respond, relapsed after an initial response, or were unable to tolerate hypomethylating agents. The primary objective is to assess the safety and tolerability of MEDI4736. Secondary objectives include: evaluation of clinical outcome in patients with MDS (International Working Group 2006 MDS response criteria), analysis of pharmacokinetics and immunogenicity of MEDI4736, and effect on patient-reported outcomes. Recruitment is ongoing, with a target enrollment of approximately 70 patients across 11 centers (United States, Germany, and United Kingdom). Clinical trial information: NCT02117219.

7500 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Bevacizumab 15mg/kg plus cisplatin-pemetrexed (CP) triplet versus CP doublet in Malignant Pleural Mesothelioma (MPM): Results of the IFCT-GFPC-0701 MAPS randomized phase 3 trial. *First Author: Gerard Zalcman, Caen Univ Hosp, Caen, France*

Background: MPM median overall survival (OS) did not exceed 13 months with pemetrexed-platinum doublet, with virtually no surviving patients at 5 years. Vascular endothelial growth factor is a potent mitogen for MPM cells. **Methods:** In this French multicenter randomized phase 3 trial, eligible patients had unresectable, histologically proved MPM, age < 76, no prior chemo, PS 0-2, no thrombosis, nor bleeding. Randomized patients (1:1) received pem 500 mg/m^2, CDDP 75 mg/m^2 at D1, with (arm B) or without bevacizumab (arm A), 15 mg/kg Q21D, for 6 cycles. Arm B non-progressive patients received bevacizumab maintenance therapy until progression or toxicity. Primary endpoint was OS. 445 patients were to be randomized, and 385 events observed, to show a significant OS improvement, with 80% statistical power, 5% a-risk. **Results:** From Feb. 2008 to Jan. 2014, 448 patients were included in 73 centers. Males: 75.4%, median age: 65.7 years (range 34.7-75.9), PS 0-1: 96.7%. The IDMC recommended a second interim analysis after 85% of events. On 01-Jan-2015, the duration since last news was < 30 days in 105 out of 106 still living patients. Overall survival was significantly longer in the experimental arm (median: 18.8 months, 95%CI[15.9-22.6] *vs.* 16.1 months, 95%CI[14.0-17.9] for the reference arm, (adj.HR = 0.76, 95%CI[0.61; 0.94], p = 0.012). With only 46/448 non-progressive patients at the date of analysis, median PFS was 9.6 months, 95%CI[8.5-10.6] in bevacizumab arm *vs.* 7.5 months, 95%CI[6.8-8.1] (adj.HR = 0.62, 95%CI[0.50-0.75], p < 0.0001). G3-4 hematological toxicities did not significantly differ in the two arms (49.5% *vs.* 47.3%). Significantly more G3 proteinuria (0.0 *vs.* 3.1%), G3 hypertension (0.0 *vs.* 23%), G3-4 arterial thrombotic events (0.0 *vs.* 2.7%) were observed in bevacizumab arm. QOL and exploratory biomarkers studies will be also presented at time of the meeting. **Conclusions:** Bevacizumab addition to pemetrexed/cis-platin provides a significantly longer survival in pts with MPM, with acceptable toxicity, making this triplet a new treatment paradigm. Clinical trial information: NCT00651456.

7501 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Phase III trial (NGR015) with NGR-hTNF plus best investigator choice (BIC) versus placebo plus BIC in previously treated patients with advanced malignant pleural mesothelioma (MPM). *First Author: Rabab M. Gaafar, National Cancer Institute, Cairo University, Cairo, Egypt*

Background: Currently, there are no standard options for MPM patients who failed a pemetrexed-based chemotherapy (CT). NGR-hTNF, a tumor-targeted antivascular agent, displays antitumor activity through a vessel normalization that improves intratumor CT uptake and T-cell infiltration. **Methods:** MPM patients who progressed on or after a front-line pemetrexed-based regimen, stratified for performance status (PS) and CT agent, were randomly assigned to receive weekly NGR-hTNF 0.8 μg/m^2 (arm A; n = 200) or placebo (arm B; n = 200), both given with BIC (gemcitabine [G], vinorelbine [V], doxorubicin [D] or supportive care). Primary endpoint was overall survival (OS). Hypothesis testing: hazard ratio (HR) = 0.72, 1-β = 0.80, α = 0.05. **Results:** Baseline characteristics were balanced between arms (A vs B): median age (65 vs 67 years); men (76% vs 74%); PS $\geq$ 1 (72% vs 69%); nonepithelial histology (15% vs 19%); poor EORTC score (30% vs 23%); prior treatment-free interval (TFI) $<$ median of 4.8 months (47% vs 53%). Investigator-selected CT (n = 381, 95%): G 55%, V 42%, D 3%. Patients completing six CT cycles: 41% vs 32% (p = 0.08). Most common grade 3/4 toxicity: neutropenia (17% vs 19%) and fatigue (5% vs 8%). After a median follow-up of 18.9 months, OS did not differ significantly between arms in ITT analysis (median 8.4 vs 7.9 months; HR = 0.94 p = 0.61). By predefined OS analyses, there was a significant interaction only between treatment group and TFI (p = 0.008). In 198 patients with TFI shorter than 4.8 months after first-line therapy, median OS for NGR-hTNF vs placebo was 9.0 vs 6.3 months and 1-year OS was 39% vs 23%, respectively (HR = 0.69 p = 0.02; stratified HR = 0.65 p = 0.01). By CT agent, median OS for NGR-hTNF plus G vs placebo plus G was 9.0 vs 6.2 months and for NGR-hTNF plus V vs placebo plus V was 9.7 vs 6.9 months. A significant treatment-by-TFI interaction was also observed for PFS (p = 0.009), with 6-month rates in the short TFI subset of 25% for NGR-hTNF and 12% for placebo (HR = 0.71 p = 0.03). **Conclusions:** Though the primary endpoint was not met, OS and PFS benefit reported with NGR-hTNF plus CT in patients with short TFI deserves a confirmatory first-line phase III trial. Clinical trial information: NCT01098266.

7502 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Pembrolizumab (MK-3475) in patients (pts) with extensive-stage small cell lung cancer (SCLC): Preliminary safety and efficacy results from KEYNOTE-028. *First Author: Patrick Alexander Ott, Dana-Farber Cancer Institute, Boston, MA*

Background: Treatment options for pts with SCLC that progresses on platinum-based chemotherapy are limited. Pembrolizumab, an anti–PD-1 monoclonal antibody designed to block the interaction between PD-1 and its ligands PD-L1 and PD-L2, has shown antitumor activity in multiple advanced malignancies, including non-small cell lung cancer. We assessed the safety and efficacy of pembrolizumab in pts with PD-L1$^+$SCLC. **Methods:** KEYNOTE-028 (ClinicalTrials.gov, NCT02054806) is an ongoing multicohort, phase Ib study of pembrolizumab in pts with PD-L1$^+$ advanced solid tumors. Key eligibility criteria for the SCLC cohort include: confirmed, measurable disease; PD-L1 expression in $\geq$ 1% of cells in tumor nests or PD-L1$^+$ bands in stroma as assessed by IHC at a central laboratory; failure of standard therapy; and absence of autoimmune disease or interstitial lung disease. Pembrolizumab 10 mg/kg is given every 2 wk for up to 2 y or until confirmed progression or unacceptable toxicity. Primary end points are safety, tolerability, and response assessed per RECIST v1.1 by investigator review every 8 wk for the first 6 mo and every 12 wk thereafter. **Results:** Of the 135 pts with SCLC screened, 37 (27%) had PD-L1$^+$ tumors. Seventeen pts were enrolled from March 2014 through January 2015 (59% men; median age, 62 y; 59% ECOG PS 1). One pt was misenrolled and did not receive pembrolizumab. All 16 treated pts received prior platinum and etoposide. 9 pts (53%) experienced a drug-related AE (DRAE); only 1 pt had a grade $\geq$ 3 DRAE. There were no treatment-related deaths or discontinuations due to DRAEs. Four of 16 (25%) evaluable pts had a partial response. One (7%) pt had stable disease, resulting in a disease control rate of 31%. Six (37%) pts had progressive disease as their best response, and 5 pts had no assessment at the time of analysis. Responses are durable, with all responders on treatment for 16+ wks with ongoing response. **Conclusions:** Pembrolizumab is generally well tolerated and has promising antitumor activity in pts with PD-L1$^+$ SCLC who have progressed on prior platinum-based therapy. Enrollment in the SCLC cohort of KEYNOTE-028 is ongoing. Clinical trial information: NCT02054806.

7503 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Phase I/II study of nivolumab with or without ipilimumab for treatment of recurrent small cell lung cancer (SCLC): CA209-032. *First Author: Scott Joseph Antonia, Moffitt Cancer Center, Tampa, FL*

Background: Patients (pts) with SCLC respond to initial platinum (PLT) based chemotherapy (CT), but rapidly progress. Combined blockade of PD-1 and CTLA-4 immune checkpoint pathways has anti-tumor activity with a manageable safety profile. Nivolumab (NIVO) is a fully human IgG4 PD-1 immune checkpoint inhibitor approved in the US & Japan. Interim safety and efficacy of NIVO +\- ipilimumab (IPI), a CTLA-4 checkpoint inhibitor, in pretreated SCLC pts are reported. **Methods:** Pts who were PLT sensitive or refractory and had progressive disease were enrolled regardless of tumor PD-L1 status or number of prior CT regimens. This open-label study randomized pts to NIVO 3 mg/kg IV Q2W or NIVO+IPI (1 + 1 mg/kg, 1 + 3 mg/kg or 3 + 1 mg/kg) IV Q3W for 4 cycles followed by NIVO 3 mg/kg Q2W. Primary objective was overall response rate (ORR). Other objectives were safety, PFS, OS and biomarker analysis. **Results:** Seventy-five pts were enrolled (NIVO, n = 40; NIVO+IPI, n = 35); 59% had $\geq$ 2 prior regimens. Drug-related adverse events (DrAEs) in $\geq$ 10% were fatigue (18%), diarrhea (13%), nausea (10%), and decreased appetite (10%) with NIVO; and fatigue (29%), diarrhea (17%), pruritus (14%), nausea, endocrine disorders and rash (11% each) with NIVO+IPI. Gr 3/4 DrAE in $\geq$ 5% included diarrhea and rash (6% each; NIVO+IPI). Drug-related pneumonitis occurred in 2 pts (1 per arm). One pt experienced a drug-related SAE of myasthenia gravis on study which was fatal. Of 40 evaluable NIVO pts, partial response (PR) was seen in 6, 15% (duration of ongoing responses [DOR] 80-251+ days); stable disease (SD) in 9, 22.5%; and progressive disease (PD) in 25, 62.5%. In 20 evaluable NIVO+IPI pts, 1 had complete response (CR), 5% (DOR 322+ days); 4 had a PR, 20% (DOR 41-83+ days); 6 had SD, 30%, and 9 had PD, 45%. In the NIVO+IPI arm, 12 pts had not reached first tumor assessment and 3 were not evaluable. Nine pts (23%) continue treatment with NIVO and 19 (54%) with NIVO+IPI. **Conclusions:** In this PD-L1 unselected SCLC population with progression post-PLT, NIVO alone or combined with IPI was tolerable. ORR was 15% (NIVO) and 25% (NIVO+IPI) for evaluable pts; durable responses were noted. Updated safety, clinical activity and biomarker analysis will be presented. Clinical trial information: NCT1928394.

