Background: Data on *EGFR*m in early stage NSCLC are limited. RADIANT was a prospectively randomized Phase 3 trial of adjuvant erlotinib (E) v placebo (P) in 973 patients (pts) with completely resected Stage IB–IIIA NSCLC that was EGFR +ve by IHC or FISH (ASCO14 #7501; ESMO14 #1178PD). **Methods:** *EGFR*m in exons 18–21 was determined by WAVE HS and confirmed by Sanger sequencing. Two *EGFR*m groups were defined: Common refers to exon del19 or L858R irrespective of the presence of another *EGFR*m; Rare Only refers to *EGFR*m without del19 or L858R. Exploratory analysis of disease-free survival (DFS) was performed by subgroup (June 11, 2014 data cutoff). **Results:** 921 pts had *EGFR*m status determined; 198 pts (21.5%) had *EGFR*m (161 Common, 37 Rare Only). There was no sex difference between the groups, but pts with Rare Only *EGFR*m were less likely to be Asian (32.4% *v* 47.2%) or non-smokers (48.6% *v* 62.7%). With a median follow-up of 5 years, updated DFS by mutation type is shown below. The DFS HR was lower in the Common group (HR [E/P] 0.75, CI 0.48, 1.16) than in the Rare Only group (HR 1.19, CI 0.44, 3.22). **Conclusions:** The effect of E on DFS in *EGFR*m subgroups remains inconclusive. Clinical trial information: NCT00373425.

7540 Poster Session (Board #287), Mon, 8:00 AM-11:30 AM

Final follow-up (f/u) results from RADIANT: A randomized double blind phase 3 trial of adjuvant erlotinib (E) versus placebo (P) following complete tumor resection in patients (pts) with stage IB–IIIA *EGFR* positive (IHC/FISH) non-small cell lung cancer (NSCLC). *First Author: Mary E.R. O'Brien, Royal Marsden Hospital, London, United Kingdom*

Background: Adjuvant chemotherapy for NSCLC has reached a plateau. The use of the tyrosine kinase inhibitor (TKI), E, was explored in the adjuvant setting given success in advanced setting.We report final f/u from RADIANT. **Methods:** Completely resected IB–IIIA NSCLC pts were randomized 2:1 to receive E 150 mg daily or P for 2 years. The primary endpoint was disease free survival (DFS) in the full analysis set (FAS). Secondary endpoints included overall survival (OS) in the FAS and DFS and OS in *EGFR* mutation (M+) subset (del19/L858R). 973 pts were randomized and the planned final analysis was performed after 410 DFS events (April 2013 data cutoff, ASCO14 #7501). A subsequent exploratory analysis occurred after final f/u (June 2014 cutoff). **Results:** The median f/u is 59.6m (95% CI 56.7–61.2). There was no statistically significant difference in DFS or OS overall or in the *EGFR* M+ group. The OS data remain immature with 33.5% deaths in the E arm and 31.4% in the P arm. The most common site of relapse (>15% pts) overall and in *EGFR* M+ were lung and brain in E treated pts and lung, bone and brain in P pts. Among the 13 pts in the *EGFR*M+ subgroup with brain as site of relapse, 11 of these patients relapsed after E cessation. There were no new safety concerns. **Conclusions:** Overall adjuvant E did not prolong DFS; a trend for E benefit previously observed (ASCO14 #7513) in *EGFR* M+ subgroup is no longer apparent. EGFR mutation status was not a stratification factor in this trial and was not a prognostic factor (ESMO14 #1177PD). Further results from ongoing trials are awaited to determine the role of TKI in *EGFR* M+ early stage lung cancer. Clinical trial information: NCT00373425.

A phase II study of concurrent chemoradiotherapy with cisplatin and oral S-1, followed by surgery for locally advanced non-small cell lung cancer. *First Author: Tomoshi Tsuchiya, Department of Surgical Oncology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background: This study was designed to evaluate the feasibility of concurrent chemoradiotherapy followed by surgery in locally advanced non-small cell lung cancer (NSCLC). We defined locally advanced NSCLC as pathologically proven hilar and/or mediastinal lymph node metastases by endobronchial ultrasound-guided transbronchial needle aspiration (E-BUS/TBNA), or chest wall invasion. **Methods:** Twenty-three patients were enrolled in this study between May 2011 and April 2014. The patients received 40 mg/m2 S-1 twice orally per day on days 1 through 14 and 29 through 42, and cisplatin (60 mg/m2) was injected intravenously on days 8 and 36. The patients also underwent radiotherapy, receiving a total dose of 40 Gy in 20 fractions beginning on day 1. Surgical resection was performed 4 to 6 weeks after completing the induction treatment. **Results:** The 23 analyzed patients consisted of 5 stage IIB and 18 stage IIIA patients. Thirteen patients with histopathological lymph node metastases were diagnosed by E-BUS/TBNA. Twenty patients completed two courses of induction chemotherapy and radiotherapy, and achieved surgery (87.0%). Grade 3 adverse reactions included neutropenia (21.7%), leukocytopenia (8.7%), pneumonia (8.7%), increased serum total bilirubin (4.3%), nausea (4.3%), and diarrhea (4.3%). No grade 4 adverse reactions were identified. Radiologically, 7 (30.4%) of the 23 patients achieved partial response, and 14 patients (60.8%) achieved stable disease. Pathologic findings suggested that all operated patients were curatively resected. Comparing preoperative and postoperative histopathology, 6 (26.1%) complete responses were identified. Accordingly, 13 patients (56.5%) were histopathologically downstaged by CRT. **Conclusions:** Induction treatment using S-1 plus cisplatin and concurrent radiotherapy followed by surgical resection is a feasible and promising new treatment modality for potentially resectable NSCLC. In addition, there was a low incidence of adverse reactions. Evaluation of histopathological downstaging revealed sufficient anticancer effects for preoperative treatment. Clinical trial information: UMIN000008205.

7542 Poster Session (Board #289), Mon, 8:00 AM-11:30 AM

Retrospective analysis between PD-L1 expression and prognosis for stage III non-small cell lung cancer patients who received concurrent chemoradiotherapy. *First Author: Takaaki Tokito, Division of Respirology, Neurology and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume, Japan*

Background: Programmed cell death 1 (PD-1) receptor-ligand interaction is a major pathway often hijacked by tumors in order to suppress immune control. We investigated whether the expression of programmed death–ligand 1 (PD-L1) is related to clinicopathologic or prognostic factors in patients with locally advanced NSCLC who received concurrent chemoradiotherapy (CRT). **Methods:** We retrospectively reviewed consecutive stage III NSCLC patients who received CRT at Kurume University. The expression of PD-L1 was evaluated by immunohistochemical analysis in specimens of NSCLC. Survival analysis was obtained by Kaplan-Meier methods. **Results:** A total of 52 patients with a median age of 67 years were eligible for this study. Forty-three patients were men, and 46 patients were current or ever smokers. The most predominant histological type was adenocarcinoma (28 patients), followed by squamous cell carcinoma (21 patients). All of the patients received platinum-based doublets. Expression of PD-L1 in tumor cells was observed in 73%. NSCLC patients with PD-L1-negative tumors showed longer progression-free and overall survival than those with PD-L1-positive (median PFS, 17 versus 11 months; $p = 0.31$, median OS, 52 vs 25 months; $P = 0.38$; respectively), and higher progression-free rate at 2 years and overall survival rate (38% and 26%, 83% and 52%, respectively). **Conclusions:** There was a trend toward a poor survival in expression of PD-L1 in stage III NSCLC patients who received CRT.

7543 Poster Session (Board #290), Mon, 8:00 AM-11:30 AM

Correlation between high-resolution computed tomography findings and IASLC/ATS/ERS classification of small lung adenocarcinomas in Japanese patients. *First Author: Yujin Kudo, Department of Thoracic Surgery, Tokyo Medical University, Tokyo, Japan*

Background: Small pulmonary nodule detection rates have increased owing to computed tomography (CT) screening of lung cancer, and new image guided-bronchoscopy techniques have been developed to improve diagnostic yield. Additionally, limited surgical resection for small peripheral lung adenocarcinomas has been reported. Recently, the IASLC/ATS/ERS classification emphasized the prognostic significance of histologic subtypes. We evaluated the correlation between high-resolution CT (HRCT) findings and this classification of small lung adenocarcinomas. **Methods:** We reviewed the data of 220 consecutive lung adenocarcinoma (≤ 3 cm) patients who received segmentectomy or more extended resection with lymph node dissection in our hospital. From the HRCT findings, the tumors were classified as pure solid, part-solid, or pure ground glass opacity (GGO) nodules. Pathologic tumor invasiveness (pTI) was evaluated by the degree of vascular invasion, lymphatic permeation, or visceral pleural invasion. **Results:** The tumors were classified as pure GGO nodules in 16 patients (7.2%), part-solid in 91 (41.3%), and pure solid in 113 (51.3%) from the HRCT findings. We pathologically diagnosed 44 noninvasive and 176 invasive adenocarcinomas (IAs) [lepidic (LPA), papillary, acinar, solid predominant adenocarcinoma, and invasive mucinous adenocarcinoma]. Lymph node metastasis was present in 31 patients (14.1%) and pTI in 101 (45.9%). All pure solid tumors were IAs with a high pTI frequency (75.2%) or lymph node metastasis (26.5%). All pure GGO nodules were non-IAs or LPA. Among the part-solid nodules, IA was detected in 67.0% of the patients and pTI in 16.5%. The consolidation/tumor (C/T) ratio and consolidation size were associated with IA (optimal cut-off values: 0.4 and 8 mm) or pTI (0.8 and 15 mm). **Conclusions:** The HRCT findings correlated with the IASLC/ATS/ERS classification and were useful for malignancy evaluation. Most pure solid tumors have malignant potential including pTI or lymph node metastasis. For part-solid tumors, the C/T ratio and consolidation size were important for predicting pTI or making a diagnosis of IA according to this classification.

7544 Poster Session (Board #291), Mon, 8:00 AM-11:30 AM

Comprehensive analysis of driver mutations in Chinese squamous cell lung carcinomas by targeted next-generation sequencing. *First Author: Sheng Yang, Department of Medical Oncology, Cancer Institute/Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College Beijing, China, Beijing, China*

Background: The aim of the study was to analyze the driver mutation profiles in a large cohort of Chinese SqCLCs to identify potential therapeutic targets. **Methods:** We detected approximately 2,800 COSMIC mutations from 50 oncogenes and tumor suppressor genes on 159 samples by using Ion Torrent semiconductor-based next-generation sequencing.We conducted FISH for fibroblast growth factor receptor 1 (*FGFR1*) and cyclin D1 (*CCND1*) amplification on 172 and 246 samples, respectively. In addtion, we analyzed PTEN expression by immunohistochemistry on 172 samples. **Results:** Somatic mutations were detected in 73.6% (117/159) of patients. The most commonly mutated gene detected in this study was *TP53* (89 cases, 56.0%), followed by *CDKN2A* (14 cases, 8.8%), *PI3KCA* (14 cases, 8.8%), *KRAS* (7 cases, 4.4%), and *EGFR* (5 cases, 3.1%). The incidences of *FGFR1* amplification, *CCND1* amplification and loss of PTEN expression in this cohort of patients were 16.9% (29/172), 11% (27/246) and 43.6% (75/172), respectively. The frequency of *EGFR* mutation was significantly higher in female and never smokers, while *TP53* mutations were significantly more common in men and smokers. The incidence of *FGFR1*amplification in current smokers was significantly higher than that in former smokers and never smokers (P_{trend}= 0.025). The incidence of *FGFR1* and *CCND1* amplification significantly increased with increment of total cigarette smoking dosage (P_{trend} < 0.001 and P_{trend} = 0.006, respectively). Loss of PTEN expression was more frequent in elders (*P*= 0.047), male gender (*P*= 0.033), patients with early stage (*P*= 0.042) and positive pleural invasion (*P*= 0.030). No significant association was observed between the molecular abnormalities and overall survival. **Conclusions:** Somatic mutations were detected in nearly three-fourth (73.6%) of Chinese SqCLC patients. *FGFR1* amplification, *CCND1* amplification and loss of PTEN expression are also frequent alterations in SqCLC. Comprehensive analysis of driver mutations in our study could facilitate the development of targetd therapies and optimize the therapeutic strategies for patients with SqCLC.

7545 Poster Session (Board #292), Mon, 8:00 AM-11:30 AM

Prognostic significance of a diagnosis of multiple lung cancers. *First Author: Jarushka Naidoo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The Martini-Melamed criteria (J Thor Card Surg, 1975) have been used since 1975 to clinically differentiate MLCs from lung metastases, which impacts upon treatment choices. The survival of patients (pts) with MLCs compared to those with one lung cancer (LC), and either local or distant recurrent LC, is unclear. Herein, we evaluated the Martini-Melamed criteria for its ability to appropriately identify patients with MLCs. **Methods:** After IRB approval, we conducted a retrospective review of all pts who underwent an R0 resection for stage IA-IIIA LC from 2008-2013 in our institution. Clinicopathologic data for all pts was collected. MLCs were defined using the Martini-Melamed criteria. We used the Kaplan-Meier method to assess overall survival (OS) of pts with one LC, recurrent LC, or an MLC, from the time of surgery/pathologic confirmation of their one LC, recurrent disease or MLC respectively. **Results:** 2,858 pts were identified: one LC (n=2403), recurrent LC (n=347), MLCs (n=108). Median OS for pts in these subgroups was: one LC (32.3mos, 95% CI: 30.8-34.6mos), MLC (not reached=NR), recurrent LC (10.5mos, 95% CI: 9.5-13.7mos). The 2-year OS for pts in these subgroups stratified by stage is depicted in the table. **Conclusions:** Pts with MLCs had a 2-yr OS that stage for stage, was similar to pts with one resected LC. Pts with recurrent LC had a poor 2-yr OS by original stage. Clearly, the Martini-Melamed criteria identify a clinically significant patient population with a different disease natural history. However, translational studies in MLCs are needed to investigate the tumor biology and patient features that underpin this distinct clinical entity.

Lung Cancers by Original Stage (n)		Two-year Overall Survival	Log-rank p value

Patterns and effectiveness of surveillance after curative intent surgery in stage I-IIIA non-small cell lung cancer. *First Author: Christine Agnes Ciunci, Hosp of the Univ of Pennsylvania, Philadelphia, PA*

Background: The optimal strategy for imaging surveillance of non-small cell lung cancer (NSCLC) patients after curative intent surgery is unknown. Current guidelines recommend computed tomography (CT) every 6-12 months for 2 years and then annually. There are no large population-based studies identifying how patients are managed, or comparing the effectiveness of chest radiography (CXR) and CT surveillance. **Methods:** We performed a retrospective cohort study using Surveillance, Epidemiology and End Results (SEER)-Medicare data to determine the primary surveillance modality following surgical resection in stage I-IIIA NSCLC between 1998 and 2009. Primary surveillance modality was defined as the imaging study used between 90-365 days after surgery. Comparative effectiveness of CT vs. CXR surveillance was explored in terms of overall survival (OS) using a stratified Cox model based on stage and adjusted for age, gender, race, CMI, Charlson comorbidity index, and adjuvant chemotherapy. **Results:** 5,968 (54%)patients were followed by CT, and 5,083 (46%) by CXR. Patients with earlier stage, older age, and lower census median income (CMI) were less likely to undergo CT surveillance (p<0.001). CT surveillance increased over the study period from 23% in 1998 to 68% in 2009 (p<0.001). In the analysis of surveillance modality and OS, a significant interaction was identified between imaging and diagnosis year (p<0.001). The effect of CT surveillance on OS steadily improved over time, and was significantly better than CXR in the most recent time periods of study (Table). **Conclusions:** OS was improved in patients with CT surveillance in the most recent time periods of analysis supporting surveillance guidelines. Further studies to determine how CT surveillance leads to improved outcomes, to evaluate the appropriate interval of CT imaging, and to elucidate why patients are not followed according to guidelines are warranted.

Multivariable Cox Regression for Overall Survival with CT surveillance as reference group.

7547 Poster Session (Board #294), Mon, 8:00 AM-11:30 AM

Prognostic role of expression levels of FABP3 and AKR1B10 genes in adenocarcinoma stage I patients. *First Author: Vienna Ludovini, Medical Oncology, S. Maria della Misericordia Hospital, Perugia, Italy*

Background: In resected lung cancer, no reliable clinical or molecular predictors are currently available for identifying patients with high risk for recurrent disease. In a previous study, we selected 5 genes up-regulated and 4 genes down-regulated which were predictive for clustering adenocarcinoma (ADC) patients in early relapse (ER) and non relapse (NR) using Affimetrix human microarray HG-U133Plus 2.0. Here we validate our results using an independent cohort of patients with lung ADC stage I to identify novel genes involved in the risk of ER compared to NR disease. **Methods:** From tissue banking of 180 consecutive resected NSCLC patients, we selected frozen specimens of ADC with corresponding normal lung of stage I patients. Quantification of mRNA expression levels of 9 genes (5 up-regulated: CLCA2, FABP3, H19, TFPI2, AKR1B10 and 4 down-regulated: CYP3A5, ALDH3A1, SCGB3A2, SCGB1A1), were analyzed by real-time one-step RT-PCR using QuantiFast assay (Qiagen).The gene expression levels and their association with relapsed disease and molecular features were assessed by t-test and Fisher's exact test, respectively. The logistic regression model was used for multivariate analysis. **Results:** Seventy-nine patients were evaluable, 23% of which had an ER. The mean expression levels of CYP3A5 and SCGB3A2 was down-regulated in ER respect to NR (0.31 vs 1.12; 0.80 vs 2.07 respectively). P53 mutations were associated with smoking history (p = 0.01) and had a tendency to significance with FABP3 (p = 0.07). In the univariate analysis the mean expression levels of AKR1B10 and FABP3 were correlated with a worse disease free survival (DFS) (p = 0.024 and p = 0.017 respectively). In the multivariate analysis the mean expression levels of all genes showed a tendency to predict the ER in the overall population (p = 0.06). The multivariate analysis adjusted for age, smoking, stage high AKR1B10 and FABP3 expression levels maintain their prognostic effect for a poor DFS (p = 0.003). **Conclusions:** It is possible to define through gene expression, a characteristic gene profiling of ER patients. Such features may have important implications for future targeted therapies. This study was supported by Italian Association for Cancer Research (AIRC).

7548 Poster Session (Board #295), Mon, 8:00 AM-11:30 AM

Utility of ^{18}F-FDG PET and CT to assess response to neoadjuvant chemotherapy. *First Author: Jamie E. Chaft, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Perioperative chemotherapy improves survival in resected NSCLCs. Neoadjuvant administration allows for *in vivo* assessment of efficacy. Major pathologic response (MPR), defined as <10% viable tumor tissue in the surgical resection specimen, strongly correlates with clinical outcomes in lung cancers. (Hellmann, Lancet Oncol 2014) Unfortunately, it is a minority of tumors that demonstrate MPR after standard induction chemotherapy and adaptive strategies are needed. The understanding of the clinical utility of non-invasive mid-and post-treatment PET and CT scans is essential for adaptive trial design. **Methods:** This analysis is derived from a completed phase 2 trial of PET response-adaptive therapy that treated 40 pts with clinical stage IB-IIIA NSCLCs (primary >2 cm & SUVmax≥4.5). Pts received 2 cycles of cis- or carboplatin + gemcitabine (squamous) or pemetrexed (adenocarcinoma/other), followed by repeat PET + CT. Pts with suboptimal response (<35% decrease in SUV) were switched to vinorelbine + docetaxel q2 wks. This analysis utilizes non-parametric tests to assess the correlation of % change in SUV of the primary tumor (PERCIST) and the % change in size on CT (RECIST) with MPR after 2 cycles and at completion of induction therapy. **Results:** 40 pts were treated. 15 pts has <35% decrease in SUV, of whom 13 were switched to vinorelbine/docetaxel, and 2 to definitive radiotherapy only. 27 pts had R_0resections. 6 tumors demonstrated MPR. In all settings, PET response correlated with MPR and CT response did not (see Table). **Conclusions:** ^{18}F-FDG PET response, but not CT response, in the primary tumor after 2 and 4 cycles of chemotherapy correlates with major pathologic response, a surrogate for survival. The use of early PET response to offer alternative therapies to pts who are not benefiting should be considered. NCT01443078 was supported in part by Eli Lilly. Clinical trial information: NCT01443078.

7549 Poster Session (Board #296), Mon, 8:00 AM-11:30 AM

Aneuploidy of anaplastic lymphoma kinase (ALK) gene and association with non squamous lung cancer patient characteristics and outcomes. *First Author: Taofeek Kunle Owonikoko, Emory Univ, Atlanta, GA*

Background: ALK gene translocation resulting in aberrant activation of ALK signaling is a genetic driver in subsets of NSCLC. Aneuploidy of the ALK gene is also frequently observed but its impact has not been well studied. **Methods:** We analyzed the results of molecular tests performed in a CLIA-certified lab for lung cancer patients treated at our institution. Patient demographics, treatment and outcome data were retrieved from the electronic records. Univariate and multivariable analysis was performed to test for association between ALK gene aneuploidy, percentage of aneuploid cells, minimum and maximum number of ALK gene copies per cell and the following covariates: ALK gene rearrangement, gender, stage, race, age, PFS and OS. Survival was estimated by the Kaplan-Meier method and compared between defined groups using a Cox proportional hazards model and log rank test. **Results:** We analyzed data from 259 patients, male (48%); Black (33%), Asian (4%), White (63%); median age 65yrs; stage: I (32%), II (12%), III (16%) and IV (40%). The median PFS and OS were 14.4 months (95% CI: 9.7 – 20.1) and 79.7 months (95% CI: 22.9 – NA), respectively. ALK FISH rearrangement was present in 3 (4.8%) of 63 patients tested by FISH. Aneuploidy of the ALK gene was present in 46 (73%) cases with 40% aneuploid cells per case. Minimum and maximum number of copies of ALK gene in aneuploid cells were 2.63 (± 0.61) and 4.02 (± 2.03), respectively. There was no association between ALK gene aneuploidy and patient characteristics but ALK gene aneuploidy, percentage aneuploid cells and high ALK polysomy were negatively correlated with presence of ALK FISH rearrangement. Absence of aneuploidy (HR: 0.29; 0.09-0.95; p,0.040) and higher stage at diagnosis were independently associated with a higher risk of progression on multivariable analysis. **Conclusions:** There is inverse association of ALK gene aneuploidy and ALK gene rearrangement. The association between ALK polysomy and higher risk of disease progression is worthy of further study to elucidate the underlying biology.

7550 Poster Session (Board #298), Mon, 8:00 AM-11:30 AM

Conditional survival estimates for lung cancer histologic subtypes in the U.S. (2004-2008). *First Author: Kailash Mosalpuria, University of Nebraska Medical Center, Omaha, NE*

Background: Conditional survival (CS) is a more accurate measure of survival probability among cancers associated with a poor prognosis. We calculated lung cancer-specific CS estimates to help clinicians and patients with informed decision making. **Methods:** Lung cancer patients with at least 3 years of follow-up were identified from the Surveillance Epidemiology and End Results registry (2004-2008). American Joint Commission on Cancer, sixth edition was used for staging non-small cell lung cancer (NSCLC). Stages 1 to 3 SCLC were classified as limited stage (LS), and stage 4 was classified was extensive stage (ES). Multivariate Cox regression models were built separately by stage to calculate the adjusted 1-6 year cancer-specific survival and overall survival. The multiplicative law of probability was then used to compute the X-year conditional survival where the (x+y) year survival is divided by y years of patients who have survived. The following were adjusted: age, sex, ethnicity, marital status, SEER region, year of diagnosis, radiation, and definitive surgery. **Results:** A total of 127,992 patients were included in the final cohort. Patients diagnosed with stage IA NSCLC had a 3-year survival probability of 73%. This increased to 76% in patients who were alive at 3 years following diagnosis. The three- year conditional overall survival (COS) estimates from diagnosis (time 0) to 3 years for the other stages were as follows: stage 1B: 54% to 68%, stage 2A: 54% to64%, stage 2B: 37% to 58%, stage 3A: 25% to 51%, stage 3B: 14% to 43%, and stage 4: 6% to 29%. For Stage 1A NSCLC 3-year conditional cancer-specific survival (CCSS) estimates improved from 82% to 87%, stage 1B: 63% to 80%, stage 2A: 62% to74%, stage 2B: 44% to 69%, stage 3A: 30% to 60%, stage 3B: 18% to 53%, and stage 4: 8% to 35%. For LS-SCLC, 3-year COS improved from 16% at diagnosis to 52% at 3 years; for ES-SCLC it increased from 3% to 47%. For LS- SCLC, 3-year CCSS improved from 19% at 0 years to 63% at 3 years whereas for ES-SCLC it improved from 4% to 53%. **Conclusions:** Three-year COS and CCSS estimates improve dramatically over time for survivors with advanced stages. These prognostic data are critical to patients for both treatment and non-treatment related life decisions.

7551 Poster Session (Board #299), Mon, 8:00 AM-11:30 AM

PD-L1, PD-1, and CTLA-4 as prognostic biomarkers in resected non-small cell lung cancer. *First Author: Taofeek Kunle Owonikoko, Emory Univ, Atlanta, GA*

Background: Reliable assessment of predictive or prognostic biomarker is critical for successful incorporation of immune checkpoint inhibitors into lung cancer management. We assessed the prognostic relevance of immune checkpoint mediators in resected NSCLC. **Methods:** We determined PD-L1 expression by immunohistochemistry using our instituional tumor bank samples. Mutations, expression and copy number variations (CNV) in genes encoding for PD1, PD-L1 and CTLA-4 were assessed using TCGA data. Survival estimates were performed by the Kaplan-Meier method. Differences in disease free and overall survival (DFS, OS) between patients with high or low PD-L1 protein expression were assessed by univariate and multivariate survival analyses using Cox proportional hazards model using different cutpoint definitions of staining intensity (0, 1, 2, 3), percent cell staining (0-100%) and immunoscore (0-300). Prognostic impact of genetic alterations was assessed in the overall population and in subsets of adenocarcinoma, squamous, smokers and non smokers. **Results:** We employed 208 institutional NSCLC samples (Caucasian 199, African American 9; Male/Female 101/107; squamous 63, non squamous 138) and 763 NSCLC cases from the TCGA database. PD-L1 protein expression was higher in smokers, non squamous cancers and females but not significantly different by race, tumor stage or grade. Low PD-L1 immunoscore in cancer cells (< 10 vs. ≥ 10, < 35 vs. ≥ 35, or < 33.33 vs. ≥ 33.33) and in adjacent normal tissue (0 vs. > 0, < 10 vs. ≥ 10, or < 2 vs ≥ 2) was significantly associated with a higher risk of recurrence and poor OS. High tumor to normal ratio for PD-L1 staining was also associated with higher risk of recurrence and poorer OS. Mutations in CTLA4, PD-1 and PD-L1 genes were very rare. No association of CTLA-4 or PD-L1 gene expression differences or CNV with survival in patients groups defined by histology or smoking status.. High ratio of PD-1 gene expression in tumor to normal was associated with higher median OS [3.8 (1.8, 6.6) vs. 1.6 (0.5, 5.4) years; $p = 0.022$]. **Conclusions:** PD-L1 protein expression is higher in females, non squamous cancers and smokers. PD-L1 protein but not PD-L1 gene expression may be a useful prognostic marker in resectable NSCLC.

7552 Poster Session (Board #300), Mon, 8:00 AM-11:30 AM

A phase II feasibility study of preoperative chemotherapy with bevacizumab for resectable stage II/IIIA non-squamous non-small cell lung cancer. *First Author: Yoshihiro Miyata, Hiroshima University, Hiroshima, Japan*

Background: Bevacizumab (Bev) has been demonstrated to improve response and survival rates in patients with advanced non-small cell lung cancer (NSCLC). This phase II trial assessed the feasibility of the addition of Bev to preoperative chemotherapy in resectable non-squamous NSCLC. **Methods:** Patients with clinical stage II/IIIA non-squamous NSCLC were recruited from 6 institutions. Three cycles of cisplatin (Cis) (75 mg/m^2), pemetrexed (Pem) (500 mg/m^2), and Bev (15 mg/kg) were administered on day 1 and every 21 days thereafter, followed by surgical resection. The primary endpoint was the complete resection rate (CRR) after completion of 3 cycles of chemotherapy. The sample size was set at 30 patients. The treatment was considered feasible if the CRR was ≥ 80%. **Results:** Thirty patients were eligible. Grade 3 toxicities included neutropenia (7%), nausea (7%), hypertension (23%), and pulmonary embolism (3%). There were no grade 4 events, and 27 (90%) patients completed 3 cycles with full doses of chemotherapy. Twenty-nine patients (97%) exhibited radiologic tumor reduction. The objective responses to chemotherapy were as follows: complete response, 0%; partial response, 37%; stable disease, 50%; and progressive disease, 10%. Five patients dropped out from the study before surgery due to the patient's decision in one patient, adverse events in three and disease progression in one. Disease control and surgical eligibility was confirmed in 25 (83%) patients after completion of 3 cycles of induction chemotherapy. These patients underwent surgery, and all achieved complete resection (CRR after completing three cycles of induction chemotherapy, 83%). Neither grade 3/4 morbidity within 28 days after surgery nor treatment-related mortality within 84 days after surgery was observed. **Conclusions:** Preoperative chemotherapy with combined Cis, Pem, and Bev for clinical stage II/IIIA non-squamous NSCLC is considered feasible. These data provide further evidence that Bev may be used as a promising candidate for future randomized trial arm for patients with locally advanced NSCLC. Clinical trial information: UMIN000004278.

7553 Poster Session (Board #301), Mon, 8:00 AM-11:30 AM

Phase I study of vorinostat with concurrent chemoradiotherapy (CRT) for locally advanced non-squamous non-small cell lung cancer (NSCLC). *First Author: Ranee Mehra, Fox Chase Cancer Center, Philadelphia, PA*

Background: Vorinostat (V) is a potent class I & II (HDAC 6) inhibitor of histone deacetylases. In A549 and A375 cell lines (CL's), V intensified RT induced decrease in clonogenic survival via impaired DNA repair. In CL's V downregulated thymidylate synthase (TS), a target of pemetrexed (P). **Methods:** This is a phase I trial of V plus C (cisplatin) or CP (carboplatin), P and RT for ECOG PS 0-1 pts with stage IIIA/B non-squamous NSCLC. V was dose-escalated in a 3+3 design (V at dose levels (DL1-3) 100, 200 and 300mg) with CRT: C (75 mg/m2) and P (500mg/m2) Q21 days x 4 with folic acid, B12, steroids), and RT (60 Gy). DL1b included CP AUC 5, P, RT and V 100mg. V was dosed for 3 consecutive days before cycle 1, and was then taken orally once a day 3 times/week during CRT. Surgical resection after CRT was allowed. The primary endpoint was to determine the MTD. Correlative analyses include TS and HDAC expression. This study was approved & funded by the National Comprehensive Cancer Network (NCCN) Oncology Research Program from general research support provided by Merck & Co., Inc. **Results:** Eighteen pts (51 - 80 years) enrolled from May 2010 to September 2014. Three evaluable (Ev) pts were treated on DL 1 (V 100), with no DLT. 3 Ev pts, and 2 Non-Ev pts (1 not eligible, 1 discontinued due to P-associated rash) were treated on DL 2 (V 200). At DL2, 2 pts had a DLT of grade (G) 4 hyponatremia (HNa). Accrual resumed with 3 pts on DL1, with 2 DLTs at DL1 (HNa and heart failure). Six pts were treated on DL1b with no DLTs. G 1 & 2 toxicities: nausea, anorexia, dysphagia, dehydration, esophagitis, fatigue, pain. G 3 toxicities: nausea, hyperglycemia, anemia, leukopenia. Fourteen pts completed 4 cycles of CRT and V. Two pts stopped V due to myelosuppression. One pt developed CLL 18 months after therapy. Among all pts the best response to date is CR:2, PR:4, SD: 8 pts. Three pts underwent resection, with no viable tumor in 2 specimens. With a median follow up of 15.4 months, the median PFS/OS have not been reached. **Conclusions:** With the exception of G4 HNa, no unexpected toxicities were noted with V and CRT. Esophagitis was mild. Assessment of PFS/OS and correlatives are ongoing. The recommended Phase 2 dose is CP AUC 5, P 500mg/m2 and V100mg 3x/week with RT. Clinical trial information: NCT01059552.

7554 Poster Session (Board #302), Mon, 8:00 AM-11:30 AM

Clinicopathological characteristics of squamous cell carcinoma of the lung with programmed cell death ligand 1 (PD-L1) protein expression. *First Author: Tiffany Huynh, Massachusetts General Hostpital, Boston, MA*

Background: PD-L1 expression by immunohistochemistry (IHC) reportedly predicts patient response to anti-PD-1/PD-L1 therapies in early phase clinical trials for solid tumors. However, there is limited data on the patient/tumor characteristics associated with PD-L1 expression in squamous cell carcinoma of the lung (SqCC). **Methods:** PD-L1 (E1L3N, 1:200, Cell Signaling Technology), PTEN, and CD8 IHC were performed on tissue microarrays of resected SqCCs (n = 162). Subsets of patients underwent clinical molecular (SNaPshot) and FISH testing. Cases with 10% or more tumor cells exhibiting negative or reduced PTEN expression were considered to have PTEN loss. PD-L1 expression in tumor cells and CD8 expression in tumor infiltrating lymphocytes (TILs) were semiquantitatively evaluated. PD-L1 expression, defined as 5% or more of the tumor cells exhibiting membranous staining, was correlated with clinicopathological and molecular features as well as patient outcomes. **Results:** The study cohort consisted of 96 Stage I, 41 Stage II, 22 Stage III, and 3 Stage IV cases. Of those, 43 (27%) exhibited PD-L1 expression, which was associated with large tumor size ($p = 0.001$), advanced pathologic stage (Stage II or higher vs. Stage I, $p = 0.041$), nodal metastasis ($p = 0.014$), increased CD8+ TILs (grade 2-3 vs. 0-1, $p < 0.001$), and PTEN loss ($p = 0.019$) by univariate analysis. In multivariate analysis, large tumor size ($p = 0.048$) and increased CD8+ TILs ($p < 0.001$) remained significant. A Cox proportional-hazards model revealed a borderline significance of PD-L1 expression with shorter progression free survival (PFS) ($p = 0.063$), while advanced pathologic stage was associated with shorter PFS ($p = 0.02$) and increased CD8+ TILs with longer PFS ($p = 0.01$). **Conclusions:** As reported in other tumors, PD-L1 expression is significantly associated with CD8+ TILs in SqCC, and it may predict unfavorable patient outcomes. Interestingly, it is also associated with PTEN loss. There are currently limited targeted therapy options for SqCC, but blockade of the PD-1/PD-L1 pathway may offer promising treatment options for SqCC patients with PD-L1 expression.

7555 Poster Session (Board #303), Mon, 8:00 AM-11:30 AM

Clinicopathological and molecular parameters of lung adenocarcinomas (ADC) associated with programmed cell death ligand 1 (PD-L1) protein expression. *First Author: Tiffany Huynh, Massachusetts General Hostpital, Boston, MA*

Background: Recent efforts in targeting the PD-1/PD-L1 pathway in solid tumors have resulted in durable responses in early phase clinical trials. Additionally, it has been reported that PD-L1 overexpression by immunohistochemistry (IHC) could serve as a predictor of patient response to anti-PD-1/PD-L1 therapies. However, the association of clinicopathological and molecular features with PD-L1 expression in ADC is not well-defined. **Methods:** PD-L1 (E1L3N, Cell Signaling Technology) and CD8 IHC were performed on tissue microarrays of 242 resected ADC that underwent detailed histological analysis. Clinical molecular testing had been performed in a subset (n = 128). Membranous expression of PD-L1 (any intensity) in 5% or more tumor cells was defined as positive. CD8+ tumor infiltrating lymphocytes (TILs) were evaluated using a 4-tier grading system (0-3). PD-L1 expression was correlated with clinicopathological and molecular features as well as prognosis. **Results:** Pathologic stage was 0 in 1, I in 188, II in 37, III in 9, and IV in 7. Of the 242 cases, 38 (15.7%) exhibited PD-L1 expression which was significantly associated with smoking history ($p = 0.008$), large tumor size ($p = 0.007$), solid or acinar predominant pattern ($p < 0.001$), high nuclear grade (grade 3, $p < 0.001$), vascular invasion ($p = 0.012$), increased CD8+ TILs (grade 2-3, $p < 0.001$), and *KRAS* mutations ($p = 0.001$). By multivariate analysis high nuclear grade ($p = 0.011$), *KRAS*mutations ($p = 0.004$), and increased CD8+ TILs ($p = 0.005$) remained significant. In addition, advanced stage (II or higher vs. I, $p = 0.056$) had a borderline significance of PD-L1 expression. There was no difference in 5 year progression-free survival (PFS) for PD-L1 positive (65%) and negative (69%) patients, while advanced stage correlated with shorter PFS ($p = 0.039$) in a cox proportional-hazards regression model. **Conclusions:** PD-L1 overexpression is significantly associated with increased CD8+ TILs and *KRAS* mutations in resected ADC. The latter suggests that targeting the PD-1/PD-L1 pathway may be a viable treatment option for patients with *KRAS* mutated ADC in which there are currently no effective targeted therapies available.

7556 Poster Session (Board #304), Mon, 8:00 AM-11:30 AM

Isolated Thoracic Perfusion with Chemofiltration (ITP-F) for progressive and pre-treated malignant pleural mesothelioma. *First Author: Karl R. Aigner, Medias Klinikum, Burghausen, Germany*

Background: Treatment of patients (pts.) with progressive malignant pleural mesothelioma (MPM) after multimodal therapy remains a therapeutic challenge. Survival of the pts. is low and the treatment options are sparse. We report on a phase II study on isolated thoracic perfusion with subsequent chemofiltration as a locoregional therapeutic strategy in this situation. **Methods:** 21 pts. (19 male, 2 female, mean age 65.5 yrs.) with epitheliolid mesothelioma were included in this study after informed consent. 10 pts. had prior surgical resection, all pts. had adjuvant/additive therapy, general including cisplatin and pemetrexed. Following multimodal therapy all pts. demonstrated progress in CT scan. No pt. had abdominal, cerebral or bone metastases. After insertion of a venous and arterial 21 ch. stop flow catheter via a femoral access, the inferior caval vein was blocked distal the right atrium, the arterial catheter was blocked in the aorta at the diaphragm. Chemotherapy consisted of 60 mg/m^2 cisplatinum and 15 mg/m^2 mitoxantron q 3 weeks till progress. The agents were administered via the arterial access, followed by 15 min of thoracic perfusion followed by chemofiltration for 45 min. The procedure was done under general anesthesia. Endpoint of the study was overall survival. Median follow-up was 48 month. **Results:** A total of 107 cycles (mean 5) were administered. Toxicity was low with leucopenia and thrombocytopenia CTC grad I in 9 pts. and mucositis grad II in 6 pts.. Surgical complications CTC grad I occurred in 40 % of the pat. (lymphatic fistula). There was no gastrointestinal or neuro- toxicity. One year survival was 50% (Kaplan-Meier), 2 year survival was 37.5% and 3 year survival was 37.5%. Median survival was 12 months. **Conclusions:** Intraarterial, isolated thoracic perfusion with subsequent chemofiltration (ITP-F) for pretreated patients with MPM, which are progressive after multimodal therapy, is a valuable additional treatment option with low side effects. It offers in a palliative situation a reasonable survival with good quality of life.

7557 Poster Session (Board #305), Mon, 8:00 AM-11:30 AM

Treatment-free interval (TFI) after first-line therapy as a prognostic and predictive factor in malignant pleural mesothelioma (MPM): Findings from the NGR015 phase III trial with NGR-hTNF plus best investigator choice (BIC) versus placebo plus BIC. *First Author: Vanesa Gregorc, Department of Oncology, San Raffaele Scientific Institute, Milan, Italy*

Background: Historically, the TFI (time from end of first-line to start of second-line therapy) has been reported as a prognostic factor and predictive marker of benefit of next treatment line across various tumors. Prognostic and predictive TFI values were assessed on MPM patients failing a front-line pemetrexed-based regimen and randomly assigned to receive NGR-hTNF 0.8 μg/m^2 (n = 200) or placebo (n = 200) both given with BIC (gemcitabine, vinorelbine, doxorubicin or supportive care). **Methods:** The prognostic value of TFI, treated as continuous variable or split at sample median (4.8 months; 95% CI 4.2-5.1), was tested exclusively in the NGR015 placebo arm. Multivariate Cox models for OS and PFS were adjusted for age, sex, PS, histology, EORTC score, prior disease control and neutrophil to lymphocyte ratio. To assess whether TFI was predictive of benefit with NGR-hTNF, treatment-by-covariate interaction tests were applied on the whole dataset. **Results:** Continuous TFI data were independently related to OS (p = .005). Compared with patients with long TFI ($\geq$ median, n = 201), those with short TFI ($<$ median, n = 198) had a significantly worse OS (median, 6.3 vs 11.7 months; HR = 1.81; p $<$ .0001). Poor prognostic effects of short TFI were confirmed in multivariate models (HR = 1.98; p $<$ .0001) and persisted after stratifying for chemotherapy agent (HR = 1.96; p $<$ .0001). Similar results were shown for PFS. A significant interaction test was reported only between treatment group and TFI for OS (p = .008) and, consistently, for PFS (p = .009). In patients with short TFI, NGR-hTNF plus BIC vs placebo plus BIC significantly improved OS (median, 9.0 vs 6.3 months; HR = 0.69; p = .02) and PFS (6-month rate, 25% vs 12%; HR = 0.71; p = .03). In sensitivity analyses, similar differences in outcome were detected by moving the TFI cutpoint from the median to a more practical 6-month threshold (OS HR = 0.74; p = .04). **Conclusions:** A short TFI is an independent poor prognostic factor and predictive clinical marker of benefit with NGR-hTNF in MPM patients with rapidly progressing disease after first-line therapy. Clinical trial information: NCT01098266.

7558 Poster Session (Board #306), Mon, 8:00 AM-11:30 AM

Prognostic and predictive value of neutrophil-to-lymphocyte ratio (NLR) in previously treated patients with malignant pleural mesothelioma (MPM) enrolled in the NGR015 phase 3 trial. *First Author: Alessandra Bulotta, Department of Oncology, San Raffaele Scientific Institute, Milan, Italy*

Background: NGR-hTNF, a tumor-targeted antivascular agent, promotes a vessel normalization that improves intratumor T-cell infiltration and chemotherapy uptake. The prognostic role of baseline blood NLR, an index of host immune response to tumor, has inconsistently been reported in retrospective MPM series. We assessed NLR in a homogenous population receiving systemic therapy after failure of first-line pemetrexed-based regimen. **Methods:** We used NLR data from patients randomly assigned in the NGR015 trial to receive NGR-hTNF (n = 200) or placebo (n = 200) both given with best investigator choice (BIC: gemcitabine, vinorelbine, doxorubicin or supportive care). The prognostic effects of NLR splitted at sample median (4; 95% CI, 4 to 4) were tested exclusively in the NGR015 placebo arm through Cox models adjusted for age, sex, PS, histology, EORTC score, prior disease control and treatment-free interval (TFI). In patients with short TFI ($<$ median of 4.8 months), the addition of NGR-hTNF to BIC was associated with increased OS (p = 0.02) and PFS (p = 0.02) compared with placebo plus BIC. **Results:** NLR was univariately related to survival, along with TFI, histology, EORTC score and prior disease control. In multivariate models, high NLR (HR = 1.95; p $<$ 0.0001), short TFI (HR = 1.98; p $<$ 0.0001), nonepithelial histology (HR = 1.63; p = 0.02) and poor EORTC score (HR = 1.73; p = 0.02) remained independently associated with worse OS. Median OS in low and high NLR subsets was 9.5 and 6.3 months, respectively. Patients with low NLR resulted more sensitive to NGR-hTNF effects as measured by PFS (HR = 0.74) than those with high NLR (HR = 1.19; interaction p-value = 0.03). In patients with low NLR (n = 174), NGR-hTNF plus BIC vs placebo plus BIC tended to improve PFS (5.5 vs 2.8 months; p = 0.06). In patients with low NLR and short TFI (n = 88), NGR-hTNF plus BIC vs placebo plus BIC significantly increased PFS (5.5 vs 2.3 months; p = 0.04) and OS (17.2 vs 8.4 months; p = 0.007). **Conclusions:** NLR is an independent prognostic factor in pretreated MPM. A low NLR predicts benefit with NGR-hTNF in patients with short TFI who had a rapidly progressing disease after first-line therapy. Clinical trial information: NCT01098266.

7559 Poster Session (Board #307), Mon, 8:00 AM-11:30 AM

Phase I study of intra-pleural administration of GL-ONC1, an oncolytic vaccinia virus, in patients with malignant pleural effusion. *First Author: Lee M. Krug, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: GL-ONC1 is an attenuated vaccinia virus genetically engineered with the insertion of RUC (luciferase)-GFP, LacZ (beta-galactosidase), and gusA (beta-glucuronidase) genes. We investigated the feasibility, safety, and recommended dose of GL-ONC1 when administered intrapleurally. **Methods:** Pts with pleural effusion from malignant pleural mesothelioma (MPM), NSCLC, breast cancer, or other solid tumor, and a free pleural space were eligible. Single doses of 1x10^7, 1x10^8, 1x10^9, or 3x10^9 plaque forming units were administered, and escalation used a 3+3 design. Virus was infused with 500cc Ringer's Lactate over 1hr through a pleural catheter. Fluorescent-imaging guided, thoracoscopic pleural biopsies were performed 2-9 days later. Blood, sputum, urine, and pleural fluid were analyzed for viral shedding by viral plaque assays (VPA). No chemotherapy or radiation was administered during the course of the study (-14 days to 60 days). **Results:** 14 pts have been treated: MPM (11), NSCLC (2), breast (1). Among 13 evaluable pts (1pt with NSCLC was not evaluable due to the rapid development of brain metastases) no dose limiting toxicities occurred. The most common toxicities were fever (7 pts), chills (6), and flu-like symptoms (5), all grade 1/2 occurring mostly in the 24hr after infusion. One patient at dose level 4 had transient grade 3 AST/ALT elevation. 1/28 urine and 5/28 pleural fluid post-treatment samples had +VPA. Positive GL-ONC1 infection of tumor specimens was identified in 6 of 8 pts with epithelioid MPM based on VPA, IHC and GFP imaging. 5 of the 9 pts with epithelioid MPM had time to progression $\geq$ 9 mo (18 mo in one pt). Pts with NSCLC and breast cancer progressed quickly at metastatic sites. **Conclusions:** Single dose, intrapleural administration of GL-ONC1 is safe, but is best suited for patients with MPM whose disease is limited to the pleura. We are now exploring multi-day treatment, and also treatment in conjunction with pleurectomy for pts with MPM. Supported by Genelux Corporation (NCT01766739). Clinical trial information: NCT01766739.

7560 Poster Session (Board #308), Mon, 8:00 AM-11:30 AM

The association of T cells with survival in mesothelioma. *First Author: Serena J Chee, Mesothelioma Applied Research Foundation, Alexandria, VA*

Background: Mesothelioma is a rare, aggressive cancer associated with asbestos inhalation. Treatment results are poor regardless of the modality used, with median survival of 4-18 months. Immunotherapy is now established as an important therapeutic option in many solid tumours including mesothelioma, but predictive markers for benefit are absent. Previous studies suggest that CD8 infiltration in mesothelioma may confer survival benefit. TIL density may therefore identify patients with ongoing immune attack, accessible for boosting by immune activation. **Methods:** Tissue Microarrays (TMA) were constructed with triplicate 1mm cores from a consecutive series of 213 formalin-fixed paraffin-embedded samples from mesothelioma patients. TMA slides were stained for T-cell populations - CD3, CD4, CD8 and CD45RO. Positive cells in 3 high-powered fields (X40) per core were manually scored. The mean score was used to account for tumour heterogeneity. Medians were used as cut point between high and low counts and correlated with clinical data. **Results:** In contrast to previous smaller studies (Yamada et al, 2010; Ankuru et al, 2008), density of tumour infiltrating CD3, CD4 and CD8 cells was not associated with survival outcomes ($p = 0.224$, $p = 0.205$, $p = 0.243$ respectively). However, a high CD4:CD8 ratio (> 0.61) was associated with better survival ($p = 0.007$) with significant ROC curve analysis (AUC = 0.764, $p = 0.001$). Furthermore, a low CD45RO level was also associated with better survival ($p = 0.002$) in this cohort. **Conclusions:** In this unselected mesothelioma cohort, better survival is associated with a high CD4:CD8 ratio and low density of CD45RO memory T cells. Comparison with data from other cancer types suggest that, disease specific immune regulation controls outcome, which is reflected in the particulars of the immune infiltrate in each cancer. For example, a high CD4:CD8 ratio is similarly associated with better survival in cervical cancer (Shah et al., 2011) but not in colorectal cancer (Diederischsen et al., 2003). A better understanding of these immunological drivers and comparative immunometry with other solid tumours types is needed to tailor disease-specific choices for immunotherapy in mesothelioma.

7561 Poster Session (Board #309), Mon, 8:00 AM-11:30 AM

Activity and safety of trabectedin in patients with sarcomatoid / biphasic malignant pleural mesothelioma (MPM). *First Author: Diego Luigi Cortinovis, Az Ospedale S. Gerardo, Monza, Italy*

Background: The efficacy of available MPM therapies is poor in patients (pts) with sarcomatoid/biphasic histotypes , and their prognosis remains dismal. The use of Trabectedin (T) in MPM is justified by its peculiar mechanism of action, involving modulation of the tumor's inflammatory microenvironment, and the demonstrated activity against a range of tumours, including sarcomas. We aimed to study the activity and safety of T in pts with both epithelioid and biphasic/sarcomatoid MPM. **Methods:** *ATREUS,* an Italian multicenter single arm phase II trial, evaluates T as second line therapy in pts with epithelioid histotype and as first/second line in biphasic/sarcomatoid pts. In the latter cohort, the study needed to enroll 17 evaluable pts to reject with a 10% one sided alpha error the null hypothesis that 12-week progression free survival (12w PFS) is $\leq 15\%$ and an 85% power to show 12w PFS in $\geq 40\%$ of pts. Overall survival and safety were secondary endpoints. Pts were treated with T, 1.3 mg/m^2, over 3 hours every 21 days, until progression or unacceptable toxicity. **Results:** The cohort of sarcomatoid/biphasic pts is now complete and results are reported below. Twenty three pts were enrolled and 17 were evaluable (14 M and 3 F, median age 67.9 years). Ten, six and one pts had stage IV, III and II disease, respectively. Seven (41.2%) were treatment naïve. At 12 weeks 7/17 pts (41.2%, 95% CI: 18.4-67.1) were alive and free of progression. Five patients (29.4%) had sustained response with PFS ≥ 18 weeks. By the time of analysis all pts interrupted treatment. Interruption reasons were disease progression in 12 pts, death (4 pts) and consent withdrawal in one pt. The most frequent grade ≥ 3 treatment related toxicities were non febrile neutropenia (11.8%), nausea (17.6%), vomiting, mucositis and fever/infection (each observed in one patient, 5.9%). Two serious adverse events , classified as possibly related to T, occurred. One was fatal. **Conclusions:** T demonstrated its activity in terms of PFS and was well tolerated in this population of patients with advanced sarcomatoid/biphasic MPM. These optimistic results merit to be further investigated in a larger sample. Clinical trial information: NCT02194231.

7562 Poster Session (Board #310), Mon, 8:00 AM-11:30 AM

MicroRNA prognostic signature in malignant pleural mesothelioma. *First Author: Francesco Grossi, Lung Cancer Unit, IRCCS AOU San Martino - IST - Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy*

Background: Malignant pleural mesothelioma (MPM) is an aggressive tumor mainly associated with asbestos exposure and characterized by a poor outcome (median overall survival (mOS) $<$ 1 year), therefore requiring novel therapeutic approaches. MicroRNA (miR) play a role in tumorigenesis and progression in MPM. This study aimed to identify miR associated with poor prognosis. **Methods:** We identified 26 unresected MPM patients (11 long survivors (LS), OS $>$ 3 years and 15 short survivors (SS), OS $<$ 1 year). Total RNA, from formalin-fixed paraffin-embedded biopsy and 3 normal pleura (NP) samples, were miR profiled using the Agilent Human miR Microarray including 2006 miR. Expression data were normalized by GeneSpring software (*v.*12.6). Class-comparison analysis between MPM/NP and SS/LS was performed using a t-test adjusted for multiple comparisons using Benjamini-Hochberg.OS curves were estimated using the Kaplan-Meier method and compared with the log-rank test. *In silico*validation was performed using miRseq data from TCGA portal based upon 16 patients (LS: 8; SS: 8). Candidate miR were assessed by univariate analysis using Kaplan-Meier method and median as cutoff. **Results:** Patients' characteristics: median age 67 years (53-77); 81% males, 19% females; 73% epithelioid histotype, 12% sarcomatoid, 12% biphasic, 3% not otherwise specified. No differences in age, gender and histotype observed among LS and SS. Class-comparison analysis reported 30 miR significantly up-regulated and 11 down-regulated in MPM *vs* NP; univariate analysis reported 14 miR significantly associated with OS and differentially expressed in MPM. A miR signature, based on the top prognostic miR (miR-99a, miR-125b, let-7b, let-7c, let-7i, miR-1224), classified patients into low or high-risk. The latter had a significantly shorter mOS (4.1 months, 95% CI 2.2-5.9) compared to low-risk patients (mOS not reached, Log-rank $p < 0.001$). *In silico*validation confirmed low expression of miR-99a, miR-125b and let-7c associated with shorter OS. PI3K/AKT, WNT were associated with these top miR by pathway analysis. **Conclusions:** A prognostic miR signature was identified by profiling a cohort of unresected MPM, underlying the clinical potential of miR as predictors of survival.

7563 Poster Session (Board #311), Mon, 8:00 AM-11:30 AM

High throughput therapeutic screening of malignant pleural mesothelioma (MPM) to identify correlation of sensitivity to FGFR inhibitors with BAP1 inactivation. *First Author: Constantine Alifrangis, Imperial College London, London, United Kingdom*

Background: Small molecule inhibitors have failed to find a role in the treatment of MPM patients. We utilised a high throughput therapeutic screen to identify novel compounds with efficacy in MPM, and performed comprehensive molecular characterisation to identify clinically relevant subgroups within a panel of MPM cell lines. **Methods:** 26 MPM cell lines including immortalised and primary early passage lines underwent Illumina whole exome sequencing, copy number analysis and Affymetrix array transcriptome profiling. In parallel a high throughput drug screen was performed utilising a panel of targeted therapeutic agents. **Results:** From a drug screen of 896 cancer cell lines across all tumour types, MPM lines featured amongst the most sensitive 5% to FGFR inhibitors. We validated this sensitivity in a panel of early passage MPM cultures and with multiple FGFR inhibitors and also siRNA silencing of FGFR family members. We did not detect FGFR mutations or amplifications in the MPM. However we identified *BAP1* loss, either through truncating mutations or promoter methylation-induced silencing, in those MPM lines with enhanced responses to FGFR inhibition. This association was further confirmed using *BAP1* overexpression constructs and *BAP1* shRNA knockdown, which modulated response to FGFR inhibition in mesothelioma cell lines. Baseline gene expression pathway analysis shows significant activation of MAPK pathway signalling in *BAP1* mutant compared to wild type MPM. Furthermore, we observe significantly increased levels of both FGFR1 and FGFR3 receptor transcripts and of FGF9 and FGF18 in *BAP1*mutant versus wild type MPM cell lines. We validated this observation in a panel of 54 human MPM tumours. **Conclusions:** We show that a subgroup of mesotheliomas demonstrate exquisite sensitivity to FGFR inhibition when compared to other tumour types. We identify *BAP1* loss as a potential biomarker for FGFR inhibitor efficacy to define this subgroup and furthermore describe activation of FGFR signalling in *BAP1* inactivated MPM. This data would suggest a clinically relevant MPM subgroup against which FGFR inhibition could be directed in future clinical studies.

7564 Poster Session (Board #312), Mon, 8:00 AM-11:30 AM

Confirmation of high prevalence of BAP1 inactivation in mesothelioma. *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Efforts to elucidate tumorigenic mutations in mesothelioma are essential to advance therapy. Prior efforts to characterize the molecular heterogeneity of this disease have been limited by sample condition and testing platforms. Herein, we describe efforts to prospectively test patients using next-generation sequencing with matched patient germline controls. **Methods:** Sequential mesothelioma patients were approached for consent to our IRB protocol NCT01775072 to perform MSK-IMPACT (Integrated Mutation Profiling of Actionable Cancer Targets), a comprehensive molecular profiling platform based on solution-phase exon capture and next generation sequencing to detect somatic genetic alterations in FFPE tumor specimens. MSK-IMPACT involves hybridization capture and deep sequencing of all protein-coding exons of 341 key cancer-associated genes, including all genes that are druggable by approved therapies or are targets of experimental therapies being investigated in clinical trials at MSKCC. **Results:** 40 patients with mesothelioma underwent MSK-IMPACT testing (see Table 1). 6 samples had low tumor content and in 3 of those no alterations were identified. In 2 samples with sufficient tumor content, no alterations were identified. Among 37 samples with results, *BAP1* was the most common alteration (57%). **Conclusions:** Using MSK-IMPACT, *BAP1* inactivation is the most common alteration. Other aberrations previously reported at high frequency were identified but albeit at lower frequencies (*NF2* and p16, previously reported as 40% and 75% respectively). For multiple samples with deep coverage, no alterations were identified. The high incidence of BAP1 mutations in this systematic testing makes this pathway ideal for developing and testing targeted therapies.

7565 Poster Session (Board #313), Mon, 8:00 AM-11:30 AM

Mesothelin-targeted immunotherapy CRS-207 in combination with standard of care chemotherapy as treatment for malignant pleural mesothelioma (MPM). *First Author: Raffit Hassan, Thoracic and Gastrointestinal Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: MPM is an aggressive disease with poor prognosis and is relatively refractory to currently available therapies. CRS-207 is live-attenuated *Listeria monocytogenes* engineered to express the tumor-associated antigen mesothelin. Stimulation of potent innate and adaptive immunity by CRS-207 may act synergistically in combination with chemotherapy that alters the tumor environment to be more susceptible to immune-mediated killing. **Methods:** Eligible patients were chemotherapy-naïve with unresectable MPM, good performance status (ECOG 0 or 1) and adequate organ function. Patients received 2 prime vaccinations with CRS-207 (1×10^9 CFU) 2 weeks apart, followed by 6 cycles of pemetrexed (500 mg/m^2) and cisplatin (75 mg/m^2) 3 weeks apart and 2 CRS-207 boost vaccinations 3 weeks apart. Subjects were followed every 8 weeks until disease progression. Clinically stable patients received CRS-207 maintenance vaccinations every 8 weeks. Objectives of the study include safety, immunogenicity, objective tumor responses and tumor marker kinetics. **Results:** Twenty-six subjects (88% male; median age: 69) have been enrolled as of Jan 15 2015. As of Jan 2015, 10/26 were on treatment. Median time on treatment was 7.1 months (range: 1.0-22.5). No treatment-related unexpected toxicities have been observed. The most common adverse events related to CRS-207 were Grades 1/2 infusion-related fever, chills/rigors, hypotension and nausea/vomiting. Of 24 subjects evaluable, 63% (15/24) had confirmed partial response (PR) post CRS-207 and chemotherapy and 29% (7/24) had stable disease (SD). Median duration of response was 4.8 months (range: 3.6-7.2) and PFS was 7.5 months (range: 7.1-8.6) for the first 16 subjects enrolled. Treatment, follow-up, median overall survival and immune response evaluations are ongoing and will be presented at the meeting. **Conclusions:** CRS-207 can be safely combined with chemotherapy and showed encouraging anti-tumor activity with 63% of subjects having objective tumor responses and 92% disease control. These results are considerably better than those expected with chemotherapy alone and warrant further evaluation. Clinical trial information: NCT01675765.

7566 Poster Session (Board #314), Mon, 8:00 AM-11:30 AM

Immune escape correlates with an inflamed phenotype in malignant mesothelioma. *First Author: Arun Khattri, The University of Chicago, Chicago, IL*

Background: Malignant mesothelioma (MM) is commonly associated with an inflammatory reaction, although the specific patterns of immune escape remain incompletely understood. We used emerging, high-fidelity gene expression data from the TCGA Mesothelioma cohort to interrogate subgroups based on expression of immune related genes, and determined associated immune escape mechanisms. **Methods:** RNA-seq data from 76 MM from *TCGA* were analyzed using genes representative of 1. T-cells, 2. NK-cells, 3. neutrophils, 4. dendritic cells/macrophages, as well as genes associated with immune escape (immune checkpoints and cellular immune escape). Using this gene set, unsupervised, hierarchical clustering was performed to identify intrinsic immune subgroups. Groups were correlated with T-cell inflammation (Kindler ASCO 2014), based on the 12-gene inflammation signature (Harlin/Gajewski Cancer Res 2009). **Results:** MM tumors readily clustered into two large groups with 35% of tumors showing high levels of inflammation (group 1), presence of all four immune cell components, and 80% of tumors showing a TCIP-high phenotype. Non-inflamed tumors (group 2) showed low immune cell related gene expression and were 85% non-T-cell inflamed. Prominent immune escape was present in all group 1 tumors, including expression of PD-1/PD-L1, CTLA4, LAG3, and FOXP3 (however not B7H3). Inflammation strongly correlated with presence of immune escape (functional immune response) in group 1, while group 2 tumors exhibited neither infiltration with immune cells, nor immune escape (immunological ignorance). **Conclusions:** MM can be classified into inflamed/group 1 and non-inflamed/group 2 tumors. Group 1 tumors show simultaneous infiltration with multiple immune cell components, and prominent immune escape. Inflamed and non-inflamed MM may require differential treatment strategies for immunotherapy.

7567 Poster Session (Board #315), Mon, 8:00 AM-11:30 AM

Evaluation of CXCR4 expression on tumor and circulating tumor cells (CTCs) as predictive response marker for CXCR4 antagonist LY2510924 in combination with carboplatin-etoposide in extensive-disease small cell lung cancer (ED-SCLC). *First Author: Ravi Salgia, The University of Chicago, Chicago, IL*

Background: Small cell lung cancer (SCLC) can express CXCR4 chemokine receptor, and inhibition potentially synergizes with cytotoxic and targeted therapeutics in vitro in SCLC. Baseline CXCR4 expression on tumor tissue or CTCs may help predict response to treatment with CXCR4 antagonist LY2510924 (LY). **Methods:** In an open-label, randomized phase 2 study (NCT01439568), patients (pts) with ED-SCLC received up to six 21-day cycles (C) of carboplatin (Day [D] 1) and etoposide (D1-3) (SOC) alone or in combination with 20 mg qd sc LY (D1-7) (LY+SOC). Exploratory analyses evaluated CXCR4 expression on available baseline tumor tissue (IHC H-score) and on CTCs collected at baseline, C1D7, and C2D1 (CellSearch). Receiver operating characteristic (ROC) curves and their AUCs (95% CIs) were generated to determine optimal cutoff values for CXCR4 expression on tissue and CTCs and number of CTCs as predictors of 6-month progression-free survival (PFS). Hazard ratios (HRs) through 4 months (end of treatment), using the optimal cutoffs at baseline, were generated. **Results:** 90 pts were randomized to SOC (N = 43) or LY+SOC (N = 47). Optimal ROC cutoffs were $\geq$ 210 (H-score) for CXCR4+ tissue ($\geq$ 210: N = 31, $<$ 210: N = 38; AUC = 0.631 [0.496, 0.765]); $\geq$ 7% CXCR4+ on CTCs ($\geq$ 7%: N = 44, $<$ 7%: N = 26; AUC = 0.702 [0.577, 0.828]); and $\geq$ 6 CTCs/7.5 mL blood ($\geq$ 6: N = 60, $<$ 6: N = 18; AUC = 0.607 [0.471, 0.742]). In evaluating pts with a baseline value above each optimal cutoff, the HR (95% CI) was 0.787 (0.211, 2.933) for CXCR4+ tissue (LY+SOC: N = 16, SOC: N = 15); 0.476 (0.147, 1.548) for % CXCR4+ on CTCs (LY+SOC: N = 20, SOC: N = 24); and 0.403 (0.151, 1.076) for CTCs (LY+SOC: N = 31, SOC: N = 29). For pts considered high risk (ie, $\geq$ 6 CTCs and $\geq$ 7% CXCR4+ CTCs), the HR was 0.489 (0.150, 1.589) (LY+SOC: N = 18, SOC: N = 23). **Conclusions:** Selected ED-SCLC pts with high levels of CTCs and/or CXCR4 expression on CTCs and/or tumor tissue at baseline may benefit by the addition of LY to SOC. Further investigation of LY in a preselected pt population is warranted. Clinical trial information: NCT01439568.

7568 Poster Session (Board #316), Mon, 8:00 AM-11:30 AM

Prophylactic cranial irradiation (PCI) and consolidation thoracic radiotherapy (TRT) for extensive stage small cell lung cancer (ES-SCLC): A systematic review and meta-analysis. *First Author: Yu Yang Soon, National University Cancer Institute, Singapore, Singapore*

Background: The role of PCI and TRT in ES-SCLC is controversial. We performed a systematic review of all comparative studies to investigate the benefits and harms of PCI and TRT in ES-SCLC. **Methods:** We searched MEDLINE, CENTRAL from date of inception and various conference proceedings from 2009 to November 2014 for eligible studies. The primary outcome is overall survival (OS). Secondary outcomes include progression-free survival (PFS), freedom from brain metastasis and toxicity. The Cochrane risk of bias instrument was used to assess the risk of methodological bias and the Grading of Recommendations Assessment Development and Evaluation (GRADE) approach was used to assess the quality of evidence. Hazard ratios (HR), confidence intervals (CI), p values (p) was estimated with random effects models using Revman 5.3. **Results:** We found 2 randomized controlled trials (RCTs) and 3 non-RCTs, including 2192 patients comparing PCI versus no PCI; 4 RCTs and 1 non-RCT including 782 patients comparing TRT versus no TRT. The risk of methodological bias was low for 2 RCTs evaluating PCI and 2 RCTs evaluating TRT. Meta-analysis of these low risk bias RCTs showed that PCI decreased the risk of brain metastasis development (HR 0.43, 95% CI 0.30 to 0.60, $p < 0.001$, high quality evidence) but did not improve OS (HR 0.95, 95% CI 0.48 to 1.91, $p = 0.89$) or PFS (HR 0.91, 95% CI 0.63 to 1.32, $p = 0.62$) (moderate quality of evidence). There was high quality evidence that TRT improved OS (HR 0.82, 95%CI 0.69 to 0.97, $p = 0.02$) and PFS (HR 0.76, 95%CI 0.64 to 0.89, $p < 0.001$). The incidence of grade 3-4 toxicities of PCI and TRT ranged from 1 to 20%. **Conclusions:** There was high quality evidence that PCI reduced the risk of brain metastasis development and TRT improved survival in ES- SCLC. Toxicity rates were variable and are probably related to dose and treated volume effects.