7504 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Results from a randomized study of carboplatin and etoposide (CE) with or without palifosfamide (Pa) in extensive stage small cell lung cancer (ES-SCLC): The MATISSE study. *First Author: Shadia Ibrahim Jalal, Indiana University School of Medicine, Indianapolis, IN*

Background: Extensive stage small cell lung cancer (ES-SCLC) is a disease with high mortality. SCLC is initially exquisitely sensitive to chemotherapy with carboplatin and etoposide (CE), considered the standard first-line regimen in ES-SCLC in the US. In a previous phase III trial, the combination of cisplatin, etoposide, and ifosfamide (VIP) improved overall survival (OS) as compared to cisplatin and etoposide in ES-SCLC but with increased toxicity (JCO 13: 2594-2599,1995). Palifosfamide (Pa), a bi-functional DNA alkylator is the active metabolite of Ifosfamide that does not generate toxic metabolites facilitating its combination with CE. This trial was therefore pursued comparing CE with or without Pa in ES SCLC. **Methods:** This was a multi-center, open-label trial in chemotherapy-naive patients (pts) with ES SCLC with planned enrollment of 548 pts. Pts were randomized 1:1 to receive CE (C at AUC 5mg/mL/min day 1 with E 100mg/m^2/day days 1-3) or PaCE (Pa at 130mg/m2/day, E at 100mg/m^2/day both on days 1-3 and C at AUC 4mg/mL/min day 1). The primary endpoint was overall survival (OS). The secondary endpoints included progression-free survival, objective response rate, and quality of life assessment. Pts were stratified based on age, gender, and Eastern Cooperative Oncology Group (ECOG) performance status. **Results:** The MATISSE trial closed prematurely in light of the negative phase III trial evaluating the addition of Pa to doxorubicin in sarcoma (PICASSO). ES-SCLC pts (N = 188) were randomized to CE (n = 94) or PaCE (n = 94). Pt characteristics were well balanced with median age of 61 and the majority of pts having an ECOG PS of 0-1. Median OS in the Intent to treat population was 10.0 months (95% CI: 7.7-10.5) with PaCE and 10.4 months (95% CI: 8.7-13.4) with CE (p value 0.096). Serious treatment-related adverse events were observed in 28.3% pts receiving PaCE and 27.5% pts receiving CE with febrile neutropenia occurring in 4.3% of pts on PaCE arm and 5.5% of pts on CE arm. **Conclusions:** The addition of Pa to CE did not improve survival in ES-SCLC. The safety profile was as anticipated and the addition of Pa did not lead to increased toxicity. Clinical trial information: NCT01555710.

7505 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

A multicenter, randomised, phase III trial comparing fixed dose versus toxicity-adjusted dose of cisplatin + etoposide in advanced SCLC patients. The STAD-1 trial. *First Author: Alessandro Morabito, National Cancer Institute of Naples, San Nicola La Strada Caserta, Italy*

Background: Classic dosing of chemotherapy does not account for pts' variability and some pts could be underdosed. We tested whether toxicity-adjusted dosing of chemotherapy was more active than classic dosing in advanced SCLC pts. (ClinicalTrials.gov NCT00526396). **Methods:** Advanced chemonaïve SCLC pts, aged $\leq$ 75, ECOG PS $<$ 2, were randomised to either control (fixed-dose cisplatin/etoposide: C 80mg/m2, d1 + E 100mg/m2,d1-3, q3w) or experimental arm (toxicity-adjusted CE where, in absence of toxicity, dose of both agents were escalated according to the table). Primary endpoint was the objective response rate (ORR) according to RECIST 1.0. 160 pts were required based on 80% power, 2-sided $\alpha = 0.05$; $\geq$ 80% ORR in the experimental vs $\leq$ 60% ORR in the standard arm. **Results:** 161 patients were randomly assigned either to standard (n = 81) or experimental arm (n = 80). Two patients withdrew the consent immediately after the randomisation, one in each arm, and were excluded from the analysis. Median age was 64, most of the patients were males (72%), had PS1 (55%), had not been pre-treated with RT (89%) and did not show brain metastases (75%). A median number of 6 chemotherapy cycles was administered in both the arms. The ORR was 54% and 57% in the control and the experimental arms (p = 0.75). With 44 mos of median follow up, median PFS was 6.0 mos in the control arm and 5.6 mos in the experimental arm (HR = 1.02; 95% CI: 0.73-1.43, p = 0.90), whilst median OS was 9.6 mos and 9.2 mos in the control and experimental arm (HR = 1.01, 95% CI: 0.71-1.42; p = 0.97). Six patients died while on treatment, one in the control arm and 5 in the experimental one. Among grade 3-4 toxicities, neutropenia (p = 0.005) and fatigue (p = 0.04) were significantly more frequent in the experimental arm. **Conclusions:** As expected, toxicity-adjusted dosing increases side-effects. However, it does not improve the ORR, nor does prolong PFS or OS in advanced SCLC patients. Clinical trial information: NCT00526396.

	C (mg/m^2)	E (mg/m^2)
Level –2	stop	stop
Level –1	60 (-25%)	80 (-25%)

7506 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Final overall survival (OS) results of the phase III PROCLAIM trial: Pemetrexed (Pem), cisplatin (Cis) or etoposide (Eto), Cis plus thoracic radiation therapy (TRT) followed by consolidation cytotoxic chemotherapy (CTX) in locally advanced nonsquamous non-small cell lung cancer (nsNSCLC). *First Author: Suresh Senan, VU University Medical Center, Amsterdam, Netherlands*

Background: Efficacy and safety of concurrent Pem+Cis and TRT followed by consolidation Pem vs other CTX regimens were evaluated; interim safety results (concurrent phase) were presented previously (Vokes et al. 2013). **Methods:** Five hundred and ninety-eight patients (pts) with stage III unresectable nsNSCLC were randomized 1:1 to Pem+Cis (Pem 500 mg/m^2+Cis 75 mg/m^2, intravenously, plus vitamins) plus concurrent TRT (66.0 Gy) every 21 days (q21d) x 3 cycles followed by Pem consolidation q21d x 4 cycles vs the control arm Eto+Cis (Eto 50 mg/m^2+Cis 50 mg/m^2, intravenously) plus concurrent TRT (66.0 Gy) q28d x 2 cycles followed by 2 cycles of a consolidation CTX of choice: Cis+Eto, Cis+vinorelbine, or paclitaxel+carboplatin. The primary objective was OS. Progression-free survival (PFS), objective response rate (ORR), and safety were key secondary objectives. This superiority trial was designed to achieve 80% power, assuming an OS HR of 0.74 with 355 events at 0.05 α (two-sided) using a log-rank test. **Results:** Five hundred and fifty-five pts were treated: 283 Pem+Cis, 272 Eto+Cis. Baseline characteristics were balanced between arms (Pem+Cis/Eto+Cis): median age, 59.5/58.7; female, 41.2%/40.1%; stage IIIB, 53.5%/51.2%; positron emission tomography scans, 83.1%/81.1%; and Eastern Cooperative Oncology Group performance status 1, 50.5%/50.2%. Pem+Cis vs Eto+Cis median OS was 26.8 vs 25.0 mos (HR 0.98; 95% CI: 0.79, 1.20; p = 0.831) and median PFS was 11.4 vs 9.8 mos (HR 0.86; 95% CI: 0.71, 1.04; p = 0.130). Pem+Cis/Eto+Cis ORR was 35.9%/33.0% (p = 0.458) and disease control rate was 80.7%/70.7% (p = 0.004). Possibly related grade (G) 3/4 toxicities (Pem+Cis vs Eto+Cis) occurred in 64.0% vs 76.8% of pts (p = 0.001). The Pem+Cis arm had a lower incidence of possibly related G3/4 neutropenia/granulocytopenia vs the Eto+Cis arm: 24.4% vs 44.5% of pts (p $<$ 0.001). Pem+Cis vs Eto+Cis rates of G3/4 pneumonitis/pulmonary infiltrates and esophagitis were 1.8% vs 2.6% and 15.5% vs 20.6%, respectively. **Conclusions:** The Pem+Cis arm did not improve OS vs the control arm, but did have a better safety profile than the Eto+Cis arm. Clinical trial information: NCT00686959.

7507 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Randomized phase III trial of customized adjuvant chemotherapy (CT) according BRCA-1 expression levels in patients with node positive resected non-small cell lung cancer (NSCLS) SCAT: A Spanish Lung Cancer Group trial (Eudract:2007-000067-15; NCTgov: 00478699). *First Author: Bartomeu Massuti, Alicante University Hospital, Alicante, Spain*

Background: Postop platinum-based CT improves outcomes in resected NSCLC with N+ (St II-IIIA). Analysis of expression of genes involved in DNA repair could be used to individualize optimal CT. BRCA1 may act as a differential regulator of response to cisplatin (Cis) and antimicrotubule agents. **Methods:** Phase III multicenter trial. After surgery, patients (p) with St II and III were random 1:3 to control arm (Cis-Docetaxel) or to experimental arm with treatm. according BRCA1 express. levels (low : Cis-Gemcitabine; intermediate : Cis-Doc; high: Doc alone). Stratification factors: N1 vs N2; age $<$ or $>$ 65 y; non-squamous vs squamous (Sq) ; lobectomy vs pneumonectomy). Planned PORT in N2. Primary end-point OS. Secondary: DFS, toxicity, compliance, recurrence pattern. Statistical hypothesis: 20% increase 5y surv. control group (45%). **Results:** From June 2007 to May 2013, 591 p were screened and 500 of them were random: 108 in control, 392 experimental (110 p Cis-Gem, 127 Cis-Doc and 110 Doc alone). No disbalance between arm for prognostic factors: Median age 64 y; 79% males, 21% females; 43% Sq, 49% Adeno; pneumonectomy 26%; N1 58%, N2 48%; smoking habit: 57% former, 32% current, 11% never. Median tumor size 4.4 cm (0.8-15.5). Median mRNA BRCA1 levels 15.78 (0.73-132). Mean BRCA1 levels 6.95 Adeno vs 20.29 Sq (p $<$ 0.001). Median f-u 30 months (0-79 m). With a cut-off of March 15th median survival has not reached both arms and no significant diffs. have been seen for OS with HR 0.866 (p = 0.45) or DFS (HR 1). In exper. group HR for OS was 0.842 (NS) comparing low with high-BRCA1 levels. In p with high-BRCA1 levels control treatm. (Cis-Doc) was superior to exper. (Doc) with HR 1.24 (NS). For p receiving all planned treatm. HR is 0.63 with p = 0.043 compared with p not able to complete treatm. P with Sq histology showed a longer DFS (HR 0.73; p = 0.05) but without diff. in OR (HR 1). **Conclusions:** BRCA1 based adjuvant CT does not improve OS. In p with high-BRCA1 levels Doc alone is inferior to Cis-Doc. Full dose of planned treatm. confers a survival advantage, however, longer follow-up is still warranted. Clinical trial information: 00478699.

Final results of phase Ib of tarextumab (TRXT, OMP-59R5, anti-Notch2/3) in combination with etoposide and platinum (EP) in patients (pts) with untreated extensive-stage small-cell lung cancer (ED-SCLC). *First Author: Maria Catherine Pietanza, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Notch signaling is implicated in cancer stem cell self-renewal and proliferation; thus being an appealing target in the treatment of SCLC. Tarextumab (TRXT), a fully human IgG2 antibody targeting Notch2 and 3 receptors, has shown preclinical efficacy in SCLC models with cisplatin. This Phase Ib study explores the MTD, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of TRXT with EP in chemo-naive ED-SCLC. **Methods:** Notch signaling is implicated in cancer stem cell self-renewal and proliferation; thus being an appealing target in the treatment of SCLC. Tarextumab (TRXT), a fully human IgG2 antibody targeting Notch2 and 3 receptors, has shown preclinical efficacy in SCLC models with cisplatin. This Phase Ib study explores the MTD, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of TRXT with EP in chemo-naive ED-SCLC. **Results:** By November 18, 2014, 27 pts were treated with TRXT at dose range from 5 mg/kg to 15 mg/kg. The MTD was not reached and TRXT 15 mg/kg was determined to be the Phase 2 dose. One DLT of Grade 3 nausea and vomiting was reported in the 10 mg/kg dose cohort. Frequently reported ($\geq$ 15%) TRXT-related adverse events were: diarrhea (59.3%), fatigue (44.4%), nausea (40.7%), anemia (25.9%), decreased appetite (25.9%) and vomiting (25.9%); most were Grade 1 or 2 and managed with supportive care. The overall response rate was 84%. The median duration of treatment was 128 days (6 cycles) with mPFS and mOS of 124 and 228 days, respectively. The median follow-up for PFS and OS was of 86 and 107 days respectively. **Conclusions:** TRXT with EP is well tolerated. Encouraging anti-tumor activity has been observed. Final safety, efficacy, PK, immunogenicity and predictive biomarker results will be presented. TRXT at a dose of 15 mg/kg has been selected for the phase 2 randomized, placebo-controlled portion of the study, which is ongoing. Clinical trial information: NCT01859741.

Lurbinectedin (PM01183) with doxorubicin (DOX), an active treatment as second-line therapy in small cell lung cancer (SCLC). *First Author: Martin Forster, University College London, London, United Kingdom*

Background: PM01183 inhibits transactivated transcription and acts on the tumor microenvironment. It lacks cross-resistance with platinum. PM01183 and DOX are synergistic *in vitro*. Recommended dose (RD): 4 mg (or 2 mg/m^2) + 50 mg/m^2, respectively, both on day (D) 1 every 3 weeks. Compelling activity was observed earlier in 2nd line SCLC patients (pts), leading to a cohort expansion. The historical response rate (RR) of DOX-based combinations is around 20%. **Methods**: SCLC pts $\leq$ 75 years with ECOG PS 0-1, adequate organ function and 1 prior chemotherapy-containing line were included. Stable asymptomatic brain metastases were allowed. DOX was discontinued before reaching 450 mg/m^2, non-progressing pts could continue on PM01183 alone. CSF prophylaxis was not mandatory. **Results:** 21 pts were treated and evaluable for efficacy [response rate (RR) by RECIST v1.1]. Male: 76%; median age: 62 y (r, 48-73); ECOG PS = 0/1 in 43%/57%; 29% had brain metastases, 62% had bulky disease and 81% responded to 1st line, 5% CRs. Median chemotherapy-free interval (CTFI) was 3.1 months; 48% were resistant (R = CTFI $\leq$ 90 d). Confirmed RR was 67% (95%CI: 43-85%), including ~10% CRs. CTFI was predictive of RR (100% *vs.* 30% in R pts; p = 0.001). Grade (G) 4 neutropenia, thrombocytopenia or anemia occurred in 86%/19%/5%, respectively and febrile neutropenia (G3/4) in 29%. Other toxicities were generally mild: fatigue (G3 = 14%), anorexia, nausea/vomiting, alopecia, stomatitis (G3 = 10%), dysgeusia, constipation and pneumonia (10%). Three pts discontinued due to toxicity (myelosuppression in 2), no cardiac toxicity or G5 events occurred. As of January 2015, 5 pts (24%) are still ongoing. Progression-free survival (PFS) is 4.7 months (95%CI: 3.5-not reached). **Conclusions:** The PM01183 and DOX combination showed compelling clinical activity as 2nd line treatment in SCLC. RR could be comparable to those achieved in 1st line. Reversible myelosuppression was the most frequent and expected side effect; DOX dose adjustment and/or CSF prophylaxis might be appropriate to improve tolerance. A randomized study is planned to help define the role of this combination in relapsed SCLC pts. Updated results will be presented. Clinical trial information: NCT01970540.

Pazopanib (P) or placebo in completely resected stage I NSCLC patients: Survival results of the phase II trial IFCT-0703. *First Author: Benjamin Besse, Gustave Roussy, Villejuif, France*

Background: P is an anti-angiogenic agent approved in metastatic renal cell carcinoma and sarcoma. We have previously reported compliance of adjuvant P (*i.e.* % of patients (pts) able to receive at least 3 months (m.) of P, whatever the dose) in stage I NSCLC. Compliance has already been reported (WCLC 2013) and has been found adequate at the dose 400 mg/d (69% [95%CI 50-84] (p = 0.027, compared to 38% in P 800 mg/d) vs 93% [95%CI 77-99] in placebo. Here we report survival data. **Methods:** In this double-blind non-comparative randomized multicenter phase II trial, 143 pts with resected stage I NSCLC (7thTNM edition) were randomized to receive placebo or P 800 mg/d during 6 m. The Fleming's two-stage primary endpoint was compliance. After 64 pts included (interim analysis), IDMC recommended to start with P 400 mg/d because of initial insufficient compliance. A one-step Fleming design was used with the new dose. Here, we present survival data for which the intent to treat analysis was performed in 142 pts (1 consent withdrawal). **Results:** Between Mar 2009 and Aug 2012, 71 pts were enrolled in each arm. Most pts were male (61%) and smokers (91%), median age was 60. Pathological stage was IA in 103 pts (72%) and 16% were squamous cell carcinomas. No toxic deaths were observed. 2 pts had grade (G) 4 toxicities in P800 (fatigue in P arm, GGT in the placebo arm). Most common G3 toxicities in P800 were diarrhea (9%), hypertension (13%), and increased transaminases (16% vs. 0% in P400); in P400 gastro-intestinal disorders (16%, 6% diarrhea) and hypertension (6%). Median follow-up was 47 m. The number of events for disease free survival (DFS) is 17 in the P arm and 13 in the placebo arm: 3 yrs DFS rates were 77% [95%CI 67%-87%] and 83% [95%CI 74%-92%] respectively (Hazard Ratio (HR) = 1.3 [95%CI 0.6-2.8], p = 0.53). Among the 14 deaths, 9 occurred in the P arm and 5 in the placebo arm. All deaths were secondary to tumor recurrence but 2, related to cardiac events (1 in each arm). 5 yrs overall survival rates were 83% [95%CI 72-94] in the P arm and 94% [95%CI 88-100] in the placebo arm (HR = 1.9 [95%CI 0.6-5.5], p = 0.27, unplanned analysis). **Conclusions:** Although comparison of survival was unplanned in this phase II, our results do not support a phase III trial. Clinical trial information: NCT00775307.

ARQ 197 in patients with previously-treated malignant mesothelioma (MM): A phase II trial from the University of Chicago Phase II Consortium. *First Author: Steven Brad Maron, University of Chicago, Chicago, IL*

Background: The MET receptor tyrosine kinase plays a key role in MM biology. MET and its ligand, hepatocyte growth factor (HGF), are each over-expressed in ~80% of MM; MET is mutated and/or amplified in ~10% of MM. Cancers with MET over-expression or mutation are potentially more sensitive to MET inhibitors, such as ARQ 197 (tivantinib), which inhibits MM growth and proliferation in preclinical models. **Methods:** We conducted a multicenter phase II trial of ARQ 197 in previously-treated pts with histologically-confirmed pleural (PL) or peritoneal (PER) MM, measurable disease, PS 0-1, and $\leq$ 2 prior chemotherapies. Primary endpoint: response. ARQ 197 360mg was given orally BID. CT scans were obtained Q8 weeks. A Simon, optimal, 2-stage design required 2 responses in 16 pts to proceed to a 2nd stage. Correlatives: MET mutation, gene amplification, IHC, and serum HGF. **Results:** 18 pts enrolled at 4 centers between 2/13 and 12/13. Male 61%; median age 66 (range 19-81); PS 0: 50%; epithelial/biphasic/sarcomatoid histology: 89%/5%/5%; PL/PER: 61%/39%; Median # cycles: 3 (range 2-14). There were no objective responses. Stable disease (SD): 50% (33% PL pts, 71% PER pts). 3 PER pts had SD for 9.7, 11, and 15.2 months, respectively. Median PFS: 1.9 mo (95% CI: 1.8-5.4); PL/PER 1.8/3.8 mo (95% CI: 1.8-5.4/1.8-11). Median OS 12.2 mo (95% CI: 7.1-22.2); PL/PER: 8.0/22.2 mo (95% CI: 4.6-12.2/7.1-NR). Grade 3/4 toxicities: leukopenia, lymphopenia, abdominal pain, fatigue, infection 6% each. Correlatives: N = 16. IHC expression (0/1+/2+/3+): c-MET (38%/31%/19%/13%), p-MET (0%/0%/31%/69%,) and p-AKT (0%/13%/31%/56%). One pt had a T1101 mutation in the MET juxtamembrane domain. There was no correlation between MET pathway IHC expression or mutation and PFS or OS upon preliminary analysis. **Conclusions:** The trial did not meet its pre-specified response endpoint. However, 43% of peritoneal pts had SD for > 9 months. Though p-MET expression was high, MET IHC expression or mutation did not correlate with disease control. Alternative biomarkers predictive of the activity of ARQ 197 in PER MM pts should be evaluated. Funded by NCI N01-CM-2011-0071C.

A randomized phase II study of TS-1 plus cisplatin versus vinorelbine plus cisplatin with concurrent thoracic radiotherapy for locally advanced non-small cell lung cancer (LA-NSCLC): WJOG 5008L. *First Author: Takashi Seto, National Kyushu Cancer Center, Fukuoka, Japan*

Background: Cisplatin-based chemotherapy and concurrent radiotherapy is the standard treatments for LA-NSCLC. Thistrial evaluated two experimental regimens of chemotherapy with concurrent radiotherapy. **Methods:** Eligible patients with unresectable stage III NSCLC, 20 to 74 years of age, and ECOG PS of 0–1 were randomized to either Arm SP, S-1 (40 mg/m^2/dose per oral, b.i.d, on days 1-14) and cisplatin (60 mg/m^2 on day 1) repeated every 4 weeks or Arm VP, vinorelbine (20mg/m^2 on day 1, 8) and cisplatin (80 mg/m^{2}on day) repeated every 4 weeks with early concurrent thoracic radiotherapy of 60 Gy at 2 Gy per daily fraction. The primary endpoint was overall survival rate at 2-year (2yr-OS). A pick-the-winner design was used to identify the treatment regimen most likely to be superior. The planned sample size was 55 patients per arm, assuming in each arm that the null hypothesis for 2yr- OS was 50% versus an alternative hypothesis for 65% with one-sided alpha of 0.10 and power of 80% (Study ID: UMIN000002420). **Results:** One hundred eleven patients were registered between Sep 2009 and Sep 2012. Of 108 patients for efficacy analysis, the 2yr-OS was 76% (95% CI, 62-85%) for SP and 69% (95% CI, 54-79%) for VP. The hazard ratio (HR) of death between the two arms was 0.85 (0.48-1.49). The median progression-free survival (PFS) was 14.8 months for SP and 12.3 months for VP with a HR of 0.92 (0.58-1.44). 80% and 48% of patients completed the protocol treatment in SP and VP, respectively. Common grade 3-4 toxicities in SP v VP were neutropenia 33.3% v 75.9%, platelets 9.3% v 3.7%, hemoglobin 1.9% v 27.8%, febrile neutropenia 9.3% v 16.7%, diarrhea 5.6% v 0%. There were 4 and 5 treatment-related deaths in SP and VP, respectively. **Conclusions:** Both arms rejected the null hypothesis for 2yr-OS. In this study Arm SP was declared the winner in terms of 2yr-OS, PFS, treatment completion, and toxicity. Clinical trial information: 000002420.

Survival following stereotactic body radiation therapy or conventionally fractionated radiation for definitive non-operative treatment of stage I non-small cell lung cancer: A review of the National Cancer Data Base. *First Author: Cliff Grant Robinson, Washington Univ in St Louis, St. Louis, MO*

Background: Despite a dramatic increase in utilization of stereotactic body radiation therapy (SBRT) for non-operative treatment of clinical stage I NSCLC over the last decade, there are no reported clinical trials or large scale comparisons with standard conventionally fractionated radiation (CFRT). We sought to compare overall survival (OS) between these modalities using the National Cancer Data Base (NCDB). **Methods:** Patients with clinical stage I (AJCC 6th edition T1-T2N0M0) NSCLC who underwent definitive non-operative treatment with either SBRT or CFRT from 1998 to 2010 were identified from the NCDB. Cox regression was used to assess the impact of patient and treatment variables on OS. Inverse probability adjusted Kaplan-Meier survival curves were calculated to assess differences in OS while adjusting for baseline imbalances between the treatment groups. **Results:** A total of 19373 patients met inclusion criteria (5944 SBRT, 13429 CFRT). Median follow-up was 18.7 months. On multivariable analysis, improved OS was independently correlated with younger age, female gender, non-Caucasian race, lower Charlson comorbidity score, smaller tumor size, use of chemotherapy, treatment at an academic facility, and was most strongly associated with use of SBRT (HR .775, 95% CI, .737 to .817). Chemotherapy was delivered in 32.9% of CFRT patients and 4.2% of SBRT patients. Chemotherapy was correlated with improved OS on multivariable analysis for CFRT but not SBRT. In an adjusted Kaplan-Meier comparison, SBRT was associated with a significant increase in median (29.8 v 26.2 months) and 3-year (42.3% *v* 36.4%) OS compared with CFRT ($P < .0001$). **Conclusions:** In a large population-based analysis of outcomes in a modern cohort of patients with clinical stage I NSCLC treated with definitive non-operative therapy, SBRT was associated with a significant improvement in OS compared with CFRT.