7569 Poster Session (Board #317), Mon, 8:00 AM-11:30 AM

Loss of somatostatin receptor 2 expression and lung cancer growth. *First Author: Jonathan Lehman, Vanderbilt Univ School of Medcn, Nashville, TN*

Background: Small cell lung cancer (SCLC) is a neuroendocrine cancer of the lung responsible for up to 25% of lung cancer deaths. Targeted therapies for SCLC are sorely needed. Somatostatin receptors (SSTR) are G protein-coupled receptors with effects on cell cycling, angiogenesis, and apoptosis which signal by inhibition of adenylate cyclase, Ca influx, and act through multiple kinases. SSTR2 is highly expressed in SCLCs and we hypothesize that its signaling supports cancer growth. **Methods:** Tumor microarrays containing 98 SCLCs were scored based on SSTR2 staining intensity and % tumor staining. Tumors were categorized as SSTR2 expressing (score > 0) which comprised 48% of the samples, or non expressing, and analyzed by Cox proportional hazard model including: age, smoking hx, stage, and SSTR2 expression. These results led to evaluation of SSTR2 expression and immunoblotting of multiple cell lines and tumors. We established SSTR2 shRNA knockdown lines including bronchial carcinoid, squamous cell carcinoma (SCC), and SCLC lines. We evaluated these lines with proliferation, flow cytometry, clonogenic assays, and a SCC cell line *in vivo* with mouse xenografts. **Results:** Non SSTR2 expressing SCLCs had a median survival by Kaplan Meier in limited stage (LS) disease of 36 compared to 12 months in SSTR2 expressing SCLCs suggesting SSTR2 expression has clinical relevance ($p = 0.001$). The 95% confidence interval for the hazard ratio was 0.23-0.87 for LS disease. There was no significant difference in survival in extensive stage disease. Most SCLC and a subset of SCC lines expressed SSTR2. Knockdown led to up to 3 fold decreases in cell viability *in vitro* in multiple lines and constructs. Xenograft experiments showed dramatically reduced ki67 staining and reduced tumor weight and growth curves in an SSTR2 shRNA H520 line. Phosphoprotein array and immunoblots suggest dysregulation of pAKT and AMPK signaling with SSTR2 knockdown. **Conclusions:** SSTR2 expression in SCLC is associated with worse outcomes suggesting a role in cancer progression. Our data support this hypothesis and suggest downstream changes in pAKT and AMPK contribute to this phenotype. Overall, this suggests SSTR2 antagonism or downstream mediators may be future targets in lung carcinoma.

7570 Poster Session (Board #318), Mon, 8:00 AM-11:30 AM

New ARCHITECT plasma pro-gastrin-releasing peptide assay and lung cancer: Implications for diagnosis, follow-up, and prognosis. *First Author: Benjamin Nisman, Hadassah Hebrew University Medical Center, Jerusalem, Israel*

Background: Pro-gastrin-releasing peptide (proGRP) is a precursor of the neuropeptide hormone produced by small cell lung cancer (SCLC) and considered as a potential serum marker for this disease. However, proGRP was shown to be more stable in plasma compared to serum. In this prospective study we evaluated the new proGRP assay in plasma format. **Methods:** Plasma proGRP was determined using the ARCHITECT i System (Abbott Diagnostics, Wiesbaden, Germany) in four cohorts: healthy individuals ($n = 100$) and patients with benign lung diseases (BLD, $n = 102$), non-small cell lung carcinoma (NSCLC, $n = 241$), and SCLC ($n = 90$). **Results:** The median (95 percentile) concentrations of plasma proGRP in healthy, BLD, NSCLC and SCLC were: 38 (64), 39 (64), 40 (121) and 680 (17695) pg/ml, respectively. There was no association with age, gender or smoking. The proGRP assay proved to be effective in distinguishing SCLC from NSCLC with area under the curve 0.941, 95%CI 0.906-0.975, 84.4% sensitivity, 95% specificity, at a cut-off 121 pg/ml. False-negative results in SCLC were associated with lack of thyroid transcription factor-1 (Fisher's Exact Test, $P = 0.0006$). False-positive results in NSCLC were associated with large cell neuroendocrine carcinoma (LCNEC) (Fisher's Exact Test, $P < 0.0001$). The elevated proGRP was found in 44.5% (5 of 11) patients with LCNEC. Fifty patients with SCLC were followed by plasma proGRP during chemotherapy. The decline of proGRP during chemotherapy below a cut-off (121 pg/ml) was associated with objective image based response (Fisher's Exact Test, $P = 0.0003$). In multivariate Cox regression analysis the proGRP response adjusted for imaging response and ECOG performance status independently affected progression free survival (PFS, hazard ratio [HR] = 0.38, 95%CI 0.20-0.74, $P = 0.009$) and overall survival (OS, HR = 0.32, 95%CI 0.16-0.63, $P = 0.003$). **Conclusions:** Plasma proGRP is a highly specific and sensitive marker supporting diagnosis of high grade neuroendocrine lung tumors, mainly SCLC. Elevation of proGRP in NSCLC is associated with LCNEC. The changes in the plasma proGRP during SCLC chemotherapy showed a significant association with imaging assessments of response, PFS and OS.

7571 Poster Session (Board #319), Mon, 8:00 AM-11:30 AM

Survival impact of switching to different topoisomerase I or II inhibitors-based regimens (topo-I or topo-II) in extensive-disease small cell lung cancer (ED-SCLC): supplemental analysis from JCOG0509. *First Author: Shogo Nomura, Center for Research Administration and Support, National Cancer Center, Kashiwa, Japan*

Background: The J0509 (phase III study for chemotherapy-naive ED-SCLC) demonstrated amrubicin plus cisplatin (AP) was inferior to irinotecan plus cisplatin (IP). However, median overall survival (OS) of both AP and IP (15 and 17 mo) was more favorable than those of previous trials (9-12 mo), probably because switching to different topo-I or topo-II in the second-line therapy, especially the use of topo-II in IP arm, was frequent. This analysis aimed to investigate whether observed survival benefit of IP arm can be explained by the treatment switching, and how post-protocol chemotherapy affected the result of J0509. **Methods:** Two analysis sets from J0509 were used: all randomized 283 pts and 250 pts who received post-protocol chemotherapy. One pt without initiation date of second-line therapy was excluded. A rank-preserving structural failure time (RPSFT) model was used to estimate "causal survival benefit" that would have been observed if all pts had been followed with the same type of regimen as randomized throughout the follow-up period. Additionally, to assess the survival impact of second-line use of topo-II, OS after initiating second-line therapy (OS2) was analyzed by multivariate Cox models. **Results:** %treatment switching in IP arm and AP arm was 65.2% (92/141) and 43.7% (62/142). By RPSFT model, estimated OS excluding the effect of the treatment switching was 2.7-fold longer in IP (topo-I) arm than AP (topo-II) arm. This causal survival benefit was stronger than the original report of J0509 (nearly 1.4-fold extension by Cox model), indicating that re-challenging topo-I in IP arm appeared beneficial. The multivariate Cox analysis for OS2 ($n = 250$) revealed second-line use of topo-II was detrimental (hazard ratio, 1.5; 95%CI, 1.1-2.1). Among sensitive relapsed pts in IP arm, OS2 was favorable in the following order: irinotecan-based regimen $>$ the other topo-I $>$ topo-II. **Conclusions:** IP remains the standard therapy. Re-challenging topo-I, especially irinotecan-based topo-I, seemed beneficial for IP-sensitive pts. This result should be confirmed in further investigations with large sample size. Clinical trial information: 000000720.

7572 Poster Session (Board #320), Mon, 8:00 AM-11:30 AM

Phase II study of topotecan and cisplatin with sequential radiotherapy in elderly small cell lung cancer patients (Okayama Lung Cancer Study Group; OLCSG 0102). *First Author: Toshio Kubo, Department of Respiratory Medicine, Okayama University Hospital, Okayama, Japan*

Background: The standard treatment for elderly patients with localized small cell lung cancer (LD-SCLC) has not been established. The Okayama Lung Cancer Study Group previously performed a phase I trial using low-dose split cisplatin and topotecan (TP) therapy for elderly SCLC patients and determined the recommended dose. Here, we performed a phase II trial using low-dose split TP therapy with sequential thoracic radiotherapy (TRT) for elderly LD-SCLC patients. **Methods:** Patients aged ≥76 years with untreated LD-SCLC and a performance status of 0–2 were enrolled. Topotecan (1.0 mg/m^2, days 1–3) and cisplatin (20 mg/m^2, days 1–3) were administered for a maximum of four courses, and sequential TRT (1.8 Gy/day for a total of 45 Gy) was added. The primary endpoint was the overall response rate (ORR). We assumed that an ORR of 0.90 in eligible patients would indicate potential usefulness, whereas an ORR of 0.70 was the lower limit of interest, with $\alpha = 0.05$ and $1-\beta = 0.80$. **Results:** A total of 22 cases were registered between 2004 and 2014. Of these, 19 individuals were male, the median age was 79 years, and the median Charlson Comorbidity Index value was 3. The median number of chemotherapy courses was 3, the proportion of patients who could initiate TRT was 63.6%, and the proportion of patients who could complete whole planned treatment was 45.5%. The ORR was 0.68 (15/22 cases; 95% confidence interval, 0.47–0.89), which was below the threshold. The median progression-free survival and overall survival were 9.1 months and 22.2 months, respectively. The observed grade 3–4 toxicities included neutropenia in 95.5% of patients, thrombocytopenia in 50.0%, anemia in 36.0%, and febrile neutropenia in 32.0%. **Conclusions:** Although low-dose split TP and sequential TRT exerted positive effects on survival, the primary endpoint was not met and severe bone marrow suppression was observed. Therefore, further consideration of the regimen including the timing of TRT is required. Clinical trial information: C000000134.

7573 Poster Session (Board #321), Mon, 8:00 AM-11:30 AM

Detection of circulating tumor cells in the peripheral blood of patients with small cell lung cancer (SCLC) using both the CellSearch platform and immunofluorescence: Correlation with clinicopathological features. *First Author: Ippokratis Messaritakis, Laboratory of Tumor Cell Biology, School of Medicine, University of Crete, Heraklion, Greece*

Background: The diagnosis of SCLC is based on morphology and immunocytochemistry using cytokeratins and neuroendocrine markers. We aimed to evaluate the clinical significance of the detection of Circulating Tumor Cells (CTCs) in patients with SCLC using the CellSearch system (CS) and immunofluorescence (IF). **Methods:** Peripheral blood was obtained from 101 patients with SCLC before treatment, 68 patients after one cycle of 1st line chemotherapy (etoposide/platinum) and 52 patients at the time of disease progression. CTCs were detected by double immunofluorescent staining of one million PBMC's on cytospins using anti-TTF1 and anti-CD56 antibodies, and by the CS using anti-CK antibody. **Results:** Prior to the initiation of 1st line treatment, 61% of patients had detectable CTCs by IF and 78% with the CS (range: 1-169 and 2-10000 CTCs, respectively). After 1 cycle of chemotherapy, the positivity of CTC detection decreased to 44% (range: 1-56 CTCs) and 45% (range: 1-4882 CTCs) using IF and CS, respectively; at the time of disease progression (PD) the detection of CTCs almost reached the baseline levels (60% and 74%; range: 2-186 and 1-11143 CTCs for IF and CS, respectively). The detection of CTCs at baseline, after 1 cycle of chemotherapy and on PD was significantly associated with decreased PFS (7.0 vs 8.5 months, p = 0.021; 5.6 vs 8.1 months, p = 0.018; 5.7 vs 7.6 months, p = 0.014, respectively) and OS (11.0 vs 26.0 months, p = 0.021; 8.9 vs 17.0 months, p = 0.009; 10.0 vs 17.0 months, p = 0.021, respectively) compared to the patients with undetectable CTCs. Multivariate analysis revealed that performance status, disease stage and the detection of CTCs after 1 cycle of chemotherapy and at the time of progression emerged as independent factors associated with reduced PFS and OS. **Conclusions:** Detection of CTCs using either immunofluorescence or the CellSearch is an adverse prognostic factor correlated with poor clinical outcome in patients with SCLC receiving 1st line chemotherapy.

7574 Poster Session (Board #322), Mon, 8:00 AM-11:30 AM

Distribution and clinical significance of CTLA4, PD-1 and PD-L1 in peripheral blood of patients with small-cell lung cancer. *First Author: Ying Cheng, Jilin Provincial Cancer Hospital (JPCH), Changchun, China*

Background: Cytotoxic T lymphocyte associated antigen 4 (CTLA4), programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) are key components of immune checkpoints and the most attractive targets in immunotherapy for cancer. These antigens are abundant in tumor samples, however their distribution and clinical value in liquid biopsy (such as blood) of small-cell lung cancer (SCLC) patients remains unclear. **Methods:** 60 healthy and 230 chemotherapy-naïve patients with SCLC were recruited. Venous blood samples were collected prior to chemotherapy (baseline) and after the second cycle of chemotherapy (2nd cycle), and flow cytometry was used to analyze the level of CTLA4, PD-1 or PD-L1 with or without CD3, CD4, CD8 or CD25. Immunohistochemistry was used to detect PD-L1 expression in SCLC cell line H446. **Results:** Cells of CTLA4$^+$, CD3$^+$CTLA4$^+$ and CD4$^+$CTLA4$^+$ in SCLC were (1.06±1.51)%, (4.12±5.30)% and (3.95±2.80)%, respectively and PD-1$^+$, CD3$^+$PD-1$^+$, and CD4$^+$PD-1$^+$ were (7.96±3.38)%, (25.86±8.49) % and (20.92±8.31) %, which were not different from those in control. However, level of CD4$^+$CD25$^+$CTLA4$^+$cells were higher in SCLC than that in control, (6.77±4.71)% vs (1.91±1.27)%, $P<$ 0.001 and CD8$^+$ PD1$^+$cells were less in SCLC than that in control, (11.49±5.23) % vs (22.56±4.21)%, $P<$ 0.001, neither of which were associated with age, sex, smoke or disease stage. Level of CD4$^+$CD25$^+$CTLA4$^+$cells was dropped to (5.77±3.77)% after 2nd cycle compare to that at baseline ($P=$ 0.04), but level of CD8$^+$PD1$^+$cells was not altered. Interim analysis showed neither the level of CD4$^+$CD25$^+$CTLA4$^+$ nor CD8$^+$PD1$^+$cells before or after treatment was related to progression–free survival or overall survival of patients. Although PD-L1 was highly expressed in H446, it was rarely found in peripheral blood. **Conclusions:** We for the first time showed that CTLA4 was highly expressed in regulatory T cells and PD-1 decreased in CD8 in peripheral blood of SCLC patients, suggesting their unique mechanisms involved in immune regulation. CD4$^+$CD25$^+$CTLA4$^+$level changed after treatment implies its potential role in predicting treatment efficacy.

7575 Poster Session (Board #323), Mon, 8:00 AM-11:30 AM

Clinical correlation of genomic mutations in small cell lung cancer. *First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Genomic studies in small cell lung cancer (SCLC) lag far behind those performed in non-small cell lung cancer (NSCLC). Unlike NSCLC, where specific mutations such as ALK and EGFR are associated with distinct clinical behavior, no such data exists for SCLC. We have established a clinical- pathologic database on all SCLC patients treated at our medical center and recently added genomic analysis. **Methods:** Targeted exome sequencing data of 324 genes was obtained on a total of 36 patients. Genes were organized for analysis into two groups: (I) genes with mutations validated to be oncogenic, and (II) genes harboring any detectable mutation, validated or not. The specific type of mutation was not considered, only its presence/absence, except for TP53, which were additionally characterized as either disruptive (D) or non-disruptive (ND). Principal clinical correlates were OS, PFS, and chemo-response. Survivor distribution was estimated using Kaplan-Meier methods and difference of OS, PFS between/among groups was examined by log-rank test. The effect of continuous measurements including age, and number of genes alternated on survival (OS, PFS) was estimated using Cox model. **Results:** The cohort was typical for SCLC, containing a majority of extensive disease (78%), chemo-sensitive (66%) male (56%) patients. The median OS for all patients was 11.4 mo (95% CI: 7.9-55.5 mo). While no Group I genes significantly correlated with OS, PFS was significantly worse for patients with no TP53 mutation (NEG) compared to its presence (p = 0.023); as well as when comparing NEG, D and ND mutations (p = .047). There was a trend for PTEN loss to negatively impact OS (p = .101) and PFS (p = .171). When Group II genes were considered, two: GPR124 (p = .035) and IL7R (p = .094) were predictive of OS; and 3 genes: TP53 (p = .028), CREBBP (p = .057) and GPR124 (p = .056) were predictive of PFS. The total number of mutated genes had no significant clinical correlation. No gene mutation significantly correlated with chemo-response. **Conclusions:** This study is the first to describe gene mutations, including TP53 and several novel genes, with significant clinical correlation to OS and PFS. We can expect that as our cohort grows, a full landscape of genes important to SCLC will emerge.

7576 Poster Session (Board #324), Mon, 8:00 AM-11:30 AM

Identification of *RICTOR* amplification as a recurrent and potentially actionable alteration in small cell lung cancer patients. *First Author: Snehal Dabir, Case Western Reserve University, Cleveland, OH*

Background: Genomic analysis of SCLC is in its infancy relative to NSCLC and no known correlations to clinical outcomes have been reported for any SCLC mutation. Thus, we tested SCLC cancer diagnostic biopsies for genomic mutations by targeted exome sequencing of a panel of cancer-related genes using FFPE tissue. We identified recurrent *RICTOR* amplification in 5 of 36 total patient tumors examined. Here we report the clinical importance of *RICTOR* amplification in our SCLC cohort and its potential to represent a new actionable subgroup in this disease. **Methods:** Survivor distribution was estimated using Kaplan-Meier methods and the difference of OS, PFS between/among groups was examined by log-rank test. All tests are two-sided and p-value ≤ 0.05 were considered statistically significant. SCLC cell lines were assayed for growth inhibition in the IncuCyte ZOOM using drugs that target the PI3K/AKT/mTORC1/2 pathways. **Results:** *RICTOR* amplification was found in 4 men and 1 women, with a median age of 63 years. RICTOR typically co-amplified with the nearby genes *IL7R* and *FGF10*; suggesting a focal amplification of these genes on chromosome 5p13. *RICTOR* was the most frequent amplified gene identified in our SCLC cohort; greater than *FGFR1* and *MYC*. The OS of patients with RICTOR amplification was significantly decreased ($p = 0.036$) while PFS approached significance ($p = 0.062$). Cell growth inhibition studies with SCLC cell lines demonstrated sensitivity towards mTORC1/2 inhibitors (INK128 and AZD2014) by cells with higher CNV for *RICTOR*. Ongoing experiments will expand the number of cell lines studied to determine the correlation between *RICTOR* CNV, protein and growth inhibition. **Conclusions:** Amplification of *RICTO*R may represent a clinically significant mutation in SCLC and may represent a predictive marker for targeted therapy with mTORC1/2 inhibitors in small cell lung cancer patients.

7577 Poster Session (Board #325), Mon, 8:00 AM-11:30 AM

Conditional survival estimates for small cell lung cancer receiving prophylactic cranial irradiation in the U.S. (1988-1997). *First Author: Yan Xing, Mt Auburn Hosp, Belmont, MA*

Background: Conditional survival (CS) has emerged as a clinically useful measure of prognosis for cancer patients with poor prognosis. We examined the efficacy of prophylactic cranial irradiation (PCI) on cancer-specific CS estimates for small cell lung cancer (SCLC) patients. **Methods:** SCLC patients on whom PCI data was available were identified from the Surveillance Epidemiology and End Results registry (SEER) from 1988-1997. PCI data were not available after 1997. Multivariate Cox regression models were built separately by each stage to calculate the adjusted 1-6 year cancer-specific survival and overall survival. The multiplicative law of probability was then used to compute the X-year conditional survival where the (x+y) year survival is divided by y years of patients who have survived. Variables adjusted for included age, sex, ethnicity, marital status, SEER region, year of diagnosis, and radiation. **Results:** Data on 9,134 patients was included. Utilization of PCI in limited stage (LS)-SCLC increased from 18% in 1988 to 23% in 1997 ($P < 0.001$). Patients with LS-SCLC from Midwest were less likely to receive PCI (36% vs. 40%, $p < 0.001$) compared to other SEER regions and those aged 50-79 years with LS-SCLC were less likely to receive PCI (59% vs. 16%, $p < 0.001$). The 3- year conditional overall survival (COS) from diagnosis (time 0) to 3 years for LS-SCLC receiving PCI improved from 23% (all patients at diagnosis) to 54% (patients alive at 3 years from diagnosis) whereas similar estimates for those not receiving PCI were 17% and 48%. For extended stage (ES) SCLC receiving PCI, the 3-year COS improved from 4% to 49% whereas the 3-year COS for those not receiving PCI improved from 5% to 50%. Three-year conditional cancer-specific survival (CCSS) for LS-SCLC receiving PCI improved from 28% to 65% and for those not receiving PCI improved from 20% to 59%. For ES-SCLC receiving PCI, the 3-year CCSS improved from 5% to 60% whereas in those not receiving PCI, it improved from 6% to 62%. **Conclusions:** Three-year COS and CCCS estimates improve dramatically over time for SCLC survivors. These prognostic data provide more accurate prognosis helping clinicians and patients with informed decision making.

7578 Poster Session (Board #326), Mon, 8:00 AM-11:30 AM

Small cell lung cancer: Why has it become an orphan disease? *First Author: Shakun M. Malik, Clinical Investigations Branch CTEP/DCTD, Rockville, MD*

Background: Lung cancer remains the leading cause of death in US and worldwide. Substantial progress has recently been made in non-small cell lung cancer (NSCLC) with the discovery of molecular targets leading to the targeted drug development. Positive trials have led to the approval of a number of targeted therapies in NSCLC. However, therapies for small cell lung cancer (SCLC) have lagged behind with the current standard treatment reflecting the prevailing state-of-the-art from the early 1980s. We wanted to identify the reasons for the lack of progress in the treatment of SCLC. **Methods:** We searched all the randomized clinical trials of SCLC through a search of the National Cancer Institute Cancer Therapy Evaluation Program database (through June 31, 2014). We also conducted a search of Medline with the MeSH terms "Small Cell Lung Carcinoma", "phase III", and "phase II", for peer-reviewed randomized clinical trials. **Results:** Trials for limited-stage SCLC have decreased over time with 9/44 trials being positive. Of these 9 positive trials, 8 studied radiation dose/sequencing. In extensive-stage SCLC, there were 14 positive trials, with a number of these being either non-inferiority trials or studying chemotherapy intensification rather than a new drug. In relapsed/refractory disease, 7/13 trials were positive and the majority tested topotecan. **Conclusions:** The discovery of molecular drivers in SCLC that are targetable lag far behind NSCLC. The number of randomized trials studying new drugs in SCLC trials is limited. Since the approval of topotecan in 1996 the US FDA has approved no new drugs for the treatment of small cell lung cancer patients.

Randomized comparative trials in SCLC.

Stage and publication year	No. of trials	Total sample size on all trials	Median trial sample size
Limited stage	44	11149	262

7579 Poster Session (Board #327), Mon, 8:00 AM-11:30 AM

Impact of accurate staging with ^{18}F-FDG-PET and brain MRI on clinical benefit of prophylactic cranial irradiation (PCI) in patients with limited stage (LS) small cell lung cancer (SCLC). *First Author: Mihong Choi, National Cancer Center, Goyang, South Korea*

Background: The latest randomized study using brain MRI as initial brain assessment has suggested PCI had a negative survival effect in extensive stage SCLC (Abstr 7503, ASCO, 2014), which is contrary to the results of earlier studies that had not necessarily included brain MRI and PET as initial evaluation. Furthermore, as the survival of LS-SCLC pts improves, there has been a great need to critically address the benefit-risk issue of PCI (*Lee J* et al, J Clin Oncol, 2006). Thus, we sought to evaluate the effect of initial brain MRI and PET evaluation on the clinical outcome and benefit of PCI in LS-SCLC pts. **Methods:** We retrospectively collected data from 264 pts with histologically-proven LS-SCLC who had complete or partial response after concurrent chemoradiotherapy including platinum-based regimen from April 2001 to April 2013 at National Cancer Center Hospital (Goyang, Korea). Among them, 130 pts who had both brain MRI and whole body ^{18}F-FDG-PET as initial staging work-up are included in this analysis. **Results:** In the 130 pts, the 5-year cumulative brain metastasis (BM) rate was 39.6% and the 5-year overall survival rate was 53.2%. Among them, 46 received PCI (25 or 30Gy in total) and 84 did not. There was no difference in clinical characteristics such as age (60 v 63 years; $p = 0.140$) and TNM stage (I-II/IIIA/IIIB) (22/28/45% v 24/43/33%; $p = 0.147$). Between the two groups (PCI vs No PCI), there was no significant difference in the 5-year cumulative BM rate (36.7 vs 41.8%, $p = 0.231$) and the 5-year overall survival rate (56.9 vs 51.5%, $p = 0.985$). Subgroup analysis showed PCI tended to decrease the 5-year cumulative BM rate in patients with stage I-IIIA SCLC ($n = 79$) (29.5 vs 41.7%, $p = 0.104$) but not in patients with stage IIIB SCLC ($n = 51$) (46.5 vs 41.3%, $p = 0.876$). **Conclusions:** LS-SCLC pts accurately staged with brain MRI and PET exhibited excellent overall survival with the 5-year survival rates after achieving objective response after CCRT, exceeding 50% regardless of PCI. Considering the risk of neurotoxicity, the role of PCI should be more critically readdressed in this group of LS-SCLC pts with greater potential for long-term survival and even cure.

7580 Poster Session (Board #328), Mon, 8:00 AM-11:30 AM

Phase II trial of single agent amrubicin (A) in patients (pts) with previously treated advanced thymic malignancies (TM). *First Author: Heather A. Wakelee, Stanford Cancer Institute/Stanford University School of Medicine, Stanford, CA*

Background: There are limited treatment options for pts with TM and chemotherapy efficacy is often restricted by cumulative toxicity such as neuropathy (taxanes) and cardiomyopathy (anthracyclines). This trial investigated single agent amrubicin (A), a third generation anthracycline and topoisomerase II inhibitor with minimal cardiac toxicity, in TM pts. **Methods:** This was an open-label investigator-initiated single drug trial at 2 institutions with overall response rate (RR) as the primary endpoint. Eligible pts had TM (thymoma (T) or thymic carcinoma (TC)) with progressive disease (PD) or relapse after $\geq$ 1 prior chemotherapy regimen, and adequate organ function including left ventricular ejection fraction (LVEF) of $>$ 50%. The initial treatment plan consisted of A at 40 mg/m^2 IV days 1-3 repeated in 21-day cycles with growth factor support. **Results:** 33 pts (14T/19TC) enrolled from 7/2011 to 4/2014: 14 women/19 men; age 30-81 yo; 9 Asian, 1 African-American, 23 White. A high rate of febrile neutropenia (FN) led to an amended starting dose of 35 mg/m^2 days 1-3 of 21-day cycles. In total, 7 pts experienced FN with 1 related death. Other grade 3/4 possibly related events included thrombocytopenia (n = 3), neutropenia (without fever, n = 3), anemia (n = 7), lethargy/fatigue (n = 7), perirectal abscess (n = 2), palmar-plantar erythrodysesthesia (n = 3), syncope (n = 2), venous embolism (n = 2), and 1 pt each with sepsis, oral abscess, pneumonia, UTI, mucositis, chest pain, and epigastric pain. Other toxicities were mild and A was generally well tolerated. No significant changes in LVEF were noted on serial echocardiograms. RR was 18% (n = 6, all partial): 29% (n = 4) in T and 11% (n = 2) in TC. Disease control rate (DCR) at first evaluation was 88% overall (n = 29): 100% (n = 14) in T and 78% (n = 15) in TC. 4 pts had PD or died before first assessment. All but 5 pts received at least 4 cycles, and 17 received 10 or more cycles, with 34 cycles as the highest number to date. 5 pts remain on therapy. **Conclusions:** Amrubicin, at 35 mg/m^2 IV days 1-3 on a 21-day cycle, shows promise as a single agent in pre-treated pts with T and TC with an 18% RR and no unexpected toxicity. Further exploration as a single drug or in combination is warranted. Clinical trial information: NCT01364727.

7581 Poster Session (Board #329), Mon, 8:00 AM-11:30 AM

Somatostatin analogs as mainteinance therapy in heavily pretreated thymic epithelial tumors. *First Author: Giovannella Palmieri, Department of Clinical Medicine and Surgery and Rare Tumors Reference Centre Campania Region, University, Napoli, Italy*

Background: Thymic epithelial tumors are rare neoplasms with a particular biological behavior, treated with a combination of therapeutic strategies such as surgery, chemotherapy, radiotherapy and target agents. No continuation maintenance therapy exists for these rare tumors. An high uptake of indium-labeled octreotide (111In-DTPA-D-Phe1-octreotide) and curative application of somatostatin analogs in thymic tumors have been widely demonstrated. **Methods:** Eighteen patients (nine women and nine men, median age 54.5 years; range 32-78) with advanced thymic tumors (seven patients with stage III; seven with IVa; Four with IVb according to the Masaoka-Koga staging system), histotype sec WHO revised by central review (three AB, two B1, three B2, five B3, three B2/B3, two thymic carcinoma) with a partial response or stable disease to conventional chemotherapeutic regimens platinum or not platinum-based, after performed OctreoScan, were enrolled in this monocentric referral center study. The schedule includes administration of long-acting analog octreotide (30 mg/every 28 days intramuscularly), until progression of disease was documented. Median time to progression and toxicity were evaluated. **Results:** Median follow-up was of 43 months with a median time to progression of 14,5 months (range 77-2). Treatment was generally well tolerated with acceptable toxicity: Grade 1 diarrhea (5 patients), Grade 2 hyperglycemia (4 patients). No patients interrupted treatment because of toxicity. **Conclusions:** The current study indicates that single-agent somatostatin analogs maintenance therapy is a potential treatment strategy for advanced TETs OctreoScan positive which responde to previous conventional chemotherapy. In particular, somatostatin analogs may provide an effective maintenance treatment duration regardless of histotype and stage of disease with an acceptable toxicity and an improved patients'compliance.

7582 Poster Session (Board #330), Mon, 8:00 AM-11:30 AM

Effectiveness of somatostatin analogs plus prednisone in aggressive histotype and advanced stage of thymic epithelial tumors. *First Author: Margaret Ottaviano, Department of Clinical Medicine and Surgery and Rare Tumors Reference Centre Campania Region, University, Naples, Italy*

Background: Thymic epithelial tumors (TETs) are rare neoplasms characterized by histological variability. Efficacy of octreotide/lanreotide with or without prednisone in TETs OctreoScan positive has been widely demonstrated in thymoma, but no clearly in thymic carcinoma. **Methods:** Twelve patients (five men, seven women; median age 47 years; range 27-70) with advanced stage disease according to the Masaoka-Koga staging system (seven with IVa stage; five with IVb stage), and aggressive histotype according to WHO classification, revised by central review (two B2/B3; five B3; one B3/thymic carcinoma; four thymic carcinoma) were enrolled in this monocentric referral study. All the patients showed a progressive disease according to RECIST 1.1 criteria to previous conventional chemotherapeutic regimens platinum or not platinum-based. All the patients performed OctreoScan. The schedule includes administration of long-acting analog octreotide (30 mg/every 28 days intramuscularly) plus prednisone 0.2 mg/kg/day until progression of disease was documented. Median time to progression, overall response rate and toxicity were evaluated. **Results:** The median time to progression was 6 months (range 3-24), the overall response rate was 74.9%, particularly three patients (25%) obtained stable disease; four patients (33.3%) partial response; two patients (16.6%) complete response; three patients (25%) progression disease. One patient with Good Syndrome interrupted treatment after 6 months for infection disease. One patient has been lost to follow-up after 24 months of treatment. One patient died after progression disease for PRCA. Treatment was generally well tolerated with acceptable toxicity: no symptomatic cholelithiasis (1 patient), Grade 1 diarrhea (two patients) hyperglycemia (1 patient). One patient with thymic carcinoma and IV b stage had PS improvement from 2 to 1 sec ECOG, and one patient had complete remission of pericardial and pleural effusion after six months treatment with symptomatic relief. **Conclusions:** Somatostatin analogs plus prednisone is an effective treatment in aggressive histotype and advanced stage disease of TETs.

TPS7583 Poster Session (Board #331a), Mon, 8:00 AM-11:30 AM

ALCHEMIST: a clinical trial platform to bring genomic discovery and molecularly targeted therapies to early-stage lung cancer. *First Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Molecularly targeted therapies, specifically those directed toward epidermal growth factor receptor (EGFR) mutations and anaplastic lymphoma kinase (ALK) rearrangement have improved outcomes in a subset of patients with advanced non-small cell lung cancer (NSCLC). However, the role of molecular testing and targeted therapies for earlier stage disease remains unclear. Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trial (ALCHEMIST) is a National Cancer Institute (NCI) sponsored National Clinical Trials Network (NCTN) initiative to address these unanswered questions. **Methods:** ALCHEMIST is a clinical trial platform that currently consists of three integrated protocols: ALCHEMIST Screening (A151216; NCT02194738), ALCHEMIST-EGFR (A081105; NCT02193282), and ALCHEMIST-ALK (E4512; NCT02201992). In ALCHEMIST-Screening, up to 8,000 patients with pathologically confirmed stage IB ($\geq$ 4 cm)-IIIA non-squamous NSCLC will be enrolled either before or after surgical resection. Tumors will be centrally genotyped for *EGFR* mutations and *ALK* rearrangements. Blood and tumor samples will also be collected for advanced genomic analysis at the NCI. Patients with *EGFR* mutations or *ALK* rearrangements will be referred to ALCHEMIST-EGFR or-ALK treatment trials, respectively. All other patients will be followed for relapse and survival. Available biopsies at recurrence will be collected to characterize clonal evolution. In the treatment trials, patients will be randomized to placebo vs. erlotinib or crizotinib after completion of standard adjuvant therapy. Treatment will continue for two years. Both trials are double blind studies with a primary endpoint of overall survival (OS). ALCHEMIST-EGFR will enroll 410 patients, which provides 85% power with one-sided type I error rate of 0.05 to demonstrate an OS hazard ratio (HR) of 0.67 favoring erlotinib. ALCHEMIST-ALK will enroll 378 patients to provide 80% power and one-sided type I error of 0.05 to demonstrate an OS HR of 0.67 favoring crizotinib. ALCHEMIST is currently enrolling patients at over 500 centers nationwide. Additional treatment trials for specific molecular subsets may be added in the future. Clinical trial information: NCT02194738.

TPS7584 Poster Session (Board #331b), Mon, 8:00 AM-11:30 AM

Neoadjuvant erlotinib in stage III NSCLC patients (pts) with activating EGFR mutations (EVENT trial). *First Author: Cengiz Inal, Albert Einstein Coll of Medcn, Bronx, NY*

Background: Results with standard chemoradiotherapy for stage III NSCLC pts have plateaued and systemic relapse remains the biggest challenge. Genomic driven strategies are desperately needed as there is yet to be an approved targeted agent for locally advanced disease. Erlotinib improved objective response rate (ORR) and prolonged progression free survival (PFS) compared with chemotherapy in pts with EGFR-mutated advanced NSCLC. Mediastinal nodal clearance (pN0) after neoadjuvant therapy is a consistent surrogate marker for long term survival.We aim to evaluate rates of pN0 following neoadjuvant erlotinib in stage III NSCLC pts with activating EGFR mutation. **Methods:** 3 out of 55 planned pts have been enrolled in this single arm, open label phase II study. Based on historical data, pN0 rate of $\geq$ 30% will justify further study and the rate of $\leq$ 15% will be considered ineffective. With optimal two-stage design, if $\geq$ 3 out of initial 19 pts have pN0, additional 36 pts will be accrued in the second stage. Neoadjuvant erlotinib will be considered for further studies if pN0 is observed in $\geq$ 12 among total 55 pts. With 80% power and type I error of 0.05, the probability of early stopping at the first stage is 68.4% if the true response rate (TR) is 15% and 13.3% if TR is 30%. Total of 55 pts will ensure that the 95% CI for the estimated TR will be within +/- 15.7% by the end of this study. Stage IIIA/B NSCLC patients with N2 disease, activating EGFR mutations, ECOG PS 0-2, preserved organ function and no prior chemotherapy or radiation are eligible. Pts are treated with neoadjuvant erlotinib 150 mg PO daily for two months and then restaged. Pts with significant clinical down staging and deemed medically fit for surgery will have surgical resection. Pts with non-progressive disease who do not undergo surgery will have mediastinal restaging. Therapy after surgery or mediastinal restaging is at the discretion of the treating physician. The primary objective is to estimate the rate of pN0 after neoadjuvant erlotinib. Secondary objectives include PFS, OS, ORR from neoadjuvant erlotinib, and surgical resection rate. The translational studies in pre and post erlotinib tumor biopsy are also planned. Clinical trial information: NCT01857271. Clinical trial information: NCT01857271.

TPS7585 Poster Session (Board #332a), Mon, 8:00 AM-11:30 AM

NCI 9448: Phase I study of trametinib in combination with chemoradiation for KRAS-mutant non-small cell lung cancer. *First Author: Steven H. Lin, Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Concurrent chemoradiotherapy is the standard management approach for unresectable, non-metastatic locally advanced non-small cell lung cancer (NSCLC). However, progress has been slow in making substantial improvements in the outcomes of these patients. Preclinical data suggests that adding molecular targeted drugs affecting specific pathways could enhance radiation effects, and Kras mutated NSCLC may be particularly susceptible for MEK1/2 inhibition for radiation sensitization. This trial tests the safety of combining trametinib (GSK1120212), a potent MEK1/2 inhibitor, with standard carboplatin and paclitaxel chemoradiotherapy, for the treatment of locally advanced NSCLC. **Methods:** This is a multi-center, NCI UM1-sponsored, phase I clinical trial. Patients with unresectable stage II-III NSCLC with Kras mutation who can receive concurrent carboplatin (AUC 2.0) and paclitaxel (50 mg/m2) with once-daily trametinib and 60 Gy radiotherapy delivered in 30 fractions are eligible. Two additional cycles of consolidation chemotherapy (carboplatin AUC 6.0 and paclitaxel 200 mg/m2) are given after completing concurrent chemoradiotherapy. Trametinib is delivered at the starting dose level of 1.0 mg, and Time-to-Event-Continuous Reassessment Method (TiTE-CRM) is used for dose escalation at 4 levels (0.5, 1.0, 1.5, and 2.0 mg). CTCAE v4.0 is used to determine dose-limiting toxicity (DLT), with the Pr(tox) within 70 days at 0.6 for general DLTs, and 0.3 for severe DLTs. Primary objective of the trial is to determine the maximum tolerated dose (MTD) and safety of trametinib as measured by rate of grade 3 or worse non-hematologic toxicities attributed to chemoradiation within 70 days of start of therapy, as well as pharmacokinetic studies. Secondary objectives include response rate, overall survival, patterns of recurrence, dose delay and percentage of dose delivered, and biomarker exploratory endpoints. The maximum number of patients is 30. **Conduct to Date:** The trial was activated October 28, 2013 at MD Anderson, and recently at Ohio State University. So far 7 patients have enrolled on study. Clinical trial information NCT01912625. Clinical trial information: NCT01912625.

TPS7586 Poster Session (Board #332b), Mon, 8:00 AM-11:30 AM

Phase I/II study of tumor-infiltrating lymphocyte (TIL) infusion and low-dose interleukin-2 (IL-2) in patients with advanced malignant pleural mesothelioma (MPM). *First Author: Mark Doherty, Department of Medical Oncology, University College Hospital Galway, Galway, Ireland*

Background: MPM is a disease with poor outcomes, and only modest benefits from existing systemic therapies. Preclinical studies have shown that MPM often contains populations of TILs, and that these can be expanded ex vivo. Therapy using autologous TIL infusions and IL-2 following lymphodepleting chemotherapy has been successfully used in advanced melanoma. The therapeutic potential for TILs in MPM has not yet been explored. **Methods:** This is a single arm, phase I/II study to evaluate the feasibility, safety, and efficacy of TIL therapy for advanced MPM at the Princess Margaret Cancer Centre. Eligibility criteria include: advanced MPM, suitable surgical candidate for TIL harvesting from tumor, ECOG performance status 0-1, adequate organ function, and successful expansion of TILs. TILs are harvested from fresh tumor tissue, evaluated for suitability, and expanded ex-vivo. Patients are treated with a lymphodepleting chemotherapy regimen containing cyclophosphamide (60mg/m^2 x 2 days) and fludarabine (25mg/m^2 x 5 days), followed by infusion of expanded TILs. This is followed by low-dose IL-2 therapy (125000 IU/kg/day subcutaneously) for 2 weeks. The treatment protocol is adapted from that used in melanoma TIL studies, and no dose exploration is planned. The primary objective is determining the feasibility and safety of the regimen. Efficacy as measured by objective response rate (modified RECIST) is a secondary objective. The planned sample size is 10 patients. An informal interim analysis will be performed after 6 patients have been treated to review treatment toxicities and feasibility, given the lack of previous experience with this treatment in MPM. Correlative studies include analysis of peripheral blood mononuclear cells and assessment of persistence of infused TILs. Patients are currently being screened for TIL expansion at the Princess Margaret Cancer Centre.

8000 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

AZD9291, a mutant-selective EGFR inhibitor, as first-line treatment for *EGFR* mutation-positive advanced non-small cell lung cancer (NSCLC): Results from a phase 1 expansion cohort. *First Author: Suresh S. Ramalingam, The Winship Cancer Institute of Emory University, Atlanta, GA*

Background: AZD9291 is an orally administered EGFR TK inhibitor with activity against the sensitizing *EGFR* mutations (EGFRm) and the T790M resistance mutation. It has demonstrated anticancer activity in patients with EGFR-TKI pre-treated EGFRm T790M positive advanced NSCLC. **Methods:** Treatment-naïve patients with EGFRm advanced NSCLC received AZD9291 at doses of 80 mg/day or 160 mg/day (sequential cohorts) in the first-in-human phase I study (AURA, NCT01802632). EGFRm status was tested locally at the treating site and/or confirmed by central testing (cobas EGFR mutation test). Salient eligibility included presence of measurable disease, WHO performance status of 0 or 1, and acceptable organ function. Stable brain metastases were permitted. The objective of these cohorts was to investigate safety, tolerability, and anticancer activity of AZD9291 in the first-line EGFRm treatment setting. **Results:** Sixty patients were enrolled (30 each in 80 mg and 160 mg dose cohorts). Patient baseline characteristics: median age 63.5; male 25%; WHO performance status 0.57%, 1.43%; Asian 72%, and white 23%; central mutation test result exon 19 del 37%, L858R 40%, other *EGFR* sensitizing mutations 3%, T790M 8%. At the data-cutoff of 2 December 2014, 52 out of 60 patients remain on study treatment with a median treatment exposure of 260 days and 171 days for 80 mg and 160 mg cohorts, respectively. The objective response rate was 70% (95% CI 57, 81): 80 mg, 60%; 160 mg, 80% and the median progression-free survival (PFS) has not been reached. The disease control rate was 97% (95% CI 89, 100): 80 mg, 93%; 160 mg, 100%. Overall, the 3- and 6-month PFS rates were 93% and 87%, respectively (7/60 events, 12% mature). Grade ≥ 3 AEs were reported by 33% of patients. The incidences of grade 3 skin rash and diarrhea for the two dose cohorts combined were 1/60 and 2/60, respectively. **Conclusions:** AZD9291 has a manageable tolerability profile and is associated with promising anticancer activity as first-line treatment of EGFRm advanced NSCLC. A Phase III study to compare AZD9291 to erlotinib or gefitinib has been initiated (NCT02296125). Clinical trial information: NCT01802632.

8001 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Efficacy of rociletinib (CO-1686) in plasma-genotyped T790M-positive non-small cell lung cancer (NSCLC) patients (pts). *First Author: Lecia V. Sequist, Massachusetts General Hospital, Boston, MA*

Background: Rociletinib is an oral inhibitor of mutant EGFR, including the T790M resistance mutation. We reported robust activity in T790M positive pts identified by tumor genotyping treated at 500mg-1000mg BID (active doses) [NCT01526928]. We now present data from the pt subset with T790M detected by plasma genotyping. **Methods:** For the overall phase 1/2 study, pts had EGFR-mutant NSCLC and treatment with ≥ 1 EGFR inhibitor, ECOG PS 0-1. Brain metastases were allowed. In phase 2, T790M pos by central tumor genotyping was required. Plasma EGFR status was assessed by BEAMing (Sysmex), a quantitative assay using emulsion PCR then flow cytometry. **Results:** 345 pts were enrolled at active doses, median age 62 yrs, 66% female, 69% ECOG 1, 87% from US sites, median prior therapies 3 (45% ≥ 2 prior TKIs). Response data are available for 219 with tissue genotyping and 113 with plasma genotyping. The RECIST objective response rate (ORR) was ~48% in T790M pos pts, regardless of genotyping method. ORR was 33-36% among T790M neg pts, (see Table). There were 17 pts T790M pos in plasma but with neg (9) or failed (8) tissue genotyping, and 5/17 responded. There were 16 pts T790M pos in tissue but with neg plasma genotyping and 6/16 responded. 3/8 who were neg by both methods responded. The majority of T790M negative responders were on an EGFR TKI immediately before rociletinib (10/12 tissue and 10/10 plasma). Serial plasma data typically showed a decrease in the levels of T790M over time. Related all grade AEs in ≥ 15% patients were: hyperglycemia (40%), diarrhea (28%), nausea (23%), fatigue (21%), decreased appetite (17%). **Conclusions:** Rociletinib is associated with durable response and is well tolerated in pts with EGFR mutant T790Mpos NSCLC. One-third of T790M neg pts also respond, which cannot be explained by retreatment effect. Serial plasma data shows T790M decrease in most pts, including non-responders, suggesting T790M is not always the dominant growth driver. Plasma genotyping by BEAMing may be a complementary method to select patients. Clinical trial information: NCT01526928.

Table: Outcome by genotype/ biopsy type		T790M +	T790M -
Tissue genotype	ORR (%)	ORR: 91/186 (49)	12/33 (36)
	DoR (days)	1-394+	1-283+
Plasma genotype	ORR	40/83 (48)	10/30 (33)
	DoR	1-394+	74-329

8002 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Afatinib (A) vs erlotinib (E) as second-line therapy of patients (pts) with advanced squamous cell carcinoma (SCC) of the lung following platinum-based chemotherapy: Overall survival (OS) analysis from the global phase III trial LUX-Lung 8 (LL8). *First Author: Jean-Charles Soria, Gustave Roussy Cancer Campus and University Paris-Sud, Paris, France*

Background: Treatment options for pts with advanced SCC of the lung progressing after platinum-based chemotherapy are limited. Overexpression of EGFR, ErbB receptors and the dysregulation of their downstream pathways are implicated in SCC pathobiology. Primary analysis of LL8 (2nd line A, an irreversible ErbB family blocker vs E, a reversible EGFR tyrosine kinase inhibitor [TKI; only TKI approved in this setting], in pts with SCC of the lung) showed significantly better progression-free survival (PFS) with A. OS and updated PFS are reported here. **Methods:** Pts with stage IIIB/IV disease were randomized 1:1 to receive A (40 mg/day) or E (150 mg/day) until disease progression. Primary endpoint: PFS; key secondary endpoint: OS. Other endpoints: objective response (ORR), disease control (DCR), patient reported outcomes and safety. 632 events and a sample size of 800 pts was needed to detect a HR of 0.8 with 80% power for OS. **Results:** OS was significantly better with A (n = 398) vs E (n = 397), with a 19% reduced risk of death (median 7.9 vs 6.8 mos; HR [95% CI] 0.81 [0.69–0.95]; p = 0.008). Significant differences in OS were seen at 6 (63.6 vs 54.6%; p = 0.010), 12 (36.4 vs 28.2%; p = 0.016) and 18 (22.0 vs 14.4%; p = 0.013) mos. PFS (median 2.6 vs 1.9 mos; HR [95% CI] 0.81 [0.69–0.96]; p = 0.010), ORR (5.5 vs 2.8%; p = 0.055) and DCR (50.5 vs 39.5%; p = 0.002) were all better for A vs E. More pts had improved global health status/quality of life (35.7 vs 28.3%; p = 0.041), cough (43.4 vs 35.2%; p = 0.029) and dyspnea (51.3 vs 44.1%; p = 0.061) with A vs E. Adverse event (AE) profiles were comparable (G ≥ 3 AEs: 57.1 and 57.5% for A vs E) with a higher incidence of drug-related G3/4 diarrhea (9.9/0.5 vs 2.3/0.3%), G3 stomatitis (4.1 vs 0%) with A and a higher incidence of G3 rash/acne with E (5.9 vs 10.4%). Preliminary data from FoundationOne analysis of tumor blocks will be shown. **Conclusions:** A significantly improved OS vs E in pts with SCC of the lung in a 2nd line setting. PFS and DCR were also significantly better. With a manageable AE profile, added QoL benefit, and symptom control seen in LL8, A should be preferred over E for these pts. Clinical trial information: NCT01523587.

8003 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Cabozantinib (C), erlotinib (E) or the combination (E+C) as second- or third-line therapy in patients with EGFR wild-type (wt) non-small cell lung cancer (NSCLC): A randomized phase 2 trial of the ECOG-ACRIN Cancer Research Group (E1512). *First Author: Joel W. Neal, Stanford Cancer Institute/Stanford University School of Medicine, Stanford, CA*

Background: Cabozantinib (C) is a small molecule inhibitor of multiple receptor tyrosine kinases, including MET, VEGFR2 & RET. MET is involved in tumor differentiation & VEGFR2 is a mediator of angiogenesis. Erlotinib (E) is FDA approved for the treatment of NSCLC. **Methods:** The primary objective of this randomized phase II study was to compare progression-free survival (PFS) of patients (pts) treated with E vs. C, & E vs E+C; each comparison had 91% power to detect a PFS hazard ratio (HR) of 0.5 with a 1-sided 0.10-level test stratified on prior number of therapies & ECOG PS. Secondary objectives included overall survival (OS), RECIST 1.1 response & CTCAE v4 toxicity. Pts were selected with previously treated (1-2 regimens) metastatic non-squamous EGFR wt NSCLC. Submission of archival tissue for central MET IHC testing was required. Oral daily dosing was: E-150 mg; C-60 mg; E+C-150 mg E, 40 mg C. Imaging was performed every 8 weeks. Pts optionally crossed over to E+C following progression on E or C. **Results:** One hundred and twenty-five pts were enrolled, of which 115 were eligible and treated (E, n = 39; C, n = 39; E+C, n = 37). Pt characteristics were balanced between arms except for lower rate of brain mets history on E (p = 0.02). Median follow up is 8.5 m. Compared with E (median 1.9 m), PFS was significantly improved on C (3.9 m, HR 0.33, p = 0.0002, 80% CI 0.22-0.49) and E+C (4.1 m, HR 0.31, p = 0.0002, 80% CI 0.21-0.46). Similarly, compared with E (median 4.0 m), OS was significantly improved on C (HR 0.52, p = 0.02) and E+C arm HR 0.50, p = 0.02). Grade 3-4 treatment-related hypertension & mucositis were higher on C and grade 3-4 diarrhea was higher on E+C. Overall worst grade toxicities were also significantly higher on C and E+C. MET IHC results were available on 88 patients from the primary analysis & 85% were positive (1-3+ membrane or cytoplasm staining with MET4 antibody). There was no correlation between MET status and PFS. **Conclusions:** C & C+E significantly improved PFS over E alone in pts with EGFR wt NSCLC. Cabozantinib-based regimens are promising for further investigation in this patient population. Funded by ECOG-ACRIN and NCI Contract No. HHSN261200800001E. Clinical trial information: NCT01708954.

8004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Randomized phase III study of nedaplatin (N) plus docetaxel (D) versus cisplatin (C) plus D for advanced or relapsed squamous cell carcinoma of the lung (SqLC): WJOG5208L. *First Author: Takehito Shukuya, Department of Respiratory Medicine, Juntendo University, Tokyo, Japan*

Background: N is a second-generation platinum compound with lower nausea/vomiting and nephrotoxicity than C. N plus D (ND) showed a promising efficacy with acceptable toxicity for advanced SqLC in the previous phase II study. **Methods:** Eligible patients (pts) were those with pathologically proven SqLC with stage IIIB/IV or postoperative recurrence, aged 20-74 and ECOG PS 0-1. Pts were randomized 1:1 to ND (N 100 mg/m^2 and D 60mg/m^2 intravenous, q3w, up to 6 cycles) or C plus D (CD) (C 80 mg/m^2 and D 60mg/m^2 intravenous, q3w, up to 6 cycles) according to stage, gender and institution. The primary endpoint was overall survival (OS), and secondary endpoints included progression-free survival (PFS), response rate (RR) and adverse events (AEs). Target sample size of 350 provided 90% statistical power to detect a hazard ratio of 0.71 with *one-sided* type I error of 0.05. **Results:** Between July 2009 and July 2012, 355 pts were randomized. Of 349 for efficacy analysis (ND 177; CD 172), baseline characteristics were well-balanced between two arms. ND had a significantly longer OS ($p = 0.037$, *one-sided stratified log-rank test*). The OS HR was 0.81 (90%CI, 0.67-0.98) with a median OS of 13.6 months [m] for ND and 11.4 for CD. ND had a longer PFS ($p = 0.050$) with a HR of 0.83 (0.69-1.00) and a median PFS of 4.9 m in ND and 4.5 in CD. RR was 54.5% in ND vs 52.9% in CD ($p = 0.829$). Grade 3 or higher AEs of nausea (4.0% vs 14.3%), fatigue (3.4% vs 10.9%), hyponatremia (13.6% vs 30.3%) and hypokalemia (2.3% vs 8.6%) are more frequent in CD. Grade 3 or higher AEs of neutrophils (82.5% vs 70.3%) and platelets (9.0% vs 0.0%) are more frequent in ND, but there was no difference in grade 3 or higher febrile neutropenia (13.6% vs 15.4%). Treatment related deaths occurred in 4 and 3 pts in ND and CD, respectively. **Conclusions:** ND showed a significantly longer OS as compared to CD with different toxicity profile. ND will be considered as a new standard treatment for advanced or relapsed SqLC. Clinical trial information: UMIN000002015.

8005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Whole brain radiotherapy for brain metastases from non-small lung cancer: Quality of life (QoL) and overall survival (OS) results from the UK Medical Research Council QUARTZ randomised clinical trial (ISRCTN 3826061). *First Author: Paula Mary Mulvenna, Department of Clinical Oncology, Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom*

Background: Brain metastases affect up to 40% of patients with non-small cell lung cancer (NSCLC), and for inoperable cases whole brain radiotherapy (WBRT) and dexamethasone is standard treatment. However there are no randomised clinical trials to show whether WBRT improves either QoL or survival. **Methods:** A phase III randomised non-inferiority trial with a primary outcome measure of quality adjusted life years (QALYs). Patients with brain metastases from NSCLC (not suitable for resection or stereotactic radiotherapy) were randomly allocated to either optimal supportive care, including dexamethasone, plus WBRT 20 Gy/5f (OSC+WBRT) or OSC alone. QALYs were generated from OS and patients' weekly completion of the EQ-5D questionnaire. OSC alone was considered non-inferior to OSC+WBRT if not greater than 7 QALY days worse (80% power and a 1-sided 5% significance level required 534 patients.) Secondary outcome measures include sub-group analyses to identify/validate predictive classifications. **Results:** From 2007-2014 538 patients were recruited from 69 UK and 3 Australian centres. Baseline characteristics were balanced between arms and reflect everyday clinical practice: male 58%, median age 66 years (range 38 – 85), Karnofsky performance status < 70 38%, 54% had extracranial metastases, 30% had a solitary brain metastasis and 59% diagnosed with brain metastases within 28 days of randomisation. By January 2015 522/538 patients had died. There was no significant difference in OS from randomisation (hazard ratio 1.05 (95% CI 0.89 – 1.26) median survival OSC+WBRT v OSC (65 v 57 days)), overall QoL or steroid use between the 2 groups. The difference between the mean QALYs was -1.9 days (OSC+WBRT 43.3 v OSC 41.4 QALY days), two-sided 90% confidence interval for difference -9.1 to +6.6 QALY days. **Conclusions:** This is the only large randomised trial evaluating the utility of WBRT in this disease. Although the results include the pre-specified non-inferiority margin, the estimate of the difference in QALYs suggests WBRT provides no additional clinically significant benefit for this group of patients. Clinical trial information: 3826061.

8006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Interim results of a phase II study of the BRAF inhibitor (BRAFi) dabrafenib (D) in combination with the MEK inhibitor trametinib (T) in patients (pts) with *BRAF* V600E mutated (mut) metastatic non-small cell lung cancer (NSCLC). *First Author: David Planchard, Gustave Roussy, Villejuif, France*

Background: In 78 *BRAF* V600E mut NSCLC pts, single agent D induced an overall response rate (ORR) of 32%. The combination of D and T (DT) has demonstrated significant improvements in efficacy compared with BRAFi monotherapy in *BRAF*V600 mut metastatic melanoma. Here, we report interim safety (33 pts) and efficacy (24 pts) data for NSCLC pts enrolled in this phase II DT study. **Methods:** This single-arm, 2-stage, phase II study was in advanced *BRAF*V600E mut NSCLC pts who failed at least 1 line of chemotherapy. D was dosed at 150 mg orally twice daily and T at 2 mg once daily. The primary endpoint was investigator-assessed ORR per RECIST 1.1 criteria. A minimum response rate (≥ 6 out of first 20 pts) was required to continue into the second stage. **Results:** Median age of 33 pts was 66 yrs (range 49–88 yrs). Most pts were female (64%), White (82%), former smokers (73%), and had adenocarcinoma (88%). Twenty-seven pts (82%) remain on therapy, and 6 have stopped (4 with disease progression, 2 due to adverse events [AEs]). Twenty-four pts were evaluable for efficacy (confirmed response). ORR was 63% ($n = 15$, partial responses; 95%CI 40.6%–81.2%), with responses being observed by the first scan (6 weeks) and disease control rate (DCR) for > 12 weeks was 88% (95% CI 67.6%–97.3%). Independent review response rates were consistent with investigator-assessed response. Most common ($> 20\%$) AEs were pyrexia, diarrhea, nausea, vomiting, decreased appetite, asthenia, cough, peripheral edema, and rash, mostly grade 1 or 2. Grade 3 AEs occurred in 39% of pts; most frequent were hyponatremia (6%), neutropenia (6%), and dehydration (6%). One pt (3%) had a grade 4 AE (hyponatremia) and 1 pt (3%) had a fatal serious AE of pleural effusion. AEs leading to a dose reduction were reported in 9 pts (27%). Cutaneous squamous-cell carcinoma and keratoacanthoma occurred in 2 pts (6%). **Conclusions:** DT in *BRAF* V600E mut advanced NSCLC pts shows early antitumor activity with an ORR of 63% and a manageable safety profile. The study met the criteria for progression to the second stage. Clinical trial information: NCT01336634.

8007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase II study of cabozantinib for patients with advanced *RET*-rearranged lung cancers. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: RET rearrangements are found in 1-2% of non-small cell lung cancers and are drivers of growth in vitro and in vivo. Cabozantinib is a multi-tyrosine kinase inhibitor with activity against RET. **Methods:** This is a single-institution, open-label, phase II trial. Eligible patients (pts) had stage IV *RET*-rearranged lung cancer, KPS $> 70\%$, and measurable disease (RECIST v1.1). Cabozantinib was administered at 60 mg daily until progression or unacceptable toxicity. Study endpoints included response at 12 weeks, objective response, progression-free survival (PFS), overall survival (OS), and toxicity. Simon two-stage minimax design: H_0 10% vs H_A 30% overall response rate (ORR). Five responses of a maximum of 25 patients were required to meet the primary endpoint. **Results:** Twenty pts were treated. The median age was 56 (range 38-80 years). All pts had adenocarcinoma and 60% (12/20) were female. The median number of prior chemotherapy lines was 1 (range 0-5). There were no complete responses. The rate of any partial response (PR) at 12 weeks was 33% (5/15, 95% CI 12-62%). ORR was 28% (5/18, 95% CI 10-53%) with 5 confirmed PRs. Stable disease rate was 72% (13/18, 95% CI 51-93%) including 2 unconfirmed PRs. Median PFS was 7 mo (95% CI 3 mo-not reached). Median OS was not reached. Toxicities were mostly grade 1 or 2 and included fatigue, diarrhea, palmar-plantar erythrodysesthesia, transaminitis, and thrombocytopenia. At least 1 dose reduction was required in 60% (12/20) of pts. Eight patients remain on treatment between 1 and 23 mo. **Conclusions:** Cabozantinib is active in patients with *RET*-rearranged lung cancers and responses can be durable. This study has met its primary endpoint. A larger, confirmatory, multi-center trial is now warranted. Clinical trial information: NCT01639508.

8008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Efficacy and safety of the ALK inhibitor alectinib in *ALK*+ non-small-cell lung cancer (NSCLC) patients who have failed prior crizotinib: An open-label, single-arm, global phase 2 study (NP28673). *First Author: Sai-Hong Ignatius Ou, Chao Family Comp Cancer Ctr UC Irvine Medcl Ctr, Orange, CA*

Background: The ALK inhibitor crizotinib is approved for patients (pts) with *ALK*-rearranged (*ALK*+) NSCLC, but most pts progress within a year and CNS progression is common. The NP28673 study (NCT01801111) investigated the efficacy and safety of alectinib, a highly selective, CNS-active ALK inhibitor, in *ALK*+ NSCLC pts who had progressed on crizotinib. **Methods:** Eligible pts (≥ 18 yrs; locally advanced or metastatic *ALK*+ NSCLC [by FDA-approved FISH test]; failed on/intolerant to crizotinib) received alectinib 600mg p.o. BID until progression, death or withdrawal. Crizotinib was the only prior ALK inhibitor permitted. Primary endpoint was objective response rate (ORR) by independent review committee (IRC) using RECIST v1.1. Secondary endpoints included ORR by investigator; duration of response (DOR); CNS ORR and DOR; progression-free survival (PFS); disease control rate (DCR), CNS progression rate, overall survival, and safety. **Results:** 138 pts from 16 countries were enrolled by the 18 Aug 2014 cut-off. Median age 52 yrs; 80% had prior chemo; 60% had baseline CNS mets (60/83 treated). Median follow-up was 30 wks. In the response-evaluable population assessed by IRC (122 pts with measurable disease at baseline), ORR was 49.2% (95% CI 40.0–58.4; all PRs); DCR was 79.5% (95% CI 71.3–86.3). For patients with prior chemo and crizotinib (n = 96), ORR was 43.8% (95% CI 33.6–54.3); DCR was 78.1% (95% CI 68.5–85.9). For patients with baseline measurable CNS disease (n = 34), IRC-assessed CNS ORR was 55.9% (95% CI 37.9–72.8), including five CRs. Updated ORR, DOR and PFS data will be presented. Overall, 27.5% of pts had grade 3–5 adverse events (AEs), most commonly dyspnea (3.6%) and pulmonary embolism (2.2%); low rates of dose interruptions (19.6%), reductions (8.7%), and withdrawals (8.0%) due to AEs were seen. **Conclusions:** Alectinib was well tolerated and achieved a robust treatment response, including excellent intracranial activity, in *ALK*+ NSCLC pts who had progressed on crizotinib; most had also failed prior chemo and had CNS mets. A phase 3 trial of first-line alectinib vs crizotinib and an expanded access program are ongoing. Clinical trial information: NCT01801111.

8009 Clinical Science Symposium, Sun, 4:30 PM-6:00 PM

A phase III study (CheckMate 017) of nivolumab (NIVO; anti-programmed death-1 [PD-1]) vs docetaxel (DOC) in previously treated advanced or metastatic squamous (SQ) cell non-small cell lung cancer (NSCLC). *First Author: David R. Spigel, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: Treatment options are limited for patients (pts) with advanced SQ NSCLC who fail platinum-based doublet chemotherapy (PT-DC). We report results of a randomized, open-label, global phase III study of NIVO, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, vs DOC in pts with SQ NSCLC and with disease progression (PD) during/after one prior PT-DC regimen. **Methods:** Pts (N = 272) were randomized 1:1 to receive NIVO 3 mg/kg (n = 135) Q2W or DOC 75 mg/m^2(n = 137) Q3W until PD, discontinuation due to toxicity, or other reasons. The primary objective was overall survival (OS). Secondary objectives included investigator-assessed objective response rate (ORR; RECIST v1.1), progression-free survival (PFS), efficacy by PD-L1 expression (PD-L1 testing not required for enrollment), quality of life, and safety. **Results:** Superior OS was observed with NIVO vs DOC (HR = 0.59; 95% CI: 0.44, 0.79; p = 0.00025). NIVO improved PFS vs DOC (HR = 0.62; 95% CI: 0.47, 0.81; p = 0.0004). ORR was 20% (27/135) for NIVO and 9% (12/137) for DOC (p = 0.0083). OS HRs favored NIVO regardless of PD-L1 expression (**Table**). Grade 3–4 drug-related AEs occurred in 7% (9/131) of NIVO and 55% (71/129) of DOC pts. No deaths were related to NIVO vs 3 DOC-related deaths. **Conclusions:** CheckMate 017 met its primary objective, demonstrating superior OS of NIVO vs DOC in pts with advanced, previously treated SQ NSCLC and demonstrated PFS and ORR superiority. Tumor PD-L1 status was neither prognostic nor predictive for efficacy endpoints. The safety profile of NIVO 3 mg/kg Q2W is acceptable and favorable vs DOC. NIVO represents a significant improvement in second-line therapy for SQ NSCLC. Clinical trial information: NCT01642004.

Efficacy, safety and predictive biomarker results from a randomized phase II study comparing MPDL3280A vs docetaxel in 2L/3L NSCLC (POPLAR). *First Author: Alexander I. Spira, Virginia Cancer Specialists Research Institute, US Oncology Research, Fairfax, VA*

Background: MPDL3280A (anti-PDL1) has demonstrated promising response rates in NSCLC that correlated with PD-L1 expression on tumor-infiltrating immune cells (IC) and/or tumor cells (TC) (Horn et al, ASCO 2015). **Methods:** Previously treatedNSCLC patients (pts) were stratified by PD-L1 IC status, histology and prior lines of therapy and randomized to 1200 mg IV q3w MPDL3280A (M) or 75 mg/m^2 IV q3w docetaxel (D). PD-L1 expression was centrally evaluated by IHC using the SP142 antibody assay. Pts were scored as TC0, 1, 2 or 3 and IC0, 1, 2 or 3. The primary endpoint was OS (data cutoff, January 30, 2015; median follow-up, 12 mo). **Results:** 287 pts were randomized. In this interim analysis, improved efficacy was observed with increasing PD-L1 expression (e.g., OS HR, 0.47; PFS HR, 0.56 and ORR, 38% vs 13% in TC3 or IC3 pts), while pts with the lowest PD-L1 levels (TC0 and IC0) did not appear to benefit from M (OS HR, 1.22; see table). ITT OS HR was 0.78. Safety was evaluable for 277 pts. Despite a longer median treatment duration for M (3.6 vs 2.1 mo for D), fewer pts receiving M (43%) vs D (56%) experienced Gr ≥ 3 AEs. There were no unexpected toxicities. **Conclusions:** This is the first randomized study in non-squamous and squamous NSCLC to demonstrate that inhibition of the PD-L1/PD-1 pathway may lead to improved survival. Furthermore, these data showed that PD-L1 biomarker selection, using a highly sensitive and specific IHC assay measuring PD-L1 on both TC and IC, can identify both pts most likely to derive improved OS, PFS and ORR and pts unlikely to benefit vs standard of care (NCT01903993). A second randomized study in this pt population is ongoing. Clinical trial information: NCT01903993.