Trimodality therapy in the treatment of stage IIIA non-small cell lung cancer (NSCLC): Analysis of the National Cancer Database. *First Author: Madhusmita Behera, Winship Cancer Inst Emory Univ, Acworth, GA*

Background: Significant controversy remains regarding the care of patients (pts) with clinical stage IIIA NSCLC. While multi-modality therapy is an acceptable strategy in selected pts, the optimal approach is not firmly established. We analyzed outcomes and predictors associated with trimodality therapy (TT) in the National Cancer Database (NCDB). **Methods**: The NCDB was queried from 2003-2011 for NSCLC pts diagnosed with stage IIIA-N2 disease and treated with chemotherapy and radiation (CRT). Three cohorts of pts were studied - CRT only/no surgery (NS), CRT + lobectomy (L) and CRT + pneumonectomy(P). The univariate and multivariable analyses (MV) were conducted using Cox proportional hazards model and log rank tests. All analyses were performed using SAS Version 9.3. **Results**: A total of 29,584 pts were included in this analysis: NS-91.7%, L-7%, and P-1.5%. Pt characteristics: median age 66 years (yrs); males 56%; whites 86%; academic centers 27%; metro locations 78%; government insured 63%; Charlson/Deyo comorbidity score 0 in 66%. Pts $<$ 60 yrs were more likely to receive TT- L (47%), P (60%) vs. NS (29%); $p<$ 0.001. Pts in academic centers were more likely to get TT than NS (42% vs. 25%). On MV analysis, L and P had significantly better survival vs. NS: HR 0.43 (0.38-0.48) and HR 0.57 (0.46-0.71) respectively; $p <$ 0.001. The median survival of L, P and NS were 44.5 m vs. 25.6 m vs. 15.7 m ($p <$ 0.001) and 5- year survival rates (SR) were 44% vs. 33% vs. 14% respectively. 30-day mortality was higher in P vs. L [7% vs. 2.6%; OR 0.26(0.16-0.45); $p<$ 0.001]. Pts with $<$ 2 lymph nodes (LN) had better survival than pts with $>$ 2 LNs in L (50% vs. 37%; 60m vs. 38.8m) but worse in NS (13.8% vs.16.4%; 15.3m vs.18.5m). On MV analysis of LNs, L had better survival than NS: HR 0.4 (0.35-0.46) in $<$ 2 LN pts and HR 0.56 (0.46-0.69) in $\geq$ 2 LN pts; $p<$ 0.001. In pts with $<$ 2 LN, L had better survival than P (60m vs. 25.5m; $p<$ 0.0001). L and P had better SR than NS in all ages: 48% vs.37% vs. 19% in $\leq$ 60 yrs; 42% vs. 30% vs.14% in 61-70 yrs, 36% vs.19% vs. 10% in $>$ 70 yrs. **Conclusions**: TT was utilized in less than 10% of pts with stage IIIA-N2 disease, suggesting high degree of pt selection. In this selected group, TT was associated with favorable outcomes relative to CRT alone.

Programmed cell death 1 (PD-1) and its ligand (PD-L1) expression in thymic epithelial tumors (TETs): Impact on the treatment efficacy and alteration in expression after chemotherapy (C). *First Author: Yuki Katsuya, National Cancer Center Hospital, Tokyo, Japan*

Background: Recent studies have demonstrated the efficacy of anti-PD-1/L1 antibodies. To understand the clinical impact of PD-1/L1 expression in TETs, we evaluated the frequency of PD-1/L1 expression in pre- and post-C (Pre/Post) specimens and the correlation between PD-1/L1 expression and the treatment efficacy. **Methods:** The expression of PD-1/L1 was evaluated by immunohistochemistry in patients (pts) with thymoma (TM) or thymic carcinoma (TC) treated by chemotherapy between 2000 and 2014 at the National Cancer Center Hospital. Using formalin-fixed paraffin-embedded tissue samples and a validated PD-L1 antibody (E1L3N), the PD-L1 expression in TET cells was reported in terms of the H-score (0-300), with a score $\geq$ 1 being defined as positive. PD-1 expression in the tumor-infiltrating lymphocytes was evaluated based on the intensity (0–3) of staining using a PD-1 antibody (NAT105). The objective response rate (ORR), progression-free survival (PFS) and the difference in PD-1/L1 expression between the Pre/Post TM specimens were evaluated. **Results:** A total of 29 pts was included; TM/TC, 12/17; male/female, 14/15; median age 57; WHO histology (B1/B2/B3/Squamous/others), 1/7/3/12/6. Pre/Post serial specimens were available for 6 TMs. All pts received platinum-based C, and the ORR was 42% in TMs and 18% in TCs. Expression of PD-L1 was positive in 9 (75%) of the TMs and 8 (47%) of the TCs. In the PD-L1 positive population, ORR was 56% (5/9) in TMs and 13% (1/8) in TCs. In the PD-L1 negative population, ORR was 0% (0/3) in TMs and 22% (2/9) in TCs. There were no statistically significant differences in the PFS according to the PD-L1 expression status. Increase of the PD-L1 score and PD-1 staining intensity were observed after C in serial specimens of TM; mean Pre/Post PD-L1 score, 41.6/92.5 ($p = 0.058$); median Pre/Post PD-1 intensity, 0/2.5 ($p = 0.055$). **Conclusions:** Although there was no obvious correlation between PD-L1 expression and the efficacy of C in pts with TETs, increased expression of PD-1/L1 after C was observed in the TMs. Further efforts to develop novel therapies, including anti PD-1/L1 antibodies, are warranted.

7516 Poster Discussion Session; Displayed in Poster Session (Board #263), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Defining the immunologic phenotype of thymic epithelial tumors. *First Author: Jarushka Naidoo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Thymic epithelial tumors (TETs) are associated with immune dysfunction and are poorly responsive to conventional therapies. We aimed to characterize the immune microenvironment in TETs, to identify potential targets for immunotherapy. **Methods:** Tumor tissue from 24 TETS was identified. Tumor-infiltrating lymphocytes (TILs: CD3+ and CD8+ T-cells), PD-L1 expression on tumor cells (antibody: E1L3N), and a panel of co-stimulatory (CD137, GITR, OX40, ICOS) and co-inhibitory immune checkpoint molecules (PD-1, CTLA-4, TIM-3) on immune cells, was investigated by immunohistochemistry. PD-L1 positivity was defined as ≥ 25% of tumor cells with positive membranous staining. TILs and immune cell checkpoint molecule staining were semi-quantitatively scored as: low = 0-1, high = 2-3. Associations between clinicopathologic factors, immune checkpoint molecule expression and TILs, was evaluated. Overall survival (OS) was measured from the time of cancer diagnosis, assuming that immune markers do not change throughout the course of disease. Data was analyzed using Fisher's exact, Wilcoxon rank sum and log-rank tests, and Cox proportional hazards model. **Results:** Tumor tissue from B2/B3 thymomas (n = 12) and thymic carcinomas (n = 12) was evaluated. CD8+ TILs was seen in all tumors. Sixty-three percent of TETs (n = 15/24) were PD-L1+. PD-L1 positivity was more common in thymomas than thymic carcinomas (11/12 vs. 4/12, $p < 0.01$). When analyzed as a continuous variable, PD-L1 expression had an inverse correlation with risk of death ($p = 0.02$). Eighteen pts with TETs (n = 18/24, 75%) had high TIM-3 expression. Two immunologic parameters correlated with improved OS: PD-L1+ tumor cells ($p < 0.01$) and high TIM-3 expression ($p = 0.01$). There was a positive correlation between PD-L1+ tumor cells and CD8+ T-cells ($p = 0.02$), PD-L1+ tumor cells and high TIM-3 expression ($p = 0.03$), CD8+ T-cells and high TIM-3 expression ($p = 0.03$). **Conclusions:** TETs possess a robust TIL infiltrate. The majority of tumors have high expression of the co-inhibitory checkpoint molecule TIM-3, and are PD-L1+. These parameters may correlate with OS. These data support the immunotherapeutic targeting of the PD-1/PD-L1 and TIM-3 pathways in patients with TETs.

Evaluating causes of screen failure (SF) in non-small cell lung cancer (NSCLC) clinical trials requiring specific biomarker (BioM) results for enrollment. *First Author: Danielle J. Nameth, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

Background: Trials for NSCLC have increasingly targeted specific molecular abnormalities. This approach has led to approval of multiple drugs based on results in specific BioM populations prior to completion of randomized trials. As a result, many trials now require evaluation of a fresh biopsy prior to enrollment. Implications of potentially increased duration of screening on interpretation of clinical outcomes have not been completely explored. **Methods**: We reviewed charts of patients (pts) with NSCLC consented to 26 trials between January 2012 and December 2014 through the UCLA Jonsson Comprehensive Cancer Center lung cancer program to assess factors associated with lack of enrollment. **Results**: 385 pts consented to participate in therapeutic clinical trials, 280 of whom signed consent for one of several trials requiring specific results from a recent biopsy with 139 pts ultimately enrolling in such trials. In treated pts in whom a new biopsy was required, median number of days from informed consent to biopsy was10 and from biopsy to first dose was 25**.** Of the 141 SF pts, 34 (24.1%) were eligible based on BioM status. Of these, SF was due to worsening performance status (PS) in 18 (52.9%), pursuing alternate therapy in 3 (8.8%), screening labs out-of-range in 3 (8.8%), withdrawal of consent in 2 (5.8%), and other reasons (prohibited medications, etc.) in 8 (23.5%). **Conclusions**: Approximately one-quarter of screened pts who did not enroll on trials requiring BioM interpretation from a recent biopsy were eligible based on BioM results, most of whom experienced SF based on worsening PS. Whether these patients would have enrolled if the clinical trial had a more traditional design cannot be known. Implications of these findings for accurately assessing trial efficacy should be assessed, as should the generalizability of our results. Whether the delay in enrollment based on the duration of screening either excludes pts who would have been more likely to experience early decline or enrolls pts who have become more ill during screening should be more fully explored.

7518 Poster Discussion Session; Displayed in Poster Session (Board #265), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Prospective molecular analysis of small cell lung cancer (SCLC) using next generation sequencing (NGS). *First Author: Maria Catherine Pietanza, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recent studies using NGS on resected SCLC have provided insights into the landscape of genetic alterations in this disease. We report our experience with prospective genomic profiling of SCLC patients using the biopsy specimens available in clinical practice and a targeted, hybrid capture-based, NGS assay, MSK-IMPACT. **Methods:** Utilizing an IRB approved protocol, we are evaluating SCLC tumors of patients in active treatment. FFPE surgical resections, core biopsies, and fine needle aspirates (FNA) are being evaluated by NGS to identify single nucleotide variants, indels, and copy number alterations in a common set of 222 cancer-associated genes shared by pre-clinical and clinical versions of MSK-IMPACT. Clinical data are collected (smoking status; stage [extensive (ES), limited (LS)]; treatment response). **Results:** Currently, 50 patient samples have undergone evaluation, 58% from core biopsies or FNA. The 50 SCLC patients include 4 never smokers, 58% with ES-SCLC, and 30% resistant to first line therapy. Alterations have been noted in 202 of 222 targeted genes. The median number of non-synonymous somatic mutations is 7. Of 526 total non-synonymous mutations, 5% are hotspot COSMIC mutations, 25% are loss-of-function, and 47% are G-to-T transversions, reflective of tobacco induced carcinogenesis. We observe frequent inactivation of RB1 (96%) and TP53 (92%). Other common genomic events include alterations in SOX2 (26%), EPHA5 (22%), CDKN2C (20%), MYCL1 (20%), and PIK3CA (18%). Tumors from the 4 never smokers (0 pk yrs) displayed a median of 3 mutations, of which none were G-to-T transversions, while those from moderate (< 20 pk yrs) and heavy (20+ pk yrs) smokers contained 4.5 and 8 mutations, respectively ($P < 0.05$). ES-SCLC patients had a lower median number of mutations (5/tumor) than LS-SCLC patients (9/tumor). Diverse amplifications, deletions, and mutations are noted in sensitive tumors, while homozygous deletions are more common in refractory tumors. **Conclusions:** Comprehensive molecular evaluation of SCLC is feasible on clinically available specimens using a targeted NGS assay. Prospective analyses allow us to fully characterize the molecular diversity of SCLC in the clinical setting.