Phase 1 study of pembrolizumab (pembro; MK-3475) plus ipilimumab (IPI) as second-line therapy for advanced non-small cell lung cancer (NSCLC): KEYNOTE-021 cohort D. *First Author: Amita Patnaik, START, San Antonio, TX*

Background: Pembro is a potent anti–PD-1 monoclonal antibody. IPI, an anti–CTLA-4 antibody, has shown activity in advanced NSCLC. In melanoma, combined anti–PD-1 and anti–CTLA-4 treatment has shown robust efficacy and manageable toxicity. We report interim results from a phase 1 study evaluating pembro + IPI in patients (pts) with recurrent NSCLC. **Methods:** Pts with stage IIIB/IV NSCLC that recurred after ≤ 2 prior regimens received pembro + IPI every 3 wk for 4 cycles followed by maintenance pembro. Based on emerging data from the nivolumab + IPI advanced NSCLC study, doses were reduced from 10 mg/kg to 2 mg/kg for pembro and from 3 mg/kg to 1 mg/kg for IPI). Primary end point was safety and incidence of dose-limiting toxicities (DLTs) in the first 3 wk of dosing. Response was assessed every 6 wk per RECIST 1.1 by investigator review. **Results:** As of Dec 2014,17 pts were enrolled: 3 at pembro 10 mg/kg + IPI 3 mg/kg, 3 at pembro 10 mg/kg + IPI 1 mg/kg, and 11 at pembro 2 mg/kg + IPI 1 mg/kg. No DLTs or dose modifications were reported for the 15 pts treated at the time of analysis. 10 pts experienced drug-related AEs (DRAEs); none led to discontinuation or death. There were 2 gr 3 DRAEs, both rash. Gr 2 DRAEs were diarrhea and vomiting (n = 2 each) and chills, cough, decreased appetite, decreased weight, dehydration, depression, dysphonia, fatigue, myalgia, pruritus, and pyrexia (n = 1 each). Responses were seen in all dose groups among the 11 pts on treatment for ≥ 6 wk at the time of analysis, including 1 CR (9%) and 5 PRs (45%) (Table); all pts achieved disease control. 12 pts remain on treatment (range, 6 + to 26 + wk); 3 pts discontinued for PD. **Conclusions:** Preliminary data from KEYNOTE-021 cohort D demonstrate an acceptable toxicity profile and robust antitumor activity for pembro + IPI in pts with recurrent NSCLC.The use of lower pembro and IPI doses did not appear to negatively impact efficacy. Clinical trial information: NCT02039674.

Clinical correlation and frequency of programmed death ligand-1 (PD-L1) expression in EGFR-mutant and ALK-rearranged non-small cell lung cancer (NSCLC). *First Author: Justin F. Gainor, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: PD-L1 expression has recently been associated with response to PD-1 blockade. Given recent clinical interest in combining PD-1/PD-L1 inhibitors with EGFR and ALK tyrosine kinase inhibitors (TKIs), we evaluated PD-L1 expression patterns and clinical outcomes in EGFR-mutant and ALK-positive patients (pts). **Methods:** PD-L1 (Clone E1L3N, Cell Signaling Technologies) and CD8 immunohistochemistry were performed on biopsy and resection specimens from pts with metastatic NSCLC. Membranous expression of PD-L1 in > 5% tumor cells was defined as positive. CD8+ tumor infiltrating lymphocytes (TILs) were evaluated using a 4-tier grading system (0-3). **Results:** We evaluated PD-L1 expression and CD8+ TILs in pts with metastatic, EGFR-mutant (N = 68) and ALK-positive (N = 28) NSCLC (Table). Median progression-free survival (mPFS) on EGFR TKIs was similar between PD-L1(+) and PD-L1(-) pts at baseline (6.7 vs. 13.2 months; $P = 0.08$), as was overall survival (mOS; 31.8 vs. 35.63 months; $P = 0.307$). mPFS on ALK TKIs was similar in PD-L1(+) and PD-L1(-) pts at baseline (5.6 vs. 11.1 months; $P = 0.28$), but mOS was shorter among PD-L1(+) pts (26.5 vs. 51.6 months; $P = 0.045$). To evaluate whether targeted therapy affects PD-L1 expression, we also compared pre- and post-TKI biopsies in each cohort. Among individual EGFR-mutant pts with paired, pre- and post-TKI biopsies (N = 58), PD-L1 expression levels varied between biopsies in 13 (22%) pts. Among individual ALK-positive pts with pre- and post-TKI biopsies (N = 8), PD-L1 expression levels varied between biopsies in 2 (25%) pts. **Conclusions:** EGFR-mutant and ALK-positive lung cancers may express PD-L1 and demonstrate CD8+ TILs. Expression is dynamic in a subset of pts with changes in PD-L1 expression and immune infiltrates observed over time and/or following treatment.

	EGFR Mutant			ALK+

8013 Poster Discussion Session; Displayed in Poster Session (Board #335), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

First-in-human phase I study of EGF816, a third generation, mutant-selective EGFR tyrosine kinase inhibitor, in advanced non-small cell lung cancer (NSCLC) harboring T790M. *First Author: Daniel Shao-Weng Tan, National Cancer Centre Singapore, Singapore, Singapore*

Background: The emergence of T790M resistance mutations (mt) occurs in up to 50% of patients (pt) with NSCLC harboring a sensitizing EGFR mt treated with erlotinib or gefitinib. EGF816 is a covalent, irreversible, EGFR TKI that has nanomolar inhibitory potency against activating mt (L858R, ex19del) and T790M mt, with up to 60-fold selectivity over wild type (wt) EGFR in vitro. **Methods:** This multicenter, dose escalation study to determine the safety, tolerability and antitumor activity of EGF816, enrolled NSCLC pts with locally or centrally confirmed T790M status. Oral EGF816 was administered on a continuous 28-day schedule. Dose escalation started from 75 mg QD and was guided by an adaptive Bayesian logistic regression model to determine the maximum tolerated dose. Paired tumor biopsies were performed to evaluate pharmacodynamics. NCT02108964. **Results:** As of 26 Jan 2015, 57 pts have been treated (51 capsules, CAP; 6 tablets, TAB) across 6 cohorts (75, 150, 225, 300, and 350 mg for CAP; 225 mg for TAB). At the 4 Dec 2014 cutoff, 40 pts were evaluable for safety, median age 58.5y (range 34–76), 48% male and 80% East Asian. 2/6 pts experienced DLT at 350 mg (rash, n = 2; acute renal injury, n = 1). The most common adverse events (AE) regardless of study drug relationship were diarrhea (25%), stomatitis (22.5%), rash (17.5%) and pruritus (15%). The most common Grade 3/4 drug-related AE was rash (5%). RECIST responses and reduced pEGFR were observed at all dose levels. Amongst 22 evaluable pts, including 1 with *de novo* T790M mt, ORR (including unconfirmed responses) and disease control rate was 54.5% and 86.4% respectively. Only 1 pt experienced progressive disease at first evaluation – repeat testing revealed the tumor to be EGFR wt. PK shows rapid absorption with a median T_{max} of 3h and dose-proportional increases in C_{max} and $AUC_{(0\text{-}tau)}$ observed after single and multiple dosing. **Conclusions:** EGF816 is well tolerated with a manageable safety profile and antitumor activity against T790M mt NSCLC across all dose levels examined. Further study is ongoing to establish the optimal dose range to maximize therapeutic potential and facilitate future combinations. Clinical trial information: NCT02108964.

8014 Poster Discussion Session; Displayed in Poster Session (Board #336), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

ASP8273, a mutant-selective irreversible EGFR inhibitor in patients (pts) with NSCLC harboring EGFR activating mutations: Preliminary results of first-in-human phase I study in Japan. *First Author: Yasushi Goto, National Cancer Center Hospital, Tokyo, Japan*

Background: ASP8273 is a small molecule, irreversible tyrosine kinase inhibitor (TKI) that inhibits the kinase activity of EGFR activating mutations and T790M resistance mutation, with higher potency than wild type EGFR. **Methods:** NSCLC pts previously treated with at least an EGFR-TKI were enrolled into this open-label Phase I/II study which consists of a dose escalation and response expansion cohorts followed by the P2 at the RP2D. ASP8273 was administered orally once daily. All pts were assessed for AEs, PK and anti-tumor activity. In each dose-escalation cohort at least 3 pts were enrolled regardless of T790M status and in response expansion cohorts only pts with T790M were enrolled (NCT02192697). **Results:** As of 14 Nov. 2014, 30 Japanese pts were enrolled across 7 dose levels (25 - 600 mg) in the dose-escalation cohorts and 15 pts were enrolled in the response expansion cohorts at 4 dose levels (100 - 400 mg). Demographics of the pts were median age 65 yrs, 73% female, 62% ECOG PS1 and 51% received immediate prior EGFR-TKI. T790M status was 49% positive, 13% negative and 38% unknown, respectively. Most common AEs were diarrhea (56%), nausea (31%), vomiting (31%) and platelet count decreased (31%). A few events of rash (9%), QTc prolongation (7%), ILD-like events (2%) and no hyperglycemia have been reported. 9 DLTs were reported at doses of 400 – 600 mg (3 diarrhea, 2 colitis, 1 biliary tract infection, 2 nausea and 1 hyponatremia). Based on these safety findings, MTD was determined to be 400 mg. Median AUC and C_{max} after single- and multiple-dose of ASP8273 were increased with dose, respectively. RECIST responses were observed in pts enrolled in ≥ 100 mg. 50% (18/36) of all evaluable pts and 80% (12/15) pts with T790M have achieved PRs (includes confirmed and unconfirmed PRs). 300 mg once daily was chosen as RP2D based on the available safety, PK and anti-tumor activity data. **Conclusions:** ASP8273 under MTD has demonstrated anti-tumor activity in NSCLC pts with tumors harboring both EGFR activating mutations and T790M resistance mutation. The phase 2 part of this study will further investigate the clinical activity of ASP8273 at the RP2D in pts with T790M. Clinical trial information: NCT02192697.

Activity of AUY922 in NSCLC patients with EGFR exon 20 insertions. *First Author: Zofia Piotrowska, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: EGFR exon 20 insertions (ins20) represent a rare subtype (4%) of EGFR mutations and are refractory to EGFR-specific tyrosine kinase inhibitors (TKIs). No effective targeted therapies exist for patients (pts) with ins20; median PFS on the irreversible EGFR TKI Afatinib is 2.8 months (mos). A pt with EGFR ins20 achieved a durable RECIST partial response (PR) to AUY922, a Heat Shock Protein 90 (Hsp90) inhibitor, in a previous study (NCT01124864), so we designed this phase II investigator-initiated trial to assess the activity of AUY922 in NSCLC pts with EGFR ins20. **Methods:** This was a single-arm, multi-center, open-label study of AUY922 in advanced NSCLC pts with EGFR ins20 mutations. A Simon two-stage design was used, with a plan to enroll 10 pts in the 1st stage and an additional 19 pts in the 2nd stage if >1 PR or stable disease (SD) lasting > 3 mos was observed in the 1st stage. All pts were treated with AUY922 at 70mg/m2 IV weekly. The primary aim was to evaluate objective response rate (ORR) to AUY922. Here we report the complete results of the 1st stage. **Results:** Ten pts, including 7 females and 3 males, average age 55 (range 44-69), were enrolled. Median number of prior therapies = 1 (range 1-6.) 3 had received a prior EGFR TKI; none responded to TKI monotherapy. The most common toxicities were grade 1-2 visual changes (9 pts), diarrhea (9) and fatigue (8.) The only treatment-related grade 3 toxicity was hypertension (2).Among the 10 pts, we observed one PR and three SD lasting > 3 mos, thus triggering full enrollment to the 2nd stage of the study (Table). Median PFS estimate is 6.1 mos (95% CI, 1.2 to NR). Updated results and correlation with specific ins20 mutations will be presented. **Conclusions:** AUY922 may be an effective therapy for pts with EGFR ins20 mutations with med PFS 6.1 mo and is generally well-tolerated, though reversible low-grade ocular toxicity is common. To our knowledge, this is the first trial designed specifically for pts with this rare genotype. Further study of AUY922 in this population is warranted. **Clinical trial information:** NCT01854034 Clinical trial information: NCT01854034.

AZD3759, an EGFR inhibitor with blood brain barrier (BBB) penetration for the treatment of non-small cell lung cancer (NSCLC) with brain metastasis (BM): Preclinical evidence and clinical cases. *First Author: Dong-Wan Kim, Seoul National University Hospital, Seoul, South Korea*

Background: Increasing numbers of EGFRm+ NSCLC patients with BM have been reported, while effective treatment is lacking due to limited BBB penetration of currently available EGFR TKIs. Here we report preliminary data on AZD3759, an EGFR TKI with BBB penetration, for the treatment of BM. **Methods:** Preclinically, AZD3759 was assessed in both *in vitro* and *in vivo* assays, including MDCKII/Pgp and BCRP assays and CNS penetration in rats, mice and monkeys. PC-9 cells (Exon19Del) were transfected with luciferase and implanted through intra-carotid artery injection to establish a BM model in mice. Tumor growth was monitored weekly by a Xenogen Imaging System and the animal survival time was recorded. Blood and brain tissues were collected for pharmacokinetics, histopathology and pEGFR expression analyses. An ongoing, open label, dose escalation phase I study (NCT02228369; sponsor AstraZeneca) is investigating safety and tolerability of AZD3759 in patients with EGFRm+ advanced NSCLC. **Results:** AZD3759 has high passive permeability ($29.5x10^{-6}$ cm/sec) and is not a substrate of the efflux transporters Pgp or BCRP at the BBB. In vivo, AZD3759 reached distribution equilibrium in rats, mice and monkey ($K_{puu,brain}$ and $K_{puu,CSF} > 0.5$), suggesting BBB penetration. In the BM model, AZD3759 induced profound tumor regression and significantly improved animal survival. A correlation between free brain exposure and pEGFR modulation was also detected in tumor tissues on AZD3759 treatment. To date, 4 patients with measurable BM have been enrolled into 50mg bid and 100mg bid cohorts (3 patients and 1 patient, respectively). In the 2 evaluable patients with BM, one unconfirmed PR and one SD in the brain have been observed. C_{trough} CSF concentrations of these patients were 7.7 and 6nM, respectively, close to the pEGFR IC_{50} of AZD3759. No DLTs were reported to date and two cases of grade I skin rash were observed. **Conclusions:** Preclinical and initial clinical evidence indicate that AZD3759 is an EGFR TKI with BBB penetration with potential to treat EGFRm+ NSCLC patients with BM. Updated clinical data will be shared at the meeting. Clinical trial information: NCT02228369.

8017 Poster Discussion Session; Displayed in Poster Session (Board #339), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

A phase I study of twice weekly pulse dose and daily low dose erlotinib as initial treatment for patients (pts) with EGFR-mutant lung cancers. *First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pts with EGFR-mutant lung cancers treated with EGFR tyrosine kinase inhibitors (TKI) develop clinical resistance, most frequently due to acquisition of EGFR T790M. Modeling suggests that a twice weekly pulse dose, and daily low dose erlotinib schedule may delay the emergence of EGFR T790M. Pulse dose erlotinib may have superior central nervous system (CNS) penetration. **Methods:** We evaluated toxicity, pharmacokinetics, and efficacy of twice weekly pulse-dose and daily low dose erlotinib in pts with EGFR-mutant lung cancers (NCT01967095). Using a 3+3 dose escalation, we assessed escalating pulse doses of erlotinib on days 1 -2 (D1-2), and 50mg low-dose erlotinib on days 3-7 (D3-7) weekly. Six pulse dose levels of erlotinib were tested: 600, 750, 900, 1050, 1200, and 1350 mg. Response was evaluated by RECIST 1.1. After the maximum tolerated dose (MTD) was determined, we treated an additional 10 pts at the MTD. **Results:** From Nov 2013 to January 2015, 34 pts were enrolled. Median age: 60; Women: 20 (59%); never-smoker: 23 (68%); EGFR L858R: 11 (24%) and Ex19del: 22 (65%). Three DLTs were seen: transaminitis (1050mg), mucositis (1350mg) and rash (1350mg) during the dose-escalation period. The MTD was determined to be erlotinib 1200mg D1, D2 and 50mg D3-7 weekly. In total, 16 pts were treated at the MTD. Treatment-related AEs were all grade 1-3. The most frequent treatment-emergent AEs (any grade) were rash (85%), diarrhea (79%), elevated AST (50%) and nausea (41%). Of the 16 pts treated at the MTD, 3 (19%) required a dose reduction of the pulse dose. Of 27 evaluable patients, 22 partial responses were seen (81%). Median-progression free survival is 11 months. 17 pts remain on study. 8 (24%) pts came off for progression, 7 (21%) for toxicity and 2 (6%) for non-adherence. Of those who progressed, 5/8 (62%) had EGFR T790M identified upon rebiopsy (none at MTD). Twelve pts (35%) had CNS disease at diagnosis; no pts came off study due to progressive or new CNS metastases. **Conclusions:** This kinetics-based EGFR TKI dosing schedule of pulse-continuous erlotinib was well-tolerated. TKI dose optimization may enhance efficacy. Further studies are planned in pts with brain metastases. Clinical trial information: NCT01967095.

Clinical activity and safety of PF-06463922 from a dose escalation study in patients with advanced ALK+ or ROS1+ NSCLC. *First Author: Alice Tsang Shaw, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Anaplastic lymphoma kinase (ALK) and c-ros oncogene 1 (ROS1) fusions define 2 molecular subsets of patients (pts) with non-small cell lung cancer (NSCLC). PF-06463922 is a selective, brain-penetrant ALK/ROS1 tyrosine kinase inhibitor (TKI) with potent activity against de novo fusions as well as resistance mutations, including *ALK G1202R*, that arise during treatment with other TKIs. **Methods:** In an ongoing phase I portion of a phase I/II study, pts had ALK+ or ROS1+ NSCLC, with or without central nervous system (CNS) metastases, and were TKI-naïve or had disease progression after prior treatment with 1–2 TKIs. Tumor tissue (archival sample or de novo biopsy) was required for enrollment. A continual reassessment method was used to estimate the maximum tolerated dose (MTD) and identify the recommended phase II dose (RP2D). PF-06463922 was administered on day –7 and then once daily (QD) starting day 1. Primary objective was to estimate the MTD and identify a RP2D. Other objectives included efficacy, safety, pharmacokinetics (PK), effect on cognitive function, effect on cytochrome P450 (CYP) 3A4 activity, biomarkers of drug response/resistance, and intracranial antitumor activity. **Results:** 18 ALK+ and 4 ROS1+ pts (CNS metastases, n = 17; prior ALK TKIs, n = 19) were enrolled across 7 dose levels (10–200 mg QD). Of 15 patients evaluated for efficacy, 6 (40%) had either confirmed or unconfirmed partial responses, 5 of whom previously received 1–2 TKIs and had progression following crizotinib +/- ceritinib; intracranial responses were observed in 5 pts. Common treatment-related adverse events (AE) were hypercholesterolemia and peripheral neuropathy (23% each). The most common grade ≥ 3 treatment-related AE was hypercholesterolemia (14%). One dose-limiting toxicity occurred in a pt who received < 16 of 21 planned 200 mg QD doses due to grade 1/2 CNS effects. PK analysis showed a dose-proportional increase in exposure with a half-life of 20–28 h and moderate CYP3A4 induction. 20 pts remain on treatment. **Conclusions:** PF-06463922 was well tolerated and had clinical activity in pts with ALK+/ROS1+ NSCLC, most of whom had CNS metastases and received ≥ 1 prior TKI. Identification of MTD and RP2D is ongoing. Clinical trial information: NCT01970865.

8019 Poster Discussion Session; Displayed in Poster Session (Board #341), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

A phase II, open-label, multicenter study of the ALK inhibitor alectinib in an *ALK*+ non-small-cell lung cancer (NSCLC) U.S./Canadian population who had progressed on crizotinib (NP28761). *First Author: Leena Gandhi, Dana-Farber Cancer Institute, Boston, MA*

Background: Crizotinib is an approved treatment for patients (pts) with *ALK*-rearranged (*ALK*+) NSCLC. However, progression on crizotinib, particularly in the CNS, frequently occurs within a year. Alectinib is a highly selective ALK inhibitor; preclinical data show high CNS exposure and limited efflux. The NP28761 study (NCT01871805) investigated the efficacy/safety of alectinib in *ALK*+ NSCLC pts in the US and Canada who had progressed on crizotinib. **Methods:** Pts ≥ 18 yrs with locally advanced/metastatic *ALK*+ NSCLC (by FDA-approved FISH test) who progressed on crizotinib, with or without prior chemo, were enrolled; alectinib 600mg BID was given until progression, death or withdrawal. The primary endpoint was objective response rate (ORR) by an independent review committee (IRC) based on RECIST v1.1. Secondary endpoints included disease control rate (DCR = ORR plus stable disease); ORR and DCR in the CNS; progression-free survival; CNS progression rate; duration of response; overall survival; safety and quality of life. **Results:** By 24 Oct 2014, 87 pts were enrolled. Median age 54 yrs; 74% had prior chemo; 55% had baseline CNS mets (21/48 treated). Median follow-up was 21 wks. In the response-evaluable population assessed by IRC (69 pts with baseline measurable disease) ORR was 47.8% (95% CI 35.6–60.2); DCR was 79.7%. In pts with baseline measurable CNS disease (n = 16), IRC CNS ORR was 68.8% (95% CI 41.3–89.0), including 2 CRs; CNS DCR was 100%. When pts with baseline measurable and non-measurable CNS disease were both included (n = 48), CNS DCR was 87.5%, with 9 CNS CRs. 31% of pts had gr3–5 adverse events (AEs), most commonly increased blood CPK (8%), increased ALT (6%) and increased AST (5%); one gr5 AE (hemorrhage) occurred. Low rates of dose interruptions (29%), reductions (14%), and withdrawals (2%) due to AEs were noted. **Conclusions:** Alectinib was well tolerated and achieved a strong treatment response in *ALK*+ NSCLC pts who had progressed on crizotinib, with notable CNS activity, a common site of first progression on crizotinib. A global ph3 head-to-head trial of first-line alectinib vs crizotinib and an expanded access program are ongoing. Clinical trial information: NCT01871805.

Detection of frequent MET Exon 14 skipping events in pulmonary sarcomatoid carcinoma and response to targeted inhibition. *First Author: Xuewen Liu, Columbia University Medical Center; Sun Yat-sen University Cancer Center in China, New York, NY*

Background: Pulmonary sarcomatoid carcinoma (PSC) represents a category of highly aggressive carcinomas associated with a poor prognosis. New therapeutic strategies based on better knowledge of the molecular pathogenesis of PSC are needed. We recently identified a high frequency of a unique type of MET alterations leading to exon 14 skipping (exon 14Δ) in PSC. **Methods:** Whole-exome sequencing in a discovery set and targeted MET mutation screening in an independent validation set of PSC were performed. RT-PCR and Western blotting were performed to validate MET exon 14Δ. A lung adenosquamous cell line H596 (MET exon 14Δ and PIK3CA mutated) and a gastric adenocarcinoma cell line Hs746T (MET exon 14 Δ) were used for functional studies. Ablation of MET signaling by siRNA or pharmacological inhibitor (Crizotinib) was conducted, and subsequent MTS assays and Western blotting were then performed. Simultaneous MET signaling blockade and PIK3CA signaling inhibition using PIK3CA inhibitor (GDC0941) were performed to assess synergistic effects in H596 cells. **Results:** Alterations affecting MET exon 14 splice sites, including deletions at the 5' splice site (n = 3) and point mutations at the 3' splice site (n = 5) were found in 22% (8/36) of PSC. One PSC harbored MET exon 14Δ and a concurrent PIK3CA mutation. RT-PCR and Western blotting confirmed the presence of MET exon 14Δ in tumor and in H596 and Hs746T cells. Both MET siRNA silencing and crizotinib decreased cell proliferation and inhibited downstream AKT and MAPK activation in Hs746T cells, whereas effects were modest in H596 cells and negligible in control Calu-3 and HCC827 cells. Concomitant MET and PI3K blockade had synergistic effects in H596 cells. Migration/invasion assays in H596 and Hs746T cells, as well as further functional studies utilizing specific MET exon 14 expression constructs are ongoing. **Conclusions:** Our study finds that MET exon 14Δ alterations are a frequent and potentially targetable event in PSC. Our studies also suggest that concurrent PIK3CA mutations require combined treatment. Clinical studies assessing biomarker-driven MET/PI3K inhibition should be explored in PSC as well as other malignancies harboring MET exon 14Δ events.

Response to crizotinib and cabozantinib in stage IV lung adenocarcinoma patients with mutations that cause *MET* exon 14 skipping. *First Author: Paul K. Paik, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mutations in the *MET* exon 14 RNA splice acceptor and donor sites, which lead to exon skipping, deletion of the juxtamembrane domain, and loss of Cbl E3-ligase binding to the resultant aberrant MET protein, were previously reported to be oncogenic in preclinical models (Kong-Beltran, *Cancer Res* 2006). These mutations occur in 4% of lung adenocarcinomas but have not been clinically assessed (TCGA 2014). We now report responses to the MET inhibitors crizotinib and cabozantinib in patients with stage IV lung adenocarcinomas harboring mutations leading to *MET* exon 14 skipping. **Methods:** Patients with stage IV lung adenocarcinomas harboring *MET* exon 14 splice site mutations (N=6) or a mutation deleting Y1003 in exon 14 (N=1) were identified through a clinical assay based on hybrid capture/next-generation sequencing of 341 oncogenes and tumor suppressors (MSK-IMPACT). MET IHC was performed on archival FFPE tissue. RNA skipping was confirmed by NanoString. Radiographic response to MET inhibition was assessed using RECIST 1.1 and PERCIST criteria. **Results:** Clinicopathologic data for those treated are in the table below. To date, 3 patients have been treated with off-label crizotinib and 1 with cabozantinib (NCT01639508). 3 of 4 patients (75%) developed a PR to treatment. The remaining patient had SD by RECIST, with PET imaging demonstrating a complete PERCIST response. **Conclusions:** *MET* exon 14 skipping is a novel oncogenic target that predicts for response to MET inhibitors. This appears to be a substantially better predictor of response than either protein expression or gene amplification. Patients with these splice site mutations should be treated on a clinical trial of a MET inhibitor. For those without access to a trial, use of off-label crizotinib should be considered.

Clinical and molecular characteristics of *NF1* mutant lung cancer. *First Author: Amanda J. Redig, Dana-Farber Cancer Inst, Boston, MA*

Background: *NF1* is a tumor suppressor that negatively regulates Ras, thus *NF1* mutant tumors may also be sensitive to inhibitors of MAP kinase signaling. *NF1* variants occur in lung cancer, but their clinical significance is unknown. We evaluated clinical and molecular characteristics of *NF1* mutant lung cancers, with comparison to *KRAS* mutant tumors. **Methods:** From 07/13-10/14, 591 lung tumors at our institution underwent targeted next generation sequencing (NGS) for mutations and copy number alterations in a 275 gene panel. *NF1* and *KRAS* cohorts were identified, with clinical and genomic analysis. Fisher's exact test was used to compare frequency of gene mutations between cohorts. **Results:** Among 591 pts, 60 had *NF1* mutations (10%) and 143 (24%) had *KRAS* mutations (Stage IV: *NF1* 26, 43%; *KRAS* 58, 41%). 15 *NF1* mutations (25%) occurred with other driver mutations (BRAF (2); ERBB2 (2); KRAS (9); XRAS (2)). There were 73 unique *NF1* variants: single copy deletion (1), splice site (12), loss of function/predicted damaging (49), predicted benign (11). 10 tumors had > 1 mutation. Tumor pathology was diverse: adenocarcinoma (38, 63%); squamous cell carcinoma (11, 18%); large cell neuroendocrine (2, 3%); mixed small cell carcinoma (2, 3%); other (7, 11%). In contrast, *KRAS* mutations (G12C:51, G12D:22, G12V:27, Q61H:8, other:35) occurred in adenocarcinomas (138, 97%) and seldom with other driver mutations (2, 1%). Both mutations were common in former (> 10 pack years) or current smokers (*NF1* 49, 82%; *KRAS* 120, 84%). Among pts without co-mutation, *TP53* mutations/2-copy deletions occurred more often with *NF1* mutation (33, 65%) than *KRAS* mutation (47, 35%) ($p < .001$). Similarly, *LKB1* mutations occurred in 8 (16%) *NF1* mutant tumors and 33 (25%) *KRAS*mutant tumors ($p = .24$). **Conclusions:** *NF1* mutations define a unique population of 10% of non-small cell lung carcinoma (NSCLC). *NF1* and *KRAS* mutations present in similar pt populations. *NF1* mutations occur more often with other driver mutations and with coexisting *TP53* mutations than *KRAS* mutations. Therapeutic strategies targeting *KRAS* activation, such as MEK inhibitors, may warrant investigation in *NF1* mutant tumors. Tumor suppressor inactivation patterns in these tumors may help further define novel treatment strategies.

Assessing the performance of Watson for oncology, a decision support system, using actual contemporary clinical cases. *First Author: Mark G. Kris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: IBM Watson for Oncology (WFO), trained by Memorial Sloan Kettering (MSK), is a cognitive computing system designed to assist medical oncologists making treatment decisions for individual patients. Recommendations are consistent with established guidelines and published evidence, as reflected in MSK's practice and historical cases. Treatment options are classified as Recommended (WFO-REC), For Consideration (WFO-FC), or Not Recommended (WFO-Not REC). Published evidence, medical logic, and drug information are presented for each treatment option. We sought to assess the current performance of WFO to benchmark accuracy and identify areas for development. **Methods:** 20 de-identified cases were selected from the practices of two MSK thoracic medical oncologists. Patients presented for initial consultation regarding first-line systemic therapy during 2014 and all necessary information to make a treatment decision was available at the time of initial consultation or within two weeks, including molecular pathology. Cases were entered into WFO using structured attributes. WFO recommendations were compared to those of the MSK thoracic medical oncologist (MSKMD-REC). **Results:** WFO-REC and MSKMD-REC matched 50% of the time. 25% of the MSKMD-RECs appeared in the WFO-FC category and 25% in WFO-Not REC. In the 16 cases with metastatic lung cancers, 88% of administered regimens were returned as WFO-REC or WFO-FC. All choices were within established guidelines. Cases where the MSKMD-REC appeared as WFO-Not REC involved elderly patients with co-morbidities not yet included in WFO. **Conclusions:** While WFO's choices today fall within evidence-based standards, WFO has the capacity to provide greater precision through iterative training and development. Elderly patients for whom care choices are heterogeneous based on co-morbid illnesses represent a challenge. Benchmarking against actual cases has helped us to prioritize development work to increase the number of attributes to include more co-morbid conditions and to incorporate patient preferences to improve precision.

Electronic medical record as a research tool: Virtual clinical trial comparing pemetrexed and gemcitabine, both given with cisplatin, in patients with lung adenocarcinomas. *First Author: Alexander Grigorenko, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The electronic medical record (EMR) is a tremendous research resource, but its use for exploring hypotheses has been limited by an inability to reliably and efficiently identify patient cohorts. We have created a system that uses advanced computational techniques and Memorial Sloan Kettering's (MSK) EMR data to overcome these challenges. To validate our system, we sought to replicate a phase III clinical trial comparing cisplatin/pemetrexed (CP) to cisplatin/gemcitabine (CG) in patients with lung adenocarcinomas (Scagliotti J Clin Oncol 2008). **Methods:** We created a system that can identify a patient cohort by extracting structured cancer and outcomes data from the EMR, algorithmically identifying chemotherapy regimens, and using natural language processing to extract functional and smoking status from physician notes. Using the earlier clinical trial's eligibility criteria, we identified a patient cohort and analyzed survival on an intent-to-treat basis. Our analysis relied on the extensive data warehouse of MSK's EMR information, which contains data on the care of over a million patients since 1989. **Results:** Our system successfully extracted structured data, and accurately categorized treatment regimens (F-measure = 0.985), functional status (F-measure = 0.998), and smoking status (F-measure = 0.993). 281 patients were automatically identified as eligible. The median overall survival (OS) of patients with lung adenocarcinomas receiving CP and CG was 14.7 and 12.6 months with a hazard ratio (HR) of 0.69 (95% CI: 0.52 - 0.90) favoring CP. These results are similar to those of the prospective trial (Table). **Conclusions:** Our system replicated the results of a prospective clinical trial. Highly-accurate computational tools to extract structured and textual data from the EMR are feasible and can help address pending clinical research questions. Future steps will focus on expanding data extraction capabilities to support a broader range of hypotheses within the EMR.

Metric	Virtual Trial	Clinical Trial
OS (months; CP, CG; % difference)	14.7, 12.6; 15.4%	12.6, 10.9; 14.5%
HR (95% CI)	0.69 (0.52 - 0.90)	0.81 (0.70 - 0.94)

8025 Poster Session (Board #347), Mon, 8:00 AM-11:30 AM

First-line monotherapy with nivolumab (NIVO; anti-programmed death-1 [PD-1]) in advanced non-small cell lung cancer (NSCLC): Safety, efficacy and correlation of outcomes with PD-1 ligand (PD-L1) expression. *First Author: Scott N. Gettinger, Yale Cancer Center, New Haven, CT*

Background: NIVO, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, has demonstrated durable responses and tolerability in heavily pretreated patients (pts) with advanced NSCLC. This phase I study evaluated the efficacy and safety of NIVO monotherapy in pts with chemotherapy naïve advanced NSCLC. **Methods:** Pts (N=52) with squamous (SQ) or non-SQ advanced NSCLC received NIVO 3 mg/kg IV Q2W until progression or unacceptable toxicity (post-progression treatment was permitted per protocol). Response (RECIST v1.1) was evaluated overall, by histology and by tumor PD-L1 expression (PD-L1$^+$: ≥5% tumor cells expressing PD-L1). **Results:** Objective response rate (ORR) was 21%, with 3 confirmed complete responses; 9/11 responders (82%) achieved response by first scan (wk 11). Median duration of response (mDOR) was not reached (NR; range, 7.6+, 85.6+ wks); 9 pts (82%) had ongoing responses at last tumor assessment, with a minimum follow-up of 8 mos in all pts. Two pts had unconventional immune-pattern responses with 35% and 43% maximum reductions in target lesions, respectively, and simultaneous appearance of new lesions (not reported as responders). Median overall survival (mOS) was 98.3 wks (range, 1.0, 104.4+). Objective responses were observed in both PD-L1$^+$ and PD-L1$^-$ pts, with ORR higher in pts with PD-L1$^+$tumors. Eight pts (15%) experienced grade 3–4 treatment-related adverse events, including rash (n=2), increased amylase/lipase, increased AST/ALT, hyperglycemia, cardiac failure, lung infection, and pneumonitis (n=1 each). **Conclusions:** First-line NIVO demonstrated durable responses, encouraging survival and a tolerable safety profile in pts with advanced NSCLC. Although response rates were higher in PD-L1$^+$ pts, OS was encouraging in both PD-L1$^+$ and PD-L1$^-$ pts. Updated OS and safety data will be presented. Clinical trial information: NCT01454102.

	ORR	mDOR	mOS
	n/N (%)	wks (range)	
All pts	**11/52 (21)**	**NR (7.6+, 85.6+)**	**98.3 (1.0, 104.4+)**

8026 Poster Session (Board #348), Mon, 8:00 AM-11:30 AM

Optimizing PD-L1 as a biomarker of response with pembrolizumab (pembro; MK-3475) as first-line therapy for PD-L1–positive metastatic non-small cell lung cancer (NSCLC): Updated data from KEYNOTE-001. *First Author: Naiyer A. Rizvi, Columbia University Medical Center, New York, NY*

Background: Platinum doublets provide 6-mo PFS and 12-mo OS for treatment-naive, metastatic NSCLC without driver mutations. Preliminary data from KEYNOTE-001 revealed robust antitumor activity and manageable toxicity for the anti–PD-1 antibody pembro in treatment-naive NSCLC. In these patients (pts), PD-L1 positivity correlated with improved ORR, PFS, and OS. We explored the relationship between PD-L1 expression levels and efficacy in treatment-naive pts in KEYNOTE-001. **Methods:** 101 treatment-naive, PD-L1$^+$ metastatic NSCLC pts were randomized 1:1 to pembro 10 mg/kg Q2W or Q3W (11 pts randomized to 2 or 10 mg/kg Q3W). Pembro was given until unacceptable toxicity, PD, or pt/investigator decision. PD-L1 expression was assessed by IHC (22C3 antibody). Staining of tumor cells or stroma by a prototype assay was used for enrollment. In a prospectively defined validation set (n = 90), the percentage of PD-L1–stained tumor cells was determined with a clinical trial assay. Response was assessed centrally every 9 wk by RECIST 1.1. **Results:** There were no significant between-dose differences in ORR, PFS, or OS; 11% of pts experienced gr 3-5 drug-related AEs. In the validation set (38-wk median follow-up), ORR and DCR were highest and PFS was longest in pts with ≥50% PD-L1 tumor cell staining (Table); there was a trend toward longer OS (immature data). **Conclusions:** Pembro demonstrateddurable antitumor activity and manageable toxicity profile as first-line therapy for PD-L1$^+$ metastatic NSCLC, with the greatest efficacy observed in pts with PD-L1 staining in ≥50% of tumor cells. These data demonstrate that PD-L1 expression in tumor cells identifies those NSCLC pts most likely to respond to pembro. The efficacy and safety of pembro as first-line therapy for PD-L1$^+$NSCLC is being examined in ongoing, controlled clinical trials. Clinical trial information: NCT01295827.

Phase II studies of nivolumab (anti-PD-1, BMS-936558, ONO-4538) in patients with advanced squamous (sq) or nonsquamous (non-sq) non-small cell lung cancer (NSCLC). *First Author: Makoto Nishio, Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Nivolumab, a fully human IgG4, PD-1 immune-checkpoint inhibitor antibody, has shown durable clinical activity in phase I and II trials in several tumor types. Recently, a phase III study (CheckMate -017) demonstrated that nivolumab improved overall survival than docetaxel in second-line of sq NSCLC. Here, we report the results of two phase II studies to evaluate the efficacy and safety of nivolumab in previously treated advanced sq (JapicCTI-No.132072) and non-sq (JapicCTI-No.132073) NSCLC pts. **Methods:** Both studies require pts aged ≥ 20 years with ECOG status of 0 or 1, stage IIIB/IV, or recurrent NSCLC and at least one prior chemotherapy including platinum containing regimen.Pts received nivolumab 3 mg/kg IV Q2W until progression or unacceptable toxicity.The primary endpoint in both studies was the objective response rate (ORR) (RECIST v1.1).Planned sample size was 30 pts for Sq and 67 pts for Non-sq, respectively(P0=0.09, P1=0.26 , P0=0.09, P1=0.20 ; α=0.025 (one-side) , 1-β=0.8). **Results:** From April 2013 to April 2014, a total of 111 NSCLC pts were enrolled into two studies (35 pts with sq,76 pts with non-sq, male/female: 81/30; PS 0/1: 46/55; aged 31 to 84 [median: 65.0] years; Stage IIIB/Stage IV/recurrence: 6/86/19)Grade 3-4 drug related adverse events (G3AEs) were observed in 16.2 % (18/111) pts. Most common G3AEs were lymphocyte count decreased 3.6 % (4/111), hyponatremia 1.8 % (2/111), interstitial lung disease 1.8 % (2/111), pleural effusion 1.8 % (2/111). Any grade of Interstitial lung disease was observed in 4.5 % (5/111) pts. No grade 5 AEs were observed.Efficacy data were shown in table 1. Median follow-up was 10.4 months and 8.4 months, respectively. **Conclusions:** Nivolumab continues to demonstrate encouraging clinical efficacy in both sq and non-sq NSCLC with a manageable safety profile. Clinical trial information: 132072 and 132073.

8028 Poster Session (Board #350), Mon, 8:00 AM-11:30 AM

Clinical activity and safety from a phase II study (FIR) of MPDL3280A (anti-PDL1) in PD-L1–selected patients with non-small cell lung cancer (NSCLC). *First Author: David R. Spigel, Sarah Cannon Research Institute, Nashville, TN*

Background: MPDL3280A (anti-PDL1) has shown activity across a number of tumor types. In FIR, we assessed the efficacy of MPDL3280A in NSCLC pts based on PD-L1 expression. **Methods:** FIR is a single arm study of MPDL3280A in stage IIIB/IV NSCLC. Cohort 1 included chemo-naive pts, cohort 2 included ≥ 2L pts without brain metastases and cohort 3 included ≥ 2L pts with treated asymptomatic brain metastases. Pts received 1200 mg MPDL3280A IV q3w (last pt entered Jun 27, 2014). Here, we report investigator-assessed ORR per RECIST v1.1 (data cutoff Oct 23, 2014). PD-L1 expression was centrally assayed by an SP142 IHC antibody in archival or fresh tumor biopsies (required for cohorts 2 and 3) and scored as IC 0, 1, 2 or 3 and TC 0, 1, 2 or 3. Pts with PD-L1 TC 2/3 and/or IC 2/3 tumors were enrolled. **Results:** Of 1,009 pts screened, 205 pts were selected based on tumor PD-L1 status. Of the 138 pts that were enrolled, 137 pts were safety-evaluable. The median age was 66 y (range, 42-85 y) and 58% of pts were male. The AE profile was similar across cohorts. Treatment-related AEs occurred in 67% of pts, most often fatigue (26%), nausea (15%) and decreased appetite (14%). Related Grade 3-4 AEs occurred in 15% of pts, with one related death due to constrictive pericarditis. 114 pts were efficacy-evaluable with ≥ 3-mo follow up in cohort 1 and ≥ 6-mo follow up in cohorts 2 and 3. The highest ORR was seen in pts with PD-L1 TC3 or IC3 tumors (Table). The median DOR has not been reached in cohorts 1 and 2 (Table). **Conclusions:** MPDL3280A showed clinical efficacy in both chemo-naive and previously treated NSCLC. High PD-L1 expression (TC3 or IC3) was associated with a higher ORR. The safety profile of MPDL3280A in pts with NSCLC was consistent with previous reports. (NCT01846416) Clinical trial information: NCT01846416.

Efficacy results.

8029 Poster Session (Board #351), Mon, 8:00 AM-11:30 AM

Clinical activity, safety and predictive biomarkers of the engineered antibody MPDL3280A (anti-PDL1) in non-small cell lung cancer (NSCLC): update from a phase Ia study. *First Author: Leora Horn, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: NSCLC exhibits mutational complexity, which is associated with increased tumor immunogenicity. PD-L1 expression in the tumor microenvironment can inhibit antitumor immunity. MPDL3280A blocks PD-L1 and can restore tumor-specific T-cell immunity. **Methods:** In this dose-escalation and -expansion study, pts with NSCLC were enrolled from Oct 25, 2011 to Sep 24, 2013 and received MPDL3280A IV ≤ 20 mg/kg q3w (data cutoff Sep 2, 2014). ORRs were assessed by RECIST v1.1. PD-L1 expression on tumor-infiltrating immune cells (ICs) and tumor cells (TCs) was centrally evaluated by an IHC assay based on the SP142 antibody with pts scored as IC 0, 1, 2 or 3 and TC 0, 1, 2 or 3. **Results:** 88 NSCLC pts were safety- and efficacy-evaluable: 57% of pts were male, 28% were ECOG PS 0 and 72% were ECOG PS 1. The median age was 61 y (range, 24-84 y), and the majority of pts had 3 lines of therapy. Pts received MPDL3280A for a median duration of 15 wks (range, 0-129 wks). Treatment-related all grade AEs occurred in 73% of pts, most often fatigue (21%), nausea (15%) and decreased appetite (14%). 11% of pts had a related G3-4 AE, most often dyspnea, hypoxia, fatigue and hyponatremia (2% each). One related G5 AE due to cardio-respiratory arrest was seen. ORRs, DOR, PFS and OS were assessed by PD-L1 status (Table). Of note, pts with PD-L1 expression of TC3 or IC3 (n = 20) had an ORR of 45% (95% CI, 23-68%) vs 14% (95% CI, 6-25%) for pts with PD-L1 expression of TC 0/1/2 and IC 0/1/2 (n = 58). **Conclusions:** PD-L1 expression in the tumor microenvironment appeared to be a predictive biomarker for MPDL3280A clinical benefit with median OS not yet reached. Treatment with MPDL3280A was generally well tolerated. Phase III trials are ongoing. Clinical trial information: NCT01375842.

Safety and efficacy of MPDL3280A (anti-PDL1) in combination with platinum-based doublet chemotherapy in patients with advanced non-small cell lung cancer (NSCLC). *First Author: Stephen V. Liu, Georgetown Univ Hosp, Washington, DC*

Background: MPDL3280A, which preserves the PD-L2/PD-1 interaction to potentially diminish autoimmune lung toxicity, has promising activity in advanced NSCLC. Platinum-based doublet chemotherapy (chemo) remains standard first-line (1L) treatment for NSCLC with ORRs historically of ≈ 30%. Preclinical data show that chemo may prompt tumor antigen release and enhance MPDL3280A activity. Thus, we studied MPDL3280A + chemo in untreated NSCLC pts. **Methods:** This Ph Ib study evaluated MPDL3280A combined with carboplatin + either paclitaxel (Arm C), pemetrexed (Arm D) or weekly nab-paclitaxel (Arm E) in pts with chemona-ive locally advanced or metastatic NSCLC. Pts received MPDL3280A 15 mg/kg IV q3w with standard chemo dosing for 4-6 cycles followed by MPDL3280A maintenance therapy until progression. Unconfirmed ORRs were assessed by RECIST v1.1 in pts dosed by Jun 29, 2014 (data cutoff Sep 29, 2014). PD-L1 expression was centrally assayed using the SP142 IHC antibody. **Results:** 37 pts were safety evaluable (Arm C, 8; Arm D, 14; Arm E, 15). Across arms, 54% of pts were male, median age was 65 y (range, 40-82 y), 81% had non-squamous and 19% had squamous NSCLC. Median follow-up for safety was 154 d (range, 1-346 d). The most frequent all-grade AEs regardless of attribution across arms included those commonly associated with chemo, such as nausea (Arms C & D, 50%; Arm E, 73%), fatigue (Arm C, 38%; Arm D, 36%; Arm E, 73%) and constipation (Arm C, 25%; Arm D, 71%; Arm E, 27%). The most common MPDL3280A-related G3-4 AEs included anemia (Arms D & E, 7%), neutropenia (Arm C, 13%; Arm D, 7%) and thrombocytopenia (Arms D & E, 7%). No pneumonitis was seen. One MPDL3280A-related G5 AE due to candidemia after prolonged neutropenia was seen in Arm D. 30 pts were efficacy evaluable (Arm C, 5; Arm D, 12; Arm E, 13). Across all arms, the ORR (95% CI) was 67% (48%-82%): 60% (19%-92%) in Arm C (3 PRs), 75% (45%-93%) in Arm D (9 PRs) and 62% (33%-83%) in Arm E (6 PRs & 2 CRs). Responses were seen in each arm independent of PD-L1 expression. **Conclusions:** MPDL3280A + standard 1L chemo was well tolerated with no unexpected toxicities, showing promising clinical activity in advanced NSCLC pts. Ph III studies are ongoing. Clinical trial information: NCT01633970.

8031 Poster Session (Board #353), Mon, 8:00 AM-11:30 AM

Pembrolizumab (pembro; MK-3475) plus platinum doublet chemotherapy (PDC) as front-line therapy for advanced non-small cell lung cancer (NSCLC): KEYNOTE-021 Cohorts A and C. *First Author: Vassiliki Papadimitrakopoulou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: As monotherapy, the anti–PD-1 antibody pembro has shown robust antitumor activity in advanced NSCLC patients (pts). KEYNOTE-021 evaluated the safety, tolerability, and clinical activity of pembro + PDC for treatment-naive advanced NSCLC. **Methods:** Pts with stage IIIB/IV NSCLC and no prior systemic therapy were randomized 1:1 to pembro 2 or 10 mg/kg Q3W plus carboplatin AUC 6 + paclitaxel 200 mg/m^2 (cohort A; any histology) or carboplatin AUC 5 + pemetrexed 500 mg/m^2 (cohort C; nonsquamous without *EGFR* sensitizing mutation or *ALK* translocation only). Pts received pembro + PDC for 4 cycles followed by pembro maintenance in A and pembro + pemetrexed in C. The dose-limiting toxicity (DLT) observation window was the first 3 wk after initial dosing. Key eligibility criteria included ECOG PS 0-1, measurable disease, and adequate tumor sample for PD-L1 assessment. Response was assessed every 6 wk until confirmed progression (RECIST v1.1, investigator review). **Results:** As of Dec 2014, 44 pts (20 in cohort A and 24 in cohort C) were treated. One DLT was reported (hospitalization for gr 3 rash, C [pembro 10 mg/kg]). Gr 3-4 treatment-related AE rate was 27% (15% in A, 38% in C); AEs were reversible transaminase elevation (n = 3 in C), anemia (n = 1 in A, 2 in C), rash (n = 1 in A, 1 in C), and colitis (n = 2 in C); no gr 3-4 febrile neutropenia was observed. One patient in C discontinued due to treatment-related gr 3 rash. No treatment-related deaths have occurred. Preliminary ORR (confirmed and unconfirmed) is 30% in A and 58% in C (Table). At the time of analysis, 16 pts in A and 21 pts in C remained on treatment. **Conclusions:** These data suggest that pembro + PDC has a reasonable safety profile and provides antitumor activity as front-line therapy for stage IIIB/IV NSCLC. Based on the promising ORR observed for pembro + carboplatin and pemetrexed, this combination is being evaluated in a larger cohort. Clinical trial information: NCT02039674.

8032 Poster Session (Board #354), Mon, 8:00 AM-11:30 AM

Safety and clinical activity of MEDI4736, an anti-programmed cell death-ligand 1 (PD-L1) antibody, in patients with non-small cell lung cancer (NSCLC). *First Author: Naiyer A. Rizvi, Columbia University Medical Center, New York, NY*

Background: MEDI4736 (M) is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity. PD-L1 is expressed in NSCLC tumors and may be associated with response to anti-PD-L1 treatment. This ongoing Phase 1/2, multicenter, open-label study (NCT01693562) evaluates the safety and clinical activity of M in patients (pts) with multiple solid tumor types including NSCLC. **Methods:** M is administered at 10 mg/kg IV every 2 wks (q2w) until unacceptable toxicity, disease progression, or for up to 12 months. Safety evaluations occur prior to each dose (toxicities graded by CTCAE v4.0). Response is based on investigator assessment (RECIST v1.1; includes confirmed/unconfirmed responses) at 6, 12, and 16 wks, then every 8 wks. Retreatment is permitted upon progression after 12 months of therapy. PD-L1 expression within the tumor is assessed using Ventana PD-L1 IHC (SP263). Data included represent a larger population with more mature follow up than previously reported.[1] **Results:** As of 31 Oct 2014, 198 pts (116 non-squamous and 82 squamous histology; mean age 64 [range 26–87]; ECOG PS 0 [24%] or 1 [76%]; 81% current/prior smokers; median 2.5 prior treatments [1–9]) have been treated with M 10 mg/kg q2w (median 6 doses; range 1–23). Drug-related AEs were reported in 48% of pts; most frequently fatigue (14%), decreased appetite (9%), and nausea (8%). Grade ≥ 3 drug-related AEs were reported in 6% of pts. Drug-related AEs led to study discontinuation in 2% of pts. Pneumonitis (Grade 1-2) occurred in 2 (1%) pts. In all, 149 pts were evaluable for response with ≥ 24 wks of follow-up; ORR was 14% (23% in PD-L1+), and DCR at 24 wks was 24%. ORR was higher in squamous (21%) than non-squamous pts (10%). Responses were durable with 76% ongoing (DoR range 0.1+ – 35+ wks). **Conclusions:** With more mature follow up, the safety profile of M in NSCLC is manageable and consistent with previous reports. Responses are durable; ORR appears to be higher in squamous NSCLC and PD-L1+ pts. A broad development program of M alone and in combination with other treatments is underway in NSCLC. Antonia S, et al. Poster presented at ESMO 2014, 1325P Clinical trial information: NCT01693562.

8033 Poster Session (Board #355), Mon, 8:00 AM-11:30 AM

Development of a PD-L1 companion diagnostic assay for treatment with MEDI4736 in NSCLC and SCCHN patients. *First Author: Marlon Rebelatto, MedImmune, Gaithersburg, MD*

Background: A high quality PD-L1 companion diagnostic may help predict which patients are more likely to respond to PD-1/PD-L1 antibody-based therapy. Here we describe a PD-L1 immunohistochemical (IHC) diagnostic test developed by Ventana Medical Systems for use with MEDI4736. **Methods:** An anti-human PD-L1 rabbit monoclonal antibody (SP263) was optimized for use with Ventana OptiView DAB IHC Detection Kit on the automated BenchMark ULTRA platform. The PD-L1 IHC assay was validated for use in formalin-fixed, paraffin-embedded samples of NSCLC and SCCHN in a series of studies addressing sensitivity, specificity, robustness, and precision. MEDI4736 is a human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80 with high affinity and selectivity. A subset of clinical trial samples from a Phase 1/2 study of MEDI4736 (NCT01693562) was analyzed to determine optimal cut-off for enriching response to MEDI4736. Inter-reader precision was established by 3 pathologists who evaluated 81 NSCLC and 100 SCCHN samples across the range of expression levels. **Results:** The Ventana PD-L1 IHC (SP263) assay met all pre-defined acceptance criteria. The scoring algorithm was defined using statistical analysis of clinical response data and PD-L1 staining parameters observed in a set of NCT01693562 clinical trial samples. Samples of both cancer types are considered test positive when the membrane of ≥ 25% of tumor cells stain for PD-L1 at any intensity. Inter-reader precision in determining PD-L1 status resulted in an overall percentage agreement of 97% and 92% for NSCLC and SCCHN, respectively. For both NSCLC and SCCHN, PD-L1+ patients identified by the scoring algorithm had a higher response rate than PD-L1- patients. **Conclusions:** These results highlight the robustness and reproducibility of the PD-L1 IHC (SP263) assay in a clinical setting. In NSCLC and SCCHN patients treated with MEDI4736, PD-L1+ patients identified by the scoring algorithm had a higher response rate than PD-L1- patients. The clinical utility of the PD-L1 diagnostic assay will be further validated in a prospective manner using additional patients in this study and in other MEDI4736 studies. Clinical trial information: NCT01693562.

8034 Poster Session (Board #356), Mon, 8:00 AM-11:30 AM

Avelumab (MSB0010718C), an anti-PD-L1 antibody, in advanced NSCLC patients: A phase 1b, open-label expansion trial in patients progressing after platinum-based chemotherapy. *First Author: James L. Gulley, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against cancer. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody being investigated in clinical trials. We report safety and clinical activity in patients (pts) with advanced NSCLC progressing after platinum-based chemotherapy (NCT01772004). **Methods**: Pts were treated with avelumab at 10 mg/kg Q2W until progression, confirmed complete response (CR), or toxicity. A prespecified analysis of 184 pts with ≥ 3 months follow-up (range 3-13) was performed. Tumors were assessed every 6 weeks (w) (RECIST 1.1) and unconfirmed best overall response (BOR) was evaluated. Tumor PD-L1 expression was assessed by immunohistochemistry. **Results**: Median age was 65y (range 31-83) and ECOG PS was 0 (30%) or 1 (70%). Histology was adenocarcinoma (62%), squamous cell carcinoma (29%), or other (9%). Any grade drug-related treatment-emergent adverse events (TEAEs) occurred in 139 (75.5%) pts; the most common (> 5%) were fatigue, nausea, infusion-related reactions (IRRs), chills, decreased appetite, and diarrhea. Drug-related grade ≥ 3 TEAEs occurred in 22 (12%) pts, including 4 IRRs. Drug-related deaths were reported (n = 3; radiation pneumonitis, acute respiratory failure, and disease progression). Objective responses (OR) were observed in 22 (12%) pts (95% CI: 7.6, 17.5; 1 CR, 21 partial responses; 18 were ongoing at data cutoff). BOR of stable disease was observed in 70 pts (38%). Median progression-free survival (PFS) was 11.6 w (95% CI: 8.4, 12.1) and the PFS rate at 24 w was 25.4% (95% CI: 18.3, 33.2). Tumors were PD-L1(+) in 86% of evaluable pts (1% cutoff). The ORR in PD-L1(+) pts (n = 118) was 14.4% and 10.0% in PD-L1(-) pts (n = 20). Median PFS in PD-L1(+) pts was 11.7 w vs 5.9 w in PD-L1(-) pts. **Conclusions**: In pts with previously treated NSCLC, avelumab was administered safely with a toxicity profile similar to other anti-PD-1/anti-PD-L1 agents. A trend of greater activity in pts with PD-L1(+) tumors was observed. A randomized phase 3 trial of avelumab in pts with advanced NSCLC is planned. *Proposed INN. Clinical trial information: NCT01772004.

8035 Poster Session (Board #357), Mon, 8:00 AM-11:30 AM

Activity and safety of pembrolizumab in patients with metastatic non-small cell lung cancer with untreated brain metastases. *First Author: Sarah B. Goldberg, Yale Cancer Center, New Haven, CT*

Background: Brain metastases (BrMs) are common among patients (pts) with advanced non-small cell lung cancer (NSCLC) and local therapy such as surgery and radiation can add toxicity and delay systemic treatment. Pembrolizumab is a monoclonal anti-programmed death 1 (PD-1) antibody that relieves inhibition of anti-tumor immunity. In a Phase I trial of pembrolizumab, pts with advanced NSCLC showed a 21% response rate with good tolerability and durable responses, however pts were required to have local therapy to BrMs prior to enrollment. This trial aims to determine the activity and safety of pembrolizumab in patients with advanced NSCLC and untreated BrMs. **Methods:** This is a Phase II trial with 2 independent arms: one for pts with advanced NSCLC (reported here) and the other for pts with metastatic melanoma (NCT02085070). Pts are eligible if they have ≥ 1 BrM that is previously untreated or progressing after prior local therapy. BrMs must be between 5mm and 20mm, asymptomatic, and not requiring immediate local therapy or corticosteroids. Tumor biopsy demonstrating PD-Ligand 1 (PD-L1) expression is required. Pts are treated with pembrolizumab 10mg/kg intravenously every 2 weeks. Extra-cerebral response is determined by RECIST 1.1, and BrM response is determined by modified RECIST (mRECIST), in which brain lesions ≥ 5mm are considered measurable and up to 5 target lesions are allowed. The primary endpoint is BrM response rate (RR) by mRECIST. **Results:** Ten NSCLC pts were accrued between April and December 2014, 9 of whom were evaluable for response. BrM RR was 44% (4/9 partial responses, 2 unconfirmed due to limited follow-up time); 34% (3/9) had progressive disease (PD) as their best BrM response, and 22% were unevaluable in the brain due to rapid systemic progression. Systemic RR was 34% (3/9, 1 unconfirmed); only 1 pt who responded systemically had PD in the brain. There were no grade ≥ 3 adverse events that were considered treatment-related or attributed to BrMs. **Conclusions:** Pembrolizumab shows promising clinical activity in patients with NSCLC and untreated BrMs with a favorable safety profile. Recruitment for this Phase II trial and correlative analysis from tumor tissue is ongoing. Clinical trial information: NCT02085070.

8036 Poster Session (Board #358), Mon, 8:00 AM-11:30 AM

Validation of ERCC1 (E1) for response prediction to platinum-gemcitabine. *First Author: Gerold Bepler, Karmanos Cancer Institute, Detroit, MI*

Background: E1 had been suggested as a predictive marker for platinum drugs. However, it has 4 different isoforms with differential DNA repair functions, antibodies used for quantitation lack specificity, and a phase 3 trial designed to validate E1's predictive power failed to demonstrate the anticipated benefit (trial A). We investigated the interaction of E1 mRNA levels with therapeutic benefit from various therapeutic doublets in pts with advanced NSCLC. **Methods:** FFPE specimens from trial A were microdissected; RNA was extracted, and analyzed for E1 levels using commercially validated primers and probes. Median and optimized cut-offs were investigated for interaction of E1 levels with survival and validated using a second randomized phase 3 trial (trial B, Ann Oncol 25: 2147–55, 2014). **Results:** E1 expression analysis on 84 pts in trial A, 38 treated with PG and 46 with other doublets, showed a significant ($p = 0.044$), inverse association between E1 mRNA levels and disease response in pts treated with PG; i.e., the higher the E1 levels the worse the tumor response. An analysis for treatment interaction (PG vs others) using the optimized E1 cut-off level of 1.44 showed E1 was highly predictive of OS and PFS in pts on PG, with high levels predicting short survival (Cox model interaction $p = 0.002$ for OS and 0.003 for PFS). Using the median E1 level of 1.73, the interaction p-value was 0.028. E1 levels were not associated with histology, sex, age, and smoking status. Specimens from 86 pts in trial B yielded sufficient RNA for a successful E1 analysis. 19 pts had been treated with PG, 55 with P-docetaxel, and 12 with docetaxel. E1 values were similar to those in trial A. Using the optimized E1 cut-off level of 1.44 from trial A, we found a log-rank p-value of 0.029 for PFS, with high levels predicting short survival for pts treated with PG. A 2ndvalidation on pts treated with PG in Torino, Italy is in progress. We also attempted to develop an RTPCR assay specific for the E1-202 isoform. Despite optimized primer/probe designs and validation using in vitro samples, the majority of FFPE samples failed analysis. **Conclusions:** E1 mRNA levels, as determined by a commercially available and CLIA/CAP certified assay, are predictive of treatment benefit from PG in advanced NSCLC.

8037 Poster Session (Board #359), Mon, 8:00 AM-11:30 AM

Pre-treatment 5-methyltetrahydrofolate levels and response to pemetrexed in stage IV adenocarcinoma of the lung. *First Author: Stephen Joseph Bagley, University of Pennsylvania, Philadelphia, PA*

Background: The anti-folate drug pemetrexed (PMX) is used in treatment regimens for non-small cell lung cancer (NSCLC). Recent evidence suggests that differences in cellular folate metabolism may confer variation in tumor response to PMX. We investigated whether the pre-treatment intra-erythrocyte (RBC) level of 5-methyltetrahydrofolate (5-MTHF), a key component of folate metabolism, is associated with response to PMX-based chemotherapy in stage IV lung adenocarcinoma. **Methods:** We conducted a single-center, prospective cohort study of patients with newly diagnosed stage IV lung adenocarcinoma receiving first-line chemotherapy with a PMX-containing regimen. RBC 5-MTHF levels were quantified using a mass spectrometry-based method from blood drawn prior to initiation of chemotherapy. Clinical response was assessed by determining radiographic tumor response after 4-6 cycles of PMX-based chemotherapy and categorized as partial response, stable disease, or progression. We explored the relationship between pre-treatment RBC 5-MTHF levels and response to PMX-based chemotherapy. A log-binomial model was used to adjust for age and sex. **Results:** 54 patients were enrolled; the median age was 61 (IQR 55-68) and 29 (54%) were female. RBC 5-MTHF ranged from 37 to 1,667 nM (mean 588, median 518). Following 4-6 cycles of chemotherapy, 23 patients (43%) had an objective radiographic response and 15 (28%) had stable disease. The remaining 16 patients (29.6%) had progression (7 during cycles 1-3, 9 during cycles 4-6). Patients with 5-MTHF levels in the lowest quartile were significantly less likely to achieve radiographic response compared to patients in the highest three quartiles (response rate 8% vs. 54%; risk difference 0.46, 95% CI 0.25-0.67). After controlling for age and sex, there remained a significantly higher likelihood of lack of response to PMX for patients in the lowest 5-MTHF quartile (RR 6.86, 95% CI 1.01 – 46.92). **Conclusions:** Low pre-treatment RBC 5-MTHF levels are associated with an inferior response to PMX-based chemotherapy in stage IV lung adenocarcinoma. Multicenter prospective studies are needed to validate RBC 5-MTHF as a predictive marker of response to PMX in NSCLC.

8038 Poster Session (Board #360), Mon, 8:00 AM-11:30 AM

Smoking status to predict sensitivity to PARP inhibitor, veliparib, in patients with advanced NSCLC. *First Author: Suresh S. Ramalingam, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Tobacco-related non-small cell lung cancer (NSCLC) is associated with reduced survival and greater genomic instability. Veliparib (V) is a PARP inhibitor that augments platinum-induced DNA damage in preclinical studies, and a recent Ph 2 trial of advanced NSCLC trended to improved survival (HR 0.80; CI 0.54–1.18) when V was added to carboplatin (C) and paclitaxel (P). Here we report outcomes based on smoking status from a randomized Ph 2 study of CP with either V or placebo in advanced NSCLC. **Methods:** Patients (pts) with previously untreated advanced/metastatic NSCLC were randomized 2:1 to CP with either V at 120 mg BID or placebo (pre-specified stratification by histology and smoking history). Cotinine (COT) was measured in pt plasma samples as an index of recent tobacco use. **Results:** Of 158 pts, 68% were male, and 49% had squamous NSCLC. At study entry, 60% of pts were self-reported current smokers (CS), 27% former smokers, and 13% never smoked. There were no significant differences in V PK parameters between the COT-high and low pts.Most common AE in CS were neutropenia (41% VCP; 27% CP), alopecia (36%; 33%), and anemia (31%; 40%). G3/4 AEs were elevated in CS treated with VCP vs CP (66% vs. 40%, p=0.026); all-grade AEs and SAEs were similar between the two groups. In a COT sensitivity analysis of OS, HR VCP/CP for COT-high was 0.52 (0.29–0.92) and COT-low was 1.07 (0.63–1.81). **Conclusions:** Smoking status was a strong predictor of efficacy for veliparib-chemotherapy combination in advanced NSCLC. No differences in PK of V were seen based on plasma COT; toxicity of VCP was acceptable regardless of smoking history. A Ph 3 study has been initiated in pts with smoking history. Clinical trial information: NCT01560104.

8039 Poster Session (Board #361), Mon, 8:00 AM-11:30 AM

An open-label, randomized, multicenter, phase III study of S-1 and cisplatin versus docetaxel and cisplatin in patients with untreated advanced non-small-cell lung cancer. *First Author: Jianxing He, The First Affiliated Hospital of Guangzhou Medical College, Guangzhou,Guangdong Province, China*

Background: Platinum-based doublet chemotherapy is the standard chemotherapy regimen for treatment-naïve advanced Non-Small-Cell Lung Cancer (NSCLC). S-1, an oral fluoropyrimidine, combined with carboplatin or cisplatin (CDDP) has shown no less efficacy than standard platinum doublet chemotherapy in Japanese NSCLC patients. However, the effectiveness in Chinese NSCLC patients is uncertain. We aimed to compare the efficacy and safety of these chemotherapy regimens in Chinese NSCLC patients. **Methods:** In this study, we recruited patients aged 18-70 years with stage IIIB, IV or recurrence, histologically or cytologically confirmed NSCLC, ECOG performance status of 0-1, have at least one measurable lesion, and adequate organ function. Patients were randomized in 1:1 ratio to receive either S-1 (80–120 mg/day, PO, BID, days 1 to 21) with 60 mg/m^2 CDDP on day 8 every 5 weeks (SP) or docetaxel and CDDP (both 75 mg/m^2) on day 1 every 3 weeks (DP), for up to 6 cycles. The primary endpoint was progression-free survival (PFS) and all CT scans were extramurally reviewed by Independent Review Committee (IRC). Non-inferiority study design was employed as upper confidence interval (CI) limit for hazard ratio (HR) < 1.33. **Results:** Between March 2011 and November 2012, 246 patients from 21 institutions in China were randomly assigned and received SP or DP treatment (124 vs 122) with 18-month follow-up period from the last patient randomized. In the SP and DP group, median PFS was 5.9 and 5.7 months (HR = 0.68; 95% CI, 0.48 to 0.96) respectively, median overall survival was 19.1 and 14.8 months, respectively (HR = 0.84; 95% CI, 0.61 to 1.14). The most common grade 3 or worse adverse events in both treatment groups were neutropenia 3.3% vs 55.1%, leukopenia 1.7% vs 39.0%, and febrile neutropenia 0.8% vs 5.9%, of 121 patients in the SP group and of 118 patients in the DP group, respectively. **Conclusions:** The efficacy of SP was non-inferior to DP. Well-tolerated safety could be provided by SP regimen. SP would be a new first-line chemotherapy regimen for Chinese patients with advanced NSCLC. Clinical trial information: Japic CTI-111479.

8040 Poster Session (Board #362), Mon, 8:00 AM-11:30 AM

SWOG 0709: A randomized phase II "pick-the-winner" trial of erlotinib (ERL) vs. ERL plus carboplatin/paclitaxel (C/T) in patients (pts) with advanced non-small cell lung cancer (NSCLC) and impaired performance status (PS 2) as selected by serum proteomics. *First Author: Primo Lara, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Advanced NSCLC pts with Zubrod PS2 are often excluded from clinical trials and platinum-based therapy. In SWOG 0341, ERL in PS 2 pts yielded progression-free (PFS) and overall survival (OS) of 2.1 and 5 months respectively. In a trial of ERL versus C/T in PS2 pts (Lilenbaum, JCO 2008), PFS for ERL and C/T were 1.9 and 3.5 months. Early reports suggested a potential role for serum proteomics in predicting ERL benefit beyond that of EGFR mutational status. We conducted a trial in PS2 pts enriched by serum proteomics (Veristrat-good). **Methods:** NSCLC pts with PS2 and Veristrat-good status were randomized to either Arm A (ERL 150 mg po QD) or Arm B (ERL 150 mg po QD d2-16 + carbo AUC 5 IV day 1, paclitaxel 200 mg/m2 IV d1 x 4 cycles, then ERL 150 mg QD). Cycles were q3 weeks. Arm B agents were pharmacodynamically separated to mitigate potential antagonism. The arm with superior observed median PFS would be selected for further evaluation, but only if ≥ 3 months. A sample size of 98 pts was based on a variety of assumed PFS probabilities for each arm. The trial prematurely closed after the FDA determined an IDE application was required for VeriStrat; however SWOG had limited resources available for such filing. **Results:** Of 156 pts screened, 83 (59%) were Veristrat-good, of which 59 (60%) met trial eligibility & were randomized. Treatment-related grade 4 adverse events were seen in 2 pts in Arm A (DVT, hypoMg+); 5 pts in Arm B (neutropenia 5, febrile neutropenia 1, leukopenia 1). **Conclusions:** In PS2 pts with advanced NSCLC and Veristrat-good status, ERL + C/T (vs. ERL alone) had better observed median PFS/OS and surpassed the protocol-specified benchmark of PFS >= 3 months required for further study. Clinical trial information: NCT00661193.

8041 Poster Session (Board #364), Mon, 8:00 AM-11:30 AM

A randomized Phase 3 study comparing first-line pemetrexed plus cisplatin followed by gefitinib maintenance (PC/G) with gefitinib monotherapy (G) in East Asian patients (pts) with locally advanced or metastatic nonsquamous non-small cell lung cancer (nSqNSCLC): Final survival results. *First Author: James Chih-Hsin Yang, Department of Oncology, National Taiwan University Hospital; Graduate Institute of Oncology & Cancer Research Center, National Taiwan University, Taipei, Taiwan*

Background: The primary analysis of this open-label, randomized, multicenter study found no significant difference in progression-free survival (PFS) between PC/G and G in pts with nSqNSCLC and unknown epidermal growth factor receptor (EGFR) mutation status, although the unadjusted hazard ratio (HR, PC/G vs G) favored PC/G (0.85, 95% CI: 0.63–1.13). Final overall survival (OS) data are reported here. **Methods:** Eligible pts were chemonaïve, East Asian light ex-smokers/never-smokers aged ≥18 years with advanced nSqNSCLC, ECOG PS 0/1 and unknown EGFR mutation status. Pts (N = 236) were randomized (1:1) to PC/G (pemetrexed 500 mg/m^2 + cisplatin 75 mg/m^2 for six 21-day cycles then gefitinib 250 mg/day) or G (gefitinib 250 mg/day). EGFR mutation status was determined for 76 pts; 52 (68.4%) had mutations. OS was analyzed (intent-to-treat population) by unadjusted Cox regression analysis. **Results:** Baseline characteristics were similar between groups (both N = 118). Median OS was similar in the PC/G and G groups in the overall population, but longer in the G group in the subgroups with EGFR mutations (EGFR-mutated, Ex19del, L858R; Table). Postdiscontinuation therapy (PC/G: 60.2%; G: 72.0%) included chemotherapy (PC/G: 34.7%; G: 61.9%) and rechallenge with an EGFR tyrosine kinase inhibitor (PC/G: 22.9%; G: 7.6%). **Conclusions:** There was no significant difference in OS between PC/G and G in the overall population. As reported for PFS, there appeared to be better outcomes with G in the EGFR mutation subgroups (especially Ex19del) and with PC/G in the EGFR wild-type subgroup. Clinical trial information: NCT01017874.

8042 Poster Session (Board #365), Mon, 8:00 AM-11:30 AM

Intercalating and maintenance use of gefitinib plus chemotherapy versus chemotherapy alone in selected advanced NSCLC(ISCAN,CTONG-1102): A multicentre, open-label, randomised, phase 3 study. *First Author: Shun Lu, Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: This study investigated whether intercalating and maintenance use of gefitinib and chemotherapy improves clinical outcomes versus chemotherapy alone in selected patients with advanced NSCLC after receiving two cycles of chemotherapy with stable disease. **Methods:** We undertook an open-label, randomized, phase 3 trial at 14 centers in China. We assigned previously untreated patients in China who had stage IIIB or IV pulmonary adenocarcinoma and who were nonsmokers and EGFR mutation status unknown to firstly receive two cycles of gemcitabine plus carboplatin(GC). The patients with stable disease were randomly assigned (1:1) to receive gefitinib on days 15 to 25 of a 4-week cycle of GC or a 4-week cycle of GC alone. In the absence of disease progression, chemotherapy was continued for a maximum of four cycles, after which time patients continued to receive gefitinib or observation until disease progression or unacceptable toxicity. The primary end point was progression-free survival. Secondary end points included overall survival and safety. The trial is registered at ClinicalTrials.gov, number NCT01404260, and has completed enrolment. **Results:** 109 patients were randomly assigned to receive intercalating and maintenance use of gefitinib plus chemotherapy and 110 to receive chemotherapy alone. 109 in the intercalating and maintenance group and 109 in the chemotherapy alone group were included in analysis of the primary endpoint. Median progression-free survival was significantly longer in intercalating and maintenance use of gefitinib-treated patients than in those on chemotherapy alone(10.0 vs 4.4 months; hazard ratio 0.475, 95% CI 0.349-0.646; p < 0.0001). The addition of gefitinib to chemotherapy was well tolerated. **Conclusions:** Intercalating and maintenance use of gefitinib plus gemcitabine/carboplatin led to a significant improvement in PFS for advanced pulmonary adenocarcinoma Chinese patients with nonsmoking and EGFR mutation status unknown after receiving two cycles of gemcitabine/ carboplatin with stable disease. Clinical trial information: NCT01404260.

8043 Poster Session (Board #366), Mon, 8:00 AM-11:30 AM

Maintenance therapy with gefitinib (G)/pemetrexed (P) versus P alone after induction therapy with P/platinum for metastatic lung adenocarcinoma (MLADC) harboring no sensitizing epidermal growth factor receptor mutation (sEGFRm): A phase II multicenter randomized open-label study (GENIUS trial). *First Author: Chun-Ming Tsai, Division of Thoracic Oncology, Department of Chest Medicine, Taipei Veterans General Hospital & Department of Medicine, National Yang-Ming University, Taipei, Taiwan*

Background: Synergistic EGFR-tyrosine kinase inhibitor (TKI)-chemotherapeutic interaction in lung cancer cells has 3 basics: no platinum, cells not sensitive to EGFR-TKI, and using a synergistic chemo partner, e.g., pemetrexed (Tsai, et al. Lung Cancer 82:305, 2013). **Methods:** GENIUS (NCT01579630) was a prospective trial comparing maintenance G/P v P in patients (pts) with MLADC harboring no sEGFRm detected by high sensitivity methods following a 4-cycle P/Platinum induction therapy in frontline setting. Pts with no disease progression (PD) were 1:1 randomized to receive P (500mg/m^2, 3-week cycle) ± G (250mg, daily) until PD or treatment failure, and stratified by center and response. The primary endpoint was progression free survival (PFS) by both independent radiologist review (IRR) and investigator assessment (IA), secondary endpoints included time to treatment failure (TTF), overall survival, safety and toxicity profile. **Results:** Between 03/2011 and 11/2013, 55 pts were randomized, G/P 26, P 29. Baseline characteristics were balanced between arms (age 57; female 42%; never smoker 55%; ECOG1 91%; ≥ 2 metastatic sites 38.2%; ALK+ 16%). Median follow-up was 15.9 mo. Median cycle of treatment was G/P 8.5 (range 1-27) and P 4 (2-17). Median PFS was substantially longer for G/P than P, both by IRR (3 deemed as PD at randomization were excluded; n = 25 v 27): 8.4 v 3.8 mo; HR [95% CI] 0.35 [0.18-0.68]; p = 0.0014, and by IA: 8.5 v 2.9 mo; HR 0.34 [0.18-0.64], p = 0.0005. Response with induction therapy, age, and smoker had interactions with treatment for PFS. Median TTF: 7.0 v 2.9 mo; HR 0.43 [0.24-0.79], p = 0.005. There were more treatment-related diarrhea, liver and skin toxicities on G/P v P, but generally mild. 2 G/P pts were off-study due to liver toxicity. Death occurred in 8 G/P and 14 P pts. **Conclusions:** GENIUS is the first prospective trial to show robust PFS benefit of EGFR-TKI plus chemo in the maintenance phase of 1st line treatment for MLADC with no sEGFRm and proved our concept. This strategy deserves phase III study to confirm. Clinical trial information: NCT01579630.

8044 Poster Session (Board #367), Mon, 8:00 AM-11:30 AM

Pharmacodynamic separation (PDS) of pemetrexed (Pem) and erlotinib (Erl) in patients (pts) with advanced, EGFR wild-type (wt) Non-Small Cell Lung Cancer (NSCLC): A randomized phase II trial. *First Author: Tianhong Li, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: We previously reported that PDS of Pem and Erl (Pem 500 mg/m^2 IV on day 1 and Erl 150 mg po QD on days 2-17 of a 21-day cycle) as 2nd-line therapy has promising clinical activity over Pem alone in 75 unselected pts with advanced non-squamous NSCLC (NCT00950365; Li et al., ASCO 2013). Given pts with EGFR mutant NSCLC usually have better clinical response to Pem or Erl monotherapy, we updated the efficacy analysis restricted to those pts with confirmed EGFR wt NSCLC. **Methods:** EGFR genotype status was determined by the Clinical Laboratory Improvement Amendments-certified RT-PCR, direct sequencing, and/or Sequenom multiplex genotype tests using archival formalin fixed, paraffin embedded tumor specimens or plasma circulating tumor DNA from study pts. For those pts with only blood samples, a repeat or alternative test was used to confirm the status of EGFR wt genotype. The parent study was designed to detect an increase in median progression-free survival (mPFS) by 50%, i.e., a hazard ratio (HR) of $\leq$ 0.67. **Results:** 59 (79%) of 75 eligible pts had confirmed EGFR wt (N=52) or EGFR-mutant (N=7) genotype. The results are summarized in Table 1. Longer PFS was observed in pts with EGFR WT NSCLC treated with the combination (Arm B). **Conclusions:** PDS of Pem and Erl as 2nd-line therapy appears to have promising clinical activity in pts with advanced, EGFR wt non-squamous NSCLC, which comprises of 85% of non-Asian NSCLC pts, and warrants further confirmation. (UL1 RR024146, P30CA093373, Astellas, Eli Lilly). Clinical trial information: NCT00950365.

8045 Poster Session (Board #368), Mon, 8:00 AM-11:30 AM

A phase 1b study of the anti-cancer stem cell agent demcizumab (DEM), pemetrexed (PEM) & carboplatin (CARBO) in pts with 1st line non-squamous NSCLC. *First Author: Dusan Kotasek, Adelaide Cancer Centre, Kurralta Park, Australia*

Background: Delta-like ligand 4 (DLL4) activates the Notch pathway & is important for cancer stem cell (CSC) survival. DEM is a humanized IgG$_2$anti-DLL4 antibody that has been shown to inhibit tumor growth, decrease CSC frequency & cause dysfunctional sprouting of new vessels resulting in an antiangiogenic effect in human tumor xenograft models. **Methods:** Pts received DEM (2.5 or 5 mg/kg), PEM 500 mg/m^2 & CARBO (AUC = 6) every 3 weeks X 6 cycles followed by maintenance DEM (cohorts 1-4) or truncated DEM (5 or 7.5 mg/kg), PEM 500 mg/m^2& CARBO (AUC = 6) every 3 weeks X 4 cycles followed by maintenance PEM (cohorts 5 & 6). The objectives were to determine the MTD, safety, efficacy, immunogenicity, pharmacokinetics & biomarkers of Notch signaling. **Results:** Thirty-nine pts were enrolled; 6 received 2.5 mg/kg, 20 received 5 mg/kg, 6 received 7.5 mg/kg of truncated DEM & 7 received 5 mg/kg of truncated DEM. Related AEs in $>$ 20% of pts were: nausea (51%), fatigue (46%), hypertension (46%), vomiting (31%), edema (26%), neutropenia (26%), increased B-type natriuretic peptide (BNP) (26%) & anemia (21%). Increased BNP values are an early indicator of the cardiac effects of DEM & mildly elevated values are being used to initiate cardioprotective therapy with an ACE inhibitor or carvedilol. Two pts receiving 5 mg/kg developed reversible pulmonary hypertension & heart failure on days 167 & 183, respectively. As a result, DEM treatment was limited to 63 days in cohorts 5 & 6. One of 33 (3%) evaluable pts had a RECIST CR, 15 (45%) had a PR & 13 had SD. The Kaplan Meier estimated median progression free survivals for the 2.5, 5, truncated 5 & truncated 7.5 mg/kg pts were 4.3, 5.3, not yet reached & 4.4 months, respectively. Eight pts who discontinued the study for a reason other than progression (6 continued to receive CARBO &/or PEM off-study) were progression-free through Days 314+, 408+, 448+, 456+, 546+, 677+ 680+ & Day 850. **Conclusions:** This therapy was generally well tolerated with nausea, fatigue & hypertension being the most common drug related toxicities. Encouraging early clinical activity has been observed. Biomarker data showed modulation of the Notch pathway. Final data will be presented. Clinical trial information: NCT01189968.

8046 Poster Session (Board #369), Mon, 8:00 AM-11:30 AM

A phase Ib study of selumetinib in patients (pts) with previously untreated metastatic Non-Small Cell Lung Cancer (NSCLC) receiving standard chemotherapy: NCIC Clinical Trials Group IND.215. NCT01783197. *First Author: Garth Andrew Nicholas, Ottawa Hospital Regional Cancer Centre, Ottawa, ON, Canada*

Background: Selumetinib (AZD6244, ARRY-142886, S) is a potent inhibitor of MEK, with promising activity with docetaxel in pts with previously treated NSCLC. Non-clinical data suggest potential negative interaction with platin. We conducted a phase Ib study testing continuous or intermittent S with either cisplatin/pemetrexed (CPe; non-squamous) or carboplatin/paclitaxel (CPa) in previously untreated NSCLC. **Methods:** Pts received CPa (C AUC 6; Pa 200mg/ m2) or CPe (C 75mg/ m2 ; Pe 500mg/ m2) or for 4-6 21day cycles; single-agent S continued. A 3+ 3 design was used, dose levels (DL) were: DL1 50mg bid d2-19, DL2 75 mg bid d2-19, DL3 75 mg bid d1-21 (continuous) with an expansion cohort at RP2D. DLTs were assessed in cycle 1. **Results:** 30 pts were enrolled and 27 currently evaluable for adverse events (AE). In both cohorts, the most common S related toxicities were mild GI and skin. For CPa, 11 pts were treated, and no DLTs were seen at any DL. CPa related AEs were as expected. 2 pts had dose reductions of S (1 each of fatigue, skin toxicity). Most AEs related to S were grade (G) 1-2 and included gastrointestinal and skin. 4 pts had $\geq$ G3 AEs considered related to S (includes 1 pt with fatal lung infection also related to CPa and 1 pt with fatal stroke also related to disease & CPa). 2 pts had G3 neutropenia; 1 pt had G4 thrombocytopenia; 1 pt had G3 LFTs. For CPe, 16 pts are currently evaluable; 2 possible DLTs were seen at the continuous DL (vomiting but inadequate antiemetics). Expansion to that DL ongoing. CPe related AEs were as expected. 3 pts had dose reductions of S (1 each of CPK, fatigue, dehydration). 3 additional pts had G3 AE (retinal vascular disorder, thromboembolism, diarrhea/ dehydration/ hypertension) related to S. There were no S related G5 events. There were no G4 hematologic toxicities. One pt had a G3 increase in CPK. **Conclusions:** S can be given in combination with CPe or CPa at full single agent doses, with generally mild incremental GI and skin toxicity. Patients continue to be enrolled to the RP2D expansion cohorts at a dose of 75 mg bid d1-21. NCIC CTG plans further P2 studies of CPe with S in NSCLC. Clinical trial information: NCT01783197.

8047 Poster Session (Board #370), Mon, 8:00 AM-11:30 AM

A phase Ib study of abemaciclib in combination with multiple single agents in stage IV NSCLC. *First Author: Edward S. Kim, Levine Cancer Institute, Carolinas Healthcare System, Charlotte, NC*

Background: Abemaciclib, a cell cycle kinase inhibitor of CDK4/CDK6, demonstrated acceptable safety and early clinical activity in metastatic NSCLC, given orally as monotherapy on a continuous schedule. In preclinical models of KRAS-mutant NSCLC, combinations of abemaciclib with other agents showed greater antitumor activity compared with monotherapy. Primary aim in study NCT02079636 was safety and tolerability of combination therapy with abemaciclib; secondary aims were pharmacokinetics (PK), antitumor activity, and patient (pt) reported outcomes. **Methods:** In this phase Ib open-label 3 + 3 dose-escalation study with expansion cohorts, pts received abemaciclib in combination with pemetrexed (Part A, nonsquamous), gemcitabine (Part B), ramucirumab (Part C), or LY3023414 (dual PI3K-mTOR inhibitor, Part D). Pts with stage IV NSCLC, ECOG PS $\leq$ 1, and 1-3 prior therapies were eligible. In escalation, pts were dosed continuously until progression with abemaciclib at 150 mg or 200 mg orally Q12H. Doses for other agents were: pemetrexed (500 mg/m^2 IV day 1), gemcitabine (1250 mg/m^2 IV days 1 and 8), ramucirumab (8 mg/kg IV days 1 and 8, or 10 mg/kg IV day 1) (Q21). In Part D, pts will receive LY3023414 at 100 mg, 150 mg or 200 mg orally Q12H. **Results:** Asof 27-OCT-2014, 40 pts received $\geq$ 1 dose of treatment; 15 pts at 150 mg and 25 pts (including all 10 pts in expansion) at 200 mg Q12H abemaciclib. In escalation, 3 dose-limiting toxicities were observed: 2 in Part A (150 mg: G4 neutropenia, 200 mg: G4 febrile neutropenia), and 1 in Part C (200 mg: G3 diarrhea). Possibly related G3/4 TEAEs in $\geq$ 2 pts (% Parts A, B, C) were: neutropenia (38, 15, 9), leukopenia (19, 8, 9), diarrhea (0, 8, 18), fatigue (13, 8, 0), anemia (13, 8, 0), and thrombocytopenia (0, 8, 9). Among 25 pts remaining on treatment, 5 pts (3 in Part A; 2 in Part C) received treatment $\geq$ 4 cycles. In Part C, 2 pts had unconfirmed PRs (RECIST v1.1), 1 pt (150 mg) with nonsquamous histology and KRAS mutation, and 1 pt (200 mg) with squamous histology and unknown KRAS status. **Conclusions:** Abemaciclib could be combined with other agents in NSCLC. Toxicities of combinations were consistent with those of the single agents. Findings will be reviewed with PK to support the recommended dose for each combination. Clinical trial information: NCT02079636.

8048 Poster Session (Board #371), Mon, 8:00 AM-11:30 AM

Individual patients data analysis (IPD) of three randomized studies comparing erlotinib (E) with chemotherapy (CT) in patients with advanced wild-type epidermal growth factor receptor (wtEGFR) non-small cell lung cancer (NSCLC). *First Author: Valter Torri, IRCCS-Mario Negri Institute, Milano, Italy*

Background: While the benefit of EGFR tyrosine kinase inhibitors in EGFR mutated NSCLC patients (pts) is undisputed, their usefulness in wtEGFR pts is still questioned. The TAILOR, DELTA and PROSE trials singularly showed a significant gain in Progression-Free Survival (PFS) favoring CT. We present here the mature results from the IPD analysis of the three studies. **Methods:** In each trial, pts with wtEGFR stage IIIB/IV NSCLC, progressing after first line platinum-based therapy, were randomized 1:1 to receive either E or CT at standard doses. Primary endpoints of this IPD were PFS and Overall Survival (OS); summary measures were Hazard Ratio (HR) and Difference in Mean Survival Time (DMST), which is the difference in the areas under the Kaplan-Meier curves of two treatment arms. Cox regression analyses were used to estimate the HR. All analyses were stratified by trial. **Results:** The analysis included all 587 pts randomized into the trials (Overall E/CT 303/284; TAILOR 109/110; DELTA 109/90; PROSE 85/84); 464 deaths and 570 progressions or deaths were observed. Compared with CT, E treatment was associated to an increased risk of both progression (40%) and death (12%) (HR-PFS: 1.40, 95%CI: 1.18-1.65, $p < 0.0001$; HR-OS: 1.12, 95%CI: 0.93-1.35; $p = 0.221$). Importantly, patients treated with CT gained 1.6 and 1.5 months, in progression-free and life-time respectively (DMST-PFS 95%CI: 0.6-2.1; DMST-OS 95%CI: -0.5-3.4). Results were preserved after adjustment by age, gender, smoking habit, performance status and histotype. **Conclusions:** The IPD analysis of TAILOR, DELTA and PROSE conclusively confirm the superiority of CT over E in the disease control of wtEGFR NSCLC patients, and corroborate the original results of each single trial.

8049 Poster Session (Board #372), Mon, 8:00 AM-11:30 AM

Randomized phase III trial of erlotinib vs. docetaxel in patients with advanced squamous cell non-small cell lung cancer (SqNSCLC) failing first line platinum based doublet chemotherapy stratified by VeriStrat Good vs VeriStrat Poor: The European Thoracic Oncology Platform (ETOP) EMPHASIS trial. *First Author: Solange Peters, University Hospital of Lausanne (CHUV), Lausanne, Switzerland*

Background: Docetaxel (D) or Erlotinib (E) are registered second-line treatments for *EGFR* wild type NSCLC. Previous studies suggested a predictive value of the serum proteomic VeriStrat test (VS), assigning a good (VSG) or poor (VSP) classification in second-line therapy of patients (pts.) with NSCLC. EMPHASIS aimed at exploring a predictive interaction in SqNSCLC pts. The trial closed prematurely due to low accrual. **Methods**: EMPHASIS is a randomized phase III multicenter trial exploring the differential activity of second line E vs D on progression-free survival (PFS) in VSG vs VSP SqNSCLC. The expected hazard ratio (HR) of E vs D was 0.675 for the VSG patients (median PFS, E: 4.0 and D: 2.7 mo.), and 1.23 for the VSP patients (median PFS, E: 2.2 and D: 2.7 mo.). A sample size of 500 was needed to achieve 86% power for testing the expected interaction HR of 1.82 at a two-sided p-value of 0.05. Pts were randomized to receive treatment E150 mg p.o. daily or D 75 mg/m2 i.v. on day 1 of each 21 day cycle. **Results**: From 1/2013 to 1/2014, a total of 80 patients were randomized to the study, with 72.5% categorized as VSG. Median age was 69 years with the majority being male (83%), smokers (94%), and having good performance status (91%). No unexpected serious adverse events (SAEs) were observed in either treatment arm. All pts are off treatment (median time to treatment failure: 2.1 mo.), while 73 progression events (median PFS: 2.7 mo.) and 56 deaths (median OS: 7.1 mo.) were observed. Median PFS for VSG is 4.1 and 1.6 mo. under D and E respectively, and 1.9 and 2.1 mo. for VSP pts (HR = 1.04, interaction p-value = 0.94). Median OS for VSG is 7.8 and 8.4 mo. for D and E and 4.4 and 5.2 mo. for VSP. **Conclusions**: The final analysis of EMPHASIS did not show a differential activity on PFS of E vs D in SqNSCLC pts stratified by VS status. These results are at variance with trial assumptions and previous studies. In addition to the EMPHASIS results (PFS & OS), we will present a combined PFS/OS analysis with the subgroup of SqNSCLC from the PROSE study. **EudraCT number: 2012-001896-35.** Clinical trial information: NCT01652469.

8051 Poster Session (Board #374), Mon, 8:00 AM-11:30 AM

Open-label, randomized study of individualized, pharmacokinetically (PK)-guided dosing of paclitaxel combined with carboplatin in advanced non-small cell lung cancer (NSCLC) patient. *First Author: Markus Joerger, Cantonal Hospital, St. Gallen, Switzerland*

Background: Variability of chemotherapy exposure may cause severe toxicity or lack of efficacy. Paclitaxel (PTX) exposure (time above a plasma concentration of 0.05mM, Tc > 0.05) has been shown to predict toxicity. Whereas carboplatin dose is adapted to kidney function, PTX dosing only accounts for body-surface area. We developed a PTX dosing algorithm for avoidance of supra- or subtherapeutic PTX exposure based on Tc > 0.05 determined from a single blood sample drawn 18-30 hours after starting PTX infusion. This study was initiated to validate PK-guided PTX dosing in advanced NSCLC patients. **Methods:** 304 patients with advanced NSCLC were randomly assigned to receive up to 6 cycles of first-line 3-weekly carboplatin AUC 6 combined with PTX either at a standard dose of 200mg/m^2 (Arm A) or at a PK-guided dose (Arm B). Initial PTX dose in Arm B was between 150 to 200 mg/m^2 based on age and sex, and subsequent PTX doses were adjusted according to the previous cycle PTX Tc > 0.05 to target a Tc > 0.05 between 26 and 31 hours. Dose reductions were permitted in both arms for chemotherapy-associated toxicity. The study had a power of 90% to detect a 11% reduction of grade 4 neutropenia with PK-guided PTX dosing. **Results:** Major patient characteristics were male gender in 67%, current smokers in 38%, ≥ 65 years of age in 50%, performance status of 2 in 8%, squamous-cell histology in 21%.Compared to standard dosing, PK-guided dosing of PTX reduced the incidence of grade 4 neutropenia (measured on day 15 of each cycle) (15% v 21%, P = 0.029), grade ≥ 2 neuropathy (14% v 27%, P < 0.001), and grade ≥ 3 neuropathy (1% v 8%, P < 0.001). Median PTX dose at cycle 6 was significantly lower with PK-guided dosing (132 v 197 mg/m^2, P < 0.001), and the proportion of patients with supratherapeutic PTX exposure was reduced from 41% in cycle 1 to 2% in cycle 6. Objective response rate was 32% and 29% in Arms A and B (P = 0.70). Progression-free survival was 5.2 and 4.7 months in Arms A and B (hazard ratio 1.1, 95% CI 0.8-1.4, P = 0.54). **Conclusions:** PK-guideddosing of PTX improves the risk-benefit profile in patients with advanced NSCLC, primarily by a substantial reduction of PTX-associated neuropathy. Clinical trial information: 2010-023688-16.

8052 Poster Session (Board #375), Mon, 8:00 AM-11:30 AM

Paclitaxel (PTX) dose individualization by exposure optimization in Chinese patients with advanced non small-cell lung cancer (NSCLC) receiving first-line paclitaxel-carboplatin (PC) chemotherapy. *First Author: Jie Zhang, Department of Oncology, Shanghai Pulmonary Hospital, Tongji University, School of Medicine, Shanghai, China, Shanghai, China*

Background: PC chemotherapy is complicated by febrile neutropenia in up to 5% of patients with advanced NSCLC. PTX pharmacokinetic (PK) variability is a major factor in severe neutropenia. The time above a PTX plasma concentration of 0.05μmol/L ($T_{C > 0.05}$) is the key PK parameter to measure systemic exposure to the drug and is a predictor of severe neutropenia. Optimization of an individual's dose by exposure measures may improve PTX safety and efficacy. A randomized controlled study in Chinese NSCLC patients was performed to assess impact of PK-guided PTX dosing on safety and efficacy. **Methods:** To date, 141 stage IIIB/IV NSCLC patients receiving first-line PC chemotherapy have been enrolled. Patients are randomized to receive 4-weekly carboplatin (AUC = 5) plus paclitaxel at a starting dose of 175 mg/m^2 with subsequent PTX dosing based on body surface area (BSA) or PK-guided dosing to target a PTX $T_{C > 0.05}$ between 26 and 31 hours. Primary objective is to compare severe toxicities and response rates between BSA and PK arms. **Results:** Exposure values from 1st cycle in 90 patients show great PTX PK variability, with a mean $T_{C > 0.05}$ of 36 hr (range = 26 - 46 hr, CV = 27%). 14% of these patients had PTX exposure values within the target range (26 to 31 hr) while 86% were above target exposure. No patient showed PTX exposure below target at standard PTX dose of 175mg/m^2. Severe neutropenia rate for patients above exposure target was higher than those in target (grade 3 & 4 neutropenia of 31% vs 60%, grade 4 neutropenia of 0% vs 18%, respectively). Exposure optimization of PTX in PK arm leads to an overall 21% dose reduction. In 51 patients with 4 cycles of chemotherapy completed, severe neutropenia rate in PK arm at cycle 4 was 39% compared to 61% in BSA arm (p = 0.026). Response rate was also evaluated and showed no negative impact (24% PR rate in PK arm vs 16% in BSA arm). A higher neuropathy rate was observed in BSA arm (77%) compared to PK arm (42%). **Conclusions:** With exposure optimized PTX dose, severe neutropenia can be significantly reduced with no negative impact to clinical outcome.

8053 Poster Session (Board #376), Mon, 8:00 AM-11:30 AM

Exposure-response relationship for ramucirumab (RAM) from the randomized, double-blind, phase III REVEL trial (docetaxel [DOC] vs DOC plus RAM) in second-line treatment of metastatic non-small cell lung cancer (NSCLC). *First Author: Egbert F. Smit, Cancer Center Amsterdam, Department of Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands*

Background: An exploratory exposure-response analysis for RAM was performed using data from the REVEL trial (NCT01168973). **Methods:** Patients received RAM (10 mg/kg) or placebo (PL) + DOC (75 mg/m^2) every 3 weeks (q3w). Sparse pharmacokinetic (PK) samples were collected; a population PK (PopPK) analysis was conducted. PopPK model-predicted RAM exposure parameters ($C_{min,1}$, $C_{min,ss}$, $C_{max,ss}$, and $C_{ave,ss}$) were used to evaluate the relationship between RAM exposure and measures of efficacy and safety. $C_{min,1}$ and $C_{ave,ss}$ are presented. Kaplan-Meier, Cox regression, and ordered categorical analyses evaluated these relationships. **Results:** Analyses included 376 RAM+DOC pts and 366 PL+DOC pts. Similar trends were seen for all four exposure parameters. As RAM exposure increased, greater improvements (smaller HRs) were seen in OS and PFS (table below). A statistically significant correlation was also seen for RAM exposure and grade ≥ 3 febrile neutropenia and hypertension. **Conclusions:** Results from exposure-response analyses suggest improvements in efficacy and increased toxicity may occur with increasing RAM exposure. RAM at a dose of 10 mg/kg q3w in combination with DOC is appropriate for the NSCLC indication. Clinical trial information: NCT01168973.

		Median (months)	Hazard ratio (95% CI)[a]
OS[b]			
PL+DOC		13.3	
RAM+DOC $C_{min,1}$	Q1	11.1	1.19 (0.89, 1.59)
	Q2	14.6	0.80 (0.58, 1.08)
	Q3	12.6	0.85 (0.63, 1.14)
	Q4	17.1	0.67 (0.48, 0.93)
PFS[b]			
PL+DOC		5.5	
RAM+DOC $C_{min,1}$	Q1	5.6	0.92 (0.72, 1.18)
	Q2	7.0	0.71 (0.55, 0.90)
	Q3	5.7	0.84 (0.67, 1.07)
	Q4	7.0	0.71 (0.55, 0.90)
Grade ≥3 AE[c]		Hypertension (%)	Febrile Neutropenia (%)
PL+DOC		2.8	11.8
RAM+DOC $C_{ave,ss}$	Q1	4.3	7.5
	Q2	5.3	19.1
	Q3	13.8	22.3
	Q4	6.4	21.3

[a]Adjusted for significant prognostic factors. [b]RAM+DOC pts stratified by $C_{min,1}$ quartile (μg/mL) (n = 94 for each): Q1 ≤ 15.7; Q2 > 15.7 ≤ 20.7; Q3 > 20.7 ≤ 27.9; Q4 > 27.9; compared to PL+DOC pts. [c]RAM+DOC pts stratified by $C_{ave,ss}$ quartile (μg/mL) (n = 94 for each): Q1 ≤ 79.3; Q2 > 79.3 ≤ 97.4; Q3 > 97.4 ≤ 118; Q4 > 118; compared to PL+DOC pts.

8054 Poster Session (Board #377), Mon, 8:00 AM-11:30 AM

Docetaxel + ramucirumab (DR) versus docetaxel + placebo (D) as second-line treatment for advanced non-small cell lung cancer (NSCLC): A randomized, phase II, double-blind, multicenter trial in Japan. *First Author: Yukio Hosomi, Tokyo Metropolitan Cancer and Infectious Diseases Center, Komagome Hospital, Tokyo, Japan*

Background: A randomized global phase III trial (REVEL) demonstrated statistically significant improvement in OS and PFS for DR versus D in patients (pts) with advanced NSCLC; a limited number of East Asian pts were given docetaxel (DOC) at 75 mg/m^2, higher than 60 mg/m^{2}recommended in Japan. **Methods:** A similar phase II study was conducted in Japan to evaluate the efficacy of DR for stage IV NSCLC following disease progression during or after prior platinum-based chemotherapy. Pts with EGFR mutant NSCLC who received prior EGFR tyrosine kinase inhibitor (TKI) therapy were enrolled as exploratory. Eligibility criteria included ECOG PS 0-1, age ≥ 20 years, and adequate organ function. Pts were randomized 1:1 to receive DOC 60 mg/m^2+ramucirumab 10 mg/kg IV or placebo on Day 1 of a 21-day cycle until disease progression. Stratification factors: PS, gender, prior maintenance therapy. The primary endpoint was PFS to be analyzed after observing 134 PFS events for pts without prior EGFR-TKI therapy (primary population). The number was designed to show a high likelihood of observing PFS HR < 1. Secondary endpoints: safety profile, OS, objective response rate (ORR), disease control rate (DCR), patient-reported outcomes. We report the results of the primary population. **Results:** 157 pts (DR 76; D 81) were randomized and treated. Pts characteristics were balanced between arms. The median PFS was 5.2 months (m) [95%CI 3.52, 6.97] for DR and 4.2m [2.83, 5.62] for D; hazard ratio (HR) 0.83 [0.59, 1.16]. ORR: 28.9% (DR), 18.5% (D). DCR: 78.9% (DR), 70.4% (D). The median OS at the time of primary PFS analysis was 15.2m for DR and 14.0m for D (data are immature). Main Grade3/4 toxicites (DR vs D) were neutropenia (90% vs 86%), leukopenia (70% vs 68%), febrile neutropenia (33% vs 20%) and anorexia (7% vs 5%). The Grade3/4 febrile neutropenia did not lead to any fatal events and incidence of Grade ≥ 3 infections were 1% vs 10%. **Conclusions:** Efficacy results were consistent with those from REVEL. DR has shown clinical benefit over D in terms of PFS, ORR, and DCR in Japanese NSCLC pts. DR was well tolerated, with manageable toxicity. Clinical trial info: NCT01703091. Clinical trial information: NCT01703091.

8055 Poster Session (Board #378), Mon, 8:00 AM-11:30 AM

Exploratory analysis of safety by histology and efficacy in a nonsquamous NSCLC subgroup in REVEL: A randomized phase III study of ramucirumab (RAM) plus docetaxel (DOC) vs DOC for second-line treatment of stage IV non-small-cell lung cancer (NSCLC). *First Author: Luis Paz-Ares, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: REVEL, a study inclusive of nonsquamous (NSQ) and squamous (SQ) NSCLC, led to FDA approval of second-line RAM+DOC for patients (pts) with metastatic NSCLC based on improved survival. Neutropenia, febrile neutropenia, gastrointestinal and pulmonary hemorrhage events were similar across histologies. Additional outcomes are presented. **Methods**: A total of 1,253 pts with SQ or NSQ NSCLC received DOC (75 mg/m^2) plus RAM (10 mg/kg; N = 628) or placebo (N = 625) after disease progression on platinum-based therapy (NCT01168973). Endpoints evaluated in specified histologic subgroups were OS, PFS, response rates, safety, and QoL. OS and PFS were analyzed using Kaplan-Meier (KM) method and Cox proportional hazard model. Response was compared using the Cochran-Mantel-Haenszel test. The primary QoL analysis was time to deterioration (TtD) of the Lung Cancer Symptom scale (LCSS) using the KM method. **Results**: Of the 73% (N = 912) of NSQ tumors, the majority were adenocarcinoma (79%; N = 725). Efficacy outcomes for pts with adenocarcinoma were similar to the NSQ population (see table). Incidences of pts with ≥ 1 treatment-emergent adverse event (TEAE), ≥ 1 serious adverse event, TEAEs grade ≥ 3, and TEAEs leading to dose adjustment or discontinuation were similar between treatment arms and across NSQ and SQ histologies. The TtD for total LCSS score was similar between treatment arms in NSQ and SQ subgroups. **Conclusions**: REVEL demonstrated an acceptable benefit/risk profile for RAM+DOC, with favorable efficacy and manageable safety outcomes seen across the major histologic subtypes of NSCLC. Clinical trial information: NCT01168973.

	NSQ ITT			NSQ Adenocarcinoma		
	RAM+DOC (N = 465)	PBO+DOC (N = 447)	HR (95% CI)	RAM+DOC (N = 377)	PBO+DOC (N = 348)	HR (95% CI)
Median OS, mos	11.1	9.7	0.83 (0.71, 0.97)	11.2	9.8	0.83 (0.69, 0.99)
Median PFS, mos	4.6	3.7	0.77 (0.67, 0.88)	4.5	3.9	0.75 (0.64, 0.88)

8056 Poster Session (Board #379), Mon, 8:00 AM-11:30 AM

Bevacizumab beyond disease progression after first-line treatment with bevacizumab plus chemotherapy in advanced nonsquamous non–small cell lung cancer (WJOG 5910L): An open-label, randomized, phase II trial. *First Author: Masayuki Takeda, Department of Medical Oncology, Kinki University Faculty of Medicine, Osaka-Sayama, Japan*

Background: Bevacizumab combined with platinum-based chemotherapy has been established as a standard treatment option in the first-line setting for advanced nonsquamous non–small cell lung cancer (NSCLC). However, there have been no evidence-based studies to support the use of bevacizumab beyond disease progression in NSCLC patients receiving such treatment. **Methods:** WJOG 5910L was designed as a multicenter, open-label, randomized, phase II trial of docetaxel (60 mg/m^2) versus docetaxel (60 mg/m^2) plus bevacizumab (15 mg/kg) every 3 weeks in patients with recurrent or metastatic nonsquamous NSCLC whose disease has progressed after first-line treatment with bevacizumab plus a platinum-based doublet. The primary end point was progression-free survival (PFS). **Results:** One hundred patients were randomly assigned to receive docetaxel (Doc, $n = 50$) or docetaxel plus bevacizumab (Doc+Bev $n = 50$). The median PFS was 4.4 months for the Doc+Bev group and 3.4 months for the Doc group, with a hazard ratio (HR) of 0.71 (95% confidence interval [CI], 0.47–1.09) and stratified log-rank P value of 0.058, which met the predefined value for statistical significance ($P < 0.2$). The median overall survival also tended to be longer in the Doc+Bev group (13.1 months; 95% CI, 10.6–21.4) than in the Doc group (11.0 months; 95% CI, 7.6–16.1), with a HR of 0.74 (95% CI, 0.46–1.19; stratified log-rank $P = 0.11$). Frequent adverse events of grade ≥ 3 included neutropenia (90% in the Doc+Bev group vs. 82% in the Doc group), leukopenia (64% vs. 52%, respectively), and febrile neutropenia (26% in both groups). There were two treatment-related deaths (one in each group). **Conclusions:** The addition of bevacizumab to docetaxel in the second-line setting shows promising efficacy with regard to PFS for patients with nonsquamous NSCLC whose disease has progressed while receiving bevacizumab plus a platinum-based doublet. The addition of bevacizumab was associated with a slight increase in toxicity, although the combination regimen was tolerable. Phase III studies of this combination are warranted. Clinical trial information: 000004715.

8057 Poster Session (Board #380), Mon, 8:00 AM-11:30 AM

Efficacy and safety of BCD-021, bevacizumab biosimilar candidate, compared to Avastin: Results of international multicenter randomized double blind phase III study in patients with advanced non-squamous NSCLC. *First Author: Olga Filon, CJSC BIOCAD, St. Petersburg, Russia*

Background: BCD-021 demonstrated equivalence to Avastin in a comprehensive comparability exercise that included physicochemical, PK and PD studies, as well as phase I PK clinical study in patients with non-squamous NSCLC. **Methods:** 138 patients with advanced non-squamous NSCLC (stage IIIb/IV) were randomly assigned into 2 groups at a ratio of 1:1 to receive BCD-021 or Avastin at a dose of 15 mg/kg in combination with paclitaxel (175 mg/m^2) and carboplatin (AUC 6 mg/ml×min) every 3 weeks up to 6 cycles of therapy or until progression or unbearable toxicity. **Results:** ORR (primary endpoint) in both groups had no statistically significant differences: 42.59 % (95% CI 30.33 – 55.83) in BCD-021 group and 39.29% (95% CI 27.58 – 52.27%) in Avastin group. The lower limit of 95% CI for ORR difference between the groups (-14.96%) did not exceed the non-inferiority margin, hence BCD-021 is non-inferior to Avastin. There were also no differences between the groups for all other efficacy parameters: CR (1.85% *vs* 1.79%), PR (40.74% *vs* 37.50%), stable disease (51.85% *vs* 51.79%) and progression rate (5.56% *vs* 8.93%) in BCD-021 and Avastin group, respectively. AEs profiles of BCD-021 and Avastin were equivalent. Rate of all observed AEs including severe AEs had no statistically significant difference between the groups. Most AEs were associated with chemotherapy : neutropenia (85.29% *vs* 78,7%), anemia (88.24% *vs* 84.85%), leukopenia (79.41% *vs* 75.76%), thrombocytopenia (69.12% *vs* 62.12%), hyperglycemia (61.76 *vs* 56.06), LDH increase (48.53 *vs* 37.88), ALP increase (35.29% *vs* 30.30), ALT increase (26.47% *vs* 28.79%), alopecia (30.88% *vs* 24,24%), etc. Reactions specific for bevacizumab included: arterial hypertension (26,47% *vs* 22,73%), weakness (17.65 *vs* 16.67), lung bleeding (5.88% *vs* 3.03%), proteinuria (2.94% *vs* 0%), GIT perforation (0% *vs* 1.52%) and VTE (0% *vs* 1.52%). Binding and neutralizing antibodies were transient and detected only in 1 patient in each group that indicated to low immunogenic potential of both drugs. **Conclusions:** BCD-021 demonstrated non-inferiority to Avastin in patients with NSCLC. Clinical trial information: NCT01763645.

8058 Poster Session (Board #381), Mon, 8:00 AM-11:30 AM

Comparative efficacy of ceritinib and crizotinib in previously treated crizotinib-naïve anaplastic lymphoma kinase-positive (ALK+) advanced or metastatic non-small cell lung cancer (NSCLC): An adjusted indirect comparison. *First Author: Daniel Shao-Weng Tan, National Cancer Centre Singapore, Singapore, Singapore*

Background: Ceritinib (CER) has been studied in previously treated, crizotinib (CRZ)-naïve patients (pts) in two clinical trials (ASCEND-1: NCT01283516; ASCEND-3: NCT01685138). No randomized controlled trial has compared CER and CRZ. This analysis indirectly compared the efficacy of CER and CRZ among previously treated, CRZ-naïve pts with advanced/metastatic ALK+ NSCLC. **Methods:** Individual pt data for CER-treated pts were pooled from two single-arm trials (ASCEND-1, ASCEND-3); published summary data for CRZ-treated pts were extracted from three trials (PROFILE 1001, 1005 and 1007). To adjust for cross-trial differences, CER-treated pts were re-weighted to match their mean baseline characteristics to those reported for the CRZ-treated pts, including age, gender, race, ECOG PS, number of prior regimens and tumor histology. Progression-free survival (PFS), overall survival (OS) and overall response rate (ORR) were compared between the treatment groups after matching. **Results:** Before matching, CER pts (N = 189) were significantly different from CRZ pts (N = 557) in the distribution of race (Asian: 55% vs. 38%; P < .001) and the number of prior regimens (1/2/ ≥ 3: 49%/28%/23% vs. 45%/22%/33%; P = .028). After matching, all available baseline characteristics were balanced. Compared to CRZ, CER was associated with longer PFS (median: 13.8 vs. 8.3 months; hazard ratio (HR): 0.52; 95% CI, 0.44–0.62) and OS (HR: 0.59; 95% CI, 0.46–0.75). The 12-month OS rate was 83% with CER and 66% with CRZ. **Conclusions:** In this adjusted indirect comparison, CER was associated with prolonged PFS and OS compared to CRZ among previously treated CRZ-naïve ALK+ NSCLC.

Endpoint, 95% CI		CER	CRZ	HR	P-value
PFS	Median, mo	13.8 (11.1–NE)	8.3 (7.3–9.3)	0.52 (0.44–0.62)	< .001
	12-mo rate, %	58 (48–71)	37 (33–42)	—	< .001
OS	Median, mo	NE (19.6–NE)	20.5 (19.9–29.6)	0.59 (0.46–0.75)	< .001
	12-mo rate, %	83 (75–91)	66 (62–70)	—	< .001
ORR	rate, %	68 (61–76)	61 (57–65)	—	.102

Notes: NE = not estimable. P-values for HR were calculated by weighted Cox proportional hazards model; P-values for rate were calculated by weighted t-tests.

8059 Poster Session (Board #382), Mon, 8:00 AM-11:30 AM

ASCEND-2: A single-arm, open-label, multicenter phase II study of ceritinib in adult patients (pts) with ALK-rearranged (ALK+) non-small cell lung cancer (NSCLC) previously treated with chemotherapy and crizotinib (CRZ). *First Author: Tony Mok, Chinese University of Hong Kong, Shatin, Hong Kong*

Background: In the ASCEND-1 study ceritinib showed clinical activity in pts with ALK+ NSCLC, including in brain metastases (BM). ASCEND-2 (NCT01685060) evaluated efficacy and safety of ceritinib in ALK+ NSCLC pts pre-treated with chemotherapy (≥ 1 platinum doublet) who progressed ≤30 days from last treatment with CRZ. **Methods:** At August 2014 data cut-off, 140 pts receiving oral ceritinib 750 mg daily had enrolled worldwide. Whole body (WB) and intracranial (I) responses were assessed by investigator; Lung Cancer Symptom Scale (LCSS) and EORTC (QLQ-C30) surveys assessed patient reported outcomes. **Results:** Of 140 pts: median age (range) 51 (29–80) years; 50.0% male; 60.0% Caucasian; 37.9% Asian; 71.4% with BM, of which 28.0% had no prior brain radiation (BRT). Median duration of exposure and follow-up time were 8.8 (0.1–19.4) and 11.3 (0.1–18.9) mos, respectively. At baseline, 20 pts had investigator-assessed measurable brain lesions (MBL); IDCR was 80.0% (95% CI: 56.3, 94.3); in 5 of 6 pts with MBL and no prior brain radiation, brain responses (2 CR, 3 PR) matched or exceeded WB response. Most common AEs (mostly Grade 1/2) were nausea (81.4%), diarrhea (80.0%), vomiting (62.9%). Eleven (7.9%) pts discontinued due to AEs, with no one AE predominating. LCSS showed improvement in symptom burden (-1.4 to -6.2). Global quality of life score (QLQ-C30) was maintained on treatment, with no substantial change from baseline (-1.5 to +4.6). **Conclusions:** Ceritinib provided durable responses and safety outcomes in CRZ-pretreated patients with or without BM consistent with those seen in ASCEND-1. Clinical trial information: NCT01685060.

ASCEND-3: A single-arm, open-label, multicenter phase II study of ceritinib in ALKi-naïve adult patients (pts) with ALK-rearranged (ALK+) non-small cell lung cancer (NSCLC). *First Author: Enriqueta Felip, Vall d'Hebron University, Barcelona, Spain*

Background: Ceritinib demonstrated clinical activity in ALKi-pretreated and -naïve pts with ALK+ NSCLC, including those with brain metastases (BM; pivotal ASCEND-1 study). ASCEND-3 (NCT01685138) evaluated efficacy and safety of ceritinib in ALKi-naïve pts. **Methods:** At 27June 2014 data cutoff, 124 pts enrolled worldwide received oral ceritinib 750 mg/d. Whole body (WB) and intracranial (I) responses were assessed by investigator. Prior chemotherapy (≤3 lines) was permitted. **Results:** Median age of enrolled pts was 56 (27–82); 40.3% were male, 59.7% Asian and 38.7% Caucasian; 40.3% had BM, of which 46% had no prior brain radiation (BRT). Median time from initial diagnosis to treatment start was 13.5 (1.0–283.1) mos; median exposure duration was 8.0 (0.1–16.2) mos; median follow-up (range) was 8.3 (0.6-16.3) mos. Investigator-assessed efficacy outcomes are located in the table below. At baseline 10 pts had investigator-assessed measurable brain lesions (MBL); IDCR was 80.0% (95% CI: 44.4, 97.5); in 6 pts with MBL and no prior BRT, all responses in brain (2 PR) matched or exceeded WB response. Most common AEs (mostly Grade 1/2) were gastrointestinal: diarrhea (82.3%), nausea (74.2%), and vomiting (66.9%); 7.3% pts discontinued due to AEs, with no one AE predominating. **Conclusions:** Ceritinib achieved robust ORR and promising DOR/PFS in pts with and without baseline BM. Ceritinib showed brain responses even in pts with no prior BRT. Safety outcomes were similar to the ASCEND-1 trial. Clinical trial information: NCT01685138.

8061 Poster Session (Board #384), Mon, 8:00 AM-11:30 AM

A phase I/II study with a CNS-penetrant, selective ALK inhibitor alectinib in *ALK*-rearranged non-small cell lung cancer (*ALK*+ NSCLC) patients (pts): Updates on progression free survival (PFS) and safety results from AF-001JP. *First Author: Yuichiro Ohe, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Alectinib, a CNS-penetrant, selective ALK inhibitor with a novel scaffold, was granted approval in Japan 2014, since it showed good efficacy and tolerability in *ALK*+ NSCLC pts without previous ALK inhibitor treatment (CMSTO2014). This report describes the updated data of the 46 pts enrolled in phase II part of AF-001JP. **Methods:** *ALK*+ NSCLC pts without previous ALK inhibitor treatment were given alectinib at 300 mg b.i.d to investigate the efficacy and safety until no further clinical benefits as assessed by investigator. **Results:** Alectinib showed good tumor response to *ALK*+ NSCLC in AF-001JP study and has been already approved in Japan. Further evaluation is ongoing for PFS and OS. 28 of 46 pts were on treatment with alectinib as of October 31, 2014. In spite of the fact that median follow-up duration had passed 30 months (range: 1-36) as of then, progressive disease (PD) was confirmed in only 12 pts (26.1%) (CNS progression: 4 pts, Non-CNS progression: 8 pts).Of them, 3 pts received alectinib later than PD. Though median PFS had not been reached then, it is expected to be at least longer than 29 months. 7 of 14 pts with baseline brain metastasis still remained in the study without CNS or systemic progression at that time. PFS with brain metastasis was similar to the one without brain metastasis. There were no treatment-related Grade 4 or 5 AEs. Since safety profile was consistent with the one in the previous reports, high tolerability of long term administration of alectinib was observed. The results suggested that alectinib showed high efficacy and safety for longer period. **Conclusions:** Alectinib is a novel therapeutic option for the treatment of *ALK*+ NSCLC, since in *ALK*+ NSCLC pts without previous ALK inhibitor treatment, alectinib demonstrated excellent efficacy and tolerability for longer administration. Clinical trial information: JapicCTI-101264.

8062 Poster Session (Board #385), Mon, 8:00 AM-11:30 AM

Safety and efficacy of brigatinib (AP26113) in advanced malignancies, including ALK+ non–small cell lung cancer (NSCLC). *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: Brigatinib is an investigational oral tyrosine kinase inhibitor with preclinical activity against rearranged ALK and clinically identified crizotinib-resistant mutants. **Methods:** A phase (ph) 1/2 single-arm, open-label, multicenter study in patients (pts) with advanced malignancies is ongoing. Pts received brigatinib (30–300 mg/d total daily dose, ph 1; 90 mg/d, 180 mg/d, or 90 mg/d for 7 d followed by 180 mg/d, ph 2). Safety was evaluated in all 137 treated pts; efficacy was evaluated in all 79 ALK+ NSCLC pts. NCT01449461. **Results:** Median age: 57 y; 58% female. As of 4 Aug 2014, 47% of total pts and 71% of ALK+ NSCLC pts remained on study. Median and maximum time on treatment were 5.5 mo and 29 mo (ongoing), respectively. Most common treatment-emergent adverse events, generally grade 1/2, included: nausea 45%; diarrhea 36%; fatigue 36%; cough 26%; headache 26%. Early-onset pulmonary events, observed ≤7 d after starting treatment, included dyspnea, hypoxia, or new pulmonary opacities on chest computed tomography suggestive of pneumonia or pneumonitis and occurred in 13/137 (9%) pts (6/44 [14%] pts started at 180 mg qd [once daily]; 2/50 [4%] pts started at 90 mg qd [pts treated with 90 mg qd or 90 mg qd for 7 d followed by 180 mg qd]). Of 72 evaluable ALK+ NSCLC pts, 52 (72%) responded: 45/65 (69%) with prior crizotinib and 7/7 crizotinib-naive pts. Median duration of response: 49 wks. Median progression-free survival (PFS): 56 wks; 47 wks with prior crizotinib. In a post hoc independent radiological review of pts with baseline intracranial central nervous system metastases, 6/12 pts with lesions ≥10 mm had a brain response (≥30% decrease in sum of longest diameters of target lesions) and 8/26 pts with only nonmeasurable lesions had disappearance of all lesions. Median intracranial PFS for these pts: 97 wks. **Conclusions:** Brigatinib has promising antitumor activity in ALK+ NSCLC pts with and without prior crizotinib, including pts with brain metastases. Early-onset pulmonary events were observed less frequently with the 90-mg starting dose compared with higher doses. A randomized ph 2 trial of brigatinib 90 mg qd vs 90 mg qd for 7 d followed by 180 mg qd in crizotinib-resistant ALK+ NSCLC (ALTA) is underway. Clinical trial information: NCT01449461.

8063 Poster Session (Board #386), Mon, 8:00 AM-11:30 AM

Phase (Ph) 1/2a study of TSR-011, a potent inhibitor of ALK and TRK, in advanced solid tumors including crizotinib-resistant ALK positive non-small cell lung cancer. *First Author: Hendrik-Tobias Arkenau, Sarah Cannon Research Institute, London, United Kingdom*

Background: Both intrinsic and acquired resistance mechanisms to ALK inhibitors have been observed in ALK rearranged (ALK+) non-small cell lung cancer (NSCLC). TSR-011 inhibits ALK (IC50 = 0.7nM), tropomyosin receptor kinase (TRK) A, B, and C (IC50 < 3nM), and tumor growth in vivo. **Methods:** A Ph 1/2a study is underway to evaluate safety, pharmacokinetics (PK), and preliminary efficacy of TSR-011. The ongoing Ph 1 is evaluating patients (pts) with ALK+ tumors, including those progressing on, or naïve to ALK inhibitor therapy (ALKi). **Results:** Forty-six pts with advanced cancer, including 19 ALK+ and 11 TRK+ pts, have been treated at total daily doses of 30 to 480mg, administered 1, 2 or 3 times a day. Dose-limiting toxicities (dysesthesia, QTc prolongation) were observed above 120mg/day, not with the fractionated dosing up to 120mg/day. PK modeling showed that a fractionated schedule achieves sustained trough concentrations above the ALK IC50, and minimizes peak exposure associated with QTc prolongation. TSR-011 at the current dose level of 40mg q8h is well tolerated (Table). In evaluable ALK+ pts, 3/3 achieved a response at or above 120mg total daily dose, and 5/9 achieved disease stabilization for 7 months or longer at lower doses; investigation with the 40mg q8h cohort continues. Duration on TSR-011 exceeded that of previous ALKi in a majority of patients with clinical benefit, up to 20 months longer than prior ALKi for a pt still continuing on study. **Conclusions:** TSR-011 is a well-tolerated, promising second-generation ALKi. Overall safety and ECG findings support further development of TSR-011 in pts with ALK+ NSCLC at a fractionated schedule. Development of a controlled release formulation is planned. Clinical trial information: 02048488.

8064 Poster Session (Board #387), Mon, 8:00 AM-11:30 AM

A phase 1 study of crizotinib and ganetespib (STA-9090) in ALK positive lung cancers. *First Author: Gregory J. Riely, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with ALK + non-small cell lung cancer (NSCLC) initially respond to crizotinib, but eventually develop resistance. Treatment of patients with ALK positive lung cancer with HSP90 inhibitors leads to clinical and radiographic response. We hypothesized that treatment of patients with ALK rearranged NSCLC with crizotinib and ganetespib, an HSP90 inhibitor, would be safe. **Methods:** All patients had ALK rearranged metastatic non-small cell lung cancer not previously treated with crizotinib. Prior chemotherapy was allowed. Patients were treated with crizotinib 250 mg bid continuously; ganetespib was administered intravenously on days 1 and 8 of a 21-day cycle. In a standard 3+ 3 design, ganetespib was explored at 3 different dose levels. The primary objective was to determine the maximum tolerated dose of the combination of crizotinib and ganetespib. Secondary objectives included establishing the safety profile (CTCAE v4) of the combination in patients with ALK+ lung cancer, exploring the efficacy (RR by RECIST 1.1, PFS, and OS). **Results:** 12 patients were treated with combined crizotinib and ganetespib: 100 mg/m^2(n=3), 150 mg/m^2(n=3), and 200 mg/m^2 (n=6). Women: 8/12, Median Age: 56 (range 41-70), Prior therapy: none (7 pts), 1 line (4 pts), or 2 lines (1 pt). Median duration of treatment: 100 mg/m^2=30 weeks, 150 mg/m^2=54 weeks, and 200 mg/m^2= 6 weeks. There were no first-cycle DLTs. The maximum tolerated dose was crizotinib 250 mg bid/ganetespib 200 mg/m^2. The most common toxicities were fatigue, diarrhea, nausea, vomiting, and dizziness. Grade 4 elevation in ALT (n=1) and Grade 3 elevations in lipase (n=2), AST (n=1), and amylase (n=1) were observed. 5 patients stopped therapy due to toxicity. 4 discontinued due to progressive disease. 3 patients continue on treatment. PR = 67% (8/12), SD= 16% (2/12), PD =8% (1/12), Not Evaluable =8% (1/12). Median OS has not been reached (median f/u = 15 months, with 10 patients still alive). **Conclusions:** In patients with ALK+ lung cancers, crizotinib and ganetespib can be combined, with an MTD of crizotinib 250 mg bid continuously and ganetespib 200 mg/m^2 on days 1 and 8 of a 21 day cycle. Further evaluation of this combination in patients not previously treated with crizotinib is warranted. Clinical trial information: (NCT01579994).

8065 Poster Session (Board #388), Mon, 8:00 AM-11:30 AM

Crizotinib in patients with advanced ROS1-rearranged non-small cell lung cancer (NSCLC). Preliminary results of the ACSé phase II trial. *First Author: Denis Moro-Sibilot, Thoracic Oncology Unit Teaching Hospital A Michallon, INSERM U823, Grenoble, France*

Background: Molecular alterations of crizotinib (crz) targets (ALK, MET, ROS1) are found in a wide range of malignancies. To avoid uncontrolled off-label use and allow for a nationwide safe access to crz for patients (pts) with an ALK, MET or ROS1 positive (+) tumor, the French National Cancer Institute (INCa) launched the AcSé program, funding both access to tumor molecular diagnosis and an exploratory multi-tumor 2-stage design phase II trial. We report the preliminary results of the ROS1+ NSCLC cohort. **Methods:** ROS1 status was determined in 28 regional INCa molecular genetic centers by break-apart FISH assays. Patients with ROS1 rearrangements, progressing after at least one standard treatment (including a platinum-based doublet, unless pts were considered as unfit for chemotherapy) were proposed to receive crz 250 mg BID. Responses were centrally assessed using RECIST v1.1. The objective response rate (ORR) and disease control rate (DCR) were assessed every 8 weeks. **Results:** From Aug. 5, 2013 to Dec. 12, 2014, 34 pts with ROS1+ NSCLC were enrolled out of 37 expected pts. 32 pts had received crz, including 3 recently enrolled pts, leading to 29 pts with clinical information. Median age: 62 years (range 33–81), 69% females, 93% non-squamous histology, and 93% metastatic disease at study entry. Median number of prior treatments: 2 (range 1 –12). Twenty one pts were still on treatment at the cut-off date, 8 have stopped crz (5 PD, 2 adverse events (AEs), 1 death). Among the 24 pts evaluable for response at 8 weeks, we observed 1 CR, 14 PR, 6 SD and 3 PD, leading to ORR = 63% [95% CI:41-81], and DCR = 88% [68-97]. DCR at 6 months was 53% and disease control was achieved in 8/15 evaluable pts. Crz was well tolerated with only 9 grade $\geq$ 3 AEs or SAE. Most common AEs, mainly grade 1, were visual disorders (62% of pts), peripheral edema (55%), diarrhea (51%), nausea (41%), and elevated transaminases (51%). **Conclusions:** Crz was well tolerated and achieved a robust treatment response rate in ROS1+ NSCLC. These results underline the interest of integrating ROS1 in biomarkers routine screening. Survival data and duration of response will be presented. Clinical trial information: NCT02034981.

8066 Poster Session (Board #389), Mon, 8:00 AM-11:30 AM

***ROS1* rearrangement in non-small cell lung cancer (NSCLC): Prognostic and predicitve impact and genetic variability.** *First Author: Matthias Scheffler, Lung Cancer Group Cologne, Department I of Internal Medicine and Center for Integrated Oncology Cologne Bonn, University Hospital Cologne, Cologne, Germany*

Background: Rearrangements of the *ROS1* oncogene occur in about 1-2% of non-small cell lung cancer (NSCLC) patients. While data suggest that the EML4-ALK/MET/ROS1 inhibitor crizotinib is highly effective in these patients, few data is available about the prognostic impact, the predictive value for different treatments, and the genetic heterogeneity of *ROS1*-positive patients. **Methods:** 1137 patients with adenocarcinoma of the lung were analyzed regarding their *ROS1* status. In positive cases, next-generation sequencing (NGS) was performed. Clinical characteristics, treatments and outcome were assessed. Overall survival (OS) was compared with genetically defined subgroups of *ROS1*-negative patients. **Results:** *ROS1* status was analyzed in 1035 (91.0%) patients, whereof 19 (1.8%) had *ROS1*-rearrangement. The median OS of the patients has not been reached yet. Stage IV patients with *ROS1*-rearrangement had the best OS of all analyzed subgroups (36.7 months, $p < 0.001$). 9 of 14 (64.2%) patients had at least one response under chemotherapy. Pemetrexed-containing regimens showed higher response rates than paclitaxel-containing ones (80% vs 17%). Estimated mean OS for patients receiving chemotherapy and crizotinib was 5.3 years (median not reached). Ten patients with *ROS1*-rearrangement (52.6%) harbored additional genetic aberrations in *BRAF*, *MET*, *EGFR*, *MAP2K1*, and *TP53*. **Conclusions:** *ROS1*-rearangement is not only a strong predictive marker for response to crizotinib, but also seems to be the best prognostic molecular marker in NSCLC reported so far. In stage IV *ROS1*-positive patients, response to chemotherapy was remarkable high and overall survival regardless of systemic therapy significantly better compared to other genetically defined subgroups including *EGFR*-mutated and *ALK*-fusion-positive NSCLC.