Genomic profiling of large-cell neuroendocrine carcinoma of the lung. *First Author: Tomohiro Miyoshi, Division of Thoracic Surgery, National Cancer Center Hospital East, Kashiwa, Chiba, Japan*

Background: Large-cell neuroendocrine carcinoma (LCNEC) of the lung shares many clinical characteristics with small-cell lung cancer (SCLC). However, little is known about the molecular biology of LCNEC. We analyzed lung LCNECs for biologically relevant genomic alterations using a next-generation sequencing-based genomic profiling assay. **Methods:** Genomic DNAs extracted from surgically resected or biopsy samples were subjected to a 1.499 Mb custom target capturing panel including all exons of 244 cancer-related genes. Seventy eight LCNEC samples including 10 LCNECs combined with other non-small cell lung cancers (NSCLCs) were applied to the target sequencing. In the 10 combined LCNECs, both morphologic components of LCNEC and other NSCLCs (adenocarcinoma: 5, squamous cell carcinoma: 5) were analyzed separately. Frequencies of detected driver gene alterations were compared with those in previous reports regarding SCLC. **Results:** The demographics of the 78 patients were as follows: median age 70 years (range: 22-84); male 67 (86%); history of smoking 76 (97%); pathological stage I/II/III = 38/14/13 for 65 resected cases and clinical stage II/III/IV = 1/4/8 for 13 biopsy cases. We identified high prevalence of inactivating mutations in *TP53* (74%) and *RB1* (29%), and mutations of histone modifiers, *CREBBP* (10%) and *EP300* (4%), were detected as with the previous reports on SCLC. Genetic mutations in the PI3K/AKT/mTOR pathway were detected in 30 (40%) of the tumors: *PIK3CA* 3%, *PTEN* 6%, *AKT2* 1%, *AKT3* 1%, *TSC*1 5%, *TSC2* 3%, *RPTOR* 4%, *RICTOR* 10% and *mTOR* 5%. Other known activating mutations were also detected in *KIT* (1%), *KRAS* (4%) and *HRAS*(1%). In the combined cases, the concordance rate of types of genetic alterations between the two components was 87% (range: 50-97). **Conclusions:** The genomic profile of LCNEC was similar to that of SCLC. Genetic alterations of the individual components in combined LCNEC were closely concordant with each other despite their distinct histologic morphologies.

7520 Poster Session (Board #267), Mon, 8:00 AM-11:30 AM

Adjuvant chemotherapy for patients with T2N0M0 non-small cell lung cancer. *First Author: Daniel Morgensztern, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Adjuvant chemotherapy (CT) improves overall survival (OS) in patients with completely resected stage II and III non-small cell lung cancer (NSCLC). However, its role in patients with stage IB disease remains unclear. We therefore evaluated the role of adjuvant CT in patients with completely resected T2N0M0 NSCLC. **Methods:** Patients with pathologic stage T2N0M0 NSCLC who underwent complete (R0) resection from 2003 to 2010 were identified from the National Cancer Database (NCDB). Patients were grouped based on tumor size: 3-3.9 cm, 4-4.9 cm, 5-5.9 cm and 6-7 cm. Survival curves according to the CT status were estimated by the Kaplan-Meier product-limit method and compared by log-rank test. Cox proportional hazard model was used to evaluate whether adjuvant CT was an independent predictor for survival for each tumor size groups. **Results:** Among the 29,908 patients meeting inclusion criteria, there were 5,209 (17.4%) and 24,699 (82.6%) patients in the CT and observation groups respectively. Patients treated with CT were younger (median age 65 vs 71 years, $p < 0.001$), had smaller median tumor sizes (3.7 vs 4.1 cm, $p < 0.001$), and a lower incidence of sub-lobar resection (5.6% vs 8.2%, $p < 0.001$). Adjuvant CT improved median OS compared to observation for all tumor size groups in both univariate (UVA) and multivariate (MVA) analyses (Table). **Conclusions:** Adjuvant CT was associated with improved OS in all tumor size groups for patients with completely resected T2N0M0 NSCLC. Despite the biases inherent in a database study, the benefit from adjuvant CT in patients with tumors < 4 cm suggests a possible role in this patient population and the need for revisiting its current status as an exclusion criteria for adjuvant trials.

Adjuvant chemotherapy versus observation.

	Median OS (months)	5 year OS	UVA-HR(95% CI)	MVA-HR(95% CI)
All patients	95.6 vs 67.0	67.9 vs 54.6%	0.64 (0.61-0.68)	0.70 (0.66-0.74)
3-3.9cm	NR vs 71.3	70.5 vs 57.9%	0.66 (0.61-0.73)	0.75 (0.68-0.85)
4-4.9cm	90.7 vs 64.7	66.5 vs 52.7%	0.61 (0.55-0.68)	0.70 (0.63-0.77)
5-5.9cm	87.9 vs 58.8	65.9 vs 49.3%	0.60 (0.53-0.69)	0.68 (0.60-0.78)
6-7cm	86.9 vs 54.6	65.3 vs 46.8%	0.55 (0.47-0.64)	0.62 (0.53-0.72)

7521 Poster Session (Board #268), Mon, 8:00 AM-11:30 AM

Prognostic effect of single versus multiple somatic mutations in non-small cell lung cancer (NSCLC). *First Author: Kevin Jao, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Somatic mutations are becoming increasingly important biomarkers for treatment selection and outcome in patients with NSCLC. **Methods:** Tissue from 200 patients with NSCLC at the Princess Margaret Cancer Centre, were analyzed by next-generation genomic sequencing using Mi-SEQ or Sequenom multiplex platforms. *TP53* analysis was added for DNA sequenced by Sequenom. Mutation status was correlated with clinical and demographic data retrieved from patient records. **Results:** Somatic mutations were identified in 139 patients (70%): single (n = 67) and multiple (≥ 2, n = 72). The most common mutations were *TP53* (n = 70, 30%), *KRAS* (n = 48, 21%) and *EGFR* (n = 45, 20%). Multiple mutations were significantly associated with younger age (p = 0.02), but not with sex, histology, stage, ethnicity or smoking status. Multiple mutations occurred most frequently with *TP53* (n = 53, 32%), *EGFR* (n = 35, 21%) and *KRAS* (n = 25, 20%). Among multiple mutations, the most common co-mutations were *KRAS-TP53* (25%) and *EGFR-TP53* (19%); 10% of patients had 2 *EGFR* mutations. On univariate analysis, there was a trend for multiple mutations to be associated with poorer overall survival (OS) (HR 1.65, CI 0.95-2.87, p = 0.07) in the entire group, and significantly shorter OS in adenocarcinoma (n = 116) (HR 2.12, CI 1.47-2.01, p = 0.028). In the subgroup of 94 surgically resected stage I-III patients, multiple mutations (n = 49) were associated with shorter relapse-free survival (median 1.7 *v* 3.2 yrs, HR 1.92, CI 1.17-3.14, p = 0.008) and OS (median 5.8 v 7.8 yrs, HR 2.29, CI 1.06-4.94, p = 0.026). No OS difference was seen in advanced stage III/IV patients with single (n = 21) *v* multiple mutations (n = 23) (HR 0.93 CI 0.4-2.2, p = 0.88). No significant OS difference was seen in adenocarcinoma patients with *KRAS* mutation alone (n = 21) v *KRAS* with other mutations (n = 24) (HR 1.53, CI 0.61-3.86, p = 0.366). **Conclusions:** Multiple mutations are associated with poorer outcomes in resected NSCLC. The differences are both statistically significant and clinically relevant. Larger datasets are required to validate whether mutational status is an independent prognostic factor or predictive of a differential benefit from adjuvant chemotherapy in early stage NSCLC.

7522 Poster Session (Board #269), Mon, 8:00 AM-11:30 AM

Validation of a cell cycle progression score for 5-year mortality risk in patients with stage I non-small cell lung cancer. *First Author: Takashi Eguchi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The aim of this study was to validate a molecular expression signature [cell cycle progression (CCP) score] and a Prognostic Score [(PS) combination of CCP and pathological stage (IA or IB)] that identify stage I non-small cell lung cancer patients with a higher risk of cancer-related death after surgical resection. **Methods:** Formalin-fixed paraffin-embedded surgical tumor samples from 1200 patients diagnosed with stage I adenocarcinoma who underwent definitive surgical treatment without adjuvant chemotherapy were analyzed for 31 proliferation genes by quantitative RT-PCR. The prognostic discrimination of the CCP score and the PS were assessed by Cox proportional hazards regression using 5-year lung cancer death as primary outcome. **Results:** In a multivariate model the CCP score was a significant prognostic marker of 5-year lung cancer mortality [hazard ratio (HR) = 1.54 per interquartile range (95% confidence interval = 1.10–2.15; $p = 0.0110$)]. Other significant variables included age, tumor size, lymphatic invasion, morphology grade and type of surgery. Gender, smoking status, pathological stage, pleural invasion and vascular invasion were not significant. In a separate multivariate model the PS was a significant prognostic marker of 5-year lung cancer mortality [hazard ratio (HR) = 1.76 per interquartile range (95% confidence interval = 1.14–2.72; $p = 0.0112$)]. Using a previously established threshold (85^{th} percentile) of the PS, there was a significant difference in lung cancer survival between low-risk and high-risk patient groups ($p < 0.0001$). **Conclusions:** This study validates both the CCP score and PS as independent prognostic markers of lung cancer death in patients with Stage I lung adenocarcinoma treated with surgery alone. Significantly, in the Stage IB population, CCP and PS provide quantitative risk information above that captured by current NCCN high risk features. Patients with resected stage I lung adenocarcinoma and a high CCP and PS may be candidates for adjuvant therapy to reduce cancer related mortality.

7523 Poster Session (Board #270), Mon, 8:00 AM-11:30 AM

The effect of platinum based adjuvant chemotherapy on survival in the surgically resected lung adenocarcinoma according to the expression of EGFR mutation specific antibody and c-MET. *First Author: In-Ho Kim, Division of Oncology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea*

Background: To assess the role of mutant EGFR and C-MET in survival benefit obtained from platinum-based adjuvant chemotherapy (PBAC) among resected lung adenocarcinoma (RLADC) patients. **Methods:** From 2005 through 2013, the RLADC patients (stage IB-IIIA) receiving either PBAC (Paclitaxel/Carboplatin, Paclitaxel/Cisplatin, or Vinorelbine/Cisplatin) or to be observed were enrolled. We did immunohistochemistry (IHC) study with mutant EGFR-specific antibody (mutEGFR-sAb) and C-MET in tissue microarray with 301 cases. We assessed the effect of PBAC on survival according to the expression of mutEGFR-sAb and C-MET. **Results:** Until Oct. 2014, 85 patients experienced relapse and 65 patients died among 301 patients. The median follow-up period for survival was 22.4 months. 137 patients received PBAC. Clinical characteristics is as follows; F: M = 165:136, stage Ib 170, II 74, IIIa 47**.** The IHC were positive for mutEGFR-sAb in 78 cases (42 in exon 19, 36 in exon 21) and for C-MET in 136 cases. Compared with EGFR mutation by direct sequencing ,the specificity and sensitivity of mutEGFR-sAb were 99% and 88%, respectively. PBAC prolonged overall survival (OS) in mutEGFR-sAb (+) group of stage II,III patients with statistical significance (p = .040), not in mutEGFR-sAb (-) group (p = .460). Among all patients, PBAC was an independent prognostic factor for relapse free survival(RFS) (HR = 0.29, P = .034) and OS (HR = 0.17, P = .033) in mutEGFR-sAb (+) group. By contrast, in patients with mutEGFR-sAb (-), PBAC was not associated with RFS (HR = 0.63, p = .144) and OS (HR = 0.55, P = .091). Meanwhile, in C-MET (+) subgroup of stage II and IIIa patients, PBAC showed significantly longer survival (RFS; p = .088, OS; p = .015), not in C-MET (-) subgroup. (RFS; p = .979, OS; p = .839). The multivariate analysis indicated that PBAC may be an important factor for increased survival among C-MET(+) patients (RFS; HR = 0.53, p = .086, OS; HR = 0.34, p = .010) but not among C-MET (-) (RFS; HR = 0.74, p = .472, OS; HR = 0.77, p = .597). **Conclusions:** Taken together, our data suggests that overexpression of mutEGFR-sAb and C-MET may be favorable predictive biomarkers for PBAC among RLADC patients.