8067 Poster Session (Board #390), Mon, 8:00 AM-11:30 AM

Defining the spectrum and "overlap" of HER2 aberrations in lung cancers: Associations of HER2 protein overexpression, *HER2* amplification, and *HER2* mutation. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor receptor 2 (HER2, *ERBB2*) aberrations have been identified as oncogenic drivers and potential therapeutic targets in lung cancers. The molecular associations of HER2 protein overexpression, *HER2* gene amplification and *HER2*mutation in lung cancers have not been distinctly defined. To explore these associations, Memorial Sloan Kettering and the University of Colorado combined their data on HER2 in lung cancers. **Methods:** Tumor specimens from 175 patients with lung adenocarcinomas with no prior targeted therapy were evaluated for the presence of HER2 overexpression, *HER2* amplification and mutation. Overexpression was assessed by immunohistochemistry (IHC) using the 4B5 Ventana antibody. Amplification was assessed by fluorescence in-situ hybridization (FISH) using FDA approved probe sets (PathVysion, Abbott and *HER2* IQFISH pharmDx, Dako) and defined as HER2/CEP17 ratio $\geq$ 2.0. Mutation was assessed by fragment analysis and mass spectrometry genotyping for indels and recurrent point mutations in exon 20, respectively. The frequencies of HER2 overexpression, *HER2* amplification and mutation were calculated and their concordance examined. **Results:** *HER2* amplification by FISH was detected in 5 of 175 (3%) cases, and 46 (26%) showed polysomy (HER2 copy $\geq$ 4 but HER2/CEP17 ratio $<$ 2). HER2 overexpression (2+, 3+) on IHC was not detected in the 25 specimens tested to date and negative IHC correlated with negative results on FISH. *HER2* mutation was detected in 4 of 145 (3%) specimens, including 3 identical 12bp insertions [(p.A775_G776insYVMA (c.2324_2325ins12)] and a 9bp insertion, all in exon 20. None of the *HER2* mutant cases were amplified and 3 had polysomy. **Conclusions:** *HER2* mutations are not associated with *HER2* amplification or HER2 protein overexpression suggesting a distinct entity and therapeutic target. "HER2-positive lung cancers" may not be an adequate term and patient cohorts for the study of HER2 targeted agents should be defined by the specific HER2 aberrations present. Funded in part by Boehringer-Ingelheim, NCI 1 RC2 CA148394-01, NCI P50CA058187, and NCI CCSG P30CA046934.

8068 Poster Session (Board #391), Mon, 8:00 AM-11:30 AM

Outcomes with chemotherapies and molecular characteristics of *HER2*-mutant lung cancers. *First Author: Juliana Eng, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor receptor 2 (*HER2, ERBB2*) mutations occur in 3% of lung adenocarcinomas and are increasingly being identified with the growing adoption of multiplex next-generation genotyping. *HER2*-mutant lung cancers impart a distinct natural history with a median overall survival from stage IV diagnosis of 1.6 years (Kris JAMA 2014). While case reports and series have shown activity of HER2-targeted agents in these patients, little is known about outcomes of systemic treatments. **Methods:** Patients with stage IV *HER2*-mutant lung cancers at Memorial Sloan Kettering were reviewed. Patient demographics, types of *HER2* mutations, survival, and duration of systemic treatments were documented. **Results:** 37 patients with *HER2*-mutant lung cancers were identified: median age 62; majority were women (n = 24), never smokers (n = 21), and had adenocarcinomas (n = 36, 1 adenosquamous). A 12bp in-frame insertion in exon 20 (p.A775_G776insYVMA c.2324_2325ins12) was present in 23 (62%, 95% CI 45-78%) patients. In addition, there were four 9bp insertions, one 6bp insertion, and five 3bp insertions in exon 20, and four single base pair substitutions (3 exon 20, 1 exon 8). The median overall survival from date of diagnosis of stage IV disease was 2.3 years (95% CI 1.2-2.7). The median duration of all chemotherapy was 8 months (range 0.8-43 months). Median duration of treatment was 6 months for pemetrexed ±platinum/bevacizumab, 3 months for taxane ±platinum/bevacizumab, 4 months for gemcitabine, 4 months for vinorelbine, 5 months for mitomycin vinblastine. The median duration of targeted therapy was 3 months for trastuzumab, 4 months for small molecule HER2 tyrosine kinase inhibitors, 3 months for erlotinib. No objective responses were noted with trastuzumab (n = 2) or lapatinib (n = 4) alone. **Conclusions:** Most *HER2*-mutant lung tumors demonstrate an identical 12bp in-frame insertion (YVMA) in exon 20. In our cohort, the median duration of treatment with chemotherapy was double that of HER2-targeted therapies. Pemetrexed-containing regimens had the longest duration of treatment. As we search for better targeted therapies for patients with *HER2*-mutant lung cancers, chemotherapy remains an important component of care.

8069 Poster Session (Board #392), Mon, 8:00 AM-11:30 AM

EGFR mutation pattern in African American population in a community-based academic center. *First Author: Haiying Cheng, Montefiore Medical Center, Eastchester, NY*

Background: The two most common EGFR mutations, L858R in exon 21 and deletions in exon19, represent around 90% of all EGFR mutations in NSCLC and convey sensitivity to EGFR TKIs. Little is known about the patterns of EGFR mutations in different racial groups. Montefiore Medical Center (MMC), a community based academic center, treats a large minority patient population. For example, 33% (693/2104) of patients with lung cancer were identified as African American from 01/2009 to 06/2014. We initiated reflex molecular testing on all non-squamous NSCLC patients in 01/2012 at MMC. **Methods:** We retrospectively reviewed our cancer registry database from 01/2009 to 06/2014 and analyzed all non-squamous NSCLC patients with pathology available in our system for rates and patterns of EGFR mutations. EGFR testing was performed by Integrated Oncology (Labcorp) by PCR-based technology. **Results:** 1032 patients with non-squamous NSCLC had their pathological diagnosis at MMC: 386 (37.4%) were African American, 475 (46%) white, 46 (4.5%) other (Asian and others), and 125 (12.1%) race unknown, respectively. EGFR mutation analysis was performed in 446 patients and 63 were positive for EGFR mutations. The EGFR mutation rate was 14.1% (63/446) for all races, 12.4% (22/178) for African Americans and 14% (27/193) for whites. Interestingly, 25.4% (16/63) of mutations were uncommon EGFR mutations on exon 18 or exon 20, which is higher than the rates reported in the literature (~10%). In particular, 31.8% (7/22) of African Americans with EGFR mutations had uncommon mutations. The mean age at diagnosis of these 7 patients was 66 years, 5 were female, 2 never-smokers, and 5 had stage 3 or 4 disease. The types of uncommon mutations included S768I, V769L, N771_H773dupNPH, H773L, V774M mutations in Exon 20, G719A mutation in Exon 18 or combinations. **Conclusions:** This is the first report of a high uncommon EGFR mutation rate in African American lung cancer patients. Most uncommon EGFR mutations are less sensitive to EGFR TKIs than L858R and del 19. These results justify confirmation studies in larger cohorts of patients.

8070 Poster Session (Board #393), Mon, 8:00 AM-11:30 AM

EGFR mutations in Latinos from the United States and Latin America. *First Author: Ariel Lopez-Chavez, Sylvester Comprehensive Cancer Center at Univ of Miami, Miami, FL*

Background: Activating mutations in the epidermal growth factor receptor gene (EGFR) confer hypersensitivity to EGFR tyrosine kinase inhibitors in patients with advanced non–small-cell lung cancer (NSCLC). Racial and ethnic differences in the frequency of such mutations have been previously described; however, there are limited and conflicting reports on its frequency in the Latino population. **Methods:** We collected samples from 642 patients with NSCLC from 7 institutions in the US and Latin-America. Activating EGFR mutation analysis of exons 18 through 21 was performed at 2 CLIA certified central laboratories. Statistical analyses were performed using Fisher's exact test or Mehta's modification to Fisher's exact test to determine relationships among parameters. All p-values are two-tailed and reported without adjustment for multiple comparisons. **Results:** EGFR mutation analysis was successfully performed in 480 of 642 patients (75%) of which 90 (19%) were Latinos, 318 (66%) non-Latino Whites, 35 (7%) non-Latino Asians, 30 (6%) non-Latino Blacks and 7 (2%) from other race/ethnicities. EGFR mutations were found in 21 of 90 (23%) Latino patients and its frequency varied according to country of origin. The highest frequency was observed in Latinos from Peru (37%) followed by US (23%), Mexico (18%), Venezuela (10%) and Bolivia (8%). In Latinos never smokers and Latinos with adenocarcinoma histology, the frequency of EGFR mutations was 38% and 30% respectively. There was a significant difference in the frequency of EGFR mutations among the different racial/ethnic subgroups analyzed ($p < 0.001$) with non-Latino Asians having the highest frequency (57%) followed by Latinos (23%), non-Latino Whites (19%) and non-Latino Blacks (10%). However, there was no difference between Latinos (23%) and non-Latinos (22%) ($p = 0.78$) and Latinos and non-Latino Whites ($p = 0.37$). While patients from Peru had an overall higher frequency of mutations (37%) than all other Latinos (17%), such difference was not statistically significant ($p = 0.06$) and diminished greatly when smoking and adenocarcinoma histology subgroups were analyzed independently. **Conclusions:** There was no significant difference between the frequency of EGFR mutations in NSCLC in Latinos and non-Latinos.

8071 Poster Session (Board #394), Mon, 8:00 AM-11:30 AM

Clinical predictors of 5-year survival in patients with EGFR-mutant metastatic NSCLC treated with EGFR-TKIs. *First Author: Jessica Jiyeong Lin, Brigham and Women's Hosp, Brighton, MA*

Background: Activating mutations of the epidermal growth factor receptor (EGFR) were discovered over 10 years ago. EGFR mutations predict increased response rates and progression-free survival (PFS) when treated with EGFR tyrosine kinase inhibitors (TKIs) compared to combination chemotherapy in advanced NSCLC. However, long-term outcomes including 5-year survival among patients (pts) with EGFR-mutant metastatic NSCLC treated with EGFR-TKIs remain heterogeneous. Herein, we define clinical factors associated with prolonged overall survival (OS) in this cohort. **Methods:** A retrospective analysis was performed of pts with metastatic NSCLC harboring a sensitizing EGFR mutation and treated with EGFR-TKIs at Dana-Farber Cancer Institute between Jan 1, 2002 and Sept 31, 2009. Pts alive at time of analysis must have had at least a 5-year survival. OS was compared based on clinical features using log-rank test. Cox's proportional hazards models were used to estimate hazard ratios. **Results:** Among 134 pts, median PFS and OS were 13.1 mos (95% CI, 10.8-14.6) and 30.9 mos (95% CI, 28.2-35.7), respectively. 19 pts (14.2%) were long-term survivors (OS $\geq$ 5 years), of whom 10 remained alive at the time of analysis with median follow-up of 89.8 mos (range, 60.1-91.6). Multivariate analysis adjusted for factors significant at the 0.10 level in univariate models revealed that sensitizing EGFR mutations in exons other than exon 19 ($n = 55$) (HR 1.53; 95% CI, 1.05-2.23; $p = 0.03$), extrathoracic mets ($n = 77$) (HR 1.58; 95% CI, 1.04-2.43; $p = 0.03$) or brain mets ($n = 29$) (HR 2.17; 95% CI, 1.34-3.51, $p = 0.002$) at the time of diagnosis, and current smoking status ($n = 5$) (HR 4.31; 95% CI, 1.64-11.32; $p = 0.003$) were independent predictors of shorter OS. Age, gender, disease stage at diagnosis, liver or adrenal mets at diagnosis, specific TKI (erlotinib vs gefitinib), or line of TKI treatment did not correlate with OS. **Conclusions:** Our data estimate 5-year OS among EGFR-mutant metastatic NSCLC pts treated with EGFR-TKIs at 14%--vs less than 5% in historic results for an unselected population with distant-stage NSCLC. Planned studies will elucidate the genetic alterations that may co-occur with EGFR mutations and influence treatment outcomes.

8072 Poster Session (Board #395), Mon, 8:00 AM-11:30 AM

The impact on overall survival (OS) of first-line gefitinib (G) and erlotinib (E) and of clinical factors in advanced non-small cell lung cancer (NSCLC) with activating epidermal growth factor receptor mutations (EGFR mut) based on meta-analysis of 1,231 patients (pts) enrolled in 6 major randomized trials. *First Author: Chee Lee, NHMRC Clinical Trials Centre, Sydney, Australia*

Background: We performed an individual pts data meta-analysis using trials that compared G or E vs platinum doublet chemotherapy (CT) on OS outcome. **Methods:** Treatment-naïve pts with common EGFR mut (Del19 or L858R), stage IIIB/IV/post-operative recurrence were randomized to either G (IPASS, NEJ002, WJTOG3405) or E (ENSURE, EURTAC, OPTIMAL) vs CT. We performed Cox regression to obtain hazard ratios (HR) and 95% confidence intervals (CI) for the overall population and pre-specified subgroups. We calculated pooled treatment estimate using the inverse variance weighted method. **Results:** Amongst 1231 pts (Del19 = 682, L858R = 540, Del19 and L858R = 9), 632 received EGFR tyrosine kinase inhibitor (TKI) and 599 received CT. The median follow-up was 35.0 months, and 780 (63%) pts had died. Following progression, 74% (CT group) received EGFR-TKI and 66% (EGFR-TKI group) received CT. There was no difference in OS between EGFR-TKI and CT (median 25.8 vs 26.0 months, HR = 1.01 [CI 0.88-1.17; P = 0.84]). There was no significant difference between Del19 (HR = 0.96, CI 0.79-1.16, P = 0.64) and L858R (HR = 1.06, CI 0.86-1.32; P = 0.59) subgroups (P-interaction = 0.47). There was also no significant difference according to smoking status (P-interaction = 1.00), sex (P-interaction = 0.80), performance status (P-interaction = 0.88), age (P-interaction = 0.61), ethnicity (P-interaction = 0.63), histology (P-interaction = 0.84), and staging (P-interaction = 0.43). Performance status (0 vs 1 vs 2: median 34.0 vs 24.1 vs 15.7 months, P-logrank < 0.001) and staging (IV vs IIIB vs post-operative recurrence: median 23.9 vs 31.0 vs 42.7 months, P-logrank < 0.001) were prognostic for OS. **Conclusions:** Despite significant PFS benefit, there is no OS difference with first-line G or E when compared with CT in advanced NSCLC with common EGFR mut, probably due to high rate of cross-over at progression. There is no significant difference in EGFR-TKI treatment benefit in all subgroups. Poor performance status and stage IV cancer are associated with poorer OS.

8073 Poster Session (Board #397), Mon, 8:00 AM-11:30 AM

Influence of dose adjustment on afatinib safety and efficacy in patients (pts) with advanced *EGFR* mutation-positive (*EGFRm+*) non-small cell lung cancer (NSCLC). *First Author: James Chih-Hsin Yang, National Taiwan University Hospital and National Taiwan University, Taipei, Taiwan*

Background: Afatinib 40 mg/day (oral) is approved for the treatment of pts with advanced *EGFRm+* NSCLC. Dose adjustment is recommended according to pre-defined tolerability criteria. We performed post-hoc analyses on the influence of afatinib dose reduction on adverse events (AEs), pharmacokinetics (PK) and progression-free survival (PFS) in the Phase III LUX-Lung 3 (LL3) trial, and analyzed dose reduction data collected in clinical practice. **Methods:** All pts treated with afatinib in LL3 were included in the analyses (n = 229). Pts experiencing drug-related grade 3 or selected prolonged grade 2 AEs on the initial 40 mg dose could dose reduce by 10 mg decrements to 30 mg or a final dose of 20 mg. Frequency and severity of the most common AEs before and after dose reduction were analyzed. Final PK data collected as part of the standard visit schedule (Day 43) were used to compare plasma afatinib concentrations in pts who reduced to 30 mg vs those remaining at 40 mg. PFS was compared between pts who dose reduced within the first 6 months of treatment and those who did not. Real-world data were collected by practicing experts. **Results:** Dose reductions occurred in 53% (122/229) of pts; the majority (86%) within the first 6 months of treatment. In pts who dose reduced, decreases in the incidences of drug-related all grade (grade ≥ 3) AEs were 99.2% (20.5%) to 46.7% (4.1%) for diarrhea, 88.5% (26.2%) to 38.5% (3.3%) for rash/acne, 77.0% (12.3%) to 27.9% (0%) for stomatitis, and 44.3% (16.4%) to 36.9% (4.9%) for nail effects. Dose reduction was more likely in pts with higher plasma concentrations of afatinib. On Day 43, pts who dose reduced to 30 mg ≥ 4 days previously (n = 38) had geometric mean plasma afatinib concentrations of 24.4 ng/mL, vs 23.7 ng/mL in pts who remained on the 40 mg dose (n = 126). Median PFS was 11.3 months in pts who dose reduced during the first 6 months of treatment, vs 11.0 months in pts who did not (HR = 1.25 [95% CI, 0.91–1.72]). Dose reduction outcomes from daily clinical practice will also be presented. **Conclusions:** Tolerability-guided dose adjustment of afatinib is an effective measure to reduce treatment-related AEs without reducing therapeutic efficacy. Clinical trial information: NCT00949650.

8074 Poster Session (Board #398), Mon, 8:00 AM-11:30 AM

Reduced-dose versus full-dose erlotinib for advanced EGFR-mutant non-small cell lung carcinoma (NSCLC): A retrospective analysis. *First Author: Benjamin L. Lampson, Brigham and Women's Hospital, Boston, MA*

Background: Erlotinib is an EGFR tyrosine kinase inhibitor (TKI) which is FDA-approved at the maximum tolerated dose (MTD) of 150mg daily with dose limiting toxicities of diarrhea and rash. Preclinical data and small clinical series suggest that lower doses of erlotinib are biologically active against EGFR mutations. However, this has not been systematically studied. We aimed to study whether reduced-dose erlotinib is as effective as full-dose erlotinib for EGFR-mutant NSCLC. **Methods:** An institutional database was reviewed to identify patients (pts) who received erlotinib for advanced NSCLC carrying an EGFR exon 19 deletion or L858R mutation. Using a retrospective chart review, erlotinib dose was determined at treatment start and after 4 months of therapy. Progression free survival (PFS) was calculated from time of treatment start until date when the treating clinician documented clinical disease progression. **Results:** 206 eligible pts were identified: 118 exon 19 del, 88 L858R; 144 1st-line, 62 later-line. 34 pts (17%) initiated erlotinib at a reduced dose: 100mg (n = 29), 50 mg (n = 4), 25 mg (n = 1). Reduced-dose pts were older than full-dose pts (median age 70 vs. 64 yrs, $p < 0.01$), but otherwise clinically similar (Table). Reduced-dose pts had a median PFS of 8.8 months, not significantly different from those at full-dose (11.2 months, HR = 1.3, p= 0.14). Of 173 pts who had not progressed at 4 months, the 86 (50%) on reduced-dose erlotinib at that time had a significantly lower median PFS (11.7 vs. 14.0 months, HR = 1.5, $p< 0.05$). **Conclusions:** This is the largest series to date describing outcomes when initiating treatment for EGFR-mutant lung cancer with reduced-dose erlotinib. PFS was acceptable when treating at a reduced biologically active dose, though trends towards a lower PFS than with MTD dosing. A multivariate analysis controlling for baseline differences is underway.

	Full dose (n = 172)	Reduced dose (n = 34)	p
Median age (years)	64	70	0.004
PS: 0-1, 2+	113, 8	20, 3	0.383
Brain mets at start	57 (33%)	9 (26%)	0.548
Line: 1, 2+	120, 52	24, 10	1.000
Median PFS	11.2	8.8	0.14 (HR 1.3)

8075 Poster Session (Board #399), Mon, 8:00 AM-11:30 AM

Single institution experience with 75 mg dose of erlotinib in Latin American patients with mutated metastatic non-small cell lung cancer. *First Author: Osvaldo Rudy Aren, Centro Internacional de Estudios Clínicos, Santiago, Chile*

Background: The recommended dose for erlotinib of 150 mg was developed based on the maximum tolerated dose (MTD); meanwhile the suggested dose for gefitinib is only one third of its MTD. Studies suggest that the optimal biologic dose of erlotinib should be lower and dependent of the body mass index. Hereby we present results and toxicity with 75 mg/day dose in South American patients. **Methods:** We performed a retrospective review of patients with histologically proven (+) EGFR (+) mutation mNSCLC treated with 75mg/day erlotinib as starting dose at Centro Internacional de Estudios Clinicos. Clinical information, including toxicity grade 1-4, drug discontinuation, clinical evolution and radiological evaluation were revised. Overall survival from initiation of treatment was obtained from death certificate information. **Results:** Twenty-eight patients received 75mg/day of erlotinib as starting dose. Twenty-one (75%) patients were treated in first and seven (25%) in second line treatment. Mean age was 61years (range 36-89 years and nineteen (67%) patients were female. All patients had mutation positive EGFR, 22 (78 %) had Del19 and 6 (22%) exon 21 mutation. One patient had partial response and one had complete response. Progression free survival was 17 months and median overall survival 19 months. The main grade 1-2 toxicities were rash (33%) and diarrhea (25%). No grade 3-4 toxicity and no cases of drug discontinuation were reported. As of the writing of this abstract six patients are without progression and continue on treatment. **Conclusions:** In South American population with mutated mNSCLC, a dose of 75mg/day of erlotinib was well tolerated. This dose resulted in comparable benefits in PFS and OS when compared to those reported in the literature with the standard dose. Genetic polymorphism in metabolic enzymes and lower body mass index could explain the same efficacy at lower dose. More studies are needed to explore the use of adjusted doses of biological agents in different ethnic backgrounds.

8076 Poster Session (Board #400), Mon, 8:00 AM-11:30 AM

A phase II trial of erlotinib for *EGFR* mutant NSCLC to prospectively assess biopsy feasibility and acquired resistance at disease progression. *First Author: Amanda J. Redig, Dana-Farber Cancer Inst, Boston, MA*

Background: Erlotinib is a first-line therapy for patients (pts) with advanced *EGFR* mutant non-small cell lung carcinoma (NSCLC). However, tumors develop acquired resistance; choice of further therapy, including third-generation EGFR inhibitors in development, often depends on the mechanism driving resistance. We performed a prospective trial to assess biopsy feasibility and resistance mechanisms in *EGFR* mutant pts with acquired erlotinib resistance. **Methods:** Advanced, EGFR TKI naïve *EGFR* mutant NSCLC pts were enrolled in a phase II trial of erlotinib. At study entry, eligible pts consented to undergo re-biopsy at progression. The primary endpoint was feasibility of re-biopsy and evaluation of acquired resistance. Re-biopsies underwent pathology review and genomic analysis. Secondary objectives included evaluating biopsy features and reason(s) why re-biopsy could not be performed. **Results:** Between 02/10 and 1/15, 60 EGFR mutant pts (44 women, 34 never-smokers) were enrolled (L858R (17); exon 19 deletion (38); other (5)). 16 pts remain on study. Median age (range): 62.5 years (34-90). Median PFS: 11.0 months. 44 pts discontinued therapy (39 for progression, 5 for adverse events); 31 (70%) underwent re-biopsy. 8 pts did not undergo re-biopsy because of pt refusal (3); clinical contraindication (3); sudden death (1); or discovery of germline T790M (1). 31 re-biopsies identified: T790M mutation (17, 55%); SCLC transformation (3, 10%); no T790M or SCLC (6, 19%); inadequate tissue (3, 10%). Re-biopsy targeted enlarging lesions (26) and stable lesions (5), with T790M identified in 5/5 stable lesions and 12/26 enlarging lesions. Genotyping was done on effusions (3/4), lymph node (8/8), lung lesion (15/17), peritoneal deposit (1/1), and bone (1/1). **Conclusions:** Repeat biopsy at disease progression on first-line *EGFR*-directed therapy is feasible in 70% of pts and yields clinically meaningful results for subsequent therapy. It may be possible to identify resistance mechanisms from biopsy of focally stable yet easily accessible sites of disease. However, non-invasive means of detecting acquired resistance will be important, as re-biopsy is not always possible. Clinical trial information: NCT00997334.

8077 Poster Session (Board #401), Mon, 8:00 AM-11:30 AM

Clinical implications of repeat tumor biopsy (RTB) in patients (pts) with advanced lung cancer (LC): The Cleveland Clinic (CC) experience. *First Author: Eberechi Sandra Agwa, Cleveland Clinic Foundation, Taussig Cancer Institute, Cleveland, OH*

Background: RTB at disease progression (PD) is increasingly used to profile tumor biomarkers and identify drug resistance mechanisms. However, information on safety and clinical consensus on the use of RTB remain lacking. **Methods:** The aim of this study is to review RTB patterns and safety in LC pts at CC and impact on treatment (Rx) decisions. Pts who were diagnosed and underwent RTB for suspected LC PD between 2007 and 2013 were studied. Statistical analysis is primarily descriptive. **Results:** The study involved 184 (56% male) pts. Median age at diagnosis was 65Y (21-87). 100 (54%) were treated initially with single modality (Surgery = 41; Chemo = 33; Radiation = 17; targeted therapy = 9) and 83 (45%) with multimodality Rx (2-modality = 57, 3-modality = 26), 1 (1%) unknown. # Of RTB per patient: 1 in 66.3% (n = 122), 2 in 20.1% (n = 37), 3 in 11.4% (n = 21), and 4 in 2.2% (n = 4). The most common procedure at 1st RTB was bronchoscopy (44.6%, n = 82), followed by CT guided biopsy (bx) (20.7 %, n = 38), surgery (10.3%, n = 19), excision bx (8.2%, n = 15), fine needle aspiration of skin & lymph node (LN) (7.6%, n = 14), ultrasound guided bx (5.9%, n = 11) & others (2.7%, n = 5). Lung was the most commonly re-biopsied site (46%) followed by LN (15%). Complications occurred in 13 of 181 (7.2%) pts at 1st RTB (data missing in 3 pts), 3 of 61 (4.9%) at 2nd RTB, 1 of 25(4%) at 3rd RTB, and 0 of 4 (0%) at 4th RTB. The 17 (6.2%) complications are shown in the table below. Histologic change was seen in 13 cases, including adeno-to-squamous carcinoma (at erlotinib resistance) and vice-versa, and non-small cell to small cell histology. The T790M-EGFR mutation was noted in 6 cases, the PIK3CA mutation in 1, and a change in ALK status in 3. Medical decision making was impacted in 16% of cases. **Conclusions:** RTB can be safely performed using minimally invasive techniques and can benefit LC Rx decision making.

Complication	n
Bleeding without hemodynamic compromise	6
Bleeding requiring transfusion	1
Pneumothorax	5
Hemodynamic instability after premedication	1
Cerebral salt wasting	1
Tracheoesophageal fistula	1

8078 Poster Session (Board #402), Mon, 8:00 AM-11:30 AM

Dynamic serial monitoring of EGFR mutations in plasma DNA samples in EGFR mutant NSCLC patients treated with EGFR TKI. *First Author: Myung-Ju Ahn, Samsung Medical Center, Seoul, South Korea*

Background: Detection of epidermal growth factor receptor (EGFR) mutation in non-small cell lung cancer (NSCLC) patients is mainly based on tissue biopsy, which is invasive and time consuming. Furthermore, there is still a need for serial monitoring of EGFR mutations and detection of EGFR tyrosine kinase inhibitors (TKIs) resistance. We hypothesized that plasma-based EGFR mutation analysis may be feasible for monitoring response to EGFR TKIs and could be used to predict the resistance. **Methods:** From February 2012 through April 2014, 200 EGFR mutant NSCLC patients were enrolled and treated with EGFR TKIs (141 patients for gefitinib, 46 patients for erlotinib, and 13 patients for afatinib). Plasma samples were prospectively obtained every 2 months from baseline until disease progression. The longitudinally collected plasma samples (n = 277) from 61 patients who progressed were analyzed using droplet digital PCR (ddPCR). We identified an association between serial EGFR mutant titers in plasma cell-free DNA (cfDNA) samples and the patient's clinical response to EGFR TKIs. **Results:** Of a total 60 baseline cfDNA samples available for ddPCR, 40 (67%) samples demonstrated same mutation in the matched tumors (i.e. sensitivity: 65% (13/20) for L858R vs 68% (27/40) for exon 19 deletions). The concordance rate of plasma with tissue results of EGFR mutation was 88% for L858R and 78% for exon 19 deletion, respectively. All the samples showing EGFR mutations in plasma showed a dramatic decrease of mutant copies (greater than 50%) in blood in the first 2 months after treatment. We also found the secondary mutation (T790M) emerged in 15 patients around 3~13 months after treatment and can be detected before disease progression as determined by CT scan. Correlation between the tumor volume and the level of cfDNA EGFR mutations will be updated. **Conclusions:** These results suggest that ddPCR is an appropriate method for determining plasma-based EGFR mutation status and may aid in monitoring response to EGFR TKIs and early detection of EGFR TKIs resistance.

Concordance between EGFR mutation status assessed by ddPCR and clinical tissue result.

	ddPCR			
prior treatment N=60	L858R +	L858R-	E19 +	E19 -

8079 Poster Session (Board #403), Mon, 8:00 AM-11:30 AM

Early prediction of response to tyrosine kinase inhibitors by quantification of EGFR mutations in plasma of non-small cell lung cancer patients. *First Author: Antonio Marchetti, Center of Predictive Molecular Medicine, SS. Annunziata Hospital, University G. D'Annunzio, Chieti, Italy*

Background: Several studies have investigated the feasibility of detecting EGFR mutations in liquid biopsies of Non-Small Cell Lung Cancer (NSCLC) patients. However, the potential to accurately quantify EGFR mutations in plasma for clinical purposes is largely unexplored. **Methods:** Plasma samples were obtained from 79 subjects: (a) 42 NSCLC patients with EGFR mutations in primary tumors tissue, from a prospective trial, where blood samples were collected at baseline prior to first-line erlotinib therapy and immediately after progression; (b) 15 previously untreated stage IIIB-IV NSCLC patients, with EGFR mutation positive tumor specimens, where plasma samples were collected at baseline and serially at 4-60 days during TKI therapy; (c) 22 negative control cases. EGFR mutation analysis in plasma was conducted by the cobas EGFR Mutation Test (EGFR test, under development, RMS, Pleasanton, CA) and ultra-deep next generation sequencing (UDNGS) by Roche 454-GS Junior and Illumina MiSeq. A semi-quantitative index (SQI) was derived from a dilution series of known mutation copy numbers. Clinical response, expressed as percent tumor shrinkage (PTS), was evaluated according to RECIST criteria. **Results:** The sensitivity and specificity of the EGFR test and UDNGS assay in plasma versus tissue was 72% and 100%, and 74% and 100%, respectively. Quantitative indices by the EGFR test and UDNGS showed a significant positive correlation ($p < 0.0001$). Serial testing of EGFR mutations revealed a progressive decrease in the EGFR semi-quantitative index (SQI) during therapy in all of the patients, starting from the 4thday of treatment in 90% of cases. The rate of SQI decrease was more than 50% at 15 days in 73% of patients (rapid responders) and less than 50% at 15 days in 27% of patients (slow responders) and was correlated with PTS at 2 months. **Conclusions:** Quantification of EGFR mutations with the cobas test in plasma is feasible. The variation of EGFR SQI during therapy could be useful for early prediction of response and diagnosis of relapse, with further implications for patient management. A prospective trial has been planned to confirm these results. Clinical trial information: EudraCT Number: 2010-023892-24.

8080 Poster Session (Board #404), Mon, 8:00 AM-11:30 AM

Association of plasma EGFR T790M ctDNA status with clinical outcome in advanced NSCLC patients with acquired EGFR-TKI resistance. *First Author: Di Zheng, Shanghai Pulmonary Hosp, Shanghai, China*

Background: *EGFR* T790M mutation occurs in around half of non-small cell lung cancer (NSCLC) patients with acquired EGFR-TKI (TKI) resistance, based on tumor tissue re-biopsies using an invasive clinical procedure. Here, we evaluated the feasibility of detecting T790M mutation in circulating tumor DNA (ctDNA), using serial plasma samples from NSCLC patients receiving TKI to further investigate its association with clinical outcome. **Methods:** Patients with advanced or recurrent NSCLC receiving TKI were enrolled consecutively and blood samples were taken every 2 months, including post-TKI failure. Upon TKI failure, patients were given continued TKI alone or TKI plus chemotherapy at the discretion of the physician. *EGFR* ctDNA in plasma was measured using Droplet Digital PCR (ddPCR) assay. Overall survival (OS) of starting from initial TKI treatment was analyzed according to the T790M ctDNA status detected in plasma. **Results:** Among 318 patients, 117 who acquired TKI resistance (with 391 plasma samples) were eligible for the analysis. T790M ctDNA was detected in the plasma of 55/117 (47%) patients. Almost half of the T790M ctDNA positive patients were identified at a median time of 2.2 months prior to clinical progressive disease (PD). Furthermore, T790M ctDNA positive patients had significantly shorter OS compared to negative patients (median OS: 808 versus 1083 days, P = 0.0418). **Conclusions:** Our study demonstrates the feasibility of monitoring EGFR mutation dynamics in serial plasma samples from NSCLC patients receiving TKI therapy. T790M ctDNA can be detected in plasma before and after PD and represents a potential poor prognostic factor.

8081 Poster Session (Board #405), Mon, 8:00 AM-11:30 AM

Kinetic monitoring of EGFR T790M in urinary circulating tumor DNA to predict radiographic progression and response in patients with metastatic lung adenocarcinoma. *First Author: Hatim Husain, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: Acquisition of the EGFR T790M resistance mutation is a hallmark of disease progression in patients with metastatic EGFR mutant lung adenocarcinoma treated with anti-EGFR inhibitors. Biopsies are challenging in relapsed patients and a non-invasive approach to detecting T790M is desired. We sought to monitor urinary circulating tumor (ct) DNA for the early acquisition of T790M and understand ctDNA kinetics in patients on anti-EGFR treatment. **Methods:** In a biomarker study of 100 patients with EGFR-mutated metastatic lung adenocarcinoma (39 patients enrolled), urine samples were obtained at different time points up to 8 months prior to radiographic progression on anti-EGFR tyrosine kinase inhibitors (TKIs) and at multiple time points post progression on next line therapy. Urinary ctDNA was extracted by a method that preferentially isolates short, fragmented ctDNA. Quantitative analysis of T790M was performed using PCR coupled with next generation sequencing (MiSeq), with standardized reporting of mutant allele copies per 10^5 genome equivalents. **Results:** Interim analysis was conducted in 22 patients. EGFR T790M mutation was detected in the urine of 15 out of 22 (68%) patients who received anti-EGFR treatment. Of 15 patients positive for T790M by urine, 10 patients had T790M mutation in tissue biopsy (CLIA test). Three patients, who were tissue T790M negative (n = 3) but had a very high clinical suspicion of T790M, had detectable T790M in both urine and plasma. EGFR T790M was detected in urine up to 3 months prior to the detection of radiographic progression on anti-EGFR TKIs. Examination of urine samples collected daily after initiation of anti-EGFR TKIs and second line therapy revealed early peaks in ctDNA one day after therapy which predicted CT radiographic response. **Conclusions:** We demonstrate for the first time that T790M can be successfully detected in urinary ctDNA months before progression on anti-EGFR TKIs. Urinary ctDNA testing identifies additional patients who are potentially eligible for anti-T790M treatment. Urine monitoring can enable dynamic assessment of response and progression from a completely non-invasive sample.

8082 Poster Session (Board #406), Mon, 8:00 AM-11:30 AM

EML4-ALK rearrangement in blood platelets and outcome to crizotinib in non-small-cell lung cancer patients. *First Author: Niki Karachaliou, Quirón Dexeus University Institute, Translational Research Unit, Barcelona, Spain*

Background: Non-small-cell lung cancer (NSCLC) with EML4-ALK rearrangements is sensitive to crizotinib. However, despite initial response most patients (p) will eventually relapse and monitoring EML4-ALK rearrangements over the course of treatment may help identify them. Challenges associated with serial tumor biopsies have highlighted the need for blood-based assays for monitoring biomarkers. Platelets can sequester RNA released by tumor cells and are an attractive source for non-invasive biomarker assessment. **Methods:** EML4-ALK rearrangements were analyzed by reverse transcription-polymerase chain reaction (RT-PCR) in platelets and plasma isolated from blood obtained from 77 NSCLC p, 38 of whom had EML4-ALK-rearranged tumors. In a subset of 29 p with EML4-ALK-rearranged tumors treated with crizotinib, EML4-ALK rearrangements in platelets were correlated with progression-free survival (PFS) and overall survival (OS). **Results:** The study was designed with three parallel objectives: firstly to determine the sensitivity and specificity of detecting EML4-ALK rearrangements in platelets with plasma serving as a control biosource; secondly, to examine the potential impact of EML4-ALK rearrangement in platelets on outcome to crizotinib; thirdly, to test the feasibility of monitoring a p throughout treatment with EML4-ALK rearrangement assessment in platelets**.** RT-PCR demonstrated 65% sensitivity and 100% specificity for detection of EML4-ALK rearrangements in platelets. In the subset of 29 p treated with crizotinib, PFS was 3.7 months for p with EML4-ALK+ platelets and 16 months for those with EML4-ALK− platelets (hazard ratio, 3.5; P = 0.02). Monitoring EML4-ALK rearrangements in platelets of one index p over a period of 30 months revealed crizotinib resistance two months prior to radiographic disease progression. **Conclusions:** Platelets may provide a useful source for non-invasive assessment of EML4-ALK rearrangements and may prove useful for predicting outcome to crizotinib. Serial analyses of EML4-ALK rearrangements in platelets may help improve clinical decisions based on radiographic imaging alone by detecting resistance to therapy sooner.

8083 Poster Session (Board #407), Mon, 8:00 AM-11:30 AM

Phase I dose escalation study of ASP8273, a mutant-selective irreversible EGFR inhibitor, in subjects with EGFR mutation positive NSCLC. *First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ASP8273 is a mutant selective, third generation irreversible inhibitor of EGFR activating mutations and the EGFR T790M resistance mutation, with less effect on wild type EGFR. **Methods:** In a phase I dose escalation study, subjects diagnosed with EGFR mutation positive NSCLC who were previously treated with an EGFR TKI were enrolled at multiple centers in the United States into dose escalation and expansion cohorts. ASP8273 was administered once daily at doses of 25 mg to 400 mg. Endpoints included safety and tolerability, PK and preliminary anti-tumor activity. Response expansion cohorts enrolled subjects with known EGFR T790M mutation and required submission of tissue samples for central confirmatory testing. **Results:** As of 08 January 2015, 35 subjects were enrolled; 24 subjects in 6 dose escalation cohorts (25-400 mg) and 11 subjects in 2 expansion cohorts (100-200 mg). The majority were female (71.4%), median age 65 (38-85), all (100%) received prior erlotinib, and the median number of prior therapies was 2. The most common treatment emergent AEs included nausea (9; 25.7%) & diarrhea (6; 17.1%); most were CTCAE Grade 1, manageable and none required dose reductions. Of 5 evaluable subjects enrolled at 400mg, 2 DLTs were observed requiring dose reduction including one event of G3 hyponatremia and one event of G3 anorexia. No ILD-like events, QTc prolongation or hyperglycemia have been reported. PK appeared to be dose proportional with mean t½ ~12 hours. Objective responses were observed at dose levels of ≥ 100mg. Among 25 subjects evaluable for response at the cutoff date, 7 (28%) subjects achieved PR and 15 (56%) achieved stable disease. Among 12 known T790M+ subjects, 3 PRs (25%) have been reported to date. **Conclusions:** ASP8273 appears well tolerated in doses ranging from 25-300 mg and has demonstrated anti-tumor activity at 100-400 mg dose levels. The most common toxicities include diarrhea and nausea which were G1 and manageable. Based on current Bayesian modeling, the MTD is anticipated to be 400 mg and the recommended phase 2 dose to be 300 mg. As the data for the T790M+ population is immature at the time of this abstract, updated data will be presented at the ASCO meeting. Clinical trial information: NCT02113813.

8084 Poster Session (Board #408), Mon, 8:00 AM-11:30 AM

Updated safety and efficacy results from phase I/II study of HM61713 in patients (pts) with EGFR mutation positive non-small cell lung cancer (NSCLC) who failed previous EGFR-tyrosine kinase inhibitor (TKI). *First Author: Keunchil Park, Division of Hematology & Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: HM61713 is an orally available EGFR mutation-specific inhibitor with sparing EGFR WT tumors that previously showed promising efficacy in T790M positive tumors at the dose of 300 mg (overall response rate; 29.2%). We report here on updated data from the ongoing phase I/II study of HM61713 in pts with advanced NSCLC who had failed previous EGFR-TKIs (NCT01588145). **Methods:** Advanced NSCLC pts with EGFR mutation positive tumor were enrolled in dose escalation cohort and received doses ranging from 75-1200 mg/day. After safety evaluation, separate expansion cohorts opened for pts who failed prior EGFR TKI pts at 800 mg QD dose, respectively to investigate efficacy and tolerability of HM61713 in pts with centrally confirmed T790M positive NSCLC. **Results:** As of 15 Dec 2014, 173 patients were enrolled, 55 and 118 in dose escalation and expansion parts, respectively. Maximum tolerated dose (MTD) was established as 800 mg once daily (QD). Dose limiting toxicities (DLTs) included abdominal pain, diarrhoea, idiosyncratic drug reaction, and elevation of aspartate aminotransferase, alanine aminotransferase, amylase and lipase. Treatment-related adverse events occurred in 87.3% of 165 pts; mainly diarrhea, rash, skin exfoliation, nausea, pruritus, decreased appetite and dry skin. In the 34 pts with centrally confirmed T790M who received HM61713 with a dose more than 650 mg, the overall response rate was 58.8%, (10 confirmed/10 unconfirmed partial responses) and 13 pts achieved disease stabilization (disease control rate; 97.1%). Updated data will be presented at the meeting. **Conclusions:** HM61713 showed an encouraging clinical anti-tumor activity with good tolerability in pts with T790M positive NSCLC. Clinical trial information: NCT01588145.

8085 Poster Session (Board #409), Mon, 8:00 AM-11:30 AM

A phase II, single-arm, efficacy and safety study of poziotinib (NOV120101) in Korean patients with advanced or metastatic lung adenocarcinoma who have acquired resistance to epidermal growth factor receptor tyrosine kinase inhibitors. *First Author: Ji-Youn Han, National Cancer Center, Goyang, South Korea*

Background: Poziotinib is an oral irreversible inhibitor of EGFR, HER2 and HER4, and has shown preclinical activity in lung cancer models with *EGFR* mutations including T790M. This phase II study was aimed to access the efficacy of poziotinib in patients with *EGFR*-mutant lung adenocarcinoma and acquired resistance to erlotinib or gefitinib. **Methods:** Eligible patients had documented activating *EGFR*mutations and developed acquired resistance after treatment with erlotinib or gefitinib based on Jackman criteria. Patients received poziotinib at a dose of 16 mg once daily in 28-day cycles. The primary endpoint was PFS. All tumor responses were evaluated by independent review and, in a supportive manner, by investigator. **Results:** A total of 39 patients were treated with poziotinib in this study (29 women, median age 62 years [range, 43-84]). Most patients received erlotinib or gefitinib as first-line (n = 27) or second-line therapy (n = 11). The median time on erlotinib or gefitinib was 13.1 months (range, 3.4-33.2). Genotyping using tumor biopsy acquired at study entry was determined in 37 patients; 19 patients had *EGFR* T790M mutation, 2 *PIK3CA* mutation and no *MET*-amplification. Partial response with poziotinib was confirmed in 3 patients (8%; 95% CI, 2-21). Twenty patients (51%; 95% CI, 35-68) had disease control of at least stable disease for ≥ 8 weeks. The median PFS and overall survival were 2.7 (95% CI, 1.8-3.7) and 15.0 months (95% CI, 9.5-not estimable), respectively. The most frequently reported AEs of grade 3 by preferred term were rash (59%), stomatitis (18%), and diarrhoea (10%). Two patients were discontinued due to treatment-related AEs (one grade 3 rash and one grade 3 myositis). **Conclusions:** Poziotinib showed modest efficacy in patients with *EGFR*-mutant lung adenocarcinoma who had progressed on erlotinib or gefitinib. Obvious clinical evidence suggesting that poziotinib may overcome acquired resistance secondary to *EGFR* T790M mutation was not captured in this study. Clinical trial information: NCT01718847.

8086 Poster Session (Board #410), Mon, 8:00 AM-11:30 AM

A phase Ib/II study of afatinib in combination with nimotuzumab in non-small cell lung cancer patients with acquired resistance to gefitinib or erlotinib. *First Author: Myung-Ju Ahn, Samsung Medical Center, Seoul, South Korea*

Background: Afatinib (A) is a potent irreversible ErbB family blocker and nimotuzumab (N) is a humanized anti-EGFR mAb. In this phase Ib/II study, we aimed to assess the safety and activity of A plus N in advanced NSCLC patients with acquired resistance to gefitinib or erlotinib. In our preclinical study, using a mouse xenograft model, Nimotuzumab enhanced the antitumor efficacy of Afatinib. **Methods:** Major inclusion criteria were advanced NSCLC with activating EGFR mutation or disease control for at least six months with previous gefitinib or erlotinib therapy. In phase Ib study using classic 3+3 dose escalation method, patients were treated with A either 40mg/d or 30mg/d in combination with N either 100mg/w or 200mg/w. One cycle was composed of 4 weeks of treatment. In phase II study, patients were treated with A plus N in the level of RP2D defined in phase Ib study. **Results:** Overall, fifty pts were enrolled and treated: 13 in phase Ib and 37 in phase II. The median age of the patients was 55 years and 62% were female. EGFR mutation types were as follows: del19 (N = 23, 46%), L858R (N = 15, 30%), and others. All patients had received prior gefitinib (N = 34, 68%) or erlotinib (N = 16, 32%). At the first cohort (A 40mg/d + N 100mg/w), 1 out of 6 pts experienced 1 DLT (G3 diarrhea), and 2 out of 6 pts experienced DLTs (G3 diarrhea and G3 neutropenia, respectively) during the 1st cycle in the next cohort (A 40mg/d + N 200mg/w). Thus, RP2D was accordingly determined as A 40mg/d + N 100mg/w per protocol. In phase II part, there was no treatment related death and 27% (10/37) of patients experienced any grade 3 adverse events (no one in grade 4 or 5), including diarrhea and skin rash. In phase II part, the response rate was 38% (14/37), disease control rate 81% (30/37), duration of response 4.0 months (range, 1.8-8.5 months) and the median PFS was 4.2 months (95% CI:2.44-5.96 months). **Conclusions:** Combination of A and N showed an acceptable safety profile and promising antitumor activity in advanced NSCLC patients with acquired resistance to gefitinib or erlotinib. Clinical trial information: 1200.189.

8087 Poster Session (Board #411), Mon, 8:00 AM-11:30 AM

Biomarker analysis of a phase II trial of cabozantinib and erlotinib in patients (pts) with EGFR-mutant NSCLC with epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) resistance: A California Cancer Consortium Phase II Trial (NCI 9303). *First Author: Karen L. Reckamp, City of Hope, Department of Medical Oncology and Therapeutics Research, Duarte, CA*

Background: Modulation of the MET and VEGFR signaling pathways are associated with resistance to EGFR TKI therapy in addition to acquired T790M mutation (mt). Cabozantinib is a TKI that targets MET and VEGFR2, and RET, AXL, IT and TIE-2. Third generation EGFR inhibitors are effective in T790M mt-pos tumors, although treatment of T790M-neg disease remains an area of unmet need. Cabozantinib and erlotinib in *EGFR*mt-positive NSCLC following PD on EGFR TKI showed benefit, and we evaluated potential mechanisms of resistance to therapy. **Methods:** Pts with *EGFR* mt and PD on an EGFR TKI immediately prior to enrollment were eligible. Erlotinib 150 mg daily + cabozantinib 40 mg daily were given on a 28 day cycle and ORR was the primary objective. Pts were required to have archival tissue available, and a subset had biopsy samples post-progression on EGFR TKI. *MET* amplification was determined by FISH and *EGFR*mt, including T790M, was analyzed by next-generation sequencing. **Results:** 37 pts were enrolled and baseline *EGFR* mt was del19 in 68%, L858R in 30%, and 1 patient had an exon 18 mt. 57% received two or more prior therapies. Fifteen (41%) had post-EGFR TKI biopsies available, with 8 T790M-pos. *MET*gene amplification was not found in any of those with post-progression biopsies. ORR was 12.5% in pts with T790M-pos tumors, but DCR and PFS was increased in pts with T790M-neg tumors (see Table). OS was longer in pts with T790M-pos mt, which may reflect post-study therapy or biologic differences. **Conclusions:** Cabozantinib and erlotinib had clinical benefit in heavily treated patients with EGFR mt and EGFR TKI resistance. Further investigation in pts with T790M-neg tumors is warranted, and remains an unmet need. Additional biomarkers will be evaluated in plasma. Supported by NCI N01CM2011-00038 and U01CA062505. Clinical trial information: NCT01866410.

	All (n = 37)	T790M-neg (n = 7)	T790M-pos (n = 8)	T790M n/a (n = 22)

8088 Poster Session (Board #412), Mon, 8:00 AM-11:30 AM

Genetic variability and clinical presentation of patients with non-small cell lung cancer (NSCLC) harboring *MET*-amplifications. *First Author: Anna Eisert, Lung Cancer Group Cologne, Department I of Internal Medicine, University Hospital of Cologne, Center for Integrated Oncology (CIO) Köln Bonn, Cologne, Germany*

Background: Amplification of *cMET* has been described as mechanism underlying resistance to EGFR-targeted therapy in EGFR-mutated NSCLC. Nevertheless, few is known about *cMET* amplification beside the EGFR-resistance setting. This study was performed in order to characterize patients with low-level, intermediate-level and high-level cMET amplification focusing on frequency, co-occuring driver mutations and clinical outcome. **Methods:** Within a regional molecular screening network *cMET* amplification status was analyzed by fluorescence in-situ hybridization (FISH) in 588 patients with NSCLC regardless of histology. Next-generation parallel sequencing (NGS) using 102 amplicons and 14 genes was performed in all analyzed samples. Clinical parameters (age, sex, UICC tumor stage, smoking status and medical and therapeutical history) of all patients were assessed. **Results:** 171 patients (29.1%) with *cMET* amplification were identified, whereof 17 (9.9%) had high-level amplification. *cMET* amplifications co-occured in 98 patients (57.3%) with a large spectrum of other driver mutations (*EGFR*, *KRAS*, *HER2*, *STK11*, *NRAS*, *BRAF*) or amplifications (*FGFR1)* in both adenocarcinoma (60.2%) and squamous cell carcinoma (21.1%). 9 patients of the high-level-amplified patients did not have an additional driver mutation, while the remaining 8 patients had mutations within *EGFR*, *KRAS*, *PIK3CA*, *BRAF* and *STK11*. *cMET* amplification was associated with a history of smoking and detected in all UICC tumor stages. **Conclusions:** Our data suggest a high prevalence of *cMET* amplification in NSCLC patients with many oncogenic driver mutations. Most patients with an additional mutations had *KRAS* mutations. These data show that screening for *MET*-amplified patients in order to identify patients for MET-targeted treatment should not be performed on the basis of sequencing results.

8089 Poster Session (Board #413), Mon, 8:00 AM-11:30 AM

Response to tyrosine kinase inhibtors in non-small-cell lung cancer with concomitant c-MET overexpression and driver genes. *First Author: Na-na Lou, Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: The common driver genes in non-small-cell lung cancer (NSCLC) include *EGFR*, *ALK* and *KRAS*. We investigate the frequency of MET overexpression coexisting with oncogenic drivers and response to tyrosine kinase inhibitors (TKIs). **Methods:** We screened 806 consecutive NSCLC patients for the presence of MET overexpression by immunohistochemistry (IHC), in which ≥ 50% tumor cells with moderate to high intensity staining were defined as MET positive. *MET* amplification and *ALK* rearrangements were detected by fluorescence in situ hybridization (FISH), and FISH positive was defined as gene focal amplification or high polysomy (at least 15% cells with ≥ 5 copy numbers). Meanwhile, *KRAS* and *EGFR*mutations were tested by DNA sequencing or Scorpion amplification refractory mutation system (ARMS). **Results:** The frequency of MET overexpression was 31.9% (257/806) in NSCLC. Among c-MET positive patients, the frequency of *EGFR* mutation was 38.1% (98/257) and that of *ALK* rearrangement was 8.7% (22/257). Response rate (RR) of EGFR-TKIs was 22.2% (8/36) in advanced NSCLC patients with concomitant *EGFR* mutation and c-MET overexpression, and 56.8% (21/37) in those with only *EGFR* mutation, *P*= 0.033. However, there was no significant difference in RR between the patients with concomitant *ALK* rearrangement and c-MET overexpression and those with only *ALK* rearrangement, 61.5% (8/13) vs. 75.0% (6/8), *P*= 0.656. Among 2 cases with concomitant *MET* amplification and *EGFR* mutations, one responded to gefitinib, but the other had stable disease. Dramatic response was observed in one with concomitant *MET* amplification and *KRAS* mutations. **Conclusions:** Advanced NSCLC patients with concomitant *EGFR* mutation and MET overexpression have significantly low RR with EGFR-TKIs, indicating that MET overexpression potentially causes intrinsic resistance to EGFR-TKIs. Similar response was observed in *ALK* positive patients with or without c-MET overexpression treated with crizotinib.

8090 Poster Session (Board #414), Mon, 8:00 AM-11:30 AM

Crizotinib in advanced non-small-cell lung cancer with *de novo* c-Met overexpression. *First Author: An Na Li, Guangdong Lung Cancer Institute, Guangzhou, China*

Background: *c-Met* gene amplification has been identified as one of the acquired resistance to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) and *de novo* activation in advanced non-small-cell lung cancer (NSCLC). However, it is not clear whether c-Met overexpression could be as the biomarker for *de novo*. **Methods:** Advanced NSCLC patients with *de novo* c-Met expression were detected by immunohistochemistry (IHC) .≥50% tumor cells with moderate to high intensity staining were defined as c-Met positive. Gene copy numbers have been detected by FISH (By Cappuzzo scoring system ≥5 copies were positive or MET/CEP7 ratio ≥1.8 was defined as c-MET amplification).The statuses of *EGFR*, *ALK*, *KRAS* and *ROS1*were also tested. **Results:** From January 2013 to December 2014, 24 eligible patients with c-Met IHC overexpression received crizotinib treatment (3 female, median age 59 years), with 19 evaluable for response.Eleven of them achieved partial response (PR), 3 were stable disease (SD) and 5 were progressive disease (PD).All responders had high c-Met IHC status, and 8 with FISH positive. (Table 1).Adverse events of grade 3 QT prolongation have been found in 1 patient. For one death with interstitial lung disease, causality to crizotinib was not ruled out. The other most frequent drug-related AEs were grade1-2, including nausea (14/19), anorexia (14/19), vomiting(10/19),visual impairment (6/19). *EGFR*, *ALK*, *KRAS* and *ROS1* were all negative . Accrual of advanced patients is ongoing. **Conclusions:** c-Met overexpression could be as a biomarker for *de novo c-Met* amplified NSCLC. c-Met inhibitor against *de novo*c-Met overexpressed NSCLC is a good strategy. IHC seems not worse than FISH in predicting efficacy for c-Met inhibitor.

Objective response to crizotinib treatment for advanced NSCLC patients with *de novo* c-Met overexpression.

Targeting c-Met overexpression for overcoming acquired resistance to EGFR TKIs in NSCLC. *First Author: Lanying Gou, Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: c-Met amplification and T790M are both recognized as the common molecular mechanisms of acquired resistance (AR) to epidermal growth factor receptor tyrosine kinase inhibitors (EGFR TKIs) in advanced NSCLC. **Methods:** Advanced NSCLC patients with AR to EGFR TKIs were detected for c-Met overexpression by immunohistochemistry ≥ 50% tumor cells with moderate to high intensity staining were defined as c-Met positive. The statuses of *EGFR*, *ALK*, *KRAS* and *ROS1* were tested. c-Met, p-Met, EGFR, p-EGFR, ERBB3, p-ERBB3, AKT, p-AKT, MAPK, p-MAPK, which were important markers in MET and EGFR signal pathway ,were tested by IHC. **Results:** From January 2013 to January 2015, 126 advanced NSCLC patients with AR to gefitinib or erlotinib were enrolled prospectively. The frequency of c-Met overexpression was 28.6% (36/126), c-Met overexpression+T790M 13.5% (17/126), T790M 24.6% (31/126), SCLC or squamous cell transformation 1.6% (2/126), *KRAS* mutation 0.8% (1/126), *ROS1* fusion 0.8% (1/126) ,*ALK* fusion 0.8%(1/126) and unknown mechanism 29.3% (37/126), respectively. Eleven c-Met overexpressed patients received gefitinib plus c-Met inhibitors crizotinib. Response rate (RR) by RECEIST was 45.5% (5/11), Disease control rate (DCR) was 54.5% (6/11), Progression disease (PD) was 45.5% (5/11). For patients with c-Met overexpression and without T790M DCR was 100% (5/5). Among these patients 40% (2/5) cases were ongoing at data cut-off. The longest duration of response to date is > 6 months. For patients with both c-Met/T790M positive no RR was found. We detected the protein expression of c-Met, p-Met, EGFR, p-EGFR, ERBB3, p-RBB3, AKT, p-AKT, MAPK, p-MAPK in tumor of 9 cases with c-Met/T790M by IHC. The results showed that all of the markers were positive in ≥ 50% cases (each marker was positive in at least 5 cases, respectively). **Conclusions:** c-Met overexpression could be as a biomarker for AR. Combination of EGFR TKIs and c-Met inhibitor is a good strategy to overcome AR for c-Met overexpressed patients, but not effective in c-Met/T790M-coexisting cases. One of the possible mechanism of resistance could contribute to both MET and EGFR signal pathway active.

8092 Poster Session (Board #416), Mon, 8:00 AM-11:30 AM

Phase I/II study of rilotumumab (R) and erlotinib (E) in previously treated patients (pts) with metastatic NSCLC. *First Author: Ahmad A. Tarhini, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: MET is frequently overexpressed in NSCLC. Amplification of MET and its ligand (HGF), are mechanisms of resistance to EGFR inhibitors. R is an IgG2 human mAb that targets HGF. This phase I/II trial evaluated the safety and recommended phase 2 dose (RP2D) of R combined with E for pts with metastatic previously treated NSCLC (Phase I) and whether efficacy is high enough to warrant further interest (Phase II). **Methods:** Phase I adopted a dose de-escalation design with R starting at 15 mg/kg IV every 3 weeks and E 150 mg orally daily (dose level 0). If dose de-escalation was needed it would proceed according to Narayana k-in-a-row design where a selected dose was estimated by isotonic regression. RP2D was the maximum below the dose associated with a 25% DLT rate. Phase II intended to test whether disease control rate (stable disease or response, DCR) of 50% for E could be improved by adding R. A Simon 2 stage design was used to select the optimal sample size for type I and II error of .10. Twenty-seven of 45 pts were required to have disease control for evidence of a statistically significant improvement over E alone. Response was assessed by RECIST every 6 weeks. **Results:** In the absence of need for de-escalation among the first 8 pts, the RP2D was defined as dose level 0. Overall, 45 response-evaluable pts with stage IV were enrolled (13 squamous and 32 adenocarcinoma; 2 EGFR and 7 KRAS mutant). Median age was 65 years. A median of 4 cycles (range 1-18+) were administered. Four pts had partial response (one with EGFR and one KRAS mutation), 23 had SD, and 18 had progression, for a response rate of 8.9% (90% CI, 3.9 - 18.1) and DCR of 60% (90% CI, 47.1 - 71.3). Median PFS 2.6 months (90% CI 1.4- 2.7). At a median follow up of 15 months, median OS was 6.6 months (90% CI, 5.6 - 8.9). Probability of surviving one year was .33 (90% CI, .23 - .47). Among grade 3/4 AEs that were considered at least possibly related were rash (3), oral mucositis (1), elevated alkaline phosphatase (3) and bilirubin (1), thromboembolic event (3), diarrhea (5). **Conclusions:** The combination of R and E in this study was found to have an acceptable safety profile and the DCR rate met the study's pre-specified criteria for success. Further investigation of this regimen is warranted. Clinical trial information: NCT01233687.

8093 Poster Session (Board #417), Mon, 8:00 AM-11:30 AM

Nationwide genomic screening network for the development of novel targeted therapies in advanced non-small cell lung cancer (LC-SCRUM-Japan). *First Author: Shingo Matsumoto, Division of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan*

Background: Various driver gene alterations have emerged as critical targets for molecular therapies in non-small cell lung cancer (NSCLC), but these alterations other than *EGFR* mutations occur in rare populations. A nationwide genomic screening network in Japan (LC-SCRUM-Japan) was established in February 2013 for the development of novel targeted therapies against advanced NSCLCs harboring these rare alterations. **Methods:** Advanced non-squamous NSCLCs without *EGFR* mutations were eligible for inclusion in LC-SCRUM-Japan. The tumors were analyzed for *ALK/RET/ROS1* fusions using RT-PCR, and detected fusions were confirmed by FISH. Between November 2013 and March 2014, fusion-negative tumors were further examined for other driver gene mutations using a next-generation sequencing (NGS) system (Ion PGM with Ion Torrent AmpliSeq Cancer Hotspot Panel, version 2), enabling the simultaneous analysis of 50 cancer-related genes. **Results:** As of December 26, 2014, a total of 188 institutions across Japan were participating and 1347 patients had been enrolled in LC-SCRUM-Japan. Among 1271 available samples, *ALK/RET/ROS1* fusions were detected in 24 (2%)/31 (3%)/55 (4%) cases, respectively. The NGS analysis was performed in 201 cases without the fusions, and 82 cases (41%) had driver mutations, including 45 *KRAS* mutations (22%), 10 *BRAF* mutations (5%), 9 *ERBB2* mutations (4%), 2 *PIK3CA* mutations (1%), and 1 *NRAS* mutation (0.5%). *MET* and *ERBB2* amplifications were also detected by the NGS in 4 (2%) and 2 (1%) cases, respectively. Among a total of 198 cases harboring targetable gene alterations, 16 with *RET* fusions, 26 with *ROS1* fusions, and 2 with *BRAF* mutations were enrolled in clinical trials for vandetanib (LURET study, Japan), crizotinib (OO12-01, East Asia), and dabrafenib (BRF113928), respectively. **Conclusions:** This nationwide and population enrichment screening system enabled various rare driver gene alterations to be efficiently detected in advanced NSCLC, thereby contributing to the rapid accrual of matched patients in clinical trials for targeted therapies.

8094 Poster Session (Board #418), Mon, 8:00 AM-11:30 AM

Migration to next-generation sequencing and the identification of *RET* and *ROS1* rearrangements plus PTEN and MET protein expression in tumor specimens from patients with lung adenocarcinomas: Lung Cancer Mutation Consortium (LCMC 2.0). *First Author: Mark G. Kris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LCMC 1.0 demonstrated that multiplexed genomic platforms can assay 10 oncogenic drivers at diagnosis in tumor specimens from patients with lung adenocarcinomas and this information can guide care. (Kris JAMA 2014) The number of molecular lesions that can be targeted with drugs continues to grow and Next-Generation Sequencing permits more comprehensive testing of more aberrations with less tumor tissue. To translate these advances, we initiated LCMC 2.0 to test initial tumor specimens for 12 oncogenic drivers and to provide the results to clinicians for treatment decisions and research. **Methods:** The 16 site LCMC 2.0 is testing tumors from 1000 patients with lung adenocarcinomas in CLIA laboratories for *KRAS, EGFR, HER2, BRAF, PIK3CA, MAP2K1, AKT1*, and *NRAS* mutations, *MET* amplification, rearrangements in *ALK*, *RET*, and *ROS1*,and PTEN (MAb 138G4) and MET (MAb SP44) expression by immunohistochemistry. All patients were diagnosed with stage IIIB/IV after May 2012, had a performance status 0-2 and available tumor tissue. **Results:** Of 986 patients registered, data is now reported for 617. An oncogenic driver has been found in 52% (95% CI 49 to 56%). Drivers detected 13 *RET* (2%, 95% CI 1 to 3%) , 17 *ROS* (1%, 95% CI $<$ 1 to 2%), 135 *KRAS* (22%, 95% CI 19 to 25%), 77 *EGFR* (13%, 95% CI 13 to 15%), 20 *ALK* (3%, 95% CI 2 to 5%), 18 *BRAF* (3%, 95% CI 2 to 4%), 4 *PIK3CA* ($<$ 1%, 95% CI $<$ 1to 1%), 9 *HER2 (*2%, 95% CI $<$ 1 to 3%), 12 *MET* amplification (2%, 95% CI 1 to 3%), 3 *NRAS* ($<$ 1%, 95% CI $<$ 1 to 1%), 1 *MAP2K1* ($<$ 1%, 95% CI $<$ 1 to 1%), 0 *AKT1*, 26 had $\geq$ 2 findings (4%, 95% CI 3 to 6%). PTEN loss was detected in15% (95% CI 12 to 17%) and MET expression in 54% (95% CI 50 to 58%). Next-Generation platforms were used at 81% of LCMC 2.0 sites. Results were used to select a targeted therapy or trial in 16%. **Conclusions:** Next-Generation Sequencing is rapidly becoming routine practice at LCMC 2.0 centers with use going from 0 to 81% of sites since 2012. LCMC 2.0 identified additional targets (*RET* and *ROS1* rearrangements and PTEN loss) and detected an actionable oncogenic driver in the majority of initial lung adenocarcinoma specimens. Supported by Free to Breathe Clinical trial information: NCT01014286.

8095 Poster Session (Board #419), Mon, 8:00 AM-11:30 AM

Clinical implementation of anchored multiplex PCR with targeted next-generation sequencing for detection of ALK, ROS1, RET and NTRK1 fusions in non-small cell lung carcinoma. *First Author: Anna F. Farago, Massachusetts General Hospital, Boston, MA*

Background: Chromosomal rearrangements resulting in expression of oncogenic receptor tyrosine kinase fusions occur in a subset of epithelial malignancies and can underlie sensitivity to tyrosine kinase inhibitors. In non-small cell lung cancer (NSCLC), rearrangements involving anaplastic lymphoid kinase (ALK), ROS proto-oncogene 1 (ROS1), and RET proto-oncogene (RET) occur at frequencies of approximately 4%, 1% and 1%, respectively. Rearrangements involving neurotrophic tyrosine kinase receptor type 1 (NTRK1) have been described, though the frequency is not well characterized. **Methods:** We implemented a multiplex polymerase chain reaction (PCR) technology, Anchored Multiplex PCR (AMP), for detection of fusion transcripts using targeted next-generation sequencing of cDNA generated from clinical samples (Zheng et al., 2014). The sequencing library targets known fusion exons in ALK, ROS1, RET and NTRK1. We retrospectively reviewed the NSCLC cases assessed by this method. **Results:** Between July 2013 and January 2015, 663 clinical NSCLC cases from our institution were assessed, providing $>$ 99% power to detect at least one fusion event at an underlying frequency as low as 1%. 584 cases were adenocarcinoma histology. We detected fusions involving ALK, ROS1, RET and NTRK1 at frequencies of 2.6%, 0.9%, 2.0% and 0.0% (17, 6, 13 and 0 cases), respectively. All were mutually exclusive. The histologic subtype was adenocarcinoma in all fusion cases except one. The average age at diagnosis was 57.0, 55.9 and 58.3 years, and average pack years were 8.5, 5.8 and 7.7 for patients with ALK, ROS1 and RET fusions, respectively. The ALK fusion partner in all cases was EML4; ROS1 fusion partners were SDC4, CD74, and EZR; and RET fusion partners were KIF5B, CCDC6, RUFY2 and TRIM24. Although no NTRK1 fusion was detected in NSCLC, we detected a PPL-NTRK1 fusion in a thyroid carcinoma. **Conclusions:** With this method, we identified ALK, ROS1 and RET fusions at frequencies and with patient characteristics consistent with previous studies. NTRK1 fusions appear to be rare in NSCLC, though it is possible that this assay may not detect all fusions.