7524 Poster Session (Board #271), Mon, 8:00 AM-11:30 AM

Therapeutic Interventional Mapping System (TIMS): A novel strategy for the selection of tri-targeted therapy combinations for non-small cell lung cancer (NSCLC). *First Author: John Mendelsohn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Combining three targeted therapies significantly improved outcomes in AIDS. A similar strategy could theoretically benefit patients with metastatic NSCLC, but a scientific method for rational selection of drug combinations is needed. **Methods:** We assessed genomics and the transcriptome (including miRNA), utilizing defined subsets of relevant genes/gene products, and scored information about the relationships between targeted drugs and genes, based in part on the biological hallmarks of cancer. Interventional points (genes/group of genes) that, when activated, could be blocked by a customized therapy combination, were identified. The underlying algorithm integrates and weighs the genomic (DNA sequencing) and transcriptomic data (mRNA and miRNA differential expression between tumor and normal -bronchial mucosa - tissues). **Results:** Key genes (N = 183) grouped in 24 interventional points forming the Therapeutic Interventional Mapping System (TIMS) were elucidated. Frequency and trends of co-activation derived from 121 NSCLC patients defined a list of candidate triple therapy combinations. The focus, in order to limit toxicity, was on the application of two small molecules (TKI) and an immune-modulator (anti-PD1L). Twenty-eight percent of NSCLC patients displayed the simultaneous activation of PD1L, Ras/Raf and mTor/PI3K interventional points. Overall, fifty two percent of NSCLC patients could be targeted by a triple combination that includes an anti-PD1L agent. Most individuals could benefit from two or even more triple combinations to overcome resistance. **Conclusions:** The TIMS's strategy enables conversion of thousands of genomic and transcriptomic measurements into a simple and actionable result (a 1 to 10 score) that may be usable by physicians to select triple drug therapy. Comparing tumor and normal tissue biopsies has proven feasible in the ongoing WINTHER trial (NCT01856296). This novel strategy may allow deployment of personalized tri-targeted therapies that will be prospectively tested in a clinical trial with the objective to significantly impact survival in advanced NSCLC and other malignancies.

7525 Poster Session (Board #272), Mon, 8:00 AM-11:30 AM

Prognostic value of cytokine profile on survival in non-small cell lung cancer patients treated with radiotherapy. *First Author: Shulian Wang, Department of Radiation Oncology, GRU Cancer Center and Medical College of Georgia, Augusta, GA*

Background: Immunomodulatory and inflammatory cytokines play an important role in cancer development and progression. This study is to investigate the prognostic value of cytokine profile on overall survival (OS) in non-small cell lung cancer (NSCLC) patients treated with radiotherapy (RT). **Methods:** The pre-RT plasma levels of 30 cytokines were measured by multiplex ELISA in 154 stage I-III NSCLC patients who were enrolled in prospective studies. Cox-regression analysis was performed to evaluate the prognostic values of cytokine levels, clinical factors on OS. **Results:** With a median follow up time of 21.3 months for patients alive, the 3- and 5-year OS was 38.3% and 18.5%, respectively. In univariate analysis, 6 out of 30 cytokines were identified as prognostic biomarkers for OS. Elevated level of TGFa ($p = 0.011$), IL-1b ($p = 0.000$), IL-4 ($p = 0.048$), IL-15 ($p = 0.005$), EGF ($p = 0.011$), sCD40L ($p = 0.020$) was significantly associated with inferior OS. Male ($p = 0.034$), older age ($p = 0.023$), poor ECOG performance status ($p = 0.002$), weight loss ($p = 0.036$), fatigue ($p = 0.005$), non-adenocarcinoma histology ($p = 0.004$), lower RT dose ($p = 0.046$) were significantly associated with inferior OS. In multivariate analysis, TGFa ($p = 0.041$), ECOG performance status ($p = 0.006$), fatigue ($p = 0.018$), histology ($p = 0.019$) were independent prognostic factors for OS. **Conclusions:** Elevated plasma level of TGFa before radiotherapy may represent an independent adverse biomarker for poor OS of NSCLC treated with RT. This result, if validated, will provide important additions to identify risk group of NSCLC patients and guide the development of new targeted therapies. [KFM1]

7526 Poster Session (Board #273), Mon, 8:00 AM-11:30 AM

Final overall survival (OS) analysis of a multicenter phase II study of concurrent high-dose (72Gy) three-dimensional conformal radiotherapy (3D-RT) without elective nodal irradiation with chemotherapy using cisplatin (CDDP) and vinorelbine (VNR) in patients with stage III non-small cell lung cancer (NSCLC). *First Author: Hidehito Horinouchi, Nantional Cancer Center Hospital, Tokyo, Japan*

Background: We previously reported the adverse events and objective responses in a multicenter phase II study of high-dose chemoradiotherapy. This is a final analysis of the pattern of recurrences, progression free survival (PFS) and OS. **Methods:** Patients with stage III NSCLC were eligible if they met the following key criteria: age between 20 and 74 years, PS 0-1 and $V_{20} \leq 30\%$. Participants received 3-4 cycles of CDDP (80 mg/m^2 day 1) and VNR (20 mg/m^{2}days 1 and 8) every 4 weeks. The 3D-RT was administered at a total dose of 72 Gy divided into 36 fractions from day 1 chemotherapy. The primary endpoint was the 2-year survival rate and the planned sample size was 60 to reject the rate of 45% under the expectation of 65% with a power of 90% and an alpha error of 5%. **Results:** Thirty-one patients were enrolled between 2009 and 2011. The median follow-up time (range) was 51.4 (28.8-65.6) months at the point of data cut-off. This trial was terminated early due to the slow accrual and appearance of grade 5 pulmonary toxicities in 2 patients. There were 25 men and 6 women with a median (range) age of 59 (32-72) years. Of the 25, 23 had adenocarcinoma and 21 had stage IIIA disease. The median (range) V_{20}value was 20 (9-30). Among the 20 patients showing disease progression, in-field failures were observed in 5 (25%) patients as the first relapse and a further 4 patients (9 [45%] patients in total) during the follow-up period. The 2-, 3-, and 5-year PFS rates (95% CI) were 44.9% (27.1-61.2), 34.6% (18.5-51.2), and 34.6% (18.5-51.2), respectively. The 2-, 3-, and 5-year OS rates (95% CI) were 64.5% (45.2-78.5), 51.2% (32.6-67.1), and 43.8% (25.8-60.5), respectively. The median PFS and median survival time were 17.1 months and 41.2 months, respectively. **Conclusions:** The higher TRT dose associated both with an unacceptable incidence of pulmonary toxicities and with relatively better long-term survival. Development of a better strategy is warranted to obtain both a better outcome and tolerable pulmonary toxicities. Clinical trial information: UMIN000001743.

7527 Poster Session (Board #274), Mon, 8:00 AM-11:30 AM

Incomplete non-small-cell lung cancer (NSCLC) resections in the National Cancer Data Base (NCDB): Predictors, prognosis and value of adjuvant therapy. *First Author: Raymond U Osarogiagbon, Baptist Cancer Center, Memphis, TN*

Background: Data are limited on the expected rate and survival impact of incomplete NSCLC resections, and the value of postoperative adjuvant therapy in this situation. **Methods:** We analyzed surgically treated stage I-IIIA NSCLC patients in the NCDB from 2004 to 2011 for clinical, sociodemographic and institutional factors associated with margin-positive resection using multivariate logistic regression models. We compared survival of patients with and without positive margins using proportional hazards (PH) models; and the impact of postoperative adjuvant therapy evaluated with multivariate PH models. **Results:** Of 113,007 resections over 8 years, 5338 (4.72%) had positive margins. Black race, age-based Medicare insurance and urban residence ($p < .01$) were associated with increased adjusted odds ratio (aOR) of resection with positive margins. Squamous histology, high tumor grade, tumor location in the main bronchus, and advancing pathologic stage were clinical factors associated with higher aOR ($p < .001$). Surgery performed at Community Cancer Programs, institutions with high proportions of underinsured patients, institutions at lower cancer resection volume quartiles, also had increased aOR ($p < .01$). The stage-adjusted 5-year survival rate of margin negative vs positive patients was 59% and 40%, respectively ($p < .0001$). After adjustment for stage and other significant factors, postoperative adjuvant therapy was associated with a lower 5-year mortality risk: adjusted hazard ratio 0.75 ($p < .0001$) for chemotherapy; 0.86 ($p < .002$) for radiotherapy; 0.75 ($p < .0001$) for chemoradiotherapy. **Conclusions:** Black race, urban residence, and certain facility characteristics (e.g., low resection volume and high percentage of underinsured patients) were independently associated with incomplete resection. Margin involvement significantly impairs survival after lung cancer resection, irrespective of stage. Contributory intra-institutional provider practices should be identified, to minimize this outcome disparity. Postoperative adjuvant therapy mitigates the mortality risk independently of stage, and should be offered to all patients.

7528 Poster Session (Board #275), Mon, 8:00 AM-11:30 AM

Phase II trial of neoadjuvant bevacizumab plus pemetrexed and carboplatin in patients with unresectable stage III lung adenocarcinoma (GASTO 1001). *First Author: Si-Yu Wang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Unresectable stage III non-small cell lung cancer is often treated with concurrent chemoradiotherapy. Bevacizumab has showed its efficacy in advanced non-squamous lung cancer. The aim of this phase II trial is to assess the efficacy and safety of induction bevacizumab (Bev) plus chemotherapy followed by surgery in unresectable stage III lung adenocarcinoma. **Methods:** This phase II trial investigated induction Bev (7.5 mg/kg) plus pemetrexed (500 mg/m^2) and carboplatin (AUC = 5) followed by surgery for patients with unresectable, stage III lung adenocarcinoma. Neoadjuvant therapy was administered every 3 weeks for 4 cycles. Surgery was scheduled 3-4 weeks after last neoadjuvant therapy and patients' resectability was assessed by a medical team, including thoracic surgeons, medical oncologists, and radiologists. The primary endpoint was resectability rate. **Results:** From April 2012 to April 2014, 42 patients were enrolled and received Bev plus pemetrexed and carboplatin (PC). Grade 3 or 4 neoadjuvant-related adverse events included fatigue in 5 patients, neutropenia in 4, hypertension in 1, anemia in 1 and thrombocytopenia in 1. The adverse events thought to be related to bevacizumab included epistaxis in 3 patients (grade 1, 2; grade 2, 1) and hypertension in 2 patients (grade 1, 1; grade 3, 1). Complete response was achieved in 1 patient, partial response in 22, stable disease in 17, and progressive disease in 2. After neoadjuvant therapy, 31 patients underwent surgery, with pneumonectomy in 11. R0 resection was achieved in 22 patients. Postoperative complications included pneumonia (4 patients), atelectasis (2), bronchial stump insufficiency (1), empyema (1), subcutaneous emphysema (2) and arrhythmia (1). No perioperative hemorrhage events, thromboembolic events and wound-healing problems were observed. No patient died in the perioperative period. The median event-free survival (EFS) was 15.4 months, and the 1-year EFS was 56.1%. **Conclusions:** The treatment modality of neoadjuvant Bev-PC followed by surgery appears to be feasible and safe in patients with unresectable stage III lung adenocarcinoma. Clinical trial information: NCT01588704. Clinical trial information: NCT01588704.

7529 Poster Session (Board #276), Mon, 8:00 AM-11:30 AM

Phase I study of bi-weekly *nab*-paclitaxel and carboplatin with concurrent thoracic radiotherapy for locally advanced non-small cell lung cancer. *First Author: Yukihiro Hasegawa, Aomori Prefectural Central Hospital, Aomori, Japan*

Background: Nanoparticle albumin-bound paclitaxel (*nab*-P) is a cremophor-free formulation of paclitaxel designed to improve solubility and intratumor delivery of active drug. A weekly paclitaxel and carboplatin during with concurrent thoracic radiotherapy (TRT) in non- small cell lugn cancer (NSCLC) is considered a standard regimen in Japan. For more efficiency and less toxicity, we conducted a phase I study of bi-weekly *nab*-P and carboplatin in combination with TRT for patients with unresectable stage III NSCLC. **Methods:** Patients (aged ≤ 75 years) with unresectable clinical stage III NSCLC and having performance status 0 or 1 and adequate organ function were eligible. They received radiotherapy (60 Gy in 30 fractions) once daily starting on day 1. Concurrent *nab*-P (day 1; 60 mg/m^2 at level 1, 80 mg/m^2 at Level 2, 100 mg/m^{2}at level 3) and C (day 1; AUC = 4 at levels 1-3) were administered every 2 weeks for 3 courses. Patients received 2 cycles of consolidation therapy with full dose nab-P (100 mg/m2 weekly for 3 weeks) and C (AUC 6 on day one of each cycle) every 3 weeks. Dose-limiting toxicity (DLT) was defined as grade 4 hematologic or grade 3 non-hematologic toxicity, and the following chemotherapy treatment delayed 15 days or more. **Results:** 18 patients were enrolled at Aomori Prefectural Central Hospital, including 17 males and one female with median age of 63 years (range: 42.4-74). Six patients have been treated at level 1, 2 and 3, respectively. At level 1, 1 to 6 patients showed DLT. At level 2, 2 to 6 patients showed DLTs. At level 3, 1 to 6 patients showed DLT. One of 4 DLTs was grade 3 pneumonitis. The other DLTs were chemotherapy treatment delays. Three patients had grade 3 leukocytopenia and one patient had grade 3 neutrocytopenia. No grade 4 hematologic toxicity was observed. One patient had grade 3 pneumonitis at level 2 but no patient had grade 3 esophagitis. Four patients achieved complete response, 12 had partial response, 1 had stable disease, and 1 had progression disease. **Conclusions:** The maximum tolerated dose was not reached, and the recommended dose was determined at level 3. Clinical trial information: UMIN000010480.

Genomic heterogeneity of lung cancers and its potential clinical implications. *First Author: Jianjun Zhang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Substantial genomic heterogeneity of lung cancers between different patients, reflecting distinct genetic background and potentially different carcinogen exposures in different patients, has been well documented, particularly under t*he Cancer Genome Atlas* (*TCGA*) efforts. On the other hand, our recent study (Zhang, et al, Science, 2014, 346:256-9) and others (de Bruin, et al, Science, 2014, 346:251-6) have revealed limited intra-tumor heterogeneity (ITH) in localized lung adenocarcinomas (LUAD). Our more recent work on synchronous multifocal lung cancers (MSLC) has demonstrated distinct genomic profiles in different tumors within the same patients in spite of identical genetic background and exposure history (Liu and Zhang et al, submitted). **Methods:** We analyzed data from the two studies on ITH of LUAD (Zhang, et al, Science, 2014, 346:256-9 and de Bruin, et al, Science, 2014, 346:251-6), our MSLC study and data from TCGA LUAD study to assess the genomic heterogeneity of lung cancers under different clinical scenarios. We are currently conducting studies to assess the genomic heterogeneity of primary lung cancers versus distant metastases, versus relapsed diseases, and versus secondary primary lung cancers. **Results:** The percent mutations in a tumor sample that are identical to mutations from another tumor sample under different clinical scenarios are: 91% between different regions within the same tumors (n = 16); 80% between primary lung cancers and metastatic lymph nodes (n = 4); 0.12% between different independent tumors within the same patients (n = 6) and 0.05% from unrelated patients (n = 519). The data from primary lung cancers versus distant metastases, versus relapsed diseases and versus second primary cancers is pending. **Conclusions:** With the caveat of small sample size, our data suggests that in localized LUADs, metastases resemble matched primary tumor closely while multifocal primary cancers within the same patients have distinct genomic profiles in spite of identical genetic background and exposure history. Genomic profiling may be useful for identification of both synchronous and metachronous multifocal lung cancers.

7531 Poster Session (Board #278), Mon, 8:00 AM-11:30 AM

The impact of a *Bim* deletion polymorphism on the survival of patients with completely resected non-small cell lung cancer. *First Author: Jun Atsumi, Department of Thoracic and Visceral Surgery,Gunma University Graduate School of Medicine, Maebashi, Japan*

Background: A deletion polymorphism of the *Bim* gene is observed in the Asian population; this polymorphism has been reported to be a prognostic factor for non-small cell lung cancer (NSCLC) patients treated with epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors and chemotherapy. We investigated the impact of the *Bim* deletion polymorphism on the survival of patients with completely resected NSCLC. **Methods:** Distribution of the *Bim* polymorphism was detected using polymerase chain reaction analysis from peripheral neutrophils in samples from 412 NSCLC patients who underwent complete resection. We measured overall survival (OS) and disease free survival (DFS) in all eligible patients, and post-recurrence survival (PRS) in 98 patients who developed recurrences and received anti-cancer therapy. **Results:** The *Bim* deletion polymorphism was detected in 63 (14.0%) patients. OS and DFS rates were significantly lower for patients with the *Bim* deletion polymorphism than those with wild type (OS, $P < .001$; DFS, $P = .006$). On multivariable analysis, *Bim* deletion polymorphism was identified as an independent prognostic factor for OS (hazard ratio [HR] = 1.99; 95% confidential interval [CI], 1.18 to 3.38; $P = .010$), but not for DFS (HR = 1.19; 95% CI, 0.78 to 1.98; $P = .367$). Among the 98 patients who developed recurrences and were treated with anticancer therapy, patients with the *Bim* deletion polymorphism had a significantly worse PRS than those with wild type (median 11.4 months vs 26.9 months, respectively, $P < .001$). This trend was consistent with subgroup analysis stratified by *EGFR* mutation status ($P = .001$ for *EGFR* mutant group; $P = .002$ for *EGFR* wild type group) or histology ($P = .012$ for adenocarcinomas; $P = .013$ for non-adenocarcinomas). A multivariate analysis suggested that the *Bim* deletion polymorphism is an independent predictor of PRS (HR = 2.99; 95% CI, 1.58 to 5.50; $P = .001$). **Conclusions:** The *Bim* deletion polymorphism is a novel indicator of shorter PRS among patients with recurrent NSCLC treated with anticancer therapy in the Asian population.

Prognostic value of miRNAs in resected lung adenocarcinomas. *First Author: Sandra Gallach, Fundación para la Investigación del Hospital General Universitario de Valencia, Valencia, Spain*

Background: Adenocarcinoma (ADC) is one of the most common types of non-small cell lung cancer (NSCLC). Deregulated microRNAs (miRNA) in tumor were associated with poor prognosis. In this study, we analyzed the prognostic value of 22 deregulated miRNAs (identified by NGS in a previous study) in a group of early-stage ADCs. **Methods:** RNA was isolated from fresh-frozen lung ADC specimens (tumor and normal lung) (N = 78). Deregulated miRNA (miR-182, -29a, -19b-1, 34a, 339-5p, -590, -31, -188, -21, -135b, -199b, -224, -196b, -451a, -144, -195, -125a, -218, -145, -30a, -126, -139) were analyzed in paired tumor/normal samples by RTqPCR using TaqMan microRNA assays. Statistical analyses were considered significant at $p<0.05$. **Results:** For survival analysis, continuous variables were dichotomized using the median expression of each miRNA as a cutoff. Of the 22 miRNAs analyzed, high expression levels of miR-34a, miR-145, miR-19b-1, miR-29a, miR-339-5p, miR-21, miR-218 and miR-188 were associated with worse OS and/or PFS (Table 1). Furthermore, patients with combined high levels of miR-188 and miR-339-5p had significantly reduced OS and PFS ($p < 0.0001$ and $p = 0.001$, respectively). The multivariate analysis revealed that this combined variable (miR-188 & miR-339-5p) is an independent prognostic marker for PFS (HR 3.119 [1.500-6.487]; $p = 0.002$) and OS (HR 2.499 [1.003-6.224]; $p = 0.003$). **Conclusions:** Expression of miR-188 and miR-339-5p seems to have a prognostic role in resectable ADC, and the combination of both could be an independent prognostic biomarker in this type of patients. Supported by grants *RTICC (RD12/0036/0025), TRACE (TRA09-0132) and Beca Roche Oncohematología.*

miRNAs univariate analysis for OS and PFS.

	OS		PFS	
miR (high *vs* low)	Median (months)	p	Median (months)	p
miR-34a	46.43 *vs* NR	0.036	19.1 *vs* NR	0.009
miR-145	46.67 *vs* NR	0.039	19.23 *vs* 49.30	0.039
miR-19b-1	42.90 *vs* NR	0.007	23.00 *vs* 49.30	0.114
miR-29a	49.63 *vs* NR	0.056	21.13 *vs* 66.97	0.047
miR-339-5p	37.00 *vs* NR	0.013	19.13 *vs* 66.97	0.037

7533 Poster Session (Board #280), Mon, 8:00 AM-11:30 AM

"The burden upon me": The complexity of healthcare utilization among Medicare patients undergoing curative lung cancer treatment. *First Author: Carolyn Jean Presley, Yale Cancer Center, Smilow Cancer Hospital, New Haven, CT*

Background: Due to new lung cancer CT-screening guidelines and the aging American population, the use of curative treatment for early-stage non-small cell lung cancer (NSCLC) will increase among older adults. Yet little is known about the treatment burden to the patient and Medicare system in terms of healthcare system encounters and number of providers seen. **Methods:** We used the SEER-Medicare database to study Medicare fee-for-service patients aged 67-94 years who were diagnosed with stage I NSCLC from 2007 through 2009 and received curative treatment with either sublobar resection, lobectomy, or stereotactic body radiotherapy (SBRT). We examined healthcare utilization in the 30 days before through 12 months after treatment initiation, determining the total number of days in contact with the healthcare system as well as the number of unique physicians seen. We described care received in the acute, outpatient, post-acute, home care, and hospice settings. **Results:** Of the 4,214 patients, 90.9% received surgery and 9.1% SBRT. During the first 100 days post-treatment, an average of 1 in 4 days was spent in contact with the healthcare system (mean: 25 encounter-days excluding home health visits). Among patients who survived the entire 13-month follow-up period, there was an average of 50 days with at least one encounter. Approximately 3% of patients had ≥ 10 acute care encounter-days, while 97.7% had ≥ 10 outpatient encounter-days and 23.5% had ≥ 10 homecare encounter-days. The median number of physicians seen was 22 (interquartile range 16-31). **Conclusions:** The burden of receiving healthcare for older patients with NSCLC is substantial in terms of frequency of encounters and number of providers seen. Interventions are needed to improve patient-centered, streamlined cancer care.