8096 Poster Session (Board #420), Mon, 8:00 AM-11:30 AM

Feasibility of next-generation sequencing (NGS) for squamous non-small cell lung cancer (NSCLC): Implications for the NCI LungMAP study. *First Author: Adrian G. Sacher, Dana-Farber Cancer Inst, Cambridge, MA*

Background: While potentially targetable genomic alterations have been identified in squamous NSCLC, none have yet been translated into effective therapy. The NCI LungMAP study was designed to match patients (pts) with advanced squamous NSCLC to genotype selected treatment using targeted NGS. We studied a large cohort of consecutive pts with squamous NSCLC to gauge the feasibility of NGS for clinical trial arm allocation. **Methods:** All patients presenting to the Dana-Farber Cancer Institute are offered targeted NGS of existing biopsy samples under an institutional protocol (#11-104). This internally developed NGS assay sequences over 300 genomic targets of interest with a mean overall target coverage of 200x. All squamous NSCLC pts seen at our institution during the study period were identified from an institutional database. The rate of test utilization, assay failure, and detected genomic alterations were studied. **Results:** 174 pts with squamous NSCLC presented to our institution from 7/1/2013-11/18/2014. Of these, 100 consented to targeted NGS. Median age was 65, 89% and 11% were heavy versus light/never smokers, 66% were stage IIIB/IV. The majority of patients underwent core biopsy (52 core, 30 resection, 14 FNA, 3 cytology) Targeted NGS was successful in 74 patients, pending in 12 patients and failed in 13 patients due to insufficient tissue (5 FNA/cytology, 8 core). The mutational rates for each target of the LungMAP study were as follows: PIK3CA mutation 12% (9), CCND1-2 amplification 16% (12), CDK4 amplification 3% (2), FGFR1-4 amplification 24% (18), FGFR1-4 mutation 7% (5) and MET amplification 3% (2). Of these, 12% (9) pts had multiple targets detected. 18% (6/33) of these amplification events were high level (ploidy estimate $>$ 5 copies). **Conclusions:** NGS in a real-world squamous NSCLC cohort is feasible and yields a high rate (51% pts) of potentially targetable genetic alterations. The majority of amplification events are low-level (2-5 copies) which may be challenging to therapeutically target. Our findings support the use of targeted NGS as a tool to facilitate trial enrollment in studies such as the NCI LungMap and Match studies.

8097 Poster Session (Board #422), Mon, 8:00 AM-11:30 AM

***KEAP1*-mutations in patients with non-small cell lung cancer (NSCLC).** *First Author: Rieke Frank, Lung Cancer Group Cologne, Department I of Internal Medicine, University Hospital of Cologne, Center for Integrated Oncology (CIO) Köln Bonn, Cologne, Germany*

Background: Mutations in genes of the KEAP1-NFE2L2 pathway of patients with NSCLC are associated with an increased tumor growth, resistence towards cytostatic drugs and reduced survival rates. KEAP1 suppresses NFE2L2 under physiological conditions. Oxidative stress or electrophiles cause NFE2L2 to stabilize and translocate to the nucleus, resulting in the transcription of various cytoprotective genes. Mutations in *KEAP1* are described for diverse tumor entities with a relatively high frequency causing an increased level of NFE2L2. This leads to resistance of cancer cells against anti-cancer drugs and irradation. This study was performed to characterize *KEAP1*-mutated NSCLC clinically and genetically. **Methods:** Tumor tissue collected from 446 patients within a regional screening network was analysed for *KEAP1* mutations using next-generation sequencing (NGS). Clinical, pathological and genetic characteristics of these patients are described and compared with a control group of patients without *KEAP1* mutation. **Results:** So far, we identified 33 patients with *KEAP1* mutations. Among these we found 34 different mutations, of which the majority was not previously described. *KEAP1* mutations were not restricted to a special exon. In 30 patients (90.9%), additional driver aberrations in *KRAS*, *EGFR, FGFR1*, *FGFR3*, *STK11*, *ALK, DDR2, HRAS, BRAF, PIK3CA, PTEN, NFE2L2, EP300, TSC1, CREBBP, NRAS, MET* and *Her2* could be detected, as well as mutations and polymorphisms in *TP53*. *KEAP1* mutations occurred in both genders (male/female ratio 3/1), in squamous-cell carcinoma (36.4%) and adenocarcinoma (60.6%) and were significantly associated with smoking. The prognostic and predictive impact of *KEAP1* mutations in a prospective cohort will be presented. **Conclusions:** Our data suggest a role of *KEAP1*-mutations as a cofactor in addition to classical driver mutations underlying the malignant phenotype of lung cancer cells. So far, this is the largest cohort of patients with *KEAP1*-mutations analysed and described. Further survival and treatment analyses will reveal the role of these mutations for the outcome of these patients.

8098 Poster Session (Board #423), Mon, 8:00 AM-11:30 AM

Clinical and molecular characteristics of non-small cell lung cancer in patients harboring *CTNNB1* mutations. *First Author: Leonie Gogl, Lung Cancer Group Cologne, Departement I of Internal Medicine, University Hospital of Cologne, Center for Integrated oncology (CIO) Köln Bonn, Cologne, Germany*

Background: Although somatic mutations of *CTNNB1* in lung cancer have been described, there is still lack of information about prevalence, genetic variability, occurrence of additional aberrations and influence on outcome. This study was performed to analyze *CTNNB1*mutations in NSCLC genetically and clinically. **Methods:** Tumor tissue collected from 3885 patients within a regional screening network was analyzed for *CTNNB1* mutations using next generation sequencing (NGS). Clinical, pathological and genetic characteristics of these patients are described and compared with a control group of patients without *CTNNB1* mutation. **Results:** We have identified 58 (1.5%) *CTNNB1*-mutated patients, whereof 51 have been analyzed so far. This cohort consisted of 32 female and 19 male patients. Adenocarcinoma histology was found in 42 patients (82.4%), but CTNNB1 mutations were also found in squamous cell and neuroendocrine carcinomas. 21 different *CTNNB1* mutations were detected on exon 3, of which most are miss-sense mutations (49) besides 2 deletions. The most frequent mutations were S37F and S37C substitutions which each occurred in nine patients. Exclusive *CTNNB1* mutations were only detected in five patients. In all remaining patients an additional driver mutation was found including mutations in *KRAS*, *EGFR*, *BRAF, AKT*, *PIK3CA* and *ERBB2* as well as *MET* amplification, *RET-KIF5b*-Inversion, *ROS1*-fusion and mutations and polymorphisms of *TP53*. **Conclusions:** *CTNNB1* mutations occur alone or in combination with other known oncogenic aberrations in NSCLC. Results of the ongoing clinical characterization of the patients as well as the prognostic and predictive impact of *CTNNB1* mutations will be presented.

8099 Poster Session (Board #424), Mon, 8:00 AM-11:30 AM

Maximum severity score (MSS) of baseline patient-reported Lung Cancer Symptom Scale (LCSS) as a prognostic and predictive factor for overall survival (OS) in the Phase III SQUIRE study. *First Author: Martin Reck, Lung Clinic Grosshansdorf, Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL), Grosshansdorf, Germany*

Background: SQUIRE, a randomized, phase III study (N = 1093) demonstrated that the addition of necitumumab (N) to gemcitabine-cisplatin (GC) improved OS in patients with stage IV squamous NSCLC. We further analyzed the results by baseline MSS and other cofactors that preliminary models suggested were prognostic for OS in this study. **Methods:** This post-hoc analysis defined the MSS for each patient as the worst (highest) score of any individual LCSS item at baseline. MSS was evaluated as a prognostic and predictive factor for OS and progression-free survival (PFS) using Cox and Kaplan-Meier methods. Cox models included baseline ECOG performance status, sum of target lesions, number of metastatic sites, body mass index, platelets, hemoglobin, and leukocytes. **Results:** As a continuous variable, MSS was prognostic for OS ($p < 0.001$) with a statistically significant interaction ($p = 0.006$) with treatment effect. These results manifested as subgroup differences shown in the table below. Results for PFS and OS were consistent. **Conclusions:** Prognosis for survival worsened with increasing LCSS severity, as shown with the MSS. The addition of N to GC was increasingly effective as severity increased, providing the greatest survival benefit in patients with more severe symptoms or more severely reduced functional ability or quality of life. This observation suggests baseline LCSS can provide information supporting treatment choice. Clinical trial information: NCT00981058.

8100 Poster Session (Board #425), Mon, 8:00 AM-11:30 AM

Afatinib (A) vs erlotinib (E) as second-line treatment of patients (pts) with advanced squamous cell carcinoma (SCC) of the lung following first-line platinum-based chemotherapy: Patient-reported outcome (PRO) data from the LUX-Lung 8 Phase III global trial. *First Author: Shirish M. Gadgeel, Karmanos Cancer Center, Detroit, MI*

Background: A is an irreversible ErbB family blocker that has shown clinical activity in pts with SCC of the head/neck and lung. The LUX-Lung 8 Phase III global trial compared A and E in pts with SCC of the lung following failure of platinum-based chemotherapy. Between Mar 2012 and Jan 2014, 795 stage IIIB/IV SCC pts were randomized 1:1 to receive A (40 mg/day) or E (150 mg/day) until progression. The primary endpoint of PFS, assessed after 414 events, was significantly higher for A than E (median: 2.4 vs 1.9 months; HR [95% CI]: 0.82 [0.68–1.00]; p = 0.04). PRO analyses of the PFS dataset are presented here. Updated PRO analysis of the OS dataset (to be undertaken after 632 deaths) will be available at the meeting. **Methods:** PROs were collected every 28 days until progression using the EORTC QLQ-C30/LC13 questionnaires. Percentage of pts improved on therapy, time-to-deterioration (TTD) and changes over time were analyzed for the pre-specified SCC symptoms: cough, dyspnea, and pain. **Results:** Improvement in global health status (GHS)/QoL was significantly greater with A than E (36.4 vs 27.1% pts; p = 0.026). More pts had an improvement in cough with A vs E (43.6 vs 32.6%; p = 0.010). The proportion of pts with improvements in dyspnea and pain were 49.4 vs 44.8% and 37.5 vs 37.5% with A and E, respectively. There were no significant differences in TTD of symptoms between treatment groups. However, trends favoring A were reported for dyspnea (HR [95% CI]: 0.82 [0.66–1.01]), fatigue (HR [95% CI]: 0.89 [0.73–1.09]), physical (HR [95% CI]: 0.81 [0.64–1.02]), and role (HR [95% CI]: 0.83 [0.67–1.03]) functioning. Changes in mean scores over time significantly favored A vs E for cough (p = 0.007), dyspnea (p = 0.021), and pain (p = 0.024), including chest pain, as well as fatigue (p = 0.006) and role (p = 0.001)/physical (0.024) functioning. **Conclusions:** Compared to E, A improved SCC symptoms, SCC symptoms over time, and overall GHS/QoL. PRO analyses of LUX-Lung 8 complement the significant improvement observed in PFS with second-line A vs E in pts with SCC of the lung. Clinical trial information: NCT01523587.

8101 Poster Session (Board #426), Mon, 8:00 AM-11:30 AM

Impact of crizotinib on patient-reported general health status compared with chemotherapy in patients with no prior systemic treatment for advanced non-squamous *ALK*-positive non-small cell lung cancer (NSCLC). *First Author: Enriqueta Felip, Vall d'Hebron University, Barcelona, Spain*

Background: The present analysis compares patient-reported general health status between crizotinib and chemotherapy in patients who had received no prior systemic treatment for advanced non-squamous *ALK*-positive NSCLC. **Methods:** Patients in the phase III PROFILE 1014 study (Pfizer; NCT01154140) were randomized to crizotinib (250 mg PO BID n = 172) or chemotherapy (pemetrexed 500 mg/m^2 + cisplatin 75 mg/m^2 or carboplatin AUC 5–6; all IV q3w for ≤ 6 cycles; n = 171). Patient-reported outcomes were assessed at baseline, day 1 of each cycle and end of treatment using EQ-5D, a standardized measure of health status that includes a descriptive system comprising 5 dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression rated at 3 levels (no, some, or extreme problems) and a single index score for health status (range 0 [dead] to 1 [full health]) calculated using a standard algorithm. In addition, a visual analog scale (VAS) measured health status from '0' (worst imaginable) to '100' (best imaginable). Repeated measures mixed-effects analyses were performed to compare overall VAS and index scores between treatments, controlling for baseline. **Results:** The mean (SD) scores at baseline were comparable between crizotinib and chemotherapy for VAS (70.78 [19.65] vs (66.64 [21.89]) and EQ-5D index scores (0.72 [0.30]) vs (0.71 [0.26]).The proportion of patients reporting presence of a problem at baseline for crizotinib and chemotherapy respectively were: mobility (27% vs 34%), self-care (13% vs 13%), usual activities (44% vs 46%), pain (56% vs 68%), and anxiety/depression (41% vs 39%). The overall mean VAS scores on treatment were statistically significantly higher ($p < 0.05$) in the crizotinib arm compared with the chemotherapy arm. The overall mean EQ-5D index scores on treatment were significantly greater ($p < 0.001$) for crizotinib [0.81] compared with chemotherapy [0.72]. **Conclusions:** Treatment with crizotinib leads to significantly greater overall general health status scores compared to chemotherapy in in advanced non-squamous *ALK*-positive NSCLC patients. Clinical trial information: NCT01154140.

TPS8102 Poster Session (Board #427a), Mon, 8:00 AM-11:30 AM

A randomized, phase III study (FLAURA) of AZD9291, a novel EGFR-TKI, versus gefitinib or erlotinib in treatment-naïve patients with advanced non-small cell lung cancer and an EGFR-TKI-sensitizing mutation. *First Author: Suresh S. Ramalingam, The Winship Cancer Institute of Emory University, Atlanta, GA*

Background: EGFR-TKI is the recommended treatment for patients with advanced NSCLC who have an EGFR-TKI-sensitizing mutation (EGFRm). However, most patients develop resistance, and in ~60% of cases the EGFR T790M mutation is the cause. AZD9291 is an oral, potent, irreversible EGFR-TKI selective for EGFRm and T790M mutations. Preliminary data from a Phase I/II study demonstrated clinical activity and a manageable tolerability profile for AZD9291 as first-line treatment of patients with EGFRm advanced NSCLC. **Methods:** This Phase III, double-blind, randomized study (FLAURA, NCT02296125) is designed to assess the efficacy and safety of AZD9291 (80 mg qd, orally) versus standard of care (SoC) EGFR-TKI (gefitinib [250 mg qd, orally] or erlotinib [150 mg qd, orally]) in treatment-naïve patients with locally advanced or metastatic EGFRm NSCLC. Eligible patients must have pathologically confirmed adenocarcinoma harboring an EGFR Ex19del or L858R mutation, alone or in combination with another EGFRm, determined by local (accredited laboratory) or central testing. Patients ≥ 18 years of age (≥ 20 in Japan), WHO performance status 0–1, will be randomized 1:1 to receive either AZD9291 or SoC EGFR-TKI, stratified by mutation status (Ex19del or L858R) and race (Asian versus non-Asian), until RECIST v1.1 defined progression or a discontinuation criterion is met. Patients may continue randomized treatment beyond RECIST defined progression if they continue to show clinical benefit, as judged by the Investigator. The primary objective is to compare progression-free survival (PFS) for AZD9291 to SoC EGFR-TKI. PFS in patients with tumors harboring T790M is a key secondary objective. Additional secondary objectives include PFS by Ex19del or L858R detectable in circulating tumor DNA, objective response rate, duration of response, disease control rate, depth of response, overall survival, PK, health-related quality of life, patient satisfaction with treatment, and the safety and tolerability profile of AZD9291 compared with SoC EGFR-TKI. The study was opened to accrual in November 2014. Clinical trial information: NCT02296125.

TPS8103 Poster Session (Board #427b), Mon, 8:00 AM-11:30 AM

KEYNOTE-024: Phase III trial of pembrolizumab (MK-3475) vs platinum-based chemotherapy as first-line therapy for patients with metastatic non-small cell lung cancer (NSCLC) that expresses programmed cell death ligand 1 (PD-L1). *First Author: Julie R. Brahmer, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: The current standard-of-care first-line therapy for patients with advanced NSCLC who lack *EGFR* sensitizing mutations or an *ALK* translocation is platinum-based combination chemotherapy with or without maintenance therapy. Median OS with platinum-based chemotherapy ranges from 10-12 months. Pembrolizumab, a humanized monoclonal antibody against PD-1, has shown antitumor activity as first-line therapy for NSCLC, particularly in patients whose tumors strongly express PD-L1. **Methods:** In the international, open-label, phase III KEYNOTE-024 trial (NCT02142738), adults with previously untreated, advanced NSCLC without *EGFR* sensitizing mutations or *ALK* translocation that expresses PD-L1 in ≥ 50% of tumor cells are randomized 1:1 to receive a 200-mg fixed dose of pembrolizumab intravenously every 3 weeks or investigator's choice platinum-based combination chemotherapy (carboplatin or cisplatin with pemetrexed or gemcitabine or carboplatin with paclitaxel). Patients with nonsquamous NSCLC may receive pemetrexed maintenance therapy. PD-L1 expression is determined by immunohistochemistry at a central laboratory. Randomization is stratified by ECOG PS (0 vs 1), histology (squamous vs nonsquamous), and region (Asia vs rest of world). Pembrolizumab will be given for up to 35 cycles or until disease progression, intolerable toxicity, consent withdrawal, or discontinuation for other reason. Pembrolizumab recipients who experience disease progression after completing 35 cycles or who stop treatment after achieving complete response may be eligible for 1 year of pembrolizumab retreatment. Patients assigned to chemotherapy who experience progression may cross over to receive pembrolizumab. Tumor response is assessed every 9 weeks by RECIST 1.1 per central review. AEs will be monitored throughout the study and graded according to NCI CTCAE v4.0. Primary end point is PFS per RECIST 1.1 by central review. Secondary end points are ORR, OS, and safety. Enrollment is ongoing and will continue until approximately 300 patients are enrolled. Clinical trial information: NCT02142738.

TPS8104 Poster Session (Board #428a), Mon, 8:00 AM-11:30 AM

A phase III study of MEDI4736 (M), an anti-PD-L1 antibody, in monotherapy or in combination with Tremelimumab (T), versus standard of care (SOC) in patients (pts) with advanced non-small cell lung cancer (NSCLC) who have received at least two prior systemic treatment regimens (ARCTIC). *First Author: David Planchard, Gustave Roussy, Villejuif, France*

Background: M is a human IgG1 mAb that blocks programmed cell death ligand-1 (PD-L1) binding to programmed cell death-1 and CD-80 with high affinity and selectivity, and T is a selective human IgG2 mAb inhibitor of cytotoxic T-lymphocyte antigen-4 (CTLA-4). Both PD-L1 and CTLA-4 are regulators, or checkpoints, of T cell activation. Preclinical data, including mouse models of transplantable solid tumors, suggest that targeting both pathways may have additive or synergistic antitumor activity. Furthermore the Phase Ib dose-escalation/expansion study of M+T in advanced NSCLC (NCT02000947) shows a manageable safety, and early signs of clinical activity. **Methods:** This randomised, open label, multi-centre, phase III study (NCT02352948) is designed to evaluate the efficacy and safety of M vs SOC (gemcitabine, vinorelbine or erlotinib) in NSCLC pts with PD-L1-positive tumours (based on archival tumour sample or recent tumour biopsy) (Sub-study A), and the combination of M+T vs M or T vs SOC in NSCLC pts with PD-L1-negative tumours (Sub-study B). Eligible pts include pts (PS of 0-1) with locally advanced or metastatic NSCLC, who have received at least 2 prior treatment regimens including 1 platinum-based chemotherapy. Pts with known EGFR mutations and ALK rearrangements are not eligible. Approximately 300 pts will be randomised 1:1 in sub-study A and 600 pts in sub-study B (randomised 1:1:1:1). The primary objective is to assess the efficacy of M (PD-L1-positive) and M+T (PD-L1-negative) compared with SOC in terms of OS and PFS (per RECIST 1.1 as assessed by the Blinded Independent Central Review). Secondary objectives include objective response rate, duration of response, safety, tolerability, pharmacokinetics, immunogenicity and health-related QoL. Tumour assessments will be performed every 8 weeks (first 48 weeks) then every 12 weeks. A confirmatory scan is required following the initial demonstration of PD. Recruitment in the study is ongoing since January 2015. Clinical trial information: NCT02352948.

TPS8105 Poster Session (Board #428b), Mon, 8:00 AM-11:30 AM

Phase 3 KEYNOTE-042 trial of pembrolizumab (MK-3475) versus platinum doublet chemotherapy in treatment-naive patients (pts) with PD-L1–positive advanced non-small cell lung cancer (NSCLC). *First Author: Tony Mok, Department of Clinical Oncology The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Tumors can evade an immune response by co-opting the PD-1 pathway. The anti–PD-1 monoclonal antibody pembrolizumab has demonstrated promising efficacy and acceptable safety across doses and schedules in pts with NSCLC enrolled in the phase 1 KEYNOTE-001 trial, with greater efficacy observed in pts with PD-L1$^+$ tumors. In 45 treatment-naive, PD-L1$^+$ pts (n = 42 evaluable by RECIST v1.1 per central review), pembrolizumab provided a 26% ORR and 64% DCR. All 11 responses were ongoing after a median follow-up of 36 wk. The randomized, open-label phase 3 KEYNOTE-042 trial (ClinicalTrials.gov, NCT02220894) will evaluate the efficacy and safety of pembrolizumab vs platinum doublet chemotherapy as first-line therapy for PD-L1$^+$ advanced NSCLC. **Methods:** Eligible pts with advanced PD-L1$^+$ NSCLC without *EGFR* sensitizing mutations or *ALK* translocation and ≥1 measurable lesion will be randomized 1:1 to pembrolizumab 200 mg every 3 wk or investigator's choice of carboplatin plus paclitaxel or carboplatin plus pemetrexed. Randomization will be stratified by ECOG PS (0 vs 1), histology (squamous vs nonsquamous), region (East Asia vs non-East Asia), and PD-L1 expression (strong vs weak [staining in ≥50% vs 1-49% of tumor cells assessed by immunohistochemistry with the 22C3 antibody]). Pembrolizumab will be continued for 35 cycles or until disease progression, intolerable toxicity, or investigator decision; discontinuation is allowed for pts with complete response. Chemotherapy will be given for a maximum of 6 cycles. Pemetrexed maintenance is optional for pts with nonsquamous NSCLC. In both treatment arms, eligible pts may be treated beyond initial radiographic progression. AEs will be collected during and for 30 d after treatment. Response will be assessed every 9 wk per RECIST 1.1 by central review. Survival follow-up will occur every 2 mo. Primary end point is OS in pts with PD-L1–strongly-positive tumors; secondary end points include PFS in strongly positive pts and PFS and OS in all pts. Enrollment began in Nov 2014 and will continue in 28 countries in Asia, Canada, Europe, and South America until the target of 1240 pts is achieved. Clinical trial information: NCT02220894.

TPS8106 Poster Session (Board #429a), Mon, 8:00 AM-11:30 AM

A phase 3 randomized trial of veliparib (ABT-888) plus carboplatin and paclitaxel versus investigator's choice of standard chemotherapy in previously untreated patients with metastatic/advanced non-squamous (NSq) non-small cell lung cancer (NSCLC). *First Author: Mark D. McKee, AbbVie Inc., North Chicago, IL*

Background: Standard chemotherapy for patients (pts) with metastatic NSq NSCLC consists of 4−6 cycles of platinum-based doublet therapy +/– subsequent maintenance monotherapy. Clinical outcomes are generally poor, with the majority of pts surviving ~1 year. Veliparib is a potent, orally bioavailable PARP1/2 inhibitor shown to enhance antitumor activity of platinum-based therapy in preclinical models. A recent phase 2 trial suggested that the addition of veliparib to carboplatin (C) and paclitaxel (T) may provide clinical benefit in pts with NSCLC (Ramalingam et al, *Ann Oncol* 2014;25(Suppl 4):1234P). Smoking status was a strong predictor of efficacy for veliparib-chemotherapy combination in advanced NSCLC. This study compares veliparib plus C and T with investigator's choice of chemotherapy in NSq NSCLC. **Methods:** This is a randomized, multicenter, open-label trial (NCT02264990). Current or former smokers (≥ 18 years) who have received no prior chemotherapy for advanced/metastatic NSq NSCLC are randomized 1:1 to veliparib (120 mg p.o. BID on Days −2 through 5 of each 21-day cycle) plus C (AUC 6 mg/mL/min i.v. on Day 1) and T (200 mg/m^2 i.v. on Day 1), or investigator's choice of chemotherapy (C + T, or C + pemetrexed [P], or cisplatin + P). Randomization is stratified by smoking status, investigator's preferred platinum therapy, gender, and ECOG PS. Treatment continues for a maximum of 6 cycles, or until disease progression or unacceptable toxicity. Pts in either arm may receive maintenance P (500 mg/m^2 i.v. q3 weeks). The trial tests if combination treatment with veliparib improves survival in current smokers (primary objective) and in the overall population (secondary objective) compared with investigator's choice of chemotherapy. PFS and objective response rate are also compared between the 2 treatment arms, both in current smokers and the overall population. Duration of overall response, safety, tolerability, ECOG PS, and quality of life are evaluated. Recruitment began in Oct 2014 and 525 pts are planned to be included. Clinical trial information: NCT02264990.

TPS8107 Poster Session (Board #429b), Mon, 8:00 AM-11:30 AM

Veliparib (ABT-888) or placebo combined with carboplatin and paclitaxel in patients with previously untreated advanced/metastatic squamous (Sq) non-small cell lung cancer (NSCLC): A randomized phase 3 trial. *First Author: Mark D. McKee, AbbVie Inc., North Chicago, IL*

Background: NSCLC is often diagnosed at an advanced stage, conferring a poor prognosis. The current standard of care for first-line treatment comprises platinum-based regimens. Veliparib is a potent, orally bioavailable PARP1/2 inhibitor that can delay DNA repair following damage induced by chemotherapeutic agents. In preclinical tumor models, veliparib has been shown to enhance antitumor activity of carboplatin, and phase 1 data show that it can be safely combined with carboplatin and paclitaxel. A phase 2 study indicated favorable efficacy for veliparib plus carboplatin and paclitaxel vs placebo plus carboplatin and paclitaxel in the subgroup of patients with Sq NSCLC (Ramalingam et al. *Ann Oncol* 2014;25(Suppl 4):1234P). Based on these results, this phase 3 pivotal trial has been initiated. **Methods:** This is a randomized, double blind, multicenter, phase 3 trial (NCT02106546). Patients (≥ 18 years) who have received no prior chemotherapy or chemoradiotherapy for advanced/metastatic Sq NSCLC are randomized 1:1 to oral veliparib (120 mg) or placebo, twice daily on Days −2 through 5 (7 consecutive days) of 21-day cycles. Randomization is stratified by tumor extent, smoking history, ECOG performance status, and geographic region. All patients receive carboplatin (AUC 6 mg/mL/min i.v.) and paclitaxel (200 mg/m^2 i.v.) on Day 1 of each 21-day cycle. Treatment continues for a maximum of 6 cycles, or until radiographic progression or unacceptable toxicity. The primary study objective is to determine if the addition of veliparib to carboplatin and paclitaxel improves overall survival, compared with placebo plus carboplatin and paclitaxel. Secondary objectives are to assess progression-free survival and objective response rate. Duration of overall response, safety, tolerability, ECOG performance status, and quality of life are also evaluated. Sites from 37 countries are planned for trial participation. Recruitment began in Apr 2014 and 900 patients are planned for enrollment. Clinical trial information: NCT02106546.

TPS8108 Poster Session (Board #430a), Mon, 8:00 AM-11:30 AM

TIGER 1: A randomized, open-label, phase 2/3 study of rociletinib (CO-1686) or erlotinib as first-line treatment for EGFR-mutant non-small cell lung cancer (NSCLC). *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: Activating EGFR mutations including exon 21 L858R and exon 19 deletions (del19) are key drivers of NSCLC in 10%–15% of patients (pts) of European and 30%–35% of Asian descent.[1] Acquired resistance (AR) to first-generation EGFR tyrosine kinase inhibitors (TKIs) such as erlotinib is driven by additional EGFR mutations, with exon 20 T790M accounting for 60%–70% of cases.[2] Rociletinib (CO-1686) was designed to inhibit T790M as well as L858R and del19 while sparing wild-type EGFR and has demonstrated response rates up to 67% and is well tolerated in pts with AR to EGFR-TKIs during dose-finding studies.[3]TIGER 1 will evaluate whether rociletinib can improve progression-free survival (PFS) in the first-line setting. Novel exploratory endpoints include tumor kinetics, treatment post-progression, circulating tumor DNA, and blood-based biomarkers. **Methods**: Pts with histologically or cytologically confirmed metastatic or unresectable locally advanced recurrent NSCLC (no prior EGFR TKI therapy and no CNS disease), with documentation of ≥ 1 activating EGFR mutation (excluding exon 20 insertions) will be enrolled in this phase 2, open-label study (NCT02186301). Pts will be randomized 1:1 to rociletinib (625 mg) twice daily or erlotinib (150 mg) once daily until disease progression according to RECIST 1.1. Pts will be stratified by sensitizing EGFR mutation (T790M, del19, L858R, or other) and race (Asian vs non-Asian). The primary endpoint is PFS; secondary endpoints include efficacy as determined by objective response rate, duration of response, disease control rate and overall survival, and PFS in pts with baseline T790M mutations detected using allele-specific PCR. PFS and OS will be summarized with Kaplan-Meier plots. The stratified log-rank and hazard ratio will compare PFS distributions for rociletinib- vs erlotinib-treated pts. Safety will be assessed via standard adverse event reporting. Planned enrollment is for phase 2 is 200 pts up to 1000 for phase 3. Enrollment is underway with multiple patients in screening. Herbst R et al. *N Engl J Med*. 2008 Yu H et al. *Clin Cancer Res*. 2013 Sequist LV *J Clin Oncol*. 2014 Clinical trial information: NCT02186301.

TPS8109 Poster Session (Board #430b), Mon, 8:00 AM-11:30 AM

TIGER-3: A phase 3, open-label, randomized study of rociletinib vs cytotoxic chemotherapy in patients (pts) with mutant EGFR non-small cell lung cancer (NSCLC) progressing on prior EGFR TKI therapy and doublet chemotherapy. *First Author: James Chih-Hsin Yang, Department of Oncology, National Taiwan University Hospital; Graduate Institute of Oncology & Cancer Research Center, National Taiwan University, Taipei, Taiwan*

Background: Rociletinib is a small molecule inhibitor that selectively targets mutant EGFR and has been shown in preclinical studies to inhibit L858R, del19 and T790M while sparing wild-type EGFR. TIGER-X, a phase 1/2 dose-ranging trial, has provided evidence that rociletinib is associated with durable response and is well tolerated in pts with NSCLC and positive T790M status following progression on a TKI.[1] TIGER-3 is designed to investigate single agent rociletinib vs chemotherapy in pts who have failed EGFR therapy and platinum-based doublet chemotherapy; a setting of acquired resistance and a high unmet need of targeted therapeutic options. TIGER-3 will evaluate pts with T790M positive and negative status based on blood and tumor tissues, and biomarkers of response or resistance. **Methods**: Pts with histologically or cytologically confirmed metastatic or unresectable locally advanced NSCLC, with radiological progression on the most recent therapy will be enrolled in a phase 3, randomized, open-label study (NCT02322281). Pts must have documented evidence of a tumor with $\geq$ 1 EGFR activating mutations excluding exon 20 insertion, and prior treatment with an EGFR TKI and platinum-containing doublet chemotherapy. Pts will be randomized 1:1 to receive rociletinib twice daily or single agent cytotoxic chemotherapy (investigator choice specified before randomization) until disease progression according to RECIST 1.1. Pts will be stratified by presence or absence of brain metastases, ECOG performance status (0 vs 1), and race (Asian vs non-Asian). The primary endpoint is progression-free survival (PFS). Secondary endpoints include objective response rate, duration of response, disease control rate, and overall survival. Kaplan-Meier methodology will assess time to event variables. The stratified log-rank and the hazard ratio (HR) will be used for comparing PFS distributions. Serial assessment of safety will be carried out based on standard adverse event reporting. Planned enrolment is 600 pts with study start planned by end of May 2015. Sequist LV *J Clin Oncol*. 2014 Clinical trial information: NCT02322281.

TPS8110 Poster Session (Board #431a), Mon, 8:00 AM-11:30 AM

IFCT-1003 LADIE trial: Randomized phase II trial evaluating treatment with EGFR-TKI versus EGFR-TKI associated with anti-estrogen in women with non-squamous advanced stage NSCLC. *First Author: Julien Mazières, Hôpital Larrey CHU Toulouse, Toulouse, France*

Background: The incidence of lung cancer is increasing dramatically in women and displays some specific epidemiological, radiological, clinical and pathological characteristics. Two main mechanisms emerged from recent findings in the field of lung carcinogenesis in women: the preferential involvement of the EGFR pathway and the potential impact of hormonal factors. The interaction of estrogen receptors with growth factor receptor signalling has also been shown. Preclinical data have shown that the combination of an EGFR-Tyrosine Kinase Inhibitor (TKI) with an anti-estrogen could overcome resistance to EGFR-TKI by postponing the reactivation of the PI3K-AKT pathway through the estrogen-mediated non-genomic pathway. **Methods:** We launched an open-label phase II randomized trial dedicated to women with advanced stage adenocarcinoma. Patients are treated by gefitinib (250 mg/d) vs. gefitinib + fulvestrant 500 mg MI / month (with a supplementary dose at day 15) in the EGFR mutated group (EGFR +) in first or second line setting and by erlotinib (150 mg/d, according to marketing authorization at trial initiation) vs. erlotinib + fulvestrant in the EGFR wild-type group (EGFR WT) in second or third line setting. Treatments are given until progression or unacceptable toxicity. Follow-up is performed in both arms every month to minimize the potential bias due to monthly fulvestrant injection. Primary objective is progression-free survival (PFS) at 3 and 9 months for EGFR WT and EGFR + patients, respectively. Secondary objectives are safety, overall survival and quality of life. Exploratory objective is biomarkers analysis. The main inclusion criteria are histologically-confirmed non-squamous NSCLC, available tumor tissue for EGFR mutation analysis, post-menopausal women, PS 0-2. The study has been approved by all ethical committees. First patients have been enrolled in May 2012. To date, 223 patients (89 EGFR+, 134 EGFR WT) have been enrolled and 394 (204 EGFR +, 190 EGFR WT) are expected. Clinical trial registry number NCT01556191. Clinical trial information: NCT01556191.

TPS8111 Poster Session (Board #431b), Mon, 8:00 AM-11:30 AM

Addition of apatorsen, an inhibitor of Hsp27, to first-line gemcitabine/carboplatin in advanced squamous cell lung cancer: Design of the Cedar study. *First Author: Peter Schmid, Queen Mary, University of London, London, United Kingdom*

Background: Outcomes remain poor in patients with non-small cell lung cancer (NSCLC) of squamous origin. There are few established therapeutic targets, and benefits of chemotherapy are frequently short-lived, with rapid development of treatment resistance. More effective therapies are urgently required. Substantial preclinical data demonstrates that heat shock protein 27 (Hsp27) affects numerous pathways implicated in cancer progression and treatment resistance. Approximately 70-98% of squamous-cell tumours express Hsp27. Apatorsen (OGX-427) is a second generation antisense oligonucleotide that effectively down-regulates Hsp27 in vitro and in vivo; clinical studies are evaluating apatorsen in lung, bladder, prostate, and pancreatic cancers. **Methods:** The phase 2, UK, investigator led, randomized, open-label trial Cedar trial was initiated in July 2014. Eligible patients have confirmed Stage IIIB/IV squamous cell lung cancer and no prior chemotherapy for advanced disease, with ECOG score of 0-2 and adequate bone marrow, renal, and liver function; patients with known EGFR mutation or ALK rearrangements are excluded. Planned enrollment is 140 patients; randomization (1:1) is stratified by stage and performance status. Patients receive 21-day cycles of gemcitabine (1250 mg/m^2) and carboplatin (AUC5) or gemcitabine/carboplatin plus apatorsen (600 mg IV/wk, preceded by 3 doses during a 9-day loading period) for up to 6 cycles. Tumor evaluation occurs q6 wks. Patients randomized to apatorsen may continue weekly single agent maintenance until progressive disease (PD), unacceptable toxicity, or withdrawal of consent. The primary efficacy measure is progression-free survival. Secondary efficacy measures include objective response (OR), change in tumour size at 12 wks, clinical benefit rate, duration of OR/clinical benefit, overall survival, and proportion without PD at 12 and 24 wks. Efficacy analyses are intent-to-treat. Adverse events and laboratory results are assessed, and interim safety analyses are planned. Pre-specified subset analyses will characterize the relevance of Hsp27 expression in tumour and blood samples. Clinical trial information: 16622.

8500 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Phase IIa study of single-agent MOR208 in patients with relapsed or refractory B-cell non-Hodgkin's lymphoma (NHL). *First Author: Wojciech Jurczak, Jagiellonian University, Krakow, Poland*

Background: MOR208 is an Fc-engineered humanized monoclonal antibody that targets the B-cell-specific antigen, CD19. There remains a high unmet medical need for new therapies for patients (pts) with relapsed or refractory (R-R) B-cell NHL. **Methods:** This is a non-randomized, open-label, multicenter, two-stage, phase IIa study of MOR208 in pts with R-R NHL previously treated with rituximab, who were not candidates for high-dose chemotherapy with stem cell support. Adult pts with diffuse large B-cell lymphoma (DLBCL), mantle cell lymphoma (MCL), follicular lymphoma (FL), or other indolent NHL (iNHL), were treated with single-agent MOR208, 12 mg/kg intravenously, weekly, over two 28-day cycles. Pts with at least stable disease by the 2007 International Response Criteria were to continue MOR208 treatment for another cycle. Pts with complete or partial response (CR or PR) could then receive maintenance MOR208 every 2 or 4 weeks, depending on investigator decision, until progression. Overall response rate (ORR) was the primary endpoint. **Results:** By 17 November 2014, all pts (n = 89) had been enrolled (DLBCL, n = 35; FL, n = 31; MCL, n = 12; iNHL, n = 11). Thirty-five (39%) pts were female, median age 67 (range 35–90), 78 (88%) had stage III-IV disease, and the median number of prior lines of therapy was 2 (1–4). The mean number of cycles completed was 2.2 (0–3). The investigator-assessed ORR across all NHL subtypes was 22% (20/89) with clinical activity seen in the DLBCL (26% [9/35]; 2 CR, 7 PR; preliminary median duration of response [mDoR] 7.7 months), FL (23% [7/31]; 1 CR, 6 PR; preliminary mDoR 2.6 months) and iNHL (36% [4/11]; 1 CR, 3 PR) cohorts (MCL, 0/12 responses). Grade ≥ 3 non-hematologic and hematologic treatment-emergent adverse events were recorded in 30/89 (34%) and 8/89 (9%) pts, respectively. Infusion-related reactions (8 pts) were all grade 1-2 (except for one case of dyspnea, grade 4). There were no treatment-related deaths. **Conclusions:** MOR208 demonstrated encouraging single-agent efficacy with CRs observed in pts with R-R DLBCL, FL, and iNHL. MOR208 is well tolerated without significant infusional toxicity. Protocols are being developed to investigate MOR208 in combination with other agents. Clinical trial information: NCT01685008.

8501 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Safety and activity of the chemotherapy-free triplet of ublituximab, TGR-1202, and ibrutinib in relapsed B-cell malignancies. *First Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Multiple novel targeted agents are emerging for B-cell malignancies, but few studies have successfully and safely combined these agents. Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies (Burris, 2014). This Ph 1 trial evaluates the safety of the first triplet combination of a novel anti-CD20 + PI3Kδ + BTK inhibitor in pts with B-cell malignancies. **Methods:** Eligible pts had rel/ref CLL (including Richter's) or B-cell NHL with an ECOG PS ≤ 2 w/o limit to number of prior therapies. Pts refractory to prior PI3Kδ or BTK were eligible. CLL & NHL cohorts were evaluated independently in a 3+3 dose escalation design to evaluate safety and dose limiting toxicities (DLT). UTX was dosed at 900mg on D 1, 8, 15 of Cyc 1 & 2 and D 1 on Cyc 4, 6, 9 & 12. TGR-1202 was dose escalated (400mg, 600mg, 800mg, 1200mg). Ibrutinib was dosed at 420mg (CLL) and 560mg (NHL). Preliminary efficacy was examined (CLL per Hallek 2008 / NHL per Cheson 2007). **Results:** As of Feb 2015, 10 pts were evaluable for safety: 4 follicular (FL), 3 CLL/SLL, 1 marginal zone (MZL), 1 mantle cell (MCL) and 1 Richter's DLBCL. Med age 61 yo (range 51-76); 8 M/2 F; median prior Tx = 3 (range 1-4). No DLTs have occurred up to the current dose (600 mg TGR-1202). AEs (all causality) included: diarrhea, constipation and fatigue (30% each, no G 3/4), Day 1 infusion related reactions at 20% (no G 3/4) and neutropenia at 20% with 1 event G 3/4. 7 pts were evaluable for efficacy. ORR was 86% with all pts except the Richter's responding (FL (2), CLL/SLL (2), MZL (1) and MCL (1)). All responses were observed by week 8 (1 CR / 5 PR's). Patients remain on study from 1 – 5+ months. **Conclusions:** To date, this is the first combination of an anti-CD20, a PI3Kδ and a BTK inhibitor. UTX + TGR-1202 + ibrutinb was well tolerated with significant early activity across heavily pre-treated and high-risk B-cell malignancies. Dose escalation continues with TGR-1202 at 800mg. Based upon the early activity of the triplet, Ph II studies are planned. Clinical trial information: NCT02006485.

LBA8502 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

GADOLIN: Primary results from a phase III study of obinutuzumab plus bendamustine compared with bendamustine alone in patients with rituximab-refractory indolent non-Hodgkin lymphoma. *First Author: Laurie Helen Sehn, BC Cancer Agency, Vancouver, BC, Canada*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

8503 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Two doses of polatuzumab vedotin (PoV, anti-CD79b antibody-drug conjugate) in patients (pts) with relapsed/refractory (RR) follicular lymphoma (FL): Durable responses at lower dose level. *First Author: Ranjana H. Advani, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Based on early evidence of cumulative toxicity of PoV at a dose of 2.4 mg/kg (Morschhauser ASH 2014 NCT01691898), a dose of 1.8 mg/kg was explored. We report updated results of the dose comparison. **Methods**: Pts with RR FL received PoV at 2.4 mg/kg or 1.8 mg/kg with R at 375mg/m^2 q21d until progression or unacceptable toxicity. 5 pts from PhI (Palanca-Wessels ASH 2013) treated at the 2.4 mg/kg dose were included. Data at completion of PoV treatment were compared with data after 8 cycles. **Results**: 25 pts received PoV+R at 2.4 mg/kg, and 20 at 1.8 mg/kg. Median follow up was 14 mos for 2.4 mg/kg and 8 mos for 1.8 mg/kg. Baseline characteristics were balanced, except for age (median 68 yrs 2.4 mg/kg, 62 yrs 1.8 mg/kg) and tumor volume (SPD 1824 mm^2 2.4 mg/kg, 2655 mm^{2}1.8 mg/kg). 40% (10/25, 2.4 mg/kg) and 50% (10/20, 1.8 mg/kg) of pts were refractory to their last treatment. Pts received a median of 10 cycles of PoV+R at 2.4 mg/kg vs. 9.5 at 1.8 mg/kg. Dose intensity through cycle 8 was 88% for 2.4 mg/kg and 99% for 1.8 mg/kg. Safety is shown in Table. An 84 yr old pt in the 2.4 mg/kg cohort died 2 months after cycle 12 due to pulmonary congestion. ORR was similar for both dose levels: 19/25 (76%) at 2.4 mg/kg, 15/20 (75%) at 1.8 mg/kg. CR: 11/25 (44%) at 2.4 mg/kg, 2/20 (10%) at 1.8 mg/kg. After 8 cycles, CR: 32% at 2.4 mg/kg and 10% at 1.8 mg/kg. Median PFS: 15 mo at 2.4 mg/kg, n.r. at 1.8 mg/kg. **Conclusions**: PoV+R in RR FL showed high ORR at both doses, with higher CR at 2.4 mg/kg. AEs and d/c rates were reduced at both doses if only the first 8 cycles are considered vs. those reported through study completion. The safety of PoV can be improved by shorter treatment and/or lower dose. Updated PFS will be presented. Clinical trial information: NCT01691898.

Safety of PoV+R.

8504 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Evaluation of complete response rate at 30 months (CR30) as a surrogate for progression-free survival (PFS) in first-line follicular lymphoma (FL) studies: Results from the prospectively specified Follicular Lymphoma Analysis of Surrogacy Hypothesis (FLASH) analysis with individual patient data (IPD) of 3,837 patients (pts). *First Author: Daniel J. Sargent, Mayo Clinic, Rochester, MN*

Background: Although PFS is the standard endpoint for new drug approvals in first-line FL, advances in efficacy (median PFS >7 y) coupled with the indolent nature of FL necessitate extended patient follow-up in clinical trials. The FLASH group conducted a meta-analysis to evaluate whether treatment effects on CR30, an earlier endpoint, could accurately predict treatment effects on PFS. **Methods:** Correlation of CR30 odds ratio (OR) with PFS hazard ratio (HR) was evaluated using both linear regression (R^2_{WLS}) and copula bivariate (R^2_{Copula}) models. Prespecified criteria for CR30 surrogacy required either R^2_{WLS} or $R^2_{Copula} \geq 0.80$ with a lower bound of the 95% confidence interval (CI) > 0.60, with neither estimate $<$ 0.70. The minimum CR30 difference to predict significant PFS difference was calculated. **Results:** Data from 13 randomized first-line trials (8 induction, 5 maintenance trials) with IPD for 3837 pts were included. The prespecified threshold for surrogacy was met: R^2_{WLS} of 0.88 (95% CI, 0.77-0.96) and R^2_{Copula} of 0.86 (95% CI, 0.72-1.00, **Table**), supporting the hypothesis that treatment effects on CR30 predict effects on PFS in pts with previously untreated FL. Multiple sensitivity and IPD surrogacy analyses supported the robustness of the primary analysis. A minimum 10% absolute improvement in CR30 over a control CR30 of 50% predicted significant improvement in PFS. **Conclusions:** This large IPD meta-analysis of chemo/immunotherapy trials establishes CR30 as a surrogate endpoint for PFS in first-line FL trials and supports its use to expedite therapeutic development.

Trial type	Trials, N (pts)	R^2_{WLS} (95% CI)[a]	R^2_{Copula} (95% CI)[a]
Overall	13 (3837)	0.88 (0.77-0.96)	0.86 (0.72-1.00)
Rituximab included	9 (2851)	0.85 (0.62-0.97)	0.80 (0.56-1.00)
No rituximab	4 (986)	0.91 (0.05-1.00)	0.96 (0.90-1.00)
Induction	8 (2207)	0.89 (0.75-0.98)	0.89 (0.74-1.00)
Maintenance	5 (1630)	0.93 (0.84-1.00)	0.89 (0.71-1.00)

[a] R^2 values range from 0 (no association) to 1 (perfect prediction).

8505 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Brentuximab vedotin plus AVD for non-bulky limited stage Hodgkin lymphoma: A phase II trial. *First Author: Jeremy S. Abramson, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: ABVD plus radiation is standard therapy for limited HL, but carries risks of bleomycin-lung injury and radiation toxicity. Brentuximab vedotin is highly active in relapsed HL. We evaluated brentuximab plus AVD (A-AVD) for non-bulky stage I-II HL. **Methods:** This is a multicenter phase 2 study. Patients received a lead in cycle of brentuximab monotherapy 1.2mg/kg on days 1 and 15, followed by a PET scan. Patients then received 4-6 cycles of A-AVD, based on interim PETCT. The primary endpoint is complete response rate (CRR). A sample size of 34 was required to detect a CRR of 93% with 91% power and alpha error of 0.10. **Results:** 34 patients were enrolled. Median age is 36 (20–75). Risk was early favorable in 62%, unfavorable in 38%. The best CRR was 100%. After the monotherapy lead in, 18/34 subjects (53%) were in CR. After 2 cycles of A-AVD, 33 were in CR (97%), and 1 was removed for toxicity. At end of treatment (EOT), 30 (88%) were in CR, 2 were interpreted as progressive disease (PD), and 2 were removed for toxicity. At EOT, 8 subjects had PET scans interpreted as positive on central review, 6 of which were felt to be reactive by investigators. All 6 subjects were in confirmed CR on brief follow-up scan with no intervening therapy, confirming false positive scans. Two cases were considered PD at EOT, 1 of whom received 2 further cycles of AVD alone and was back in CR, suggesting that scan may also have been a false positive. At a median follow-up of 14 months, the PFS and OS are 90% and 97%. The most common adverse events were peripheral neuropathy (74%), fatigue (71%), nausea (24%), neutropenia (68%), anemia (56%), constipation (56%), diarrhea (35%), abdominal pain (32%), ALT elevation (29%) and febrile neutropenia (29%). Grade 3-4 toxicity occurred in 26/34 patients: neutropenia (56%), febrile neutropenia (29%) and peripheral neuropathy (24%). One elderly patient died of neutropenic sepsis in the first A-AVD cycle. One patient was removed for grade 2 hypersensitivity despite premedication. Brentuximab reductions were required in 38%, most for peripheral neuropathy. **Conclusions:** A-AVD x 4 produced a high CRR but with more toxicity than expected from AVD alone. False positive PET scans were common on EOT imaging and warrants further attention. Clinical trial information: NCT01534078.

8506 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Updated results of a phase II trial of brentuximab vedotin combined with R-CHOP in frontline treatment of patients (pts) with high-intermediate/high-risk diffuse large B-cell lymphoma (DLBCL). *First Author: Nancy L. Bartlett, Department of Internal Medicine, Washington University School of Medicine, St. Louis, MO*

Background: Pts with high-intermediate/high-risk DLBCL have relatively poor outcomes with R-CHOP. Single-agent brentuximab vedotin has shown activity in pts with relapsed or refractory DLBCL (CD30+ pts, 17% CR; CD30– pts, 10% CR). **Methods:** In this study, pts were randomized to 6 cycles of BV+R-CHOP: 1.2 or 1.8 mg/kg BV q3 wks intravenous with standard R-CHOP. Key inclusion criteria were standard International Prognostic Index (IPI) scores of 3–5 or age-adjusted IPI (aaIPI) scores of 2–3 (high-intermediate/high risk). Disease response was per Cheson 2007 with PET/CT. **Results:** At the planned interim analysis, 53 pts were enrolled and 51 were treated. At baseline, 62% were high-intermediate risk (IPI 3, aaIPI 2) and 38% were high risk (IPI 4-5, aaIPI 3). 70% had stage IV disease and 28% had an Eastern Cooperative Oncology Group score of 2. Due to an increased rate of G3 neuropathy seen early in the 1.8 mg/kg BV+RCHOP arm (30% vs 8%), an SMC recommended treatment continue at 1.2 mg/kg BV+R-CHOP. At EOT, the overall response rate was 97% with 80% PET-negative CR (1.2 mg/kg BV+RCHOP, 86% CR; 1.8 mg/kg BV+R-CHOP, 75% CR) for 30/51 pts with an assessment. CD30+ pts (n=13) had a higher CR rate than CD30– pts (n = 16) (92% vs 69%); 4 CD30– and no CD30+ pts have progressed after a median follow-up of 5 months. CR rates were similar between ABC and GCB subtypes. Treatment-emergent adverse events (AEs) occurred in 96% of treated pts; the most frequent ($\geq$ 30%) were nausea, fatigue, peripheral sensory neuropathy, diarrhea, anemia, decreased appetite, febrile neutropenia, and vomiting. $\geq$ G3 events occurring in > 20% of pts were febrile neutropenia (27%), neutropenia (25%), and anemia (24%). AEs of neuropathy (mostly G1/2) occurred in 55% (38%, 1.2 mg/kg BV+R-CHOP; 77%, 1.8 mg/kg BV+RCHOP). AEs caused discontinuations in 10% of pts; 2 pts died due to AEs (sepsis, hypovolemic shock), and 3 pts died following progression. **Conclusions:** BV+R-CHOP has encouraging activity in frontline high-intermediate/high risk DLBCL; data suggest that the CR rate in CD30+ pts was higher than in CD30– pts. When combined with R-CHOP, BV is better tolerated at 1.2 mg/kg than 1.8 mg/kg due to reduced neuropathy. The protocol has been amended to assess the safety and activity of 1.8 mg/kg BV+R-CHOP in CD30+ high-intermediate/high risk DLBCL pts. Clinical trial information: NCT01925612.

8507 Oral Abstract Session, Mon, 9:45 AM-12:45 PM

Allogeneic or autologous transplantation as first-line therapy for younger patients with peripheral T-cell lymphoma: Results of the interim analysis of the AATT trial. *First Author: Norbert Schmitz, Asklepios Hospital St. Georg, Hamburg, Germany*

Background: AlloSCT gives encouraging results in pts with relapsed PTCL. We did the AATT (Autologous or Allogeneic Transplantation in T-Cell Lymphoma) study in newly diagnosed PTCL and present results of an interim analysis leading to termination of the trial. **Methods:** We compared alloSCT with autoSCT in younger pts with PTCL. Pts were randomized after enrolment. Treatment was four courses of CHOEP-14. Pts achieving CR/ PR/ SD proceeded to DHAP and stem cell collection in pts randomized to autoSCT or without suitable (HLA 10/10) donor. BEAM high-dose therapy and autoSCT or myeloablative conditioning and alloSCT followed within 4-6 weeks. **Results:** 58/104 pts were eligible: median age was 50 years, 64% of pts were male. 11/30 pts randomized to autoSCT did not proceed to transplantation because of progressive disease / no response (n=8), infection (n=1) or change of histology (n=2). 13/28 pts (46%) randomized to alloSCT received it. Fifteen pts were not allografted due to progressive disease (n=10) or lack of a fully matched donor (n=5). Twenty-one pts have died 68-705 days after randomization. Twelve pts died of lymphoma (7 in the auto and 5 in the allo arm), 2 pts died from salvage therapy (1 in each arm) and 1 pt from EBV-pos PTLD. Two allografted pts died early (d +21, +65) and 2 late from infections (d+549, +577). Two pts died from acute GvHD (d +24, d +85). One-year event-free survival was 41 % [95%CI 27%-54%], OS was 69% [95CI 57%-82%] on the intent-to-treat-population. **Conclusions:** This pre-planned interim analysis showed no significant survival differences for pts randomized to autoSCT or alloSCT. 38% of randomized pts did not proceed to transplantation mostly because of early lymphoma progression. A conditional power calculation showed a low probability that the primary endpoint (25% EFS improval by allo SCT) could still be met. The data safety monitoring board decided to prematurely stop patient accrual.

8508 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

ELOQUENT-2: A phase III, randomized, open-label study of lenalidomide (Len)/dexamethasone (dex) with/without elotuzumab (Elo) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). *First Author: Sagar Lonial, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA*

Background: Elo, a monoclonal antibody (mAb) targeting Signaling Lymphocytic Activation Molecule F7 (SLAMF7), kills myeloma cells with minimal effect on normal tissue. Elo showed encouraging activity with Len/dex (Ld) in a phase Ib/II study in pts with RRMM. This phase III study (NCT01239797) compared efficacy and safety of Elo/Len/dex (ELd) vs Ld. **Methods:** Pts with RRMM, 1–3 prior therapies (not Len-refractory), were randomized 1:1 to ELd or Ld in 28-day cycles to disease progression/unacceptable toxicity: Elo (10 mg/kg intravenously) weekly cycles 1+2 then biweekly; Len (25 mg) D1–21; dex weekly (40 mg or [Elo wks] 28 mg oral + 8 mg intravenous). Response/progression was assessed by independent review committee by EBMT criteria. Primary endpoints were progression-free survival (PFS) and overall response rate (ORR). Results of an interim analysis are reported. **Results:** Six hundred and forty-six pts were randomized (321 ELd, 325 Ld; median age 66; del(17p) 32%; t[4;14] 9%; refractory to last therapy 35%). Median (range) prior therapies: 2 (1–4), including bortezomib 70%, thalidomide 48%, Len 6%. At data cut-off (4 November 2014), 35% (ELd) and 21% (Ld) of pts remained on therapy; discontinuation was mainly for disease progression (42% ELd, 47% Ld). Median follow-up was 24 months; median (95% CI) PFS: ELd 19.4 (16.6, 22.2) months, Ld 14.9 (12.1, 17.2) months (HR [95% CI] 0.70 [0.57, 0.85]; p = 0.0004). 1-year PFS was 68% ELd, 57% Ld; 2-year PFS: 41% ELd, 27% Ld. PFS benefit with ELd was consistent across key subgroups. ORR (95% CI) was 79% (74, 83) ELd, 66% (60, 71) Ld (p = 0.0002). G3–4 adverse events ≥ 15% (ELd vs Ld) were neutropenia (25%, 33%); anemia (15%, 16%). Exposure-adjusted infection rate was the same in both arms (incidence rate/100 person-years of exposure, 197). Infusion reactions (IRs) occurred in 10% of pts with ELd (mostly G1–2). There were 210 deaths (94 ELd, 116 Ld). **Conclusions:** A clinically relevant 30% reduction in risk of progression or death was seen with ELd vs Ld. More pts remain on ELd vs Ld and follow-up for long-term outcomes, including survival, is ongoing. IRs were manageable. Elo, a mAb with a novel immunotherapeutic mechanism of action, showed improved PFS, with minimal added toxicity in combination with Ld vs Ld alone, in pts with multiple myeloma. Clinical trial information: NCT01239797.

8509 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Carfilzomib and dexamethasone (Kd) vs bortezomib and dexamethasone (Vd) in patients (pts) with relapsed multiple myeloma (RMM): Results from the phase III study ENDEAVOR. *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens, Athens, Greece*

Background: ENDEAVOR (NCT01568866) is comparing Kd with Vd in pts with RMM. The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall survival (OS), overall response rate (ORR), rate of peripheral neuropathy (PN), and safety. **Methods:** Adults with RMM and 1-3 prior treatments were eligible; planned enrollment was 888 pts. Pts were randomized 1:1 and stratified by prior K or V (yes vs no), prior lines of treatment (1 vs 2-3), ISS stage (1 vs 2-3), and intended route of V (IV vs SC). The Kd arm received K (30-min IV infusion) on days (D) 1, 2, 8, 9, 15, and 16 of a 28-day cycle (20 mg/m^2 on D1 and 2 [cycle 1]; 56 mg/m^2 thereafter) and dexamethasone (dex; 20 mg) on D1, 2, 8, 9, 15, 16, 22, and 23. The Vd arm received V (1.3 mg/m^2; IV or SC on D1, 4, 8, and 11 of a 21-day cycle) and dex (20 mg) on D1, 2, 4, 5, 8, 9, 11, and 12. Cycles were repeated until disease progression or unacceptable toxicity. **Results:** Data are presented for Kd then Vd. In total, 929 pts (Kd: 464; Vd: 465) from 27 countries were randomized. In the Vd arm, 83.6% of pts received SC V. At the preplanned interim analysis, median treatment exposure was 39.9 and 26.8 weeks. Kd showed a significant improvement in median PFS vs Vd (18.7 months [mo] vs 9.4 mo; hazard ratio = 0.53; P< .0001). OS data were immature (75 and 88 deaths) and continue to be followed. ORRs were 76.9% and 62.6% (P< .0001); 54.3% and 28.6% had a very good partial response or better, and 12.5% and 6.2% of pts had a complete response or better. Treatment discontinuation due to an adverse event (AE) occurred in 14.0% and 15.7% of pts. On-study death due to an AE occurred in 3.9% and 3.4% of pts. AEs of interest (grade ≥ 3) included hypertension (preferred term; 8.9% vs 2.6%), dyspnea (high-level term; 5.6% vs 2.2%), cardiac failure (grouped term; 4.8% vs 1.8%), and acute renal failure (grouped term; 4.1% vs 2.6%). Rates of grade ≥ 2 PN (grouped term) were 6.3% vs 32.0% (P< .0001). **Conclusion**: Kd demonstrated statistically significant and clinically meaningful superiority over Vd in RMM, with a two-fold improvement in median PFS. In addition, Kd had a favorable benefit-risk profile. These data suggest that K is a potential best-in-class agent for RMM. Clinical trial information: NCT01568866.

8510 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Phase II MMRC trial of extended treatment with carfilzomib (CFZ), lenalidomide (LEN), and dexamethasone (DEX) plus autologous stem cell transplantation (ASCT) in newly diagnosed multiple myeloma (NDMM). *First Author: Todd M. Zimmerman, University of Chicago, Chicago, IL*

Background: In a phase I/II study of combination treatment with CFZ, LEN, and DEX (KRd) without ASCT, KRd provided a high rate of sCR (55%) in NDMM patients (pts) and 3-year progression-free survival and OS rates of 79% and 96% (Jakubowiak et al. Blood 2012;120:1801-9; Jasielec et al. Blood 2013;122: 3220). To further improve response and outcomes, we designed a phase II study to assess activity of extended treatment with KRd and ASCT. **Methods:** Pts received 28-day (d) cycles of CFZ 20/36 mg/m^{2}IV (d1, 2, 8, 9, 15, 16), LEN 25mg PO (d1–21), and DEX 40/20 mg PO wkly (cycles1–4 induction/5–8 consolidation) with ASCT after cycle 4. For cycles 8–18, KRd was given with a modified CFZ schedule (d1, 2, 15, 16) and then LEN alone after cycle 18. Response was assessed by IMWG plus nCR. The primary endpoint is the rate of stringent complete response (sCR) at the end of cycle 8, with statistical hypothesis that the improvement of sCR from 30% (KRd without ASCT) to >50% will represent added benefit of ASCT. **Results:** As of December 31, 2014 the study accrual goal of 53 pts has been met; median age 62 yr (range 40-76), ISS stage II/III 53%, high-risk cytogenetics 27%, as per IMWG. To date, 49 pts completed induction, 41 transplant, 23 consolidation, and 7 have completed 18 cycles of KRd. A median 9.79x10^6/kg CD34+ cells were collected (range 3.89-16.79). Response improved with each phase of treatment (Table). At the end of 8 cycles, 15/17 evaluable pts (88%) were MRD-negative. After a median follow-up of 9.7 months (range 1.6-23), all pts were alive and 52 of 53 progression free. KRd was well tolerated during induction with no new or unexpected events. After ASCT, KRd-related AEs were mostly Grade (G) 1/; the, most common G3/4 AEs were lymphopenia (50%), leukopenia (14%), and neutropenia (21%). **Conclusions:** KRd with ASCT for NDMM resulted in higher sCR rates than KRd without ASCT and high rate of MRD-negative disease, suggestive of benefit of adding ASCT to KRd treatment. The results to date compare favorably to any prior treatment of NDMM. Clinical trial information: NCT01816971.

8511 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Results from two phase III studies of bortezomib (BTZ) consolidation vs observation (OBS) post-transplant in patients (pts) with newly diagnosed multiple myeloma (NDMM). *First Author: Christian Straka, Schön Klinik Starnberger See, Berg, Germany*

Background: Following ASCT, consolidation therapy including novel agents can improve outcomes in pts with MM. Here we report the combined outcomes of two large randomized phase III studies investigating BTZ consolidation or OBS in pts with NDMM. **Methods:** MMY3012 (NCT00416273; 222 pts aged ≤ 60 yrs) and MMY3013 (NCT00416208; 158 pts aged 61–75 yrs) recruited adults with NDMM who underwent induction therapy followed by ASCT. Pts were randomized 1:1 to receive BTZ consolidation (1.6 mg/m² days 1, 8, 15, 22; 4 x 35-day cycles) or OBS, 60–120 days after ASCT. Primary endpoint was progression-free survival (PFS) from start of induction; secondary endpoints included response rate, overall survival (OS), and safety. **Results:** In 371 pts, median age was 59 yrs (35–76); 62% were male, 14%/84% were Durie-Salmon stage II / III. 37% of the 278 pts assessed for cytogenetics were classified as high-risk. 50% of pts had received prior BTZ; the most common induction regimen was VCD (40%). Others included dexamethasone/idarubicin (14%), dexamethasone (13%), and VAD (9%). Outcomes are shown in the table (median follow-up 42 mos). **Conclusions:** A higher proportion of pts had a response of ≥ VGPR after BTZ consolidation than OBS. PFS was significantly improved by ~6 mos, but there was no improvement in OS, likely related to the use of effective salvage options. Subgroups that seemed to benefit from BTZ consolidation were pts with < VGPR and those with high-risk cytogenetics. The BTZ dosing regimen was generally well-tolerated. Clinical trial information: NCT00416208 and NCT00416273.

Phase II study of daratumumab (DARA) monotherapy in patients with ≥ 3 lines of prior therapy or double refractory multiple myeloma (MM): 54767414MMY2002 (Sirius). *First Author: Sagar Lonial, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

8513 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

A phase I/II study of the combination of panobinostat (PAN) and carfilzomib (CFZ) in patients (pts) with relapsed or relapsed/refractory multiple myeloma (MM). *First Author: Jesus G. Berdeja, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

Background: Histone deacetylase inhibitors (HDACi) and proteasome inhibitors (PI) act synergistically through inhibition of the proteasome and aggresome pathways. We have previously reported the combination of the HDACi, PAN and the PI, CFZ in pts with relapsed and relapsed/refractory MM with encouraging results (Blood 2013;122:1937). The maximum tolerated dose (MTD) of CFZ and PAN was never reached and we extended our original study to investigate higher dose levels. Here we present the preliminary results of this ongoing trial. **Methods:** Pts with MM who relapsed after ≥ 1 prior treatment were eligible. PAN was administered orally on D 1, 3, 5, 15, 17, 19 of each 28-day cycle. CFZ was administered IV over 30 min on D 1, 2, 8, 9, 15, and 16. The maximum planned dose (MPD) from the original study was 30 mg PAN plus 20/45 mg/m^2 CFZ, so we next escalated to 30 mg PAN plus 20/56 mg/m^2 CFZ. Due to numerous PAN dose reductions in the previous cohorts, we explored PAN at 20 mg and CFZ 20/56 mg/m^2. Treatment continued until PD or intolerable toxicity. The primary efficacy endpoint was the overall response rate (ORR) (≥ PR). AEs were assessed according to CTCAE v 4.0 and responses were assessed using IMWG criteria (plus MRs as per the EBMT criteria). **Results:** As of the data cutoff (12/2014), 26 pts (median age 62 (range 49-91), 39% poor risk FISH) were enrolled. Pts had a median of 3 (range 1-9) prior therapies including 69% with prior PI, 58% with prior IMiDs and 50% with prior stem cell transplants. 27% were refractory to either IMiDs or PIs, and 26% were refractory to their last treatment regimen. There were no DLTs, but based on PAN dose reductions observed in the previous cohorts, the 20 mg PAN plus 20/56 CFZ dose level was expanded and 23 of the 26 enrolled pts were treated at this dose level. 12 (57%) pts remain on active treatment. The most common related ≥ grade (G) 3 hematologic AEs was thrombocytopenia, (31%) and the most common ≥ G3 non hematologic AEs included, fatigue (4%)and diarrhea (4%). The ORR was 82% with 34% ≥ VGPR and 48% PR. The clinical benefit rate was 91%. **Conclusions:** The combination of PAN 20mg and CFZ 20/56 in this schedule is safe and effective in this relapsed/refractory MM population. Clinical trial information: NCT01496118.