7534 Poster Session (Board #281), Mon, 8:00 AM-11:30 AM

Effects of obesity and smoking on survival in non-small cell lung cancer. *First Author: Damien Mikael Hansra, Oncology and Radiation Associates, Miami, FL*

Background: Obesity is an emerging leading cause of morbidity and mortality in the US & the relationship between obesity, tobacco, & survival in NSCLC is unclear. **Methods:** Data (n = 87,631) were obtained from linkage of the 1996-2007 FCDS & AHCA databases providing procedure and diagnoses codes. Survival time was calculated from date of diagnosis to date of death. Smoking status was categorized as never, current, and former. Obesity (yes/no) = ICD9 code BMI > 30kg/m2, cachexia = ICD9 code "wasting syndrome", & non-obese = non-obese & non cachectic. Cox proportional regression models used to predict survival; demographic, clinical, treatment factors, & comorbidities were included in adjusted models with smoking status and obesity as the main factors. **Results:** The majority of patients (pts) were either former (49%) or current (40%) smokers, & non-obese (88%). 6.8% of pts were obese & 4.8% of pts were cachectic. There were significant differences between survival curves & median survival (months) for obese vs. non-obese vs. cachectic pts. (20 vs. 10 vs. 7.9; $P < .001$). Former & current smokers had shorter median survival than never smokers (10.8 & 9.2 vs. 11.9; $P < .001$). Survival rates (%) at 1-yr (60.1 vs. 45.2 vs. 37.7; $P < .001$), 5-yr (30.3 vs. 15.4 vs. 9.5; $P < .001$), 10-yr (18.1 vs. 7.6 vs. 2.7; $P < .001$) were better for obese vs. non-obese & cachectic pts respectively. Independent predictor of worse survival in unadjusted model was former (HR 1.08; $P < .001$) & current (HR 1.20; $P < .001$) smokers compared to never. Obese & non-obese pts had better survival vs. cachexia pts(HR 0.52; $P < .001$ and HR 0.80, $p < .001$ respectively) & obese pts had better survival than non-obese pts (HR 0.65, $p < .001$). In the adjusted model, controlling for extensive variables & comorbidities, former (HR 1.11; $P < .001$) & current (HR 1.19; $P < .001$) smokers still had significantly worse survival vs. never smokers. Obese pts still had better survival (HR 0.87; $P < .001$, & HR 0.88, $p < .001$) vs. cachexia & non-obese pts respectively, survival rate is not significantly different comparing non-obese & cachexia pts. **Conclusions:** Our results show that being a former or current smoker worsens survival while obesity improved survival when compared with cachexia & non-obese pts.

7535 Poster Session (Board #282), Mon, 8:00 AM-11:30 AM

Association between the EGFR or KRAS mutation status and the FDG-PET findings in surgically resected lung adenocarcinoma. *First Author: Kazuya Takamochi, Juntendo Univ, Tokyo, Japan*

Background: ^{18}F-fluoro-2-deoxy-glucose (^{18}F-FDG) positron emission tomography (PET) is a functional imaging modality based on the glucose metabolism. The association between *EGFR* or *KRAS* mutations and the standardized uptake value (SUV) of ^{18}F-FDG has not yet been fully elucidated. **Methods:** Correlations between the *EGFR* or *KRAS* mutation status and clinicopathological factors including SUV_{max} were statistically analyzed in 734 surgically resected lung adenocarcinoma patients. A cap analysis of gene expression (CAGE), a method to determine and quantify the transcription initiation activities of mRNA across the genome reflecting gene expression levels by determining the 5' ends of capped RNA molecules using high-throughput sequencers, was done to examine the molecular basis between the SUV_{max} and mutations in 62 lung adenocarcinomas. **Results:** *EGFR* and *KRAS* mutations were detected in 334 (46%) and 83 (11%) of the 734 lung adenocarcinomas, respectively. Univariate analyses showed *EGFR* mutations to be more frequently observed in females, never-smokers, patients with normal CEA levels, tumors without lymph node involvement and blood vessel invasion, and tumors with lower SUV_{max} values. In multivariate analyses, the smoking status and the SUV_{max} were the significant predictors of *EGFR* mutations. In contrast, no relationship was seen between the *KRAS* mutation status and the SUV_{max}. Four genes associated with the glucose metabolism and five genes associated with the cell cycle showed a lower expression in the *EGFR* mutated tumors than the wild type tumors and a positive correlation with SUV_{max}. However, no such genes were found for *KRAS* mutations. **Conclusions:** Tumors with *EGFR* mutations show lower values of SUV_{max} than wild type ones.In contrast, no relationship was found between *KRAS* mutation and the $SUV_{max.}$ These results suggest that tumors with *EGFR* mutations are less aggressive with likely lower levels of glucose metabolism.

7536 Poster Session (Board #283), Mon, 8:00 AM-11:30 AM

Comparison of concurrent use of carboplatin-Paclitaxel versus cisplatin-etoposide with thoracic radiation for stage III NSCLC patients: A systematic review. *First Author: Conor Ernst Steuer, Emory Univ, Atlanta, GA*

Background: The two most commonly used chemotherapy regimens deployed concurrently with thoracic radiation (RT) for patients with unresectable IIIA and IIIB non-small cell lung cancer (NSCLC) are carboplatin/paclitaxel (CP) and cisplatin/etoposide (CE). Because there are no prospective comparisons of these two regimens in this setting, we conducted a systematic review of published trials to compare outcomes and toxicities between CE and CP. **Methods:** Studies which enrolled stage III patients receiving RT with CP or CE were identified using electronic databases (MEDLINE, EMBASE, and Cochrane library) and meeting abstracts. Trials were excluded if they were phase I, enrolled less than 10 pts, or included surgical resection. A systematic analysis of extracted data was performed using Comprehensive Meta Analysis (Version 2.2) software using random and fixed effect models. Clinical outcomes were compared using point estimates for weighted values of median overall survival (OS), progression free survival (PFS), response rate (RR) and toxicities. Two-tailed T-test with a significance level of 0.05 was used for all comparisons. **Results**: 3194 patients were included from 32 studies in the CE arm, and 3789 patients from 51 studies in CP. Baseline characteristics of patients on the CE arm versus CP arm were: median age 61 vs. 63 years, male 67.6% vs. 78%, squamous histology 39% vs. 40%, and median radiation dose 62 Gy vs. 63 Gy. There was no significant difference in response rates between CE and CP (65% vs. 56%, $p = 0.6$), respectively. There was no significant difference in median progression free survival (11.5m vs. 9.3m $p = 0.2$), overall survival (19.8m vs. 18.4m, $p = 0.48$), or 3-year survival rate (31% vs. 25%, $p = 0.4$) for CE vs. CP. CE was associated with higher grade 3/4 hematological toxicities than CP, such as neutropenia (53% vs. 23% $p < 0.0001$), as well as grade 3/4 nausea/vomiting (20% vs. 9% $p = 0.018$), while rates of grade 3/4 pneumonitis and esophagitis were similar. **Conclusions:** CE and CP regimens were associated with comparable efficacy when used with concurrent radiotherapy for stage III unresectable NSCLC pts. The toxicity profile favored the CP regimen.

7537 Poster Session (Board #284), Mon, 8:00 AM-11:30 AM

Pulmonary sarcomatoid carcinoma: An analysis of the National Cancer Database. *First Author: Conor Ernst Steuer, Emory Univ, Atlanta, GA*

Background: Pulmonary sarcomatoid carcinomas (SC) are a grouping of five rare non-small cell lung cancer (NSCLC) subtypes. Small case series suggest that these patients have a poor prognosis. We sought to better define the clinical characteristics and outcomes of SC utilizing the National Cancer Database (NCDB), an oncology outcomes database administered by the American College of Surgeons and the American Cancer Society. **Methods:** The NCDB lung cancer database was queried from 1998 to 2011 for SC using ICD-O-3 codes. Data were extracted on patient demographics, tumor pathology, treatments, and outcomes. Overall survival (OS) data were available for patients diagnosed from 1998-2006 and co-morbitity data from 2003-2011. The univariate association with covariates between SC and other forms of NSCLC was assessed using Chi-square test or ANOVA, where appropriate. The univariate (UV) and multivariable analysis (MV) with OS were conducted by Cox proportional hazards model and/or log-rank tests. All statistical analyses were conducted using SAS Version 9.3. **Results:** Of the 1,547,531 NSCLC patients in the NCDB, 7965 were diagnosed with SC (0.7%). SC patients had a median age of 70, 59% were male, 89% were Caucasian, and 61% had a Charlson/Deyo co-morbidity status of 0. At presentation, the median primary tumor size was 5 cm and 18% of SC patients were AJCC stage I, 10% stage II, 24 % stage III, and 48% stage IV. Patients were treated with surgical resection (38.5%), radiation (38.2%), and chemotherapy (38.6%). The median OS for stage I-II SC was 16.9 months (m), 5.8 m for stage III, and 5.4 m for stage IV. The 1-year and 5-year survival rates for metastatic SC were 30% and 14%. When compared to other forms of NSCLC in MV analysis, SC patients had a higher risk of death (hazard ratio (HR) 1.34 (95% CI 1.20-1.48) $p < .001$). A propensity scored matched analysis performed for SC vs. other NSCLC confirmed our findings with worse outcomes in the SC group (HR 1.34 (CI 1.15-1.56) $p < .001$). **Conclusions:** SC represents a rare histologic subtype of NSCLC accounting for 0.7% of all lung cancers. It is associated with aggressive clinical characteristics and an inferior outcome relative to other histological subtypes of NSCLC.

7538 Poster Session (Board #285), Mon, 8:00 AM-11:30 AM

Association between radiation dose and outcomes with postoperative radiotherapy for N0-N1 non-small-cell-lung cancer. *First Author: Elyn H. Wang, Department of Therapeutic Radiology, Yale School of Medicine, New Haven, CT*

Background: To review trends in the use of postoperative radiation therapy (PORT) in the modern era for N0-N1 margin-negative non-small cell lung cancer (NSCLC) following surgical resection and evaluate the association between PORT dose and overall-survival (OS). **Methods:** We performed a retrospective study of non-metastatic stage II and III N0-N1 margin-negative NSCLC surgically-treated patients within the National Cancer Data Base from 2003-2011. Cox proportional hazards regression was performed for multivariable analyses of OS and PORT dose. Radiation modalities included non-conformal beam radiation, 3D-conformal radiation (3D-CRT), and intensity-modulated radiation therapy (IMRT). **Results:** We identified 2,167 (6.7%) and 30,269 (93.3%) patients with surgically-resected stage II or III N0-N1 margin-negative NSCLC who were treated with and without PORT, respectively. The proportion of patients treated with PORT (dose range: 45-74 Gy) decreased from 8.9% in 2003-2006 to 4.1% in 2010-2011. Among patients receiving PORT, the use of high-dose (60-74 Gy) PORT rose throughout the study period, starting at 34.8% in 2003-2006 and rising to 49.3% in 2010-2011. Overall, patients who received PORT had worse survival (HR = 1.30; 95% CI 1.20-1.40) compared to those not receiving PORT. This association was unchanged when limited to patients receiving modern treatment with 3-CRT or IMRT (HR = 1.35; 95% CI: 1.10-1.65]. Examining the association between dose and overall survival revealed that patients treated at doses < 50 Gy or ≥ 54 Gy had worse OS compared to no PORT while a trend showing decreased survival was observed among those receiving 50-53.9 Gy (HR = 1.14; 95% CI: 0.99-1.30). Limiting the analysis to patients receiving 3D-CRT or IMRT showed worse survival for patients receiving ≥ 60 Gy (HR = 1.43; 95% CI: 1.04-1.95) and similar survival between no PORT and the remaining dose groups. **Conclusions:** The use of PORT for N0-N1 margin-negative NSCLC decreased from 2003-2011. We found no evidence of benefit from PORT for resected N0-N1 margin-negative NSCLC, regardless of dose or technique. PORT should be approached with caution in this group of patients, regardless of radiotherapy technique.

7539 Poster Session (Board #286), Mon, 8:00 AM-11:30 AM

Common and rare *EGFR* mutations (*EGFR*m) in the RADIANT trial: Final follow-up with 5 year data. *First Author: Frances A. Shepherd, Princess Margaret Cancer Centre, Toronto, ON, Canada*