8514 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Cardiac and renal biomarker responses in a phase 1/2 study of NEOD001 in patients with AL amyloidosis and persistent organ dysfunction. *First Author: Morie A. Gertz, Mayo Clinic, Rochester, MN*

Background: Light chain (AL) amyloidosis is caused by an accumulation of misfolded proteins that induce the dysfunction of vital organs (e.g., heart and kidneys). NEOD001, a monoclonal antibody that targets these misfolded proteins, is hypothesized to neutralize circulating soluble protein aggregates and to clear insoluble aggregates from organs. We report data from a phase I/II dose-escalation/expansion study of NEOD001 in patients (pts) with AL amyloidosis and persistent organ dysfunction (NCT01707264). **Methods:** Pts who completed ≥ 1 prior anti-plasma cell systemic therapy, had partial response or better, did not require additional chemotherapy, and had persistent organ dysfunction received NEOD001 intravenously every 28 days (q28d). Dose levels of 0.5, 1, 2, 4, 8, 16, and 24 mg/kg were evaluated (3+3 study design). Primary study objectives were to determine safety/tolerability and maximum tolerated dose/recommended phase II dose (RP2D). Secondary and exploratory objectives included pharmacokinetics (PK), immunogenicity, and hematologic and best organ responses based on consensus criteria. **Results:** As of September 30, 2014, 27 pts in seven cohorts received 209 infusions. No deaths, drug-related serious adverse events (AEs), discontinuations due to drug-related AEs, dose-limiting toxicities, or antidrug antibodies were reported. Most frequently reported AEs were fatigue, cough, and dyspnea. 24 mg/kg was selected as RP2D. PK data support intravenous dosing q28d. Of the 14 pts evaluable for cardiac biomarker assessment, 50% met criteria for cardiac response (NT-proBNP: 30% reduction), and 50% achieved disease stabilization. Of the 14 renal-evaluable pts, 43% met criteria for renal response (24-hour urine protein: 50% reduction) and 57% achieved disease stabilization. **Conclusions:** Monthly infusions of NEOD001 were safe and well tolerated. 24 mg/kg was RP2D. Cardiac response rate was 50% and renal response rate was 43%. These organ response rates compare favorably to those reported with traditional chemotherapy. The phase II expansion phase is ongoing. A phase III study has been initiated. Antibody therapy may represent a new therapeutic platform for management of AL amyloidosis. Clinical trial information: NCT01707264.

8515 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Phase I trial of 19-28z chimeric antigen receptor modified T cells (19-28z CAR-T) post-high dose therapy and autologous stem cell transplant (HDT-ASCT) for relapsed and refractory (rel/ref) aggressive B-cell non-Hodgkin lymphoma (B-NHL). *First Author: Craig Steven Sauter, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HDT-ASCT is the standard of care for patients with rel/ref diffuse large B-cell lymphoma (DLBCL). Herein, we report safety data on the first 8 patients of our phase I clinical trial of 19-28z CAR-T post HDT-ASCT for poor-risk rel/ref aggressive B-NHL (NCT01840566). **Methods:** Eligibility for this study includes rel/ref aggressive B-NHL chemosensitive to salvage therapy with: 1) FDG-PET (+) following 2 cycles of salvage therapy or 2) bone marrow involvement of B-NHL. T cells were retroviral transduced with anti-CD19 scFV linked to CD28 and CD3ζ signaling domains. Patients underwent BEAM conditioned HDT-ASCT and 19-28z CAR-T were administered on days +2 and +3. **Results:** See table for patient characteristics and results. Seven patients were treated at dose level #1 (5 x10^6 19-28z CAR-T/kg) with one dose-limiting toxicity (DLT) of prolonged grade III-IV cytopenias and non-relapse mortality (NRM) of mucormycosis pneumonia. One patient treated at dose-level #2, 1 x10^7 CAR-T/kg, experienced a DLT related to severe cytokine-release syndrome (CRS) and fully recovered. Fifty percent of the patients experienced CRS effectively treated with tocilizumab +/- corticosteroids. All patients engrafted neutrophils post-HDT-ASCT. Five of eight remain alive and progression-free at the time of this analysis. **Conclusions:** This is the first study of 19-28z CAR-T cells following consolidative HDT-ASCT for poor-risk rel/ref aggressive B-NHL. The use of 19-28z CAR T cells is a promising approach in poor-risk PET+ B-NHL patients undergoing HDT-ASCT with manageable CRS. Clinical trial information: NCT01840566.

Patient	Age	Disease	Disease at HDT-ASCT	Dose Level	CRS	Peak CRP (mg/dL)	Status Post-HDT-ASCT

8516 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Phase IIa trial of chimeric antigen receptor modified T cells directed against CD19 (CTL019) in patients with relapsed or refractory CD19+ lymphomas. *First Author: Stephen J. Schuster, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Autologous T cells expressing a chimeric antigen receptor with an external anti-CD19 single chain antibody domain and CD3ζ and 4-1BB signaling domains (CTL019 cells) mediate anti-tumor effects in patients (pts) with relapsed/refractory (r/r) CD19+ leukemias. We are conducting a phase IIa clinical trial of CTL019 cells in r/r CD19+ non-Hodgkin lymphomas. **Methods:** Eligible pts have CD19+ follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), or mantle cell lymphoma (MCL) with anticipated survival less than 2 years. After collection of peripheral blood leukocytes, pts receive lymphodepleting chemotherapy based on histology and past therapies. One to 4 days after chemotherapy, pts receive 5 x 10^8CTL019 cells intravenously. Blood and marrow samples are collected for correlative studies. Response assessment is 3 months (mo) after infusion. Enrollment began February 2014; data reported are through January 2015. **Results:** Twenty-nine pts (19 DLBCL; 8 FL; 2 MCL) have enrolled. Median age is 56 (range: 25-77), male:female ratio 17:12, median prior therapies 4 (range: 1-8), and pts with prior ASCT 9 (31%). At enrollment, stages were: IV, 16 pts (55%); III, 5 pts (17%); II, 6 pts (21%); IE, 2 pts (7%); LDH was increased in 20 pts (69%). Eight pts are not evaluable for response (DLBCL 7; FL 1): 3 pts removed from study before T cell infusion due to progressive disease; 1 pt withdrew consent; 3 pts had inadequate T cell expansion; 1 pt received < protocol-specified cell dose. Twenty pts received CTL019 per protocol dose (12 DLBCL; 7 FL; 1 MCL). Pre-infusion chemotherapy regimens were EPOCH (2); cyclophosphamide (9); radiation + cyclophosphamide (2); bendamustine (6); cyclophosphamide-fludarabine (1). Cytokine release syndrome occurred in 15 pts (13 grade 2; 2 grade 3); neurologic toxicity in 3 pts: transient delirium (1 grade 2, 1 grade 3) and 1 possibly related, grade 5 encephalopathy. For 18 pts evaluable for response at 3 mo (12 DLBCL; 6 FL), overall response rate is 67% (DLBCL 50%; FL 100%). At median follow up 6 mo, progression-free survival for evaluable pts is 59% (DLBCL 37%; FL 100%). **Conclusions:** CTL019 cells induce durable responses in pts with r/r DLBCL and FL with acceptable toxicity. Clinical trial information: NCT02030834.

8517 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Safety and efficacy of anti-CD19 chimeric antigen receptor (CAR)-modified autologous T cells (CTL019) in advanced multiple myeloma. *First Author: Alfred L. Garfall, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: CTL019, a 2nd-generation anti-CD19 CAR transduced via lentiviral vector, can induce regression of refractory B cell malignancies. Though multiple myeloma (MM) is reported to be CD19-negative, we hypothesized that CTL019 would exhibit efficacy in MM due to low-level CD19 expression on MM plasma cells (PC) or CD19 expression in drug-resistant, disease-propagating subsets of the MM clone. Here, we report initial results of an ongoing phase 1 study of CTL019 in patients with advanced MM. **Methods:** MM patients are eligible if they experienced disease progression within one year of a prior autologous stem cell transplantation (ASCT) and are medically fit to undergo second ASCT. Study therapy consists of 1-5x10^7CTL019 cells infused 12-14 days after high-dose melphalan + ASCT. **Results:** 4 subjects have been treated and have completed 30-220 days of follow-up. Median prior lines of therapy is 7.5 (range 3-10). 3/4 have unfavorable cytogenetics; 1/4 had PC leukemia. Adverse events have included hypogammaglobulinemia (4/4) and grade 1 cytokine release syndrome (1/4). 3 subjects are evaluable for response. In all 3 subjects, CTL019 engraftment was achieved (peak 0.1-0.6% of peripheral blood T cells at days 30-42), and B cells were not detectable by flow cytometry in blood or marrow at day 42. At day 100, subject #1 attained MRD-negative stringent complete response (CR), and Subject #2 attained MRD-negative unconfirmed (due to unevaluable bone marrow core) CR. Response duration in Subject #1 has surpassed the response duration after this subject's prior ASCT (i.e., remission inversion). 99.95% of Subject #1's MM PC were CD19-negative by flow cytometry and RTPCR, indicating that efficacy in this subject is not due to direct cytotoxicity of CTL019 against the dominant MM PC population. Subject #3 experienced disease progression at day 43. Updated results on the first 5 subjects will be presented. **Conclusions:** Preliminary data suggest that CTL019 can be manufactured from and safely administered to refractory MM patients. CTL019 can engraft and induce B cell aplasia after salvage ASCT. Ongoing, deep responses in 2 of 3 evaluable subjects are encouraging with respect to potential efficacy. Clinical trial information: NCT02135406.

8518 Poster Discussion Session; Displayed in Poster Session (Board #335), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM

Combination of everolimus with R-CHOP (ever R-CHOP) as an initial therapy for diffuse large B-cell lymphoma (DLBCL): A phase I and feasibility study (NCCTG N1085 [Alliance]). *First Author: Patrick B. Johnston, Mayo Clinic, Rochester, MN*

Background: Everolimus was demonstrated to have single agent activity in relapsed DLBCL (*Leukemia*. 2011; 25(2):341-7). However, the safety and efficacy of everolimus in combination with R-CHOP is unknown. **Methods:** A phase I study was designed to determine the maximum tolerated dose (MTD) of everolimus on days 1-10 or 1-14 in combination with R-CHOP given every 21 days, with a feasibility cohort to examine response in patients with newly diagnosed CD20+ DLBCL. MTD was defined as the highest safely tolerated dose where at most 1 out of 6 patients experienced DLT. Starting everolimus dose was 10 mg days 1-10 and the planned dose escalation was 10 mg days 1-14. DLT was defined as any grade 3 or higher non-hematologic toxicity or a hematologic toxicity within the first cycle resulting in a delay of the next cycle of chemotherapy. The response was evaluated using PET/CT by standard criteria. A fourteen-patient feasibility extension was planned. **Results:** In the phase I portion, 3 patients received 10 mg everolimus daily for days 1-10 and 6 patients received 10 mg everolimus daily for days 1-14. No DLT was seen and no MTD was achieved; therefore, the dose for everolimus was determined to be 10 mg daily x 14 for the extension phase. 15 additional patients were enrolled in the feasibility portion. For the 24 patients: median age 58.5 years, 58% male, 50% with stage IV disease. The most common grade 3 and 4 adverse events in patients were febrile neutropenia (21%), anemia (17%), thrombocytopenia (21%), and neutropenia (75%). Grade 3 hypertriglyceridemia occurred in 12.5% and grade 3 pneumonitis occurred in one patient. Overall response rate at completion of 6 cycles was 100% in the phase I cohort (8 CR, 1 PR). The patient achieving a PR became PET negative by 12 months without further therapy, thus achieving a CR. Feasibility cohort data will be available for the presentation. **Conclusions:** Everolimus when combined with R-CHOP combination immunochemotherapy is well tolerated at 10 mg daily on days 1-10 and 1-14 of a 21-day cycle. The initial response rates in the phase I portion appear promising. A larger trial will be necessary to confirm the benefits of this novel combination. Clinical trial information: NCT01334502.

Multivariate analysis of PFS from the AETHERA trial: A phase III study of brentuximab vedotin consolidation after autologous stem cell transplant for HL. *First Author: Jan Andrzej Walewski, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

Background: In the phase III, randomized, placebo-controlled AETHERA trial, PFS was significantly improved with brentuximab vedotin (BV) vs placebo (HR=0·57, P=0·001) in HL pts at risk of progression post-autologous stem cell transplant (ASCT). A multivariate analysis was performed to determine which factors significantly influence PFS by investigator assessment. **Methods:** After ASCT, 329 pts were randomized to receive BV 1.8 mg/kg q3wk (n=165) or placebo (n=164) for up to 16 cycles. The primary endpoint was PFS per independent review. Multivariate analysis using a Cox-proportional hazards model was developed on the following factors: treatment, age, sex, weight, geographical region, initial disease stage, time from diagnosis, no. of treatments pre-ASCT, chemosensitivity, response to frontline (FL) and salvage, type of FL therapy, prior radiotherapy, extranodal disease pre-ASCT, ASCT conditioning regimen, B symptoms at pre-ASCT relapse, no. of risk factors, baseline ECOG, baseline lesions, and pre-existing peripheral neuropathy. Significant factors ($p<0.05$) were determined after a stepwise addition and elimination of nonsignificant factors from the model. **Results:** Multivariate modeling indicated that factors significantly associated with PFS by investigator assessment included: treatment (BV vs. placebo), salvage response, gender, no. of treatments pre-ASCT, type of FL therapy, B symptoms pre-ASCT, and weight. **Conclusions:** After adjustment for significant clinical factors in a multivariate regression analysis, consolidation treatment with BV significantly reduced the risk of treatment failure compared to placebo with a HR of 0.44. These results support the primary analysis. Clinical trial information: NCT01100502.

Multivariate analyses of PFS by investigator assessment.

Effect	Hazard Ratio (95% CI)	P value
Treatment (BV vs Placebo)	0.44 (0.31, 0.62)	<0.001
Salvage response (CR vs PR/SD)	0.44 (0.30, 0.64)	<0.001
Gender (F vs M)	0.60 (0.43, 0.85)	0.004
No. treatments pre-ASCT (2 vs >2)	0.65 (0.47, 0.90)	0.010
FL therapy (ABVD vs BEACOPP/Other)	0.63 (0.44, 0.91)	0.013
B symptoms pre-ASCT (No vs Yes)	0.64 (0.45, 0.92)	0.015
Baseline weight (≤100 vs >100 kg)	0.58 (0.36, 0.94)	0.026

Interim analysis of a phase I study of INCB040093, a PI3Kδ inhibitor, alone or in combination with INCB039110, a selective JAK1 inhibitor, in patients (pts) with relapsed or refractory (r/r) B-cell malignancies. *First Author: Tycel Jovelle Phillips, University of Michigan, Ann Arbor, MI*

Background: Inhibiting the PI3K or JAK-STAT pathways may be therapeutic in B-cell malignancies due to their contribution to tumor growth and survival and effects on the tumor microenvironment. Blocking both pathways may be synergistic due to JAK-STAT augmentation of BCR activation of the NFκB pathway. **Methods:** This ongoing dose escalation study with expansion cohorts enrolled adult pts with r/r B-cell malignancies. INCB040093 was given at doses between 100–300 mg QD or BID alone or 150–300 mg QD or BID with INCB039110 at 400–600 mg QD. Safety, efficacy, and pharmacodynamics were evaluated. **Results:** A total of 83 pts have been enrolled: FL n = 19; cHL n = 17; DLBCL n = 15; CLL/SLL n = 13; others n = 19. Median age was 61 years and 70% were men. The median number of prior regimens was 4 and 24% underwent HSCT. Median exposure was 185 days (range: 5 – 491+ [ongoing]) for INCB040093 alone and 99 days (range: 6 – 337+ [ongoing]) for INCB040093 + INCB039110. The most common AEs were fatigue (28%), headache (19%), pyrexia (19%) and the most common grade $\geq$ 3 AE was pneumonia (6%). The most common laboratory abnormalities were liver enzyme elevations and cytopenias. One pt had a DLT on INCB040093 100 mg BID (GI bleed secondary to gastric DLBCL regression). Doses of INCB040093 100 mg BID and INCB040093 100 mg BID + INCB039110 400 mg QD were selected for expansion cohorts based on the incidence of liver enzyme elevations with INCB040093 and cytopenias with INCB040093 + INCB039110 at higher doses. At the selected doses, pAKT was decreased by ~90% at trough on INCB040093 and IL6-induced pSTAT3 was decreased an average of 65% on INCB039110. Of 75 pts thus far evaluated for a response, 28 responses have been reported. Notably, ORR was 60% (3 CRs) for r/r cHL and both pts with the non-GCB subtype of DLBCL had CRs. **Conclusions:** Treatment with INCB040093 $\pm$ INCB039110 was tolerable and produced responses, including CRs, in pts with heavily pretreated r/r B-cell malignancies. Given this activity, the study was expanded to enroll additional cohorts of pts with r/r B-cell malignancies such as DLBCL and cHL, and a phase II study in pts with r/r cHL was initiated. Clinical trial information: NCT01905813.

A phase I/II trial of the combination of romidepsin and lenalidomide in patients with relapsed/refractory lymphoma and myeloma: Activity in T-cell lymphoma. *First Author: Neha Mehta-Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Epigenetic manipulation and immunomodulation are therapeutic strategies in hematologic malignancies. Romidepsin (romi), a histone deacetylase inhibitor, and lenalidomide (len), an immunomodulatory agent, both have efficacy and lack cumulative toxicity in relapsed/refractory (rel/ref) lymphoma and myeloma. **Methods:** The phase I part of the study was reported at ASCO 2014. The MTD defined in cycle 1 was romi 14 mg/m^2 IV on days 1, 8, and 15 and len 25 mg oral on days 1-21 of a 28-day cycle. Patients (pts) were treated to progression or intolerance. Disease-specific cohorts in T-cell lymphoma (TCL), B-cell lymphoma and multiple myeloma were enrolled at the MTD. We report the results of the TCL subjects. **Results:** 21 pts with TCL (10 CTCL, 11 PTCL) were enrolled with 15 treated at the MTD. Median age was 64 with 52% male (n = 11).19 pts were evaluable for efficacy with an ORR of 53% (10/19). Two pts were not evaluable for response (one due to toxicity in cycle 1 without progression, one on steroids for idiopathic thrombocytopenic purpura with PET normalization prior to dose 1). The ORR in PTCL was 50% (5/10, 5 PR). Responses were seen in PTCL-NOS (3), AITL (1), T-PLL (1). One with relapsed ATLL remains on therapy with SD ongoing at 24 weeks (w). The ORR in CTCL was 56% (5/9, 2 CR, 3 PR). CR was seen in transformed MF (1), and Sezary syndrome (1). The median time to response was 7.3 w (range: 2.8-16.9 w). Median OS was not reached. Median event free survival was 15.5 w (CTCL 30.0 w, PTCL 13.5 w). However 48% (10/21) pts remain on therapy (2 CR, 6 PR, 2 SD) at a median of 15.3 w (range: 9.0-106.6 w). 7 pts discontinued for progression, 3 for toxicity and 1 for transplant. The median number of cycles was 4 (range: 1-27). 71% of pts had AEs $\geq$ Grade 3, with the most common ($\geq$ 10%) being neutropenia (48%), thrombocytopenia (38%), anemia (33%), electrolyte abnormalities (K, Phos, glucose, Mg) (43%). **Conclusions:** The combination of romi and len appears to have significant activity in rel/ref TCL (ORR 53%) with acceptable safety profile. These results support further evaluation of romi and len in patients with TCL, including additional studies in both CTCL and PTCL. Clinical trial information: NCT01755975.

Prognostic index for chronic and smoldering types adult T-cell leukemia/lymphoma. *First Author: Hiroo Katsuya, Fukuoka University, Fukuoka, Japan*

Background: Adult T-cell leukemia/lymphoma (ATL) has been divided into 4 clinical subtypes: acute, lymphoma, chronic and smoldering. The prognosis in patients with chronic and smoldering type ATL is better than the others, but they have not been treated uniformly because of diverse clinical courses even in the same clinical type. The aim of this study is to develop a novel prognostic index (PI) for chronic and smoldering type ATL. **Methods:** We conducted a nationwide retrospective survey of ATL patients in Japan newly diagnosed between 2000 and 2009. Among chronic and smoldering types, fully eligible 248 individuals were used for this analysis; this is a largest study in chronic and smoldering ATL. We randomly selected subjects equally into training and validation samples, and developed a PI. **Results:** In univariate analysis, gender, performance status, log10[soluble interleukin-2 receptor (sIL-2R)] as well as the number of neutrophil and lymphadenopathy showed P values less than .05 in the training sample. A multivariate analysis was performed in factors above, and log10(sIL-2R) was only identified as an independent prognostic factor in the training sample. Using a regression coefficient of this variable, a prognostic model was formulated to identify different levels of risk: Indolent ATL-PI (iATL-PI) = 1.51 x log10[sIL-2R(U/ml)]. The values calculated by iATL-PI were divided into 3 groups using a quartile point. In the validation sample, median survival times (MSTs) were 1.6, 5.5 years and not reached for patients at high, intermediate, and low risk, respectively ($P<$ .0001). To make the scoring system simpler and clinically practicable, we then simplified the original iATL-PI according to trichotomizing sIL-2R at 1,000 and 6,000 U/mL using a quartile point. Patients of more than 6,000 of sIL-2R were categorized into high risk group, less than and equal to 1,000 into low risk group, and the others into intermediate risk group. MSTs were 1.6, 5.5 years and not reached at high, intermediate, and low risk, respectively ($P<$ .0001). **Conclusions:** The iATL-PI makes it possible to discriminate patients with chronic and smoldering type ATL into three distinct risk groups, and it will be a novel promising tool for risk adopted therapeutic approach.

Updated analysis of CALGB/ECOG/BMT CTN 100104: Lenalidomide (Len) vs. placebo (PBO) maintenance therapy after single autologous stem cell transplant (ASCT) for multiple myeloma (MM). *First Author: Sarah A. Holstein, Roswell Park Cancer Institute, Buffalo, NY*

Background: CALGB 100104 studied Len vs. PBO maintenance following ASCT for newly diagnosed MM patients (pts), demonstrating improved time to progression (TTP), overall survival (OS) and increase in second primary malignancies (SPM) for Len at 34 months (mos) median follow-up. This is an updated intent-to-treat analysis of TTP, OS, and SPM at 65 mos median follow-up for OS. **Methods:** 460 pts age $<$ 70 years with stable disease or better 100 days post ASCT were randomly assigned to Len (n = 231) vs. PBO (n = 229). Starting dose was 10 mg daily and was escalated to 15 mg daily after 3 mos. Primary endpoint was TTP (time of progressive disease (PD) or death from any cause). After several interim analyses, the study was unblinded at 18 mos median follow-up and 86/128 PBO pts without PD chose to cross over to Len. **Results:** SPMs diagnosed after randomization but before PD included 14 hematologic and 11 solid tumor SPMs in the Len arm vs. 3 hematologic and 7 solid tumor SPMs in the PBO arm (Table 1). Estimated median TTP is 53 mos for Len and 27 mos for PBO (hazard ratio (HR):0.54 ($p < 0.001$)). Median OS has not been reached for the Len arm and is 76 mos for PBO (HR: 0.60, $p = 0.001$). Cumulative incidence risk (CIR) of developing a SPM is higher for Len compared with PBO ($p = 0.005$) and the CIR of PD ($p < 0.001$) or death ($p < 0.001$) is higher for PBO. There was no difference in OS after PD between the Len or PBO arms. The TTP and OS benefit with Len was observed regardless of whether pts were in a complete response or not at randomization and for thalidomide vs. Len induction therapy. **Conclusions:** There is an increased incidence of SPMs for Len compared to PBO. Post ASCT Len maintenance continues to demonstrate significantly improved TTP and OS. Clinical trial information: NCT00114101.

8524 Poster Discussion Session; Displayed in Poster Session (Board #341), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM

FIRST study: Updated overall survival (OS) in stem cell transplant (SCT)-ineligible newly diagnosed multiple myeloma (NDMM) patients (pts) treated with continuous lenalidomide plus low-dose dexamethasone (Rd) vs melphalan, prednisone, and thalidomide (MPT). *First Author: Thierry Facon, Service des Maladies du Sang Place de Verdun, Lille, France*

Background: MPT is considered a standard treatment (Tx) option in many countries for SCT-ineligible pts with NDMM. The FIRST trial showed that continuous Rd improved progression-free survival (PFS) and was associated with an OS advantage vs MPT (Benboubker, *NEJM*2014). This abstract presents an updated OS and safety analysis, not initially planned, but requested by regulatory authorities. **Methods:** SCT-ineligible NDMM pts were randomized 1:1:1 to Tx with continuous Rd (28-day cycles), Rd for 18 cycles (Rd18), or MPT for 12 cycles (42-day cycles). The primary endpoint was comparison of PFS (Rd vs MPT) based on IRAC review. Secondary endpoints included OS, overall response rate, and safety. Time from randomization to second progression or death (PFS2) was an additional analysis. **Results:** 1623 pts were randomized; 535 pts received continuous Rd, 541 received Rd18, and 547 received MPT. As of March 3, 2014, 91 pts remained on Tx with Rd. 697 pts (42.9%) have died (38.9% Tx with Rd, 42.1% with Rd18, and 47.7% with MPT). With a median follow-up of 45.5 mos, median OS was 58.9 vs 56.7 vs 48.5 mos for pts treated with continuous Rd, Rd18, and MPT, respectively (for continuous Rd vs MPT, HR = 0.75 [95% CI, 0.62-0.90]). The majority of 2nd-line Tx were bortezomib-based (55.7% of pts who began 2nd line Tx). 58% of pts had a PFS2 event; median PFS2 was extended with continuous Rd vs Rd18, and MPT (42.9, 40.0, and 35 mos, respectively; HR for continuous Rd vs MPT = 0.74 [95% CI, 0.63-0.86]). Average Tx duration for continuous Rd, Rd18, and MPT was 97.8, 54.8 and 51.9 wks, respectively. Discontinuation of lenalidomide vs thalidomide due to AEs was 22.6 vs 27.0%. **Conclusions:** In this updated analysis from the FIRST trial, OS benefit was maintained with continuous Rd and it was better tolerated vs MPT in SCT-ineligible NDMM pts. PFS2 improvements suggest benefit of continuous Rd is retained through 2nd-line therapy and does not induce resistance. Safety profile remained consistent with the interim analysis. These findings reinforce continuous Rd as a new standard of care for the studied population. Clinical trial information: NCT00689936.

8525 Poster Discussion Session; Displayed in Poster Session (Board #342), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM

Effect of carfilzomib, lenalidomide, and dexamethasone (KRd) vs lenalidomide and dexamethasone (Rd) in patients with relapsed multiple myeloma (RMM) by line of therapy: Secondary analysis from an interim analysis of the phase III study ASPIRE (NCT01080391). *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens, Athens, Greece*

Background: Previously reported results from ASPIRE (N = 792 patients) showed that KRd significantly improved progression-free survival (PFS) vs Rd in RMM with a favorable benefit-risk profile (Stewart et al. *N Engl J Med*2015;372:142–52). A secondary analysis of efficacy and safety results from patients treated with KRd or Rd after first relapse (1 prior line of therapy) vs ≥ 2 prior lines of therapy are presented. **Methods:** Adults with RMM who received 1–3 prior lines were eligible. Patients were randomized (1:1) to KRd or Rd. All patients received lenalidomide (25 mg) on days 1–21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 of a 28-day cycle. Patients in the KRd arm received carfilzomib as a 10-min infusion on days 1, 2, 8, 9, 15, and 16 during cycles 1–12 (20 mg/m^2 [days 1 and 2 of cycle 1]; 27 mg/m^{2}thereafter). Carfilzomib was omitted on days 8 and 9 during cycles 13–18 and was not administered beyond 18 cycles. **Results:** Median PFS for patients receiving 1 prior line (n = 341) was 29.6 months (95% confidence interval [CI]: 23.2–33.5) for KRd vs 17.6 months (95% CI: 15.0–22.2) for Rd (hazard ratio [HR]: 0.694; *P*= .0083). Median PFS for patients receiving ≥ 2 prior lines (n = 451) was 25.8 months (95% CI: 22.2–31.0) for KRd vs 16.7 months (95% CI: 13.9–22.0) for Rd (HR: 0.688; *P*= .0017). No grade ≥ 3 adverse events (AEs) occurred ≥ 5.0% more frequently with KRd vs Rd in patients who received 1 prior line of therapy; hypokalemia was the only grade ≥ 3 AE that occurred ≥ 5.0% more frequently with KRd (11.0%) vs Rd (3.4%) in patients who received ≥ 2 prior lines. For patients on KRd, neutropenia was the only grade ≥ 3 AE that occurred ≥ 5.0% more frequently after ≥ 2 prior lines (32.4%) vs 1 prior line of therapy (26.4%). **Conclusions:** The use ofKRd after first relapse led to a 1-year improvement in median PFS vs Rd compared with a 9-month improvement in median PFS vs Rd in pts with ≥ 2 prior lines of therapy, with similar HRs. KRd had a favorable benefit–risk profile after 1 and ≥ 2 prior lines of therapy in patients with RMM. Clinical trial information: NCT01080391.

Panobinostat plus bortezomib and dexamethasone in patients with relapsed or relapsed and refractory multiple myeloma who received prior bortezomib and IMiDs: A predefined subgroup analysis of PANORAMA 1. *First Author: Jesus F. San Miguel, Clinica Universidad de Navarra, Pamplona, Spain*

Background: Panobinostat (PAN) is a potent pan-deacetylase inhibitor (pan-DACi) that targets key biological aberrations in multiple myeloma (MM), including epigenetics and protein metabolism. PAN + bortezomib (BTZ) and dexamethasone (Dex; PAN-BTZ-Dex) led to a clinically relevant and statistically significant increase in progression-free survival (PFS) of ≈4 months compared with placebo + BTZ and Dex (Pbo-BTZ-Dex) in patients (pts) with relapsed or relapsed and refractory MM in the PANORAMA 1 phase 3 clinical trial. **Methods:** The study design was described previously (San-Miguel. *Lancet Oncol.* 2014;15:1195-206). For this subanalysis, pts who received prior BTZ and IMiDs (lenalidomide or thalidomide) were analyzed for outcomes and safety. **Results:** A total of 193 pts (25%) received prior BTZ and IMiDs (PAN-BTZ-Dex [n = 94] or Pbo-BTZ-Dex [n = 99]). Median PFS as determined by investigator assessment for the PAN arm was 10.6 mo (95% CI, 7.6-13.8) vs 5.8 mo (95% CI, 4.4-7.1) for the Pbo arm (HR 0.56 [95% CI, 0.39-0.80]; *P* = .0011). Most (76%) received ≥ 2 prior lines and the difference in median PFS increased in these pts: PAN arm (n = 73): 12.5 mo (95% CI, 7.3-14.0); Pbo arm (n = 74): 4.7 mo (95% CI, 3.7-6.1; HR 0.47 [95% CI, 0.32-0.72]; *P* = .0003). For all pts who received prior BTZ and IMiDs, overall response rate was 58.5% (95% CI, 47.9%-68.6%) vs 41.4% (95% CI, 31.6%-51.8%; *P* = .0179) and ≥ near complete response rate was 22.3% (95% CI, 14.4%-32.1%) vs 9.1% (95% CI, 4.2%-16.6%) in the PAN and Pbo arms, respectively. Common grade 3/4 adverse events and laboratory abnormalities in each arm included thrombocytopenia (68.5% vs 48.0%), lymphopenia (50.0% vs 46.5%), neutropenia (35.9% vs 17.2%), diarrhea (30.4 vs 13.1%), and asthenia/fatigue (25.0% vs 12.1%). The percentage of on-treatment deaths in each arm was similar (6.4% vs 5.1%). **Conclusions:** PAN-BTZ-Dex demonstrated efficacy, with an increased median PFS of 4.8 months among MM pts who received prior BTZ and IMiDs, a population with a clear unmet need. The safety profile is consistent with that in the overall PANORAMA 1 population, although on-treatment deaths were similar. Clinical trial information: NCT01023308.

8527 Poster Discussion Session; Displayed in Poster Session (Board #344), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM

Updated results from CHAMPION-1, a phase I/II study investigating weekly carfilzomib with dexamethasone for patients (Pts) with relapsed or refractory multiple myeloma (RRMM). *First Author: James R. Berenson, Institute for Myeloma & Bone Cancer Research, Los Angeles, CA*

Background: Carfilzomib (K) is a selective proteasome inhibitor that is approved for the treatment of relapsed and refractory multiple myeloma in the US. CHAMPION-1 (NCT01677858) is a multicenter, single-arm, phase 1/2 study evaluating the safety and efficacy of weekly K with dexamethasone (dex; Kd) in pts with RRMM. **Methods:** Pts who received 1−3 prior regimens were eligible. In the phase 1 portion, pts received K as a 30-min IV infusion on days 1, 8, and 15 of a 28-day cycle using a 3+3 dose-escalation scheme. Pts received K at 20 mg/m^2 on day 1 of cycle 1; subsequent doses started at 45 mg/m^2 and were escalated to 56, 70, or 88 mg/m^2 until the maximum tolerated dose (MTD) was reached for use in the phase 2 portion. Pts received dex 40 mg (IV or oral) on days 1, 8, 15, and 22 of cycles 1–8; dex was omitted on day 22 in cycles ≥ 9. Kd was administered until disease progression or unacceptable toxicity. **Results:** The MTD was reported previously (70 mg/m^2). As of January 7, 2015, 104 pts were enrolled at the MTD (phase 1, n = 15; phase 2, n = 89). Median pt age was 68.5 y (range, 41–88). Pts received a median of 1 prior regimen (range, 1–3); 82% of pts had received prior bortezomib (BTZ). A total of 48% of pts were BTZ-refractory, 28% were lenalidomide (LEN) refractory, and 16% were refractory to BTZ and LEN. Preliminary median K treatment duration in the ongoing study was 5.3 mo (range, 0.03–18.8). The overall response rate (≥ partial response) was 72% (95% confidence interval [CI]: 63%–81%); the clinical benefit rate (≥ minimal response) was 80% (95% CI: 71%–87%). Median PFS was 10.6 mo (95% CI: 7.2–not estimable). Seven pts (7%) discontinued treatment due to an adverse event (AE). The most common grade ≥ 3 AEs were fatigue (9%), thrombocytopenia (6%), dyspnea (6%), back pain (6%), anemia (5%), and acute renal failure (5%). Four pts died on study: 1 pt had sepsis, respiratory distress, pneumonia, and acute renal failure; and 1 pt each had acute renal failure, cardiopulmonary arrest, and disease progression. **Conclusions:** At the MTD (70 mg/m^2), weekly Kd had acceptable safety and tolerability with promising efficacy in pts with RRMM. Updated results will be presented at the meeting. Clinical trial information: NCT01677858.

8528 Poster Discussion Session; Displayed in Poster Session (Board #345), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM

A phase II study of panobinostat with lenalidomide and weekly dexamethasone in myeloma. *First Author: Ajai Chari, Mount Sinai, New York, NY*

Background: Preclinical data support deacetylation of oncogenic proteins/histones with the pan histone deacetylase inhibitor (HDACi) panobinostat (pan), which renders MM cells more susceptible to other anti-MM agents. Clinically, pan added to btz & dex in the PANORMA 1 phase III study resulted in both improved CR & PFS by 3.9 months. However, grade 3/4 diarrhea also increased from 8 to 25%. Though the MTD of pan-len-dex was attained in a phase 1b study of Rel Ref MM (Mateos et al, ASCO '10), 4 day pulses of dex *3 per cycle was toxic. We modified that regimen; pan 20 mg D1, 3, 5, 15, 17, 19 + len 25 mg qd D1-21 + dex 40 mg D1, 8, 15 in 28 day cycle. **Methods:** Pts with RRMM with PD, measurable disease, & adequate PS/heme/organ function were eligible. Use of QTc prolonging agents & prior HDACIs were prohibited. Evaluation of the ORR was the primary objective & safety, DOR, OS, & PFS were secondary objectives. **Results:** 20 evaluable pts median 64 yo (45% > 65 yo) with 3 median lines of Rx over 4 years were enrolled. 13 (65%) were high molecular risk, 16(75%) were len- refr, & 35, 45, 30% were refr to each: pom, btz, & cfz. Responses include 1 CR, 3 VGPRs, 5 PRs, 8 MRs, & 2 SD, for an ORR of 45%, CBR of 85 % and a median PFS of 7.5 mos. In the 16 len-refr pts, there were 3 VGPRs, 3 PRs, 7 MRs, with a median PFS of 6.5 mos. Grade 3/4 toxicities (regardless of drug attribution) were primarily heme, with neutropenia (55%), thrombocytopenia (40%) and anemia (5%) respectively. Grade 3/4 nonheme AEs included infections in 4 (1 while neutropenic), 3 diarrhea (transient) & 2 PEs and 1 pt each with: neck pain, QTc prolongation, fatigue, & weight loss. Pts requiring dose reductions of len/pan respectively were 4/2 for ANC, 2/1 for plts, & 1 len for fatigue, & 1 pan for asymptomatic T wave inversions. No doses were held or reduced for GI toxicities. **Conclusions:** In RRMM, the completely oral pan len dex demonstrates durable responses, even in high risk len-refr pts, indicating the essential role of pan in attaining responses. In notable contrast to PANORMA 1 there were no significant GI toxicities & primarily expected heme toxicities. Updated results of planned 27 pts, including correlatives, will be presented at the annual meeting. Clinical trial information: NCT01651039.

8529 Poster Session (Board #346), Sun, 8:00 AM-11:30 AM

Idelalisib efficacy and safety in follicular lymphoma patients from a phase 2 study. *First Author: Gilles A. Salles, Hospices Civils de Lyon, Université Claude Bernard, Pierre Bénite, France*

Background: There is an unmet need for new treatment options in FL, particularly for heavily pretreated, high-risk patients refractory to anti-CD20 and chemotherapy. Idelalisib, a PI3Kδ inhibitor, showed antitumor activity and acceptable tolerability as monotherapy in a pivotal phase 2, open-label study in indolent non-Hodgkin lymphoma (iNHL) refractory to rituximab (R) and an alkylating agent (NCT01282424). This post hoc analysis evaluated efficacy and safety in the FL patient subset. **Methods:** Double refractory patients with histologically confirmed iNHL received oral idelalisib 150 mg BID until disease progression (PD) or unacceptable tolerability; patients with FL (grade 1, 2, or 3a; n = 72) were included in this analysis. Responses were evaluated by an independent review committee using standardized criteria. The primary endpoint was the overall response rate (ORR). **Results:** At study entry, patients' median age was 62 y, 54% had a high-risk FLIPI score, 22% had bulky disease, and 17% had FL grade 3a. Median (range) number of prior treatments was 4 (2–12); 86% were refractory to their last therapy (32/50 to bendamustine). At data cutoff, median (range) treatment duration was 6.5 (0.6–31.0) mo, with 65 (90%) patients off treatment (PD, 38; adverse events [AEs], 15; investigator decision, 7; death, 5). Lymph node size decreased during treatment by ≥ 50% SPD in 57%. The ORR (95% CI) was 56% (43–67; $P < 0.001$), including 10 complete responses (CR) and 30 partial responses. Kaplan-Meier (KM)—estimated median (range) time to response was 2.6 (1.6–11.0) mo, median response duration was 11 mo (27 mo in patients with CR), and progression-free survival was 11 mo, substantially longer vs the last regimen. Median overall survival (OS) was not reached; KM-estimated OS at 1, 1.5, and 2 y was 87%, 74%, and 68%.The most common AEs (any/grade ≥ 3, %) were diarrhea (51/14), cough (32/0), pyrexia (29/4), fatigue (28/0), and nausea (28/3). Rates of grade ≥ 3 transaminase elevation, pneumonitis, neutropenia, anemia, and thrombocytopenia were 14%, 4%, 22%, 3%, and 6%. **Conclusions:** Idelalisib demonstrated rapid, durable responses and acceptable safety in highly refractory, relapsed FL patients with limited treatment options. Clinical trial information: NCT01282424.

8530 Poster Session (Board #347), Sun, 8:00 AM-11:30 AM

Lenalidomide and low-dose dexamethasone (Ld) is equivalent to Ld plus autologous stem cell transplant (ASCT) in newly diagnosed multiple myeloma (NDMM): Results of a randomized, phase III trial. *First Author: Suzanne Lentzsch, Columbia University Medical Center, New York, NY*

Background: Upfront ASCT is the current standard of care for transplant-eligible NDMM. However, its use has come into question with the emergence of novel agents such as lenalidomide. This randomized phase III study evaluated the role of upfront ASCT in NDMM, with Ld administered as induction therapy. **Methods:** Patients aged 18–75 years with transplant-eligible, previously untreated, NDMM were randomized to four 28-day cycles of lenalidomide (25 mg days 1–21) plus low-dose dexamethasone (40mg days 1, 8, 15, 22) followed by stem-cell mobilization and: ASCT conditioned with 200 mg/m^{2}melphalan (Arm A; Ld+ASCT); or Ld for 4 additional cycles (Arm B; Ld). Patients subsequently received maintenance lenalidomide (10–15 mg) for ≤ 2 years or until disease progression. Patients with stable disease prior to stem-cell collection, or with progressive disease at any time, went off study. The primary objective was to compare best response in Arm A versus Arm B. Secondary objectives were comparisons of the duration of response, progression-free survival (PFS), and overall survival (OS). **Results:** Sixty patients were randomized between February 2009 and August 2014: 31 into Arm A, and 29 into Arm B. Baseline characteristics were similar in the two arms. The mean age was 62 years (range 48–75), and 43.3% of patients had International Staging System stage 1 disease. In an intention-to-treat analysis, neither the overall response (≥ partial response) rate (83.9% vs. 72.4%; p = 0.28) nor the complete response rate (21.9 vs. 19.3%; p = 0.28) differed significantly between Arm A and Arm B. The median follow-up time for the entire study population was 53.5 months (95% confidence interval [CI]: 49.5–58.3). OS and PFS at 4 years were estimated at 79.0% (95% CI: 56.2–90.8) vs. 86.5% (95% CI: 63.7–95.4) (p = 0.31) and 69.3% (95% CI: 47.6–83.4) vs. 56.8% (95% CI: 34.3–74.2) (p = 0.30) in Arm A vs. Arm B, respectively. **Conclusions:** Ld without upfront ASCT appears to provide similar treatment response, OS, and PFS benefits to Ld plus ASCT in NDMM. Clinical trial information: NCT01731886.

8531 Poster Session (Board #348), Sun, 8:00 AM-11:30 AM

Phase 1 open-label dose escalation study of the dual SYK/JAK inhibitor cerdulatinib (PRT062070) in patients with relapsed/refractory B-cell malignancies: Safety profile and clinical activity. *First Author: Ian Flinn, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Inhibition of SYK and JAK independently has demonstrated clinical activity in patients with B cell malignancies. We present here an update on the first-in-human study of a dual SYK and JAK inhibitor, cerdulatinib, in patients with relapsed/refractory B cell malignancies. **Methods:** This was a 3+3 dose escalation study with 28-day cycles beginning at 15 mg once daily oral dose. PK, PD, and safety were monitored. Response was assessed by standard criteria. **Results:** No dose-limiting toxicities have been reported to date. As of January 15th, 2015, a total of 25 patients with CLL/SLL or B cell NHL were dosed. Median age was 72 years (23-85) and median prior therapies was 4 (1-6). Treatment emergent AEs of ≥ grade 3 regardless of causality were: grade 3 hyperkalemia (n = 1) and anemia (n = 1) and grade 5 Pneumocystis pneumonia (PCP; n = 1) at 30 mg total daily dose; grade 3 fatigue (n = 1) and AST increase (n = 1) were observed at the 45mg dose. The patient with grade 3 AST had tumor progression to the liver. PK is suitable for once daily dosing with a half-life of 12-16 hours and a 2:1 peak-trough ratio. Saturating inhibition of SYK and JAK in circulating lymphocytes (80-90% inhibition) and serum inflammation markers (e.g., β2M, CRP, CCL4; 50-90% inhibition) occurs at plasma concentrations of ~ 0.6-1μM, achieved at Cmin of the 40mg dose. At 30mg once daily, one partial response was observed in a CLL patient with a 17 p deletion who relapsed on six prior regimens and was intolerant of a PI3K inhibitor. At the 45mg dose, two partial responses were observed at completion of the second cycle of therapy: the first in a follicular lymphoma patient with 3 prior regimens and the second in a CLL patient with 4 prior regimens. Dose escalation continues to identify the maximum tolerated dose. **Conclusions:** Cerdulatinib continues to demonstrate a favorable PK profile and good tolerability at high levels of SYK and JAK inhibition. The clinical responses seen at the 45mg dose level support further development. A phase II expansion study at this dose is planned to begin in the first quarter of 2015. Clinical trial information: NCT01994382.

8532 Poster Session (Board #349), Sun, 8:00 AM-11:30 AM

Idelalisib monotherapy and durable responses in patients with relapsed or refractory Waldenstroms Macroglobulinemia (WM). *First Author: Steven Coutre, Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA*

Background: Idelalisib (Zydelig), a selective oral inhibitor of PI3Kδ, demonstrated considerable anti-tumor activity in patients with relapsed/refractory iNHL in phase 1 (p1; Flinn, 2014), and refractory iNHL in phase 2 trials (p2; Gopal, 2014). This analysis evaluates the outcomes in the subset with WM. **Methods:** Eligible WM patients (pts) included those with relapsed/refractory disease (p1), or those with disease refractory to both rituximab and an alkylating agent (p2). Idelalisib dosages were 150 mg QD, and 50 mg-200 mg BID (p1), and 150 mg PO BID (p2) and were administered continuously until disease progression. WM response was assessed by IgM levels and CT-imaging (Owen, 2013). **Results:** Enrolled pts, (p1 N = 9; p2 N=10), had a median age of 63 and 60 years [range 42-83] and 78% and 80% were male, respectively. Patients had received a median of 4 prior regimens in both groups. Overall response rate (ORR) was 5/9 (56%), and 8/10 (80%; Table 1). Median time to minor or first response was 2 months, and most responses continued to improve over 6 months or longer. Median DOR was 32.8 months (p1), and not yet reached (p2). 67% have continued response at 2 years (p2). Median PFS is 33.3 months, and 22.1 months, respectively. Interestingly, > 3 gram/dL improvements in hemoglobin were noted in 5/9 and 7/10 subjects respectively over 3-6 month timeframe. Grade ≥ 3 adverse events included increased ALT/AST 5/9, and 1/10, and diarrhea/colitis 1/9, and 3/10. One G3 ALT elevation and 1 G3 diarrhea resulted in study discontinuation. **Conclusions:** These combined data suggest single agent idelalisib monotherapy is active in Waldenstroms macroglobulinemia. Durable responses were seen in the majority of subjects. Marked improvements in hemoglobin level are also associated with response. The safety profile was acceptable and manageable, with no apparent disease specific safety signals. Phase 3 clinical trials of idelalisib with combination therapy are in progress for iNHL subjects, including WM subjects.Clinical trials: (p1) NCT00710528. (p2) NCT01282424. Clinical trial information: NCT01282424.

8533 Poster Session (Board #350), Sun, 8:00 AM-11:30 AM

A phase I study combining bendamustine with rituximab, etoposide and carboplatin (TREC) in patients with aggressive relapsed or refractory lymphoma. *First Author: L. Elizabeth Budde, City of Hope National Medical Center, Duarte, CA*

Background: Traditional multi-agent salvage strategies for lymphoma are less effective after failed modern front line therapies. Bendamustine (Treanda, T) has considerable anti-lymphoma activity and a favorable toxicity profile. We hypothesized that bendamustine could replace ifosfamide within the (R)ICE regimen yielding a feasible and effective salvage strategy (TREC). **Methods:** This multicenter phase I study used a two stage design followed by 2 expansion cohorts for patients with diffuse large B cell lymphoma (DLBCL) and Hodgkin lymphoma (HL). Eligibility included measurable relapsed/refractory lymphoma, ECOG performance status ≤ 2, adequate blood counts and organ function. The primary objective was to define a maximally tolerated dose (MTD) of bendamustine associated with a dose limiting toxicity (DLT) rate of ≤ 25%. Therapy consisted of bendamustine ranging from 60 mg/m2 to 120 mg/m2 daily on days 1 and 2 with standard doses of carboplatin, etoposide, and rituximab (CD20+ disease only) used in the RICE regimen every 21 days for 2 cycles. **Results:** A total of 46 treated patients with median age of 58 years and median of 1 prior therapy, were enrolled with 3 at the dose escalation cohorts and 43 at the recommended phase 2 dose (RP2D). MTD was not reached. Primary refractory disease or early relapse was seen in 13 (65%) patients with HL (n = 20) and 14 (74%) patients with DLBCL (n = 19). All cycles were successfully given in the outpatient setting. Fourteen patients suffered ≥ grade 3 non-hematologic adverse events but without DLTs. The most common ones were febrile neutropenia (n = 4, 9%) and rash (n = 3, 4%). Per Cheson 2007 criteria overall response rates were 67% with 84% (14 CR, 2 PR) in HL, and 63% (8 CR, 4 PR) in DLBCL. Mobilization of peripheral blood stem cells (PBSC) was successful in all attempts immediately following the treatment with a median collection of 5.9 x 10^6CD34/kg. To date, 16 of 22 (77%) CR patients underwent transplant. **Conclusions:** The outpatient administration, manageable toxicity profile, and high response rate in HL and DLBCL of the TREC regimen are encouraging. These data support future evaluation of TREC. Clinical trial information: NCT01165112.

8534 Poster Session (Board #351), Sun, 8:00 AM-11:30 AM

A phase I study of gemcitabine and bendamustine in relapsed/refractory Hodgkin's lymphoma. *First Author: Jonathon Brett Cohen, Emory University - Winship Cancer Institute, Atlanta, GA*

Background: Salvage regimens for Hodgkin lymphoma (HL) can be challenging due to either need for inpatient admission or frequent dosing. Based on previously reported single agent activity of bendamustine (benda) and gemcitabine (gem), we conducted a phase I study of benda and gem in patients (pts) with relapsed/refractory classical HL who failed at least 1 prior therapy to determine the maximum tolerated dose. **Methods:** Utilizing a cohorts of 3 design, pts received gem dosed at 1000mg/m^2 on day 1 and benda doses of 60mg/m^2 to 120mg/m^2on days 1 and 2 of each cycle for up to 6 cycles, with cycle lengths of 28 (dose levels [DL] 1-3) and 21 (DL 4-5) days. Dose limiting toxicity (DLT) was determined during cycle 1. **Results:** Fourteen pts (8 males) with a median age of 38.5 years (range: 23-60) and a median of 4 (range: 1-7) prior lines of therapy have completed a median of 4 cycles at DL 1 (n = 3), 2 (n = 3), 3 (n = 3), 4 (n = 4), and 5 (n = 1). Seven pts had a prior autologous transplant (ASCT), and 1 pt had a prior ASCT and allogeneic transplant. One pt only received day 1 of therapy in cycle 1 at DL 4 and was thus not considered in dose escalation determination. The benda dose was 60mg/m^2 for 3 pts, 90mg/m^2 for 6 pts, and 120mg/m^2 for 4 pts. No DLTs have been observed. Four pts have required hospitalization, including 2 heavily pretreated pts with pulmonary symptoms after cycle 2. One underwent a biopsy that was consistent with a drug-induced pneumonitis likely gem-related, while the other had grade 5 respiratory failure that was deemed secondary to infection although a relationship with gem could not be ruled out. Additional grade 3-4 toxicities include: lymphopenia (n = 10) thrombocytopenia (n = 2), atrial fibrillation (n = 1), fever (n = 1), renal failure (n = 1), hypotension (n = 1), pneumonia (n = 1), hypoalbuminemia (n = 1), hypokalemia (n = 1), and rash (n = 1). In 13 evaluable pts, the response rate was 77% (CR, n = 3; PR, n = 7; SD, n = 2; PD, n = 1). Two pts have had an ASCT with collection of 5.1 x 10^6 CD34+ cells over 2 days and 4.94 x 10^6CD34+ cells over 3 days. **Conclusions:** The combination of benda 120mg/m^2 with gem 1000mg/m^2 is tolerable and appears efficacious. We continue to monitor closely for additional pulmonary toxicity as we complete accrual to our final dose level using a 21-day cycle. Clinical trial information: NCT01535924.

8535 Poster Session (Board #352), Sun, 8:00 AM-11:30 AM

Interim results from a dose-escalation study of the BCL-2 inhibitor venetoclax (ABT-199/GDC-0199) plus bendamustine (B) and rituximab (R) in patients (pts) with relapsed/refractory (R/R) Non-Hodgkin's Lymphoma (NHL). *First Author: Sven De Vos, Department of Hematology/Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Venetoclax (VEN) is a selective, potent, orally bioavailable BCL-2 inhibitor that has shown single agent activity in R/R NHL. The current study evaluates VEN with BR, an active regimen widely used for NHL. **Methods:** Objectives were safety, PK, preliminary efficacy, MTD, and recommended Phase 2 dose. Dose escalation (DE) used a 3+3 design on a 28 day (d) cycle (C) with 3 VEN (50–400 mg) schedules: 3, 7, and 28 d/C. The BR regimen was 6 C: B (2 d/C, 90mg/m^2) and R (1 d/C, 375mg/m^2). DLTs for DE were assessed during C1. Responses were first assessed on C3 d1. Pts who completed VEN + BR with continued tolerability and without disease progression could continue VEN monotherapy up to 2 yrs. **Results:** As of 1/9/15, 33 were treated: 20 (61%) FL, 10 (30%) DLBCL, and 3 (9%) MZL. Median age was 62 (29-90) yrs. All had prior R or R-combination, of which 32 (97%) had R-based chemotherapy and 8 (24%) had prior B or BR. 16 (48%) pts are active; 17 discontinued (12 PD, 2 AE, 1 each withdrew consent, non-compliance, pt decision). Median time on study was 90 d (1–876); 15 (45%) completed 6 C of the combination. The most common AEs (in >25%) were nausea (58%), anemia, neutropenia (each 42%), thrombocytopenia, diarrhea (each 39%), hyperglycemia (36%), and vomiting, hypokalemia, fatigue (each 27%). The most common gr 3/4 AEs (in >10%) were neutropenia (30%), leukopenia, thrombocytopenia, lymphopenia (each 21%), and anemia (18%). The most frequent SAE was febrile neutropenia (9%). There were no drug-related AEs that led to death. Co-administration of BR did not significantly impact VEN PK. 29 pts had ≥1 assessment: 6 (21%) CR and 13 (45%) PR. The ORR was 66% in all pts and 74% in pts with FL. **Conclusions:** Preliminary data demonstrate a tolerable safety profile of VEN + BR. Early responses were seen across all cohorts. Cohort 9 is enrolling at 600 mg 28 d/C. Clinical trial information: NCT01594229.

Development of the molecular diagnostic (MDx) DLBCL Lymphoma Subtyping Test (LST) on the nCounter Analysis System. *First Author: Brett Wallden, NanoString Technologies, Inc., Seattle, WA*

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive non-Hodgkin's lymphoma with two distinct molecular cell-of-origin (COO) subtypes known as germinal center B-cell (GCB) or activated B-cell (ABC). DLBCL subtypes have been reported to be prognostic and potentially predictive of treatment benefit, underscoring the need for a precise and accurate MDx test. NanoString's LST is based on the Lymph2Cx gene expression profile (GEP). These studies describe the development of the LST and analytical robustness and clinical accuracy of the Linear Predictor Score (LPS) and DLBCL subtypes (ABC and GCB). **Methods:** 51 banked formalin fixed, paraffin embedded (FFPE) DLBCL specimens were used to recalibrate the algorithm using a clinical grade assay. The subtype accuracy of the final locked algorithm was verified by testing 68 independent specimens with gold standard (GS) GEP results. Analytical precision was measured across 2 operators and 3 reagent lots by testing 10 FFPE DLBCL RNA samples. Reproducibility was measured across 2 operators and pathologists by testing replicate tissue sections from 64 FFPE DLBCL blocks following independent pathology review of H&E slides. Following guided macrodissection of pathologist identified tumor tissue, isolated RNA was tested on the NanoString nCounter system. The assay was evaluated across the assay RNA input range (62.5-1000 ng) and with the inclusion of adjacent non-tumor tissue. **Results:** The estimated misclassification rate compared to the GS result was 5.9% (95% CI: 4.6%-7.1%). The total standard deviation in LPS was $<$ 2% of the score range, including all sources of assay variation, with no significant differences between operators or reagent lots. Average LST subtype concordance with independent pathology review was $>$ 95% with no GCB to ABC misclassifications (or vice versa). The assay was robust across the specified range and against the inclusion of tissue interferents. **Conclusions:** The NanoString LST is a highly precise and accurate method for determining the COO from FFPE DLBCL tissue. The assay is well suited to clinical applications and is being used to select ABC patients for a Phase III study investigating lenalidomide (REVLIMID) in DLBCL.

8537 Poster Session (Board #354), Sun, 8:00 AM-11:30 AM

Phase 1 first-in-human trial of oral CUDC-907, a dual inhibitor of PI3K and HDAC, in patients with refractory/relapsed lymphoma or multiple myeloma. *First Author: Jesus G. Berdeja, Sarah Cannon Research Institute, Nashville, TN*

Background: CUDC-907 is an oral inhibitor of class I PI3K as well as class I and II HDAC enzymes. Anti-tumor effects of CUDC-907 have been demonstrated in B-cell lymphoma and multiple myeloma xenografts via inhibition of PI3K, MAPK, and STAT pathways. **Methods:** In a 3+3 dose escalation and expansion trial, CUDC-907 was administered on 3 dosing schedules: once daily (QD), intermittent (ie, twice [BIW] or thrice [TIW] weekly), or five days on/two days off (5/2) in 21 day cycles. Re-staging was performed every 2 cycles. **Results:** 45 subjects received CUDC-907 at doses up to 60 mg on the QD or 5/2 schedules, and up to 150 mg on the BIW or TIW schedules. Dose limiting toxicities occurred in 3 subjects: 1 at 60 mg QD (hyperglycemia and diarrhea); 1 at 150 mg BIW (hyperglycemia); and 1 at 150 mg TIW (diarrhea). No DLT occurred on the 5/2 schedule. The most common treatment-related adverse events (AEs) included diarrhea (44%), fatigue (29%), nausea (16%) and thrombocytopenia (11%). 38 subjects are evaluable for response. 4/8 subjects with DLBCL or t-FL/DLBCL (median of 4 prior therapies) achieved objective responses including 1 CR (DLBCL) and 3 PRs (1 with DLBCL; 2 with t-FL/DLBCL); with 3/8 achieving stable disease (SD). SD lasting a median of 101 days (40 – 717) has been observed in 21/38 (55%) subjects including: HL (8/10) and MM (3/4). PK plasma levels have revealed a dose-dependent increase in CUDC-907 exposure on the BIW and TIW schedules. Accumulation of active metabolite was only observed on the QD schedule. **Conclusions:** The safety profile of CUDC-907 for gastrointestinal, hematologic, and hyperglycemic AEs was predictable based on experience with other HDAC and PI3K inhibitors. AEs have been reversible and managed with standard interventions or dose interruption, and fatigue and thrombocytopenia have not been dose limiting. CUDC-907 has achieved objective responses and long-term SD across multiple tumor types and dosing schedules, with objective response achieved in a heavily pretreated DLBCL patient population. Though MTD was not reached in the intermittent or 5/2 schedules, expansion is being studied at 120 mg TIW and 60 mg 5/2 dose levels based upon their efficacy and toxicity profiles. Clinical trial information: NCT01742988.

8538 Poster Session (Board #355), Sun, 8:00 AM-11:30 AM

Phase II study of Hyper-CVAD with pegylated liposomal doxorubicin alternating with methotrexate and cytarabine (HCVIDD/MA) in patients with newly diagnosed T- and NK-cell lymphoma (T/NKCL). *First Author: Dai Chihara, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Prognosis of T/NKCL is poor after standard CHOP therapy. To prospectively evaluate the role of dose intensified chemotherapy, we conducted a phase II trial of HCVIDD/MA in patients with newly diagnosed T/NKCL. **Methods:** Eligible patients were adults with newly diagnosed untreated T/NKCL excluding ALK positive ALCL. Patients received HCVIDD/MA every 21 days for up to eight cycles. In this trial, pegylated liposomal doxorubicin at 25mg/m^{2}was used instead of conventional doxorubicin. **Results:** Fifty-three patients were enrolled (PTCL-NOS: 24, AITL: 7, Systemic ALK negative ALCL: 7, HSTL: 7, extranodal NKCL: 5, Others: 3). The median age of patients was 54 (range 20-72). Eighty-five percent of the patients were in advanced stage, 32% had bone marrow involvement and 43% had IPI score $>$ 2. The median cycle number of treatment given was five. Only 5 of 53 patients (9%) received seven or more cycles primarily due to prolonged cytopenias. Of 47 patients who were eligible for response evaluation, the overall response rate was 66% with complete response rate of 57%. Six patients (11%) underwent consolidative autologous stem cell transplant at treating physician's discretion. Median progression free survival (PFS) of all patients was 8.1 months. With the median follow-up time of 83 months, five-year PFS and overall survival (OS) rates were 22% and 49%, respectively. The patients with extranodal NKCL had shorter PFS (all 5 progressed $<$ 13 months) than other types. Patients with HSTL had slightly longer PFS (median 49 months) than other types. There was no significant difference in PFS or OS by treatment cycles beyond five and by consolidative ASCT. Grade3/4 anemia, neutropenia and thrombocytopenia were observed in 66%, 74% and 79%, respectively. Of note, 11 patients (21%) were taken off study due to thrombocytopenia with median of 5 cycles. **Conclusions:** HCVIDD/MA for the first line treatment of T/NKCL showed response rate and survival outcome similar to previously reported those with conventional CHOP, and was associated with higher hematologic toxicities. (clinicaltrials.gov identifier: NCT00290433) Clinical trial information: NCT00290433.

8539 Poster Session (Board #356), Sun, 8:00 AM-11:30 AM

Pre-treatment circulating tumor DNA as a biomarker for disease burden in diffuse large B cell lymphoma (DLBCL). *First Author: Florian Scherer, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Patients with DLBCL reveal striking heterogeneity in clinical outcomes. Plasma cell-free DNA (cfDNA) levels have been shown to be adversely prognostic. Both circulating tumor DNA (ctDNA) as a minor fraction of cfDNA and circulating tumor cells (CTCs) can be used for DLBCL monitoring with ctDNA reported to be superior (Kurtz et al 2014 ASCO). However, the relationship between ctDNA and CTC levels with DLBCL clinical indices remains poorly defined. **Methods:** We profiled 43 DLBCL patients treated with R-CHOP based therapy and quantified their pre-treatment cfDNA, ctDNA and CTC levels. Pre-treatment ctDNA levels were determined by high-throughput sequencing of tumor specific immunoglobulin genes (Ig-HTS) of plasma cfDNA, and CTCs were enumerated by Ig-HTS of blood leukocytes. Metabolic tumor volume (MTV) was measured from pre-treatment ^{18}FDG PET/CT scans using MetaVol. Parametric vs. non-parametric tests supported identical conclusions. **Results:** Blood cfDNA levels varied widely (2.8-1,713.5 ng/mL, median: 12.6), as did ctDNA levels (0-129,928 molecules/mL, median 87.5) and CTCs (0-454,400 CTCs/million cells, median 6.6). Total cfDNA levels and the amount of ctDNA were strongly associated ($r = 0.73$, $P < 0.0001$). Both cfDNA and ctDNA levels were significantly correlated with LDH ($r = 0.79$ and 0.74, $P < 0.0001$) and MTV ($r = 0.62$ and 0.53, $P < 0.0001$ and $P = 0.002$). CtDNA was detectable in 14 of 19 patients (74%) with normal LDH levels. Higher cfDNA and ctDNA levels were associated with adverse prognostic parameters including advanced stage ($P < 0.0001$ and $P = 0.04$), IPI 3-5 ($P < 0.0001$ and $P = 0.04$), marrow involvement ($P = 0.04$ and $P = 0.009$) and presence of B-symptoms ($P = 0.0003$ and $P = 0.0001$). CTCs levels were not associated with any of these prognostic parameters, despite showing a correlation with LDH ($r = 0.43$, $P = 0.02$). **Conclusions:** Our study demonstrates that, in contrast to CTCs, ctDNA levels better capture disease burden in DLBCL, including tumor volume and metabolic properties. The prognostic value of cfDNA levels appears directly related to ctDNA levels, and not to CTCs. Therefore, ctDNA is a specific biomarker of tumor burden in DLBCL and, compared to cfDNA, less prone to physiological perturbations.

8540 Poster Session (Board #357), Sun, 8:00 AM-11:30 AM

Bendamustine and rituximab and lenalidomide (BRR) in the treatment of relapsed and refractory low grade non-Hodgkin lymphoma (NHL): Final results of phase 1 study NCCTG N1088/ALLIANCE. *First Author: Grzegorz S. Nowakowski, Mayo Clinic, Rochester, MN*

Background: The combination of bendamustine and rituximab is effective in the treatment of low grade NHL. Lenalidomide shows significant synergy when combined with rituximab and rituximab-containing chemotherapy. The primary aim of this phase 1 study was to establish a maximum tolerated dose (MTD) of bendamustine, rituximab and lenalidomide. Secondary endpoints included toxicity, overall response and progression-free survival. **Methods:** Eligible patients (pts) had relapsed or refractory low grade NHL, treated with at least 1 prior regimen. A 3+3 phase was used. Dose levels are shown in the Table. Bendamustine was given on day 1 and 2, rituximab on day 1 and lenalidomide orally, daily, days 1-10 of 28-day cycle for up to 6 cycles. Pegfilgrastin was given on day 3 of the cycle. **Results:** 15 patients were enrolled. The median age was 58 years (47-71), 5/15 patients were female, 12/15 patients had stage 4 disease. The histological subtypes were: follicular lymphoma grade 1 and 2 (6/15 pts), marginal zone lymphoma (5/15 pts) and lymphoplasmacytic lymphoma (4/15 pts). No dose-limiting toxicity was seen. Dose escalation beyond 25 mg daily of lenalidomide was not performed, since 25 mg is considered a biologically effective dose. The most common toxicity was hematological, with 2/15 pts experiencing grade 3 neutropenia. The overall response was 100% (Table). Only 1/15 pts experienced grade 3 or more non-hematological toxicity (grade 3 urticaria). All patients remain alive with median follow up of 17 months (6-28) and only 1 pt disease progression at 12 months. **Conclusions:** Lenalidomide at 25 mg/day, days 1-10 of a 28-day cycle can be safely combined with the standard dose bendamustine rituximab regimen and is well tolerated. The encouraging response rates in a relapsed setting warrant further evaluation of this combination in larger trials. Support: U10CA180821, U10CA180882, CA025224 Clinical trial information: NCT01429025.

Dose escalation and response summary.

Dose level	Lenalidomide Days 1-10	Bendamustine Day 1-2	Rituximab Day 1	DLTs	Response
1	15 mg	70 mg/m2	375 mg/m2	0/3	3 PR
2	20 mg	70 mg/m2	375 mg/m2	0/3	1 CR, 2 PR
3	20 mg	90 mg/m2	375 mg/m2	0/3	2 CR, 1 PR
4	25 mg	90 mg/m2	375 mg/m2	0/6	3 CR, 3 PR

8541 Poster Session (Board #358), Sun, 8:00 AM-11:30 AM

Telomere profile of Reed-Sternberg and Hodgkin cells in diagnostic biopsy in Hodgkin lymphoma as a predictor of clinical response. *First Author: Jeffrey B Tompkins, Department of Laboratory Medicine and Pathology, University of Alberta, Edmonton, AB, Canada*

Background: Markers that predict poor response to primary therapy in Hodgkin's lymphoma (HL) are currently lacking. Much of the difficulty stems from the rarity of the malignant mononuclear Hodgkin's (H) cells and multinuclear Reed-Sternberg (RS) cells in the tumor. We have developed a 3D quantitative fluorescent in situ hybridization (3D qFISH) telomere profile, with telomere fluorescent intensity, number, distribution and aggregation, as markers of genomic instability. Telomere profiles differ between H and RS cells; increased genomic instability accompanies the switch from H to RS phenotype. Cases of relapsed/refractory HL have greater H cell genomic instability compared to those entering stable remission. Telomere profiles of H and RS cells at time of diagnosis may predict aggressive disease behavior, as indicated by relapse or refractoriness to therapy. **Methods:** Incident cases of classical HL from 2002-2010 were retrospectively identified from the provincial cancer registry in Manitoba, Canada. Patients with only palliative treatment or who had insufficient biopsy material for analysis were excluded. Primary outcome was treatment failure (primary refractory, relapse or death from HL). H and RS cell telomeres in the initial diagnostic biopsies were subject to 3D qFISH with telomere specific probes. Resultant images were analyzed with TeloView software. Subhazard ratios (SHR) were computed using competing risk models. **Results:** 295 patients were diagnosed with HL, of which 145 met the eligibility criteria, and 28 had treatment failure. Median follow up was 4.0 years. H cell mean telomere intensity (SHR 0.77; 95% CI 0.59-1.00; $p = 0.048$), total telomere intensity (SHR 0.90; 95% CI 0.83-0.98; $p = 0.013$) and the ratio of RS/H cell total intensity (SHR 1.94; 95% CI 1.43-3.52; $p < 0.001$), were predictive of treatment failure. RS/H cell total intensity was predictive of outcome while controlling for disease stage (SHR 1.95; 95% CI 1.24-3.05; $p = 0.004$). **Conclusions:** Genomic instability of the H and RS cells measured by telomere 3D qFISH is predictive of primary refractory or relapsing HL independent of disease stage and is a potential biomarker of disease behavior at time of diagnosis.

8542 Poster Session (Board #359), Sun, 8:00 AM-11:30 AM

Lenalidome in combination with rituximab for relapsed or refractory mantel cell lymphoma: Updated analysis of a phase 2 trial. *First Author: Yucai Wang, Rutgers New Jersey Medical School, Newark, NJ*

Background: We previously reported favorable safety and efficacy of lenalidomide plus rituximab in relapsed or refractory (R/R) mantle cell lymphoma (MCL) in a phase 1/2 trial (Wang *et al*, Lancet Oncol 2012). We performed an updated analysis of the phase 2 data after an extended follow up. We also investigated whether Ki-67 level affected response and survival in this study, as we recently reported that lower Ki-67 was associated with extremely high response rate to ibrutinib plus rituximab in R/R MCL (Wang *et al*, ASH 2014). **Methods:** Patients with R/R MCL were enrolled in this single arm phase 1/2 trial. In phase 2, lenalidomide was administered orally at 20 mg daily dose on days 1-21 of each 28-day cycle, and 375 mg/m^2 rituximab was administered intravenously weekly during the first cycle only. Treatment was continued until disease progression, stem-cell transplantation, or severe toxicity. The primary endpoint was overall response, and the secondary endpoint was survival. Analysis was by intention to treat. **Results:** 46 patients were enrolled, of which 42 were male. The median age was 66.5 (range 46-85). Median number of prior lines of therapy was 2 (range 1-4). At a median follow up of 24.7 months (range 1.2-96.1), 16 (34.8%) and 10 (21.7%) patients achieved CR and PR, respectively, with an ORR of 56.5%. An additional 10 (21.7%) patients achieved MR or SD. ORR was independent of age, gender, number of prior lines of therapy and Ki-67 at registration. Median time to response was 1.8 months (range 1.6-7.7). Median duration of response was 20.9 months (95% CI 10.9-NR). The median PFS was 14.1 months (95% CI 8.2-26.7), and median OS was 24.6 months (95% CI 16.8-33.7). The 12- and 24-month PFS rates were 53.1% and 39.9%, respectively. The 1-, 2- and 5-year OS rates were 82.6%, 52.2% and 26.1%, respectively. Lower Ki-67 at registration ($< 50\%$) and fewer prior lines of therapy (< 2) were predictive of better PFS (HR = 0.242, 95% CI 0.070-0.715, P = 0.012; and HR = 0.245, 95% CI = 0.071-0.841, P = 0.025) and OS (HR = 0.267, 95% CI 0.110-0.648, P = 0.003; and HR = 0.363, 95% CI = 0.147-0.896, P = 0.028). **Conclusions:** Lenalidomide plus rituximab is efficacious in treating R/R MCL. Lower Ki-67 is associated with better survival outcomes. Clinical trial information: NCT00294632.

8543 Poster Session (Board #360), Sun, 8:00 AM-11:30 AM

Analysis of "double-hit" lymphoma cases by genetic subtype. *First Author: Daniel Jeffrey Landsburg, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: "Double-hit" lymphoma (DHL), defined as a B cell non-Hodgkin lymphoma harboring rearrangements in *c-MYC* as well as *BCL2* and/or *BCL6*, carries a poor prognosis. Here we report characteristics and outcomes of DHL patients (pts) by genetic subtype. **Methods:** From our previously-described database of DHL pts (*Blood* 2014 124:2354-61), we identified cases which underwent cytogenetic testing for *c-MYC* as well as both *BCL2* and *BCL6* rearrangements. Cohorts were defined by the presence (+) or absence (-) of rearrangements: *c-MYC*+/*BCL2*+/*BCL6*- (BCL2-DHL), *c-MYC*+/*BCL2*-/*BCL6*+ (BCL6-DHL) and *c-MYC*+/*BCL2*+/*BCL6*+ (THL). Therapy was given at the discretion of the treating physician. **Results:** Data from 117 cases were included. Pts with BCL6-DHL were more likely to have extranodal disease as compared to BCL2-DHL ($p=0.04$) and THL ($p=0.04$) pts. Treatment received and outcomes are described in Table. Univariate analysis revealed that elevated LDH, stage ≥ 3 disease, IPI ≥ 4 and bone marrow involvement in BCL2-DHL pts and IPI ≥ 4 and bone marrow involvement in THL pts predicted for inferior overall survival (OS). **Conclusions:** Analysis of the largest reported series of BCL2-DHL, BCL6-DHL and THL pts by genetic subtype did not reveal significant differences in outcome, potentially due to small cohort sizes. Nevertheless, high rates of primary refractory disease and relapse seen across all subtypes provides a rationale for offering novel therapeutic approaches to these pts in the front-line setting.

Treatment received and outcomes.

	DHL subtype			p value		
	BCL2-DHL (n=76)	BCL6-DHL (n=16)	THL (n=25)	BCL2-DHL vs. BCL6-DHL	BCL2-DHL vs. THL	BCL6-DHL vs. THL
Receipt of DE[1]	55%	44%	65%	0.42	0.35	0.19
Complete response (CR1)	54%	75%	46%	0.17	0.49	0.10
If receiving DE[1]	55%	86%	63%	0.22	0.77	0.37
Stem cell transplant (SCT) in CR1	36%	22%	55%	0.47	0.31	0.18
Primary refractory disease	32%	13%	33%	0.14	1.0	0.25

[1]DE=dose-escalated front-line chemotherapy (EPOCH, hyperCVAD, CODOX-M/IVAC). [2]Median length of follow-up 12.0 months (range 0.1-85.6). [3]Not yet reached.

8544 Poster Session (Board #361), Sun, 8:00 AM-11:30 AM

Phase 1 trial of brentuximab vedotin in combination with gemcitabine for pediatric and young adult patients with relapsed or refractory Hodgkin lymphoma, a Children's Oncology Group report. *First Author: Peter D. Cole, The Children's Hospital at Montefiore, Bronx, NY*

Background: Salvage therapy followed by autologous stem cell transplantation improves outcomes for patients with primary refractory Hodgkin lymphoma (HL) or early relapse. Brentuximab vedotin (Bv) and gemcitabine each produce high overall response rates in this context. Compared to alternate retrieval regimens, this combination offers the advantage of avoiding agents that are associated with late treatment sequelae, such as anthracyclines, alkylators, or epipodophyllotoxins. This phase 1 trial was conducted to describe the toxicity of the combination and to define a recommended phase 2 dose (RP2D) for Bv when given with gemcitabine. **Methods**: Patients ≤ 30 years old with primary refractory HL or early relapse were eligible. Bv was given on day 1 of each 21-day cycle, at two dose levels (DL): DL1, 1.4 mg/kg and DL2, 1.8 mg/kg. Gemcitabine 1000mg/m^2 was given on day 1 and 8. Dose limiting toxicity (DLT) was assessed during cycle 1 to define the RP2D, and response after every 2 cycles. **Results**: Fifteen patients have enrolled (14 evaluable for hematologic toxicity), with median age of 17 years (range 5-28). No DLTs were seen among 3 patients treated at DL1. Two of six patients experienced non-hematologic DLT at DL2: one with grade 3 hypotension and one with asymptomatic Grade 3 elevation of liver enzymes. Both had resolution of all toxicity and continued on study treatment with dose reduction of Bv to 1.2 mg/kg. An expansion cohort of six patients was enrolled at DL2; none experienced DLT. Grade 3-4 neutropenia was common (13 of 14 patients during cycle 1) but self-limited. No grade 4 non-hematologic toxicity occurred. No cases of interstitial pneumonitis or pulmonary toxicity attributable to study therapy were observed. **Conclusions**: Bv can be safely given in combination with gemcitabine. The RP2D of Bv is 1.8 mg/kg. The ongoing Phase 2 trial will describe the complete response rate observed within four cycles of Bv with gemcitabine. Clinical trial information: NCT01780662. Clinical trial information: NCT01780662.

8545 Poster Session (Board #362), Sun, 8:00 AM-11:30 AM

Survival of subcutaneous panniculitis-like T-cell lymphoma (SPTCL) and peripheral T-cell lymphoma (PTCL): A propensity matched analysis of the Surveillance, Epidemiology and End Results (SEER) database. *First Author: Samyak Manandhar, UPMC Mercy, Pittsburgh, PA*

Background: SPTCL is a rare entity with no prior population-based study. Using the SEER database, we compared the characteristics and survival of SPTCL and PTCL. **Methods**: We used the SEER 18 database to identify adult patients with SPTCL and PTCL diagnosed between 1973 and 2011. Prior to 2008, T-cell receptor gamma/delta phenotype of SPTCL was not recognized as a separate entity, hence could not be excluded from this study. Actuarial, relative and cause specific survivals of SPTCL were computed. The actuarial survival of SPTCL was compared to a propensity matched cohort of PTCL. Kaplan Meier survival curves were plotted. Multivariate analysis was conducted using weighted Cox proportional hazard regression model. **Results:** Patients with SPTCL (n = 118), compared to PTCL (n = 3296), were more likely to be younger (median age of 47 vs. 62 years, $p < 0.01$), women (67 % vs 40%, $p < 0.01$) and diagnosed with stage I/II disease (46% vs. 36%, $p = 0.01$). The five year actuarial, relative and cause specific survival for SPTCL was 40%, 57% and 64% respectively. After propensity matching, the 5-year overall survival (OS) of SPTCL was better than that of PTCL (57% vs. 40%. $p < 0.01$). In a multivariate analysis, mortality was significantly lower among SPTCL vs. PTCL (hazard ratio, HR 0.54; 95% CI 0.39-0.75; $p < 0.01$) after adjusting for age, gender, race and stage of the disease. Among patients with SPTCL, advanced age ($p < 0.01$) and diagnosis before the year 2008 (p 0.02) were predictors of worse OS in a multivariate analysis. **Conclusions**: Our study provides characteristics and OS of a large cohort of this rare entity, which can be used for patient education and may provide background information for future research. As compared to PTCL, SPTCL patients were more likely to be younger, females and diagnosed at an early stage. Even though T-cell receptor gamma/delta phenotype, which has an unfavorable outcome, could not be excluded, the OS of SPTCL was found to be better than PTCL. Advanced age and year of diagnosis were the predictors of OS among patients with SPTCL.

8546 Poster Session (Board #363), Sun, 8:00 AM-11:30 AM

Treatment of refractory/relapse vitreoretinal lymphoma: Result of a multicenter retrospective study from the LOC network on temozolomide in monotherapy. *First Author: Sylvain Choquet, APHP-CHU Pitié-Salpêtrière, Paris, France*

Background: Vitreoretinal lymphoma (VRL) is a rare subset of non Hodgkin lymphoma. Its overall survival (OS) is from 35% to 68% at 5 years (Riemens et al Jama ophtalmol 2014) in first line, but relapse/refractory (R/R) VRL survival is usually of few months. Temozolomide (Tz) has been described effective in some cases of CNS lymphoma. **Methods:** VRL not eligible for IV chemotherapy or local treatment were proposed to be treated by Tz at 150mg/m^2/j 5 days/month. Diagnosis of VRL was made by vitrectomy with a cytological, phenotypical and molecular analysis, dosages of IL10 and IL6 were also made. Extra-ocular localizations were searched by brain RMI, lombar puncture and CT-scan or PET-scan. **Results:** 16 patients were included, mean age was 75 years [35-90]. 12 previously received systemic chemotherapy with high dose methotrexate or cytarabin, 8 were in second line, 3 in third, 2 in forth, and 1 in fith who relapsed after autologous stem-cell transplantation (ASCT). The 2 patients treated in first line where more than 80 years old. All but one had an isolated VRL, one an association with a cerebral localization. Median duration of treatment was 5 months. The median follow-up (fu) is 16 months. Overall response rate is 75%, with 10 CR (63%) and 2 PR (13%). At the last fu, 6 patients are still in CR. The median disease free survival is 12,3 months. The patient treated after ASCT relapse is still in CR at 77 months. The two old patients treated in first line are in CR at last fu. One patient with cerebral localization had a persistent ocular and cerebral CR. Three patients were treated a second time by Tz after relapse, obtaining 2 new CR, one of 4 months and one persistent at 12 months, and one new persistent PR. Median OS is not reached. Only 2 patients experienced hematological grade 3/4 toxicity. There was no treatment related deaths. **Conclusions:** This work represents the biggest study with an homogeneous treatment in R/R VRL. Temozolomide appears as a safe and efficient treatment of R/R VRL and first line VRL in patients in bad condition, even after high dose chemotherapy and/or in elderly patients. Longer follow-up, prospective and larger studies are necessary to confirm these data.

8547 Poster Session (Board #364), Sun, 8:00 AM-11:30 AM

Subgroup analysis of the phase II randomized MCL-002 (SPRINT) study of lenalidomide vs investigator's choice in relapsed/refractory mantle cell lymphoma. *First Author: Marek Trneny, Charles University Hospital, Dept. of Hematology, Prague, Czech Republic*

Background: Lenalidomide, an immunomodulator with antineoplastic and antiproliferative effects, showed clinically significant improved activity over investigator choice (IC) in relapsed/refractory (R/R) MCL. This preplanned MCL-002 analysis evaluated efficacy across patient subgroups receiving lenalidomide vs IC. **Methods**: Patients received lenalidomide (25 mg/day PO on days 1-21/28 days) or single-agent IC therapy (chlorambucil, cytarabine, fludarabine, gemcitabine, or rituximab). The primary endpoint was progression-free survival (PFS); prespecified exploratory analyses of PFS by subgroups were conducted. **Results**: 254 patients with R/R MCL (median 2 prior therapies) were randomized 2:1 to lenalidomide (n = 170) or IC (n = 84). Patients receiving lenalidomide showed a significant improvement in median PFS vs IC (8.7 vs 5.2 months; HR = 0.61, P= 0.004). Subgroup analysis of PFS by central review demonstrated statistically significant reductions in the risk of progression or death in favor of lenalidomide vs IC across most baseline demographic and disease characteristics including: age ≥ 65 years, females, any stage at diagnosis, ECOG PS 0-1, both high or low tumor burden, Ki-67 < 10%, normal/elevated LDH , WBC counts < 10x10^9/L, no bulky disease, high MIPI score, negative bone marrow, and normal renal function. The only subgroups without risk reduction were WBC ≥ 15x10^9/L and positive bone marrow (both statistically insignificant), partly explained by low patient numbers in the IC arm. Risk reduction in the remaining categories was insignificant. Overall, factors associated with significantly better PFS by univariate Cox regression analysis, beside treatment group (HR = 0.619; P= 0.004), were non-elevated LDH, WBC < 10x10^9/L, low+intermediate MIPI, low tumor burden, and Ki-67 ≤ 30%. Highly significant in the multivariate analysis were treatment group (HR = 0.384) and Ki-67 ≤ 30% (HR = 0.344). **Conclusions**: Multivariate and subgroup analyses of the primary study endpoint PFS favored lenalidomide over IC therapy in providing consistent clinical benefit in patients with R/R MCL irrespective of baseline demographics or disease characteristics. Clinical trial information: NCT00875667.

8548 Poster Session (Board #366), Sun, 8:00 AM-11:30 AM

Ublituximab plus TGR-1202 activity and safety profile in relapsed/refractory B-cell NHL and high-risk CLL. *First Author: Matthew Alexander Lunning, University of Nebraska Medical Center, Omaha, NE*

Background: Ublituximab (UTX) is a novel glycoengineered anti-CD20 mAb. TGR-1202 is a novel once daily oral PI3Kδ inhibitor. UTX + TGR-1202 has shown strong synergistic activity *in-vitro* (Lugano 2013). This phase I trial evaluates the safety and efficacy of the combination of UTX + TGR-1202 in patients (pts) with heavily pre-treated rel/ref NHL and CLL. **Methods**: A 3 + 3 design is utilized with rel/ref NHL or CLL pts accruing independently. No limits on prior therapies (Tx). Pts refractory to prior PI3K or BTK inhibitors are eligible. UTX administered D 1, 8, 15 of Cyc 1 & 2, followed by D 1 of Cyc 4, 6, 9 & 12. TGR-1202 is daily, with an improved micronized formulation introduced in later cohorts. Primary endpoints: Safety and dose limiting toxicities (DLT). Secondary endpoints: Efficacy (ORR, CR rate). **Results**: 32 pts enrolled and evaluable for safety: 12 CLL/SLL, 10 FL, 8 DLBCL, 1 MZL and 1 Richter's. Med age 64 yo (range 35-82); 20 M/12 F; Median prior Tx = 3 (range 1-9). AE's (all causality) include: Day 1 infusion reactions at 44%, neutropenia 41% (31% Gr 3/4), diarrhea 34%, (0% Gr 3/4), and nausea 28% (0% Gr 3/4). To date, TGR-1202 related hepatotoxicity has not been reported. One DLT has occurred: a pt with Gr 3 neutropenia at study entry which worsened (cohort 1). A dose-response relationship has been observed with TGR-1202. 28/32 are evaluable for efficacy with best response in the table below. To date, of all 32 pts, 89% (16/18) in the higher dose cohorts remain progression-free compared to 57% (8/14) in the lower dose cohorts. Of the 10 CLL pts, all remain progression-free at a median of 8 months (range 2 – 12+ months). **Conclusions:** The combination of UTX + TGR-1202 is well tolerated with activity in rel/ref NHL and CLL with a dose-response relationship observed. Dose escalation continues with enrollment ongoing at the highest dose cohort and in recently opened expansion cohorts. Clinical trial information: NCT02006485.

8549 Poster Session (Board #367), Sun, 8:00 AM-11:30 AM

Clinical significance of radiotherapy in the treatment of limited stage NK/T cell lymphoma. *First Author: Soo Jung Lee, Department of Oncology/Hematology, Kyungpook National University Medical Center, Kyungpook National University School of Medicine, Daegu, South Korea*

Background: For the treatment of limited-stage natural killer (NK)/T-cell lymphoma, combined treatment modality including radiotherapy (RT) is widely recommended. However, the best standard has not been clearly determined. In this study, we analyzed the role and the optimal timing of RT, and the difference of clinical outcome among patients with limited-stage NK/T-cell lymphoma. **Methods:** We retrospectively analyzed patients with limited-stage NK/T-cell lymphoma, diagnosed between January, 2004 and April, 2013 from six Korean institutes. These patients were categorized into 3 groups, i.e., 1) anthracycline or non-anthracycline-based chemotherapy followed by radiotherapy (CTx/RT), 2) concurrent chemoradiotherapy (CCRT) followed by non-anthracycline-based chemotherapy (CCRT/CTx), and 3) CTx alone group. **Results:** In total 104 patients, the median age was 52 years (range 28~85). According to therapeutic modalities, 29 (27.9%) and 44 (42.3%) patients were treated by CTx/RT and CCRT/CTx, respectively, and the remaining 31 (29.8%) patients were managed by CTx alone as initial therapy. Overall response (OR) rate was 80.8% including complete response (CR) rate 70.2% after initial therapy. Patients who had CTx/RT or CCRT/CTx achieved high CR rate (76.7%) comparing to those had CTx only group with 54.8% (p = 0.009). With median follow up of 47.6 months, the 5-year progression free survival (PFS) was 44.2% and overall survival was 75.1%. The 5-year PFS of patients with RT containing protocol and those with CTx only group were 52.1% and 25.8%, respectively (p = 0.003). Among patients treated with RT containing protocol, the 5-year PFS was superior in CTx/RT group as 60.6% than CCRT/CTx group as 48.8% (p = 0.001). All patients treated with CTx/RT could finish the planned protocol. **Conclusions:** Our results show the role of RT for treating limited stage NK/T cell lymphoma. Although CCRT showed a higher CR rate compared CTx followed by RT, the optimal timing of RT should be determined carefully considering the possibility of progression outside RT field prior to systemic chemotherapy or failure to complete planned treatment related with radiotherapy in particular in case of RT at upper aerodigestive tract.

8550 Poster Session (Board #368), Sun, 8:00 AM-11:30 AM

Breast implant-associated anaplastic large cell lymphoma: Proposal for optimal management. *First Author: Mark Warren Clemens, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Breast implant-associated anaplastic large cell lymphoma (BI-ALCL) is a newly identified lymphoma arising around breast implants placed for cosmetic or reconstructive indications. Patterns of disease progression and optimal treatment strategies have not been described. **Methods:** The literature was reviewed for all published cases of BI-ALCL from 1997 to November 2014, contacted corresponding authors to update clinical follow up, management, and combined data with institutional cases. A novel clinic-pathologic TNM staging system is proposed and was compared to traditional Ann Arbor staging to determine prognostic value for overall survival (OS) and progression free survival (PFS). A Prentice, Williams and Peterson (PWP) model was used to assess treatment effect on progression events. **Results:** We identified 128 unique cases of BI-ALCL, including 91 previously reported and 37 unreported cases.Pathologic slides were available in 56 patients for pathologic staging.Average follow up was 45 months (30-217 months). The median OS was 13 years, OS rate 93% at 3-years and 89% at 5-years. 18 progression events were noted and median PFS was 13 months, with 3-year and 5-year PFS at 79.4%. Total capsulectomy with implant removal (TCIR) prolonged OS (p = 0.022) and improved PFS (p = 0.014), and the effect of definitive surgery was statistically significant for PFS benefit (HR = 0.14, 95%, CI = 0.05-0.46, p = 0.001). After definitive surgery, patients had 4% of risk of having events by the end of the first year while the rates were 18%, 24% and 60% when patient had radiation, chemotherapy or limited surgery. The PFS was significantly different by Ann Arbor staging (p = 0.013) and by the newly proposed clinical staging (p = 0.030). **Conclusions:** Advanced stage, presence of mass, incomplete resection, and delay in definitive surgical treatment were associated with poor OS and PFS in patients with BI-ALCL. Surgical management with definitive excision and oncologic surveillance is adequate for most patients with BI-ALCL. The role for chemotherapy, targeted immunotherapy, and/or radiation for advanced disease requires further research in larger series.

8551 Poster Session (Board #369), Sun, 8:00 AM-11:30 AM

Rituximab maintenance Therapy in B-cell lymphoma: A meta-analysis. *First Author: Yucai Wang, Rutgers New Jersey Medical School, Newark, NJ*

Background: The role of rituximab (R) maintenance therapy (MT) in B-cell lymphoma is controversial. We reviewed data from clinical studies and conducted a meta-analysis to evaluate the efficacy and safety of R MT in follicular lymphoma (FL), diffuse large B-cell lymphoma (DLBCL) and mantle cell lymphoma (MCL). **Methods:** PubMed, ASCO and ASH databases were searched for eligible clinical studies to date that investigated survival outcomes (OS, PFS, EFS and/or TTP) and adverse events of R MT in FL, DLBCL and MCL. Pooled hazard ratios (HRs) for survival outcomes and risk ratios (RRs) for dichotomous data with 95% CI were calculated using Comprehensive MetaAnalysis (v2). **Results:** 22 clinical studies of 6785 patients, including 15 randomized controlled trials (RCTs) enrolling 5029 patients, were included in this meta-analysis. In RCTs, R MT significantly prolonged PFS (HR = 0.60, 95% CI = 0.52-0.68, $P < 0.001$) and OS (HR = 0.79, 95% CI = 0.69-0.93, $P = 0.005$) in B-cell lymphoma. Improvement of PFS with R MT was demonstrated in all types of lymphoma studied. R MT increased OS in FL (HR = 0.76, 95% CI = 0.61-0.94, $P = 0.010$) but not DLBCL (HR = 0.88, 95% CI = 0.64-1.21, $P = 0.425$) or MCL (HR = 0.77, 95% CI = 0.47-1.27, $P = 0.303$) in RCTs. The survival benefits remained after including non-randomized clinical studies and retrospective studies. R MT increased the risks of neutropenia (RR = 1.82, 95% CI = 1.40-2.37, $P < 0.001$) and infection (RR = 2.49, 95% CI = 1.61-3.85, $P < 0.001$) but not cardiac dysfunction (RR = 1.61, 95% CI = 0.73-3.57, $P = 0.242$). **Conclusions:** R MT significantly improved PFS in FL, DLBCL and MCL as well as OS in FL. Whether R MT improves OS in DLBCL and MCL needs further study.

Survival benefits of rituximab maintenance therapy in B-cell lymphoma.

CD30+ expression in Peripheral T-cell lymphomas (PTCLs): A subset analysis from the international, prospective T-Cell Project. *First Author: Massimo Federico, Dept of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, Italy*

Background: CD30 is a member of TNF-alpha receptor family that might have important therapeutic implications with the advent of targeted therapies. Several PTCLs subtypes have been reported in literature to be associated to variable CD30 expression. We investigated the frequency of CD30 expression among PTCLs subtypes registered in the T-Cell Project and correlated it with clinical features and outcome. **Methods:** The T-cell Project is a prospective, international study in patients (pts) with newly diagnosed aggressive PTCLs. Clinical, laboratory and disease localization data at diagnosis as well as therapy details and follow-up information are collected at a dedicated website via secure HTTP protocols. Central review of diagnostic biopsy is planned. **Results:** From Sept 2006 to Jan 2015, 1308 pts were registered in the T-Cell Project by 73 sites from 14 countries world-wide. As from the 792 pathology forms filled out by site local staff CD30 expression was tested in 490 pts (62%) and reported as CD30+ in 349 (71%) and CD30- in 141 (29%). Frequency of CD30 expression in different subtypes is shown in the Table. CD30+ pts tended to be younger (54 vs 58 yrs, P = .03) with less extranodal involvement (65% vs 78%, P = .01) than CD30-. CHOP like regimens were the most common irrespective of CD30 status (63% in both groups, P = 1.0). In the group of pts with any histology but ALCL, no difference in CR rate (44% vs 51%, P = .26), 5-yr PFS (29% vs 22%, P = .57) and OS (44% vs 29%, P = .17) was observed between CD30+ and CD30- pts. Brentuximab use in first line was noted in only 5 pts enrolled in clinical trials. **Conclusions:** Data from the T-cell project confirm that CD30 is expressed in many PTCLs other than ALCL, thus suggesting a routine assessment for all PTCLs. Again, this analysis suggests that CD30 expression has no prognostic significance. The very limited use of anti CD30 targeted therapy in this sample doesn't allow to establish the predictive value of CD30 expression in PTCLs.

8553 Poster Session (Board #371), Sun, 8:00 AM-11:30 AM

A phase I trial of lenalidomide maintenance after autologous stem cell transplant (ASCT) in patients with high-risk relapsed/refractory lymphomas. *First Author: Jakub Svoboda, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Lymphoma patients (pts) with residual hypermetabolic lesions on PET imaging after salvage chemotherapy have extremely poor outcomes and may benefit from continued therapy after ASCT. Lenalidomide (len) has been used as maintenance in other hematologic malignancies, but its toxicity and efficacy are not well known in lymphoma pts following ASCT. **Methods:** We conducted a phase I trial of len maintenance after ASCT in lymphoma pts at high risk for relapse defined by residual PET positive lesions of SUV $>$ 2.5 immediately prior to ASCT. Our primary objective was to determine the safety and dose-limiting toxicity (DLT) of len maintenance. A 3+3 de-escalation design was utilized with a starting dose of len at 10 mg on days 1 through 28 of each 28 day cycle (C). Len was initiated 28-100 days post-ASCT and planned for twenty four Cs. DLT was defined as non-hematologic toxicity $\geq$ grade (G)3 or hematologic toxicity $\geq$ G4 during the first 28 days of len. Enrollment began in 5/2012; reported data were collected through 1/2015. **Results:** Eight pts were enrolled and 6 pts are evaluable (4 diffuse large B-cell and 2 Hodgkin lymphomas). One pt withdrew consent and one progressed prior to initiation of len. Median age was 51 yrs (29-61), ECOG PS 0 (0- 1), prior therapies 3 (2-5). Median time on len was 7 Cs (2-24). Len was well tolerated and no DLT was observed at the 10 mg dose. Two pts required dose reduction to 5 mg due to treatment-related toxicities (after C7 and C3). Four pts had $\geq$ G2 non-hematologic adverse events possibly related to len including fatigue, bronchitis, and thrush. Three pts had transient $\geq$ G3 neutropenia. Two pts discontinued len (1 due to progression, 1 at investigator's discretion). No secondary malignancies or study-related deaths were observed. Four of 6 pts remain on len and are progression free; 5 of 6 pts are alive with median follow-up of 195 days. **Conclusions:** We established safety of len after ASCT in pts with relapsed/refractory lymphomas and determined that len 10 mg daily is a well-tolerated maintenance dose in this setting. Preliminary clinical outcomes observed in this cohort of high-risk lymphoma pts are encouraging and will be validated in the ongoing phase II trial. Clinical trial information: NCT01575860.

8554 Poster Session (Board #372), Sun, 8:00 AM-11:30 AM

Outcomes and prognostic factors in marginal zone lymphoma: Case comprehensive cancer center cumulative experience of 358 cases. *First Author: Adam Starr, Case Western Reserve University, Cleveland, OH*

Background: MZL are uncommon B-cell lymphomas. The outcomes and prognostic factors of MZL remain poorly defined. **Methods:** We retrospectively identified 485 cases of MZL diagnosed between 1994-2014 from 2 institutions. Diagnoses had been confirmed by expert hematopathologists. We excluded 127 cases because of limited data and overlapping features with other lymphoma subtypes. **Results:** Of the 358 patients (pts) included in the analysis, 216 (60%) had extranodal MZL (EMZL) with most EMZL arising from stomach (32%), 56 (16%) nodal MZL (NMZL), 64 (18%) splenic MZL (SMZL), and 22 (6%) had typical MZL phenotype but were unclassifiable. Median age was 66 (range 13-95) years, 171 (48%) pts had stage III/IV disease at diagnosis. B-symptoms were present in 33 (9%) pts and 65 (18%) had $>$ 4 nodal sites (LN) involved. Median time from diagnosis to treatment was 33 (2-1883) days and median duration of follow-up was 40.3 (2.2-236.4) months. Among treated pts, initial treatment was rituximab (R) (33%), chemotherapy +/- R (22%), radiation (16%), surgery (16%), and antibiotics (13%). Progression-free survival (PFS) and overall survival (OS) for the whole group was 5.15 (95% confidence intervals; C.I. = 2.8-10) and 19 (95% C.I. = 10-19) years respectively and there was no significant difference in PFS or OS between EMZL, NMZL, SMZL, or atypical MZL. On univariate analysis, age $>$ 60 (p = 0.002), elevated serum lactate dehydrogenase (LDH) (p = 0.003), involvement of $>$ 4 LN (p = 0.019), follicular lymphoma International Prognostic Index (FLIPI) score (p = 0.0005), and hemoglobin (Hb) level $<$ 12 g/dL at presentation (p = 0.003) were associated with inferior OS. In a multivariate analysis, only age (hazard ratio (HR) = 5.48, p = 0.002) and Hb (HR = 2.97, p = 0.009) retained significance. Transformation to aggressive lymphoma occurred in 29 (8%) pts and was associated with high serum LDH and higher FLIPI at diagnosis. In pts treated with R +/- chemotherapy, R maintenance was associated with improved OS (p = 0.04). **Conclusions:** In our MZL series, one of the largest reported, prognosis of MZL is good with a median OS of over 19 years. Age $>$ 60, Hb $<$ 12 g/dL, elevated LDH, and $>$ 4 LN involved are associated with inferior OS.

8555 Poster Session (Board #373), Sun, 8:00 AM-11:30 AM

Exercise patterns and quality of life among survivors of aggressive lymphoma. *First Author: Raina Mahajan Ferzoco, Mayo Clinic, Rochester, MN*

Background: Aerobic exercise has been associated with improved QOL in the general population, but has not been studied in non-Hodgkin lymphoma (NHL) survivors. **Methods:** Newly diagnosed patients with aggressive lymphoma were prospectively enrolled in the University of Iowa/Mayo Clinic SPORE Molecular Epidemiology Resource and systematically followed. Patient reported exercise patterns and QOL (FACT-G) were assessed at 3 years after diagnosis; patients with active disease or recent treatment were excluded from this analysis. QOL scores were normalized to a 0-100 scale for analysis. **Results:** From 2002-2009, 625 eligible patients completed the 3 year questionnaire.Themedian age was 62 years (range 18-87), 59% were male, and diagnoses included DLBCL (60%), FL grade III (11%), mantle cell (12%), other B-cell (7%), and T-cell (10%) lymphomas. Overall, 49% of 3-year survivors met CDC exercise recommendations defined as 30 minutes of moderate activity at least 5 days/week, which was comparable to the general population estimate (50%). Since their diagnosis of lymphoma, 10% of patients reported an increase in exercise and 49% reported a decrease in exercise. Males were more likely to meet exercise recommendations than females (54% v 41%, p = 0.002). Young patients (18-39 years) were more likely to increase physical activity after diagnosis than patients age $>$ 70 (16% vs. 4%; p = 0.002). Those meeting exercise recommendations had higher median functional well-being (WB) (89 vs.75), physical WB (93 vs. 88), emotional WB (88 vs. 83), social/family WB (89 vs. 86), and overall QOL (89 vs. 80) (all p $<$ 0.0001). Similarly, compared to those who reported decrease in exercise since diagnosis, patients with increased physical activity had higher median functional WB (89 vs. 75), physical WB (96 vs. 86), emotional WB (88 vs. 83), social/family WB (88 vs. 86) and total QOL (90 vs. 81) (all p $<$ 0.0001). **Conclusions:** In this cohort, half of aggressive lymphoma survivors are meeting recommendations for exercise, similar to the general population. Meeting exercise recommendations and increasing exercise are associated with significantly higher QOL. Lymphoma patients should be counseled on exercise, and studies of activity interventions and outcomes are needed.

8556 Poster Session (Board #374), Sun, 8:00 AM-11:30 AM

A new class of anti-cancer drugs targeting the tyrosine kinase receptor ROR1 in CLL. *First Author: Hakan Mellstedt, Karolinska Univer. Hosp. Solna, Stockholm, Sweden*

Background: RTK families are attractive therapeutic candidates. One of the families is the ROR receptors. ROR1 is of importance during embryogenesis but down-regulated in most adult human tissues.ROR1 has been shown to be expressed in CLL as well as in other hematological malignancies and solid tumors and is constitutively phosphorylated. ROR1 siRNA transfection of CLL cells induced apoptosis. We have produced and explored the activity of a new class of compounds, acting as inhibitors of phosphorylation of the tyrosine kinase domain of ROR1 (ROR1-TKI). We describe for the first time the activity of a lead ROR-TKI, KAN0439834. **Methods:** ROR1 inhibitors were derived from a high-through-put screen (HTS) using HTRF assay based on recombinant intracellular kinase domain of ROR1. A chemical lead series was optimized for activity on target, in vitro ADME and in vivo pharmacokinetic properties. **Results:** KAN0439834 induced apoptosis in vitro of fresh CLL cells from patients with non-progressive and progressive disease as well as from patients with fludarabine resistant disease with and without 17p abnormalities (EC50 for CLL cells $<$ 200 nM and for normal PBMC $>$ 14 μM). In vitro incubation resulted in dephosphorylated ROR1, Src, PIKδ, AKT, mTOR and CREB. 6 h incubation was sufficient to induce full apoptosis at 24 h. In NOD-SCID mice xenografted with human CLL cells orally bioavailable KAN0439834 induced a significant reduction of ROR1$^+$cells, dephosphorylated pROR1, downregulated Mcl-1 and upregulated cleaved PARP. PK analyses showed a blood concentration of KAN0439834 to be sufficient to induce apoptosis of CLL cells. Minimal animal toxicity could be noted. **Conclusions:** The RTK ROR1 is expressed in CLL cells and of importance for survival. Targeting ROR1 by a TKI induced a strong killing of leukemic cells in vitro. The drug dephosphorylated ROR1 as well as PI3K/AKT/mTOR. In an animal CLL model the lead ROR1 inhibitor compound significantly reduced xenotransplanted CLL cells with minimal animal toxicity. This is a first report of a novel class of candidate drugs targeting ROR1. The candidate drug will be further evaluated in preclinical in vivo efficacy and safety models before proceeding to clinical evaluation.

8557 Poster Session (Board #375), Sun, 8:00 AM-11:30 AM

BRD4 degraders produce long-lasting loss of BRD4 Ppotein and robust efficacy in Burkitt's lymphoma cells. *First Author: Kevin Coleman, Arvinas, New Haven, CT*

Background: We have created specific BRD4 degraders using PROTAC (PROteolysis TArgeting Chimera) technology. This involves creating bifunctional molecules, with one end having a ligand for BRD4 and the other end a recruiting element for the E3 ligase cereblon. These PROTACs promote the interaction of BRD4 with cereblon, resulting in its degradation via the proteasome degradation machinery. **Methods:** Treatment of NAMALWA, Ramos, CA-46 and Daudi Burkitt's lymphoma cells with BRD4 PROTACs leads to rapid loss of BRD4, with near complete loss observed within 4 hours. This effect is potent and long lasting, with the most effective molecules having DC_{50}s in the pM range, and with 1 hour treatment of cells resulting in BRD4 loss over a 3 day period. We examined the functional effects of BRD4 PROTACs in several Burkitt's lymphoma cell lines, comparing their effects to those observed with the clinical BRD4 inhibitor OTX015. **Results:** We found that treatment of cells with the BRD4 inhibitor OTX015 led to a rapid and robust hyper-accumulation of BRD4 that, together with the reversible nature of binding to BRD4, may have accounted for the observed moderate suppression of MYC expression, modest inhibition of cell proliferation and lack of cellular apoptosis. In contrast, BRD4 PROTACs maintained suppression of BRD4 protein throughout the several day experiment, maintained near complete MYC suppression and caused both pronounced suppression of proliferation and robust apoptotic responses, as measured by PARP cleavage. **Conclusions:** These data imply that degradation of BRD4 can provide a more robust therapeutic approach to MYC-driven hematological cancers.

8558 Poster Session (Board #376), Sun, 8:00 AM-11:30 AM

A phase 1 study of INCB040093, a PI3Kδ inhibitor, alone or in combination with INCB039110, a selective JAK1 inhibitor: Interim results from patients (pts) with relapsed or refractory (r/r) classical Hodgkin lymphoma (cHL). *First Author: Andres Forero-Torres, University of Alabama at Birmingham, Birmingham, AL*

Background: Efficacy of treatment options for pts with r/r cHL is limited. Evidence suggests blocking the PI3K or JAK-STAT pathways may be efficacious in cHL directly and through modulation of the tumor microenvironment. Blocking both pathways may provide synergistic efficacy. **Methods:** Adult pts with r/r B-cell malignancies were enrolled in this ongoing open-label, dose escalation study. INCB040093 was given at doses of 100–300 mg QD or BID alone or 150–300 mg QD or BID with INCB039110 400–600 mg QD. Safety, efficacy, and pharmacodynamics were evaluated. Data from the r/r cHL pts are reported herein. **Results:** A total of 17 pts with r/r cHL have been enrolled: median age = 34 yrs, 59% men, median of 5 prior regimens, 82% underwent HSCT, and all had failed brentuximab vedotin. Median exposure was 209 days (range: 22+ [ongoing] – 388). The most common nonhematologic AEs (all grades) in this cHL cohort were fatigue (41%), headache (35%), and decreased appetite (35%). One nonhematologic grade $\geq$ 3 AE occurred in $>$ 1 pt, pneumonia (12%). All grade neutropenia, thrombocytopenia, and anemia occurred in 47%, 47%, and 41%, respectively. Grade $\geq$ 3 thrombocytopenia occurred in 18%. Of 6 evaluable pts receiving INCB040093, ORR was 50% (1 CR); of 9 evaluable pts receiving INCB040093 + INCB039110, ORR was 67% (2 CRs). In this limited dataset of proximate dose cohorts, a dose response in efficacy was not evident. In the overall study population, INCB040093 100 mg BID and INCB040093 100 mg BID + INCB039110 400 mg QD were selected for expansion based on pharmacodynamics and the safety profile of higher dose levels. At the selected doses, ORR in the cHL cohort was 50% for INCB040093 and 75% (1 CR) for INCB040093 + INCB039110. **Conclusions:** INCB040093 $\pm$ INCB039110 was tolerable in this heavily pretreated population of pts with r/r cHL. Although the number of evaluable pts is limited, efficacy compares well to approved and promising investigational agents. These results warranted further investigation of INCB040093 alone and in combination with INCB039110 in pts with r/r cHL, leading to the initiation of a phase 2 study. Clinical trial information: NCT01905813.

8559 Poster Session (Board #377), Sun, 8:00 AM-11:30 AM

High throughput in vitro combination sensitivity screen in hematologic malignancies with the phosphoinositide-3 kinase (PI3K)-δ,γ inhibitor, duvelisib. *First Author: Kerrie Faia, Infinity Pharmaceuticals, Cambridge, MA*

Background: Signaling via PI3K-δ and PI3K-γ has distinct and complementary effects on the tumor cell/ tumor microenvironment in hematologic malignancies (HM). Duvelisib (IPI-145) is an orally active inhibitor of the PI3K-δ and PI3K-γ isoforms in clinical development in HM. To gain mechanistic insights into the cellular response to duvelisib and identify novel pairings for duvelisib in HM, a high-throughput in vitro combination screen was conducted. **Methods:** Duvelisib was evaluated alone and in combination with 35 compounds comprising a diverse panel of standard-of-care agents and emerging drugs in development for HM. These compounds were tested in 20 cell lines including diffuse large B-cell (DLBCL), follicular, T-cell, and mantle cell lymphomas, and multiple myeloma. Growth inhibition (GI) was measured by ATPLite (Perkin Elmer) in a 6x6 or 9x9 dose combination matrix. **Results:** Single agent activity was seen in 14 cell lines treated with duvelisib, with a median GI_{50} of 0.59 μM. A scalar measure of the strength of synergistic drug interactions (Synergy Score) was devised and filtering on scores exceeding the mean self-cross plus twice the standard deviation revealed a synergy hit rate of 19.3% across the matrix of drug combinations and cell lines. Synergy was most prominent in DLBCL and follicular lymphoma cell lines and seen with approved and emerging drugs used to treat HM, including, but not limited to, dexamethasone, inhibitors of the B-cell receptor signaling pathway, such as ibrutinib, and the BCL-2 inhibitor venetoclax (ABT-199). In select cell line GI studies and in vivo DoHH2 lymphoma murine xenograft models, the combination of selective PI3K-δ and PI3K-γ inhibitors showed enhanced effects compared to either inhibitor alone. Combination effects with select drugs and duvelisib were also seen in DoHH2 murine xenografts. **Conclusions:** These studies support enhanced activity of combined PI3K-δ and PI3K-γ inhibition in lymphoma models and identified synergistic pairings with the PI3K-δ and PI3K-γ inhibitor, duvelisib. These results provide a rationale for exploring the combination of duvelisib and other therapeutic agents in clinical studies.

8560 Poster Session (Board #378), Sun, 8:00 AM-11:30 AM

Early high-dose therapy and autologous stem-cell transplantation in angioimmunoblastic T-cell lymphoma: Outcome study using the National Cancer Data Base. *First Author: Pawan Kumar Karanam, Gundersen Health System, Lacrosse, WI*

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare aggressive non-Hodgkin lymphoma with a poor outcome. The role of high-dose therapy followed by autologous stem-cell transplantation as a consolidation strategy (early SCT) remains undefined. We studied the outcome of AITL patients who received early SCT using the National Cancer Data Base (NCDB). **Methods:** Patient level data were obtained from the NCDB Participant User File. The NCDB collects hospital cancer registry data representing 70% of newly diagnosed cancer cases in the US population. We identified AITL patients (ICD-O: 9705) diagnosed in 1998-2011 for demographics, disease and treatment characteristics. We included patients diagnosed from 1998-2006 in the overall survival (OS) analyses. Patients who received SCT as part of their first course of treatment were considered to have early SCT. **Results:** From 1998-2011, 515,026 patients were diagnosed with NHL and 3,160 (0.6%) had AITL. The median age at diagnosis was 69 years (range, 18-90+) and 52.8 % were males. The stage distribution was as follows: I (5.8 %), II (6.7%), III (35.4%), IV (34.8%), and unknown (17.3%). The median overall survival (OS) for the entire cohort was 17.7 months. Compared to those diagnosed in 1998-2000, patients diagnosed in 2001-2003 (HR: 1.09; 95% CI: 0.94-1.28) and 2004-2006 (HR: 0.99; 0.86-1.16) had similar OS. There were 201 patients (6.4%) who received early SCT. The use of early SCT steadily increased over time from 1.0% in 1998 to 9.5% in 2011 ($P < 0.001$). The unadjusted OS was superior among patients who had early SCT (median 94.8 versus 16.7 months; HR: 2.46; 1.68-3.60). On multivariable analysis, age > 70 years (HR: 1.65; 1.40-1.95), Black race (HR: 1.35; 1.10-1.67), stage III/IV (HR 1.24; 1.04-1.50) and not having early SCT (HR 1.89; 1.28-2.79) were associated with inferior OS. **Conclusions:** This is the largest series of AITL reported to date. The OS remains poor and has not improved during the study period. The use of early SCT has increased ten-fold in the past decade. Early SCT may improve long term outcome and warrants further evaluation.

8561 Poster Session (Board #379), Sun, 8:00 AM-11:30 AM

Association of hemophagocytic lymphohistiocytosis (HLH) with poor outcomes in adults with NK- and T-cell lymphoma (NKTCL). *First Author: Mithun Vinod Shah, Mayo Clinic, Rochester, MN*

Background: HLH is a rare life threatening disorder characterized by extreme activation of immune system. In adults, HLH may be secondary to malignancies, including NKTCL. There is limited knowledge about the differences in presenting features and outcomes of patients with NKTCL when associated with HLH and in those without HLH. **Methods:** All adult patients diagnosed with HLH per HLH-04 criteria seen at Mayo Clinic, Rochester were identified. Cases of NKTCL-associated HLH comprised of those with biopsy-proven NKTCL and a diagnosis of HLH within 1 month of each other. The comparison cohort comprised of adult patients with newly diagnosed NKTCL without HLH enrolled on the University of Iowa/Mayo Clinic Lymphoma SPORE prospective study. The study was approved by Mayo Clinic IRB. **Results:** We identified 20 patients with NKTCL-associated HLH; median age at diagnosis was 61 years, and 80% were male. At diagnosis, median serum ferritin was 4392 mcg/L (range, 1409-107100). In contrast to 147 NKTCL patients without HLH identified from the SPORE study, patients with NKTCL-associated HLH were more likely to be males, and have low serum albumin, high LDH, elevated creatinine, and ECOG performance status ≥ 2 at presentation. Of the 20 patients with NKTCL-associated HLH, 7 received CHOP, 4 received etoposide in addition to CHOP, and 5 received other intensive chemotherapy. Two patients received therapy according to the HLH-04 protocol, and 2 did not receive any NKTCL- or HLH-specific treatment. The median OS for NKTCL-associated HLH was 2.3 months vs. 45.1 months for NKTCL without HLH ($p < 0.0001$). After a median follow-up of 1.4 months, 14 (70%) patients with NKTCL-associated HLH had died. Death was secondary to progressive lymphoma in 12 (86%) patients. After adjusting for International Prognostic Index (IPI), the diagnosis of HLH in patients with NKTCL was independently associated with significantly shorter survival (HR = 8.5, $p < 0.0001$). **Conclusions:** Adult patients with NKTCL-associated HLH have an extremely poor outcome, even after adjusting for the IPI score. Standard therapy for NKTCL-associated HLH is ineffective and novel approaches are needed.

8562 Poster Session (Board #380), Sun, 8:00 AM-11:30 AM

Role of radiation (RT) in primary mediastinal large B-cell lymphoma (PMBCL): An analysis of the Surveillance, Epidemiology, and End Results (SEER) database. *First Author: Smith Giri, The University of Tennessee Health Science Center, Memphis, TN*

Background: In the rituximab era, patients with PMBCL demonstrate high complete remission rate and a plateau in survival curve beyond 2-3 years. The use of RT in these young patients may predispose to the risk of cardiopulmonary toxicities and secondary malignancies. **Methods:** We used SEER 18 database and histology code 9679/3 to identify adult patients with PMBCL between 1973 and 2011. FDA approved rituximab for diffuse large B cell lymphoma in 2006. Hence, using the year 2006 as a cutoff, we compared the survival differences among patients treated with and without radiotherapy. Kaplan Meier survival curves with log rank test were plotted to compare survival statistics. Chemotherapy regimen could not be ascertained. Cox proportional hazard regression model was done to adjust for other covariates including age, year of diagnosis, race, Ann Arbor stage and gender. All p-values were two-sided and level of significance was chosen at 0.05. **Results:** Of 358 PMBCL patients, 50.5% patients (n = 181) received RT. Those who received radiation were more likely to be younger than 50 years (90% vs. 81%, p = 0.01) but were similar in terms of gender, race and stage at diagnosis. The unadjusted five-year overall survival (OS) was higher for RT vs. non-RT group (84% vs. 74%, p = 0.02). When stratified by year of diagnosis, OS was higher for RT vs. non-RT group in pre-rituximab era (before 2006) but not in post-rituximab era (after 2006). In multivariate analysis, RT remained an independent predictor of improved OS in pre-rituximab era (HR 0.36; 95% CI 0.17-0.79; p = 0.01) but not in post-rituximab era (HR 0.96; 95% CI 0.45-2.05; p = 0.93) after adjusting for age, year of diagnosis, gender, race and stage at diagnosis. **Conclusions:** Our study suggests that the effect of rituximab may reduce the benefit of RT in select patients such as patients treated with R-EPOCH or those with important risk factors for breast cancer/coronary artery disease. However, select patients such as those with large masses, positive PET scan after chemotherapy or those treated with R-CHOP may still benefit from RT. Resolving these questions is an important topic for future research.

8563 Poster Session (Board #381), Sun, 8:00 AM-11:30 AM

Outcomes of anticoagulant (AC) or antiplatelet (AP) use in patients (pts) with chronic lymphocytic leukemia (CLL) or indolent non-Hodgkin's lymphoma (iNHL) in idelalisib (IDELA) trials. *First Author: Jacqueline Claudia Barrientos, Hofstra North Shore - LIJ School of Medicine, New Hyde Park, NY*

Background: IDELA, a selective oral PI3Kδ inhibitor, is approved for use in relapsed CLL (in combination with rituximab [R]) and iNHL (as monotherapy). Both diseases occur mainly in the elderly, who have comorbidities that increase thrombotic risk. This post hoc analysis characterized the use and outcomes of AC/AP therapy, which was allowed in IDELA registrational clinical trials. **Methods:** In the phase 3 Study 312-116 (NCT01539512), frail pts with relapsed CLL (including those with any degree of thrombocytopenia) were randomized to receive a combination of continuous IDELA 150 mg BID or placebo (PBO) with 8 R doses. In the phase 2 Study 101-09 (NCT01282424), pts with refractory iNHL received IDELA 150 mg BID until disease progression or unacceptable toxicity. Grade 1, 2, and ≥3 bleeding events were analyzed using MedDRA preferred terms and CTCAE. **Results:** The 2 trials included 343 pts. In the CLL study, 18 pts (16%) on IDELA + R and 31 (29%) on PBO + R had grade ≥3 thrombocytopenia at baseline. Concomitant AC/AP use was frequent (45% in each study); the most common were aspirin, enoxaparin, and warfarin. AC/AP use was more frequent in pts treated with IDELA + R vs PBO + R. The incidence of bleeding events was similar with IDELA, IDELA + R, and PBO + R. Grade ≥3 bleeding events occurred in 1 IDELA + R, 1 PBO + R, and 3 IDELA pts. **Conclusions:** AC/AP use involved 45% of the IDELA registrational trial population. Overall, rates of bleeding events were moderate and similar with IDELA + R vs IDELA + PBO; grade ≥3 events were uncommon. There was no specific trend with regard to AC/AP and bleeding events in the 2 arms of the CLL study. Clinical trial information: NCT01282424 and NCT01539512.

	CLL		iNHL
n (%)	IDELA + R n=110	PBO + R n=108	IDELA Monotherapy n=125

8564 Poster Session (Board #382), Sun, 8:00 AM-11:30 AM

The outcome of ALK positive and ALK negative anaplastic large cell lymphoma (ALCL) following DA-EPOCH. *First Author: Catherine Lai, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Systemic anaplastic large cell lymphoma (ALCL) is a clinically and molecularly heterogeneous type of peripheral T-cell lymphoma (PTCL). It may be sub-divided into cases with or without translocation of the anaplastic lymphoma kinase gene (*ALK*), leading to overexpression of ALK. While the outcome for patients with ALK positive ALCL - particularly in pediatric patients - has been very favorable following doxorubicin-based therapy, ALK negative cases have fared more poorly. Approaches such as autologous transplantation have been studied in this group in an attempt to improve outcome (d'Amore et al. J Clin Oncol. 2012). **Methods:** 23 patients with newly diagnosed ALK positive (15) and ALK negative (8) ALCL underwent treatment with 6 to 8 cycles of dose-adjusted infusional etoposide, vincristine and doxorubicin with prednisone and cyclophosphamide (DA-EPOCH). Both groups had similar IPI characteristics (shown below). **Results:** 19/23 (83%) patients achieved CR or CRu; 3/23 (13%) a PR and 1 patients had PD. At the median potential follow-up time of 13 years, event free survival (EFS) in ALK positive and ALK negative ALCL was 72% and 62.5% ($p = 0.50$) and overall survival was 76% and 87.5% ($p = 0.82$), respectively. Toxicity was assessed on all 135 cycles. Neutropenic fever and thrombocytopenia $< 25{,}000/mm^3$ occurred on 10% of cycles, respectively. Absolute neutrophil count (ANC) less than 500 cells/mm^3 occurred on 35% of cycles. **Conclusions:** Following DA-EPOCH, the outcome of ALK negative ALCL is equivalent to ALK positive ALCL. The incorporation of etoposide, infusional scheduling and dose adjustment may play important roles in ALCL therapeutics. DA-EPOCH should be considered a reasonable front-line regimen in ALCL and especially in older patients where approaches such as transplantation may not be feasible. Clinical trial information: NCT00001337.

Characteristics	All Patients (N = 23)	ALK + ALCL (N = 15)	ALK – ALCL (N = 8)
Median age (range)	38 (19-68)	36 (19-68)	43 (27-60)
Male sex	16 (70%)	9 (60%)	7 (87%)
Stage III or IV	17 (74%)	12 (80%)	5 (62%)
Elevated LDH	12 (52%)	8 (53%)	4 (50%)
Extranodal sites	12 (52%)	8 (53%)	4 (50%)
Bone/Bone marrow	5 (22%)	3 (20%)	2 (25%)
Lung	5 (22%)	3 (20%)	2 (25%)
Bowel	3 (13%)	2 (13%)	1 (12%)
IPI ≥ 2	14 (61%)	10 (67%)	4 (50%)

8565 Poster Session (Board #383), Sun, 8:00 AM-11:30 AM

Phase II study of rituximab plus high-dose ara-C (HDAC)-containing chemotherapy (CTX) followed by ASCT in untreated mantle cell lymphoma (MCL): Japan Clinical Oncology Group study (JCOG0406). *First Author: Michinori Ogura, National Hospital Organization Suzuka National Hospital, Suzuka, Japan*

Background: Although HDAC-containing CTX with rituximab (R) followed by high-dose CTX (HDC) with autologous stem cell transplantation (ASCT) has been recommended in younger untreated MCL patients (pts), no standard regimen has been established. **Methods:** Eligibility criteria included untreated MCL; stage II bulky, III or IV; and aged 20 to 65. In R-High-CHOP, doses of CPA and DXR were 1,500 and 75 mg/m^2, respectively. Pts received 1 cycle of R-High–CHOP followed by 3 cycles of CHASER {CPA 1,200 mg/m^2 on day (d)3, Ara-C 2 g/m^2 on d4-5, ETP 100 mg/m^2 on d3-5, R on d1 and d15} every 3 weeks. Peripheral blood stem cells (PBSCs) with $> = 2 \times 10^6$ cells/kg were harvested during CHASER. ASCT was performed to pts in CR or PR after R-High-CHOP/CHASER. HDC of LEED consisted of L-PAM 130 mg/m^2 on d1, CPA 60 mg/kg on d-4 to d-3, ETP 500 mg/m^2on d-4 to d-2. The primary endpoint was 2 yr-PFS. The planned sample size was 45 pts, which provided at least 90% power with the expected 2 yr-PFS of 50%, threshold of 30%, and a one-sided α of 10%. **Results:** From June 2008 to June 2012, 45 pts with a median age of 59 (38-65) yrs were enrolled. The numbers of pts with low-, intermediate- and high-risk group by the simplified MCL International Prognostic Index (MIPI) was 28, 15 and 2. 40 and 35 pts completed induction CTX and HDC. A median number of harvested PBSCs was 3.8 (0.4 to 38.4) x 10^6/kg in treated 43 pts. Among 36 pts with successfully harvested PBSCs, 35 pts completed HDC. At a median follow-up period of 46 (1-71) months among censored pts, 2-yr PFS was 77% (95% CI; 62-87), which met the primary endpoint. 5-yr PFS was 52% (95% CI; 34-68) and 5-yr OS was 71% (95% CI; 51-84). Overall response rate and %CR after induction CTX were 96% and 82%. Most common G4 toxicities were hematologic: %G4 neutropenia and thrombocytopenia were 80% and 0% in R-High-CHOP, 91% and 89% in CHASER, and 94% and 77% in LEED. 4 pts developed secondary malignancies; AML, prostate cancer, DLBCL, and ATL. **Conclusions:** In younger pts with untreated MCL, R-High-CHOP/CHASER/LEED with ASCT demonstrated high efficacy with durable PFS and OS and acceptable toxicity profiles, and is considered to be a standard treatment option. Clinical trial information: 000001220.

8566 Poster Session (Board #384), Sun, 8:00 AM-11:30 AM

Outcome comparison of allogeneic vs. autologous stem cell transplantation in transformed low grade lymphoid malignancies: A meta-analysis of comparative studies. *First Author: Seongseok Yun, University of Arizona, Tucson, AZ*

Background: Low grade lymphoid malignancy is incurable disease with a chronic relapsing disease course, requiring recurrent therapeutic interventions. Stem cell transplantation (SCT) has become the cornerstone in the cure of this disease. While both allogeneic and autologous SCTs have been shown to improve survival compared to conventional chemotherapy, allogeneic SCT is associated with higher treatment related mortality (TRM) and autologous SCT with higher post-transplantation relapse. We report a meta-analysis of the clinical outcomes of allogeneic vs. autologous SCT in patients with transformed low grade lymphoid malignancies. **Methods:** We searched PubMed, MEDLINE, EMBASE and Cochrane databases for comparative studies of allogeneic vs. autologous SCT in adult patients with low grade lymphoid malignancies including follicular lymphoma (FL), chronic lymphocytic lymphoma (CLL), small lymphocytic lymphoma (SLL) and marginal zone lymphoma (MZL). Relative risks (RR) and 95% CI were calculated using random effects models. **Results:** Four comparative studies were retained for the meta-analysis, and a total of 526 patients were included in the analysis. Of these, 124 underwent allogeneic SCT and 402 autologous SCT. Overall survival (OS) was 50.0% vs. 66.4% (RR 1.47, 95% CI 1.17-1.84, p= 0.001), relapse rate 37.3% vs. 35.3% (RR 1.04, 95% CI 0.70-1.55, p= 0.84), and TRM 31.5% vs. 6.7% (RR 4.53, 95% CI 2.89-7.09, $p<$ 0.00001) for allogeneic and autologous SCT, respectively. Previous rituximab treatment or a reduced intensity conditioning regimen prior to SCT did not have independent prognostic impact. **Conclusions:** Autologous SCT may be the better therapeutic option in patients with transformed low grade lymphoid malignancies regardless of previous rituximab treatment or prior SCT conditioning regimens.

Is rituximab sub-optimally dosed in indolent B cell lymphoma? *First Author: Yazeed Sawalha, Cleveland Clinic, Cleveland, OH*

Background: Rituximab (R) pharmacokinetics (PK) are affected by gender, age and weight (Wt) and can affect outcomes in aggressive B cell lymphoma (Pfreundschuh JCO 2014). Less is known about PK of R in indolent B cell lymphoma (iNHL). **Methods:** We analyzed effects of gender, age, Wt, BSA and BMI on outcomes for 303 consecutive patients (pts) at the Cleveland Clinic treated with 1st line R-based regimens for iNHL from 1997-2014. We divided pts into 3 treatment cohorts: R only (N = 119), R + Chemotherapy (CTX) (N = 120) and R-CTX followed by R maintenance (Rm) (N = 64); and by follicular (FL) (N = 184) or non-FL (N = 119) histology. Event-free survival (EFS) was based on date of relapse, progression, transformation, loss of follow-up, initiation of 2nd therapy or death. Characteristics among the 3 cohorts were compared using ANOVA, Chi-square and Fisher's exact tests. Time to event data was summarized using proportional hazards models. Recursive partitioning survival trees were used to find the cut points for continuous variables. **Results:** Characteristics for the entire group were (mean ± SD): age 62 ± 12 yrs, Wt 83 ± 20 kg, BSA 2.0 ± 0.3 m^2, BMI 24.3 ± 5.2, and 49% were male. There were no significant differences in baseline characteristics among the 3 cohorts. An event has occurred in 52%. Cut points determined were Wt ≥ 81.8 kg, BSA ≥ 2m^2 and age ≥ 70. For all pts combined, higher Wt was significantly associated with inferior EFS (HR = 1.75, p = .007) with or without adjustment for gender and age. Univariable analysis by cohort revealed outcome differences only in the R-CTX cohort, with higher Wt associated with lower EFS (HR = 2, p = .008). For FL within the R-CTX cohort, Wt (HR 2.54, p = .003) and BSA (HR 2.02, p = .024) were associated with worse EFS. Elderly females in this group had better EFS (HR = 0.32) though this did not reach statistical significance (p = .098). **Conclusions:** Our results concur with DLBCL studies in which higher Wt was associated with faster R clearance and worse outcomes for R-CTX. As this is not observed in pts after R alone or R-CTX followed by Rm, we hypothesize that higher levels of weekly R and/or prolonged R exposure exceed therapeutic threshold despite more rapid clearance. Pts with iNHL, and FL specifically, treated with R-CTX may be sub-optimally dosed with R.

8568 Poster Session (Board #386), Sun, 8:00 AM-11:30 AM

Relationship of distinct B-cell receptor (BCR) isotype in diffuse large b-cell lymphoma (DLBCL) with ABC and GCB genetic signatures and association with signaling molecules of clinical significance. *First Author: Abid Qureshi, University of Calgary, Calgary, AB, Canada*

Background: DLBCL is a heterogeneous disease. Gene expression profile (GEP) based distinction into ABC and GCB sub-types, provides basis for risk stratification in DLBCL patients. GEP is an intricate platform, which is not routinely available in clinical laboratories. Hence, surrogate markers for distinction between ABC vs GCB subtypes of DLBCL are needed. **Methods:** We used Nanostring nCounter system for gene expression analysis, utilizing RNA from diagnostic biopsy tissues. We correlated, flow-cytometry based BCR-isotype (IgM/IgG) expression with mRNA levels in a series of ABC/GCB related genes (n = 54). We also investigated gene set (n = 48) related to TLR, NF-kB and JAK/STAT pathways to determine, if BCR- isotype expression has distinct influence on specific cell signaling pathways. Median expression for each gene was compared across two BCR isotype groups utilizing fisher's exact test. **Results:** Our cohort (n = 44) comprised of IgG^+ (n = 13; 30%) and IgM^+ (n = 31; 70%) DLBCL patients. BCR-isotype expression showed significant association with specific molecular signature related to cell of origin. IgG expression was linked with GCB genetic profile and IgM expression allied with ABC related genes ($P<$ 0.001), thus confirming a previous single report (*Leukemia. 2011 Apr; 25 (4):681-8*). IgM expression related well with higher median expression of BLNK, LYN, BCL10, CARD 11 ($P<$ 0.001); while SYK/BTK expression showed no significant differences ($P<$ 0.091). In NF-kB pathway, expression levels of p100, p52, IKKα were significantly higher in IgM^+ DLBCL, compared to IgG^+ DLBCL patients ($P<$ 0.001); thus suggesting higher NF-kB activity. Genes related to TLR and PI3K/AKT pathway showed no significant differences between two BCR-isotype groups ($P=$ 0.182). In relation to JAK/ERK/STAT signaling pathway, IgM^+ DLBCL showed significantly higher expression of STAT3/JAK2 genes ($P<$ 0.001). **Conclusions:** Our data stipulates some preliminary observations that BCR-isotype is distinct between ABC and GCB subtypes of DLBCL. We have also shown linkage of BCR-isotype with some critical pathways related to disease biology in DLBCL.

8569 Poster Session (Board #387), Sun, 8:00 AM-11:30 AM

Overall survival in patients with Hodgkin lymphoma: Disparities by insurance status. *First Author: Rahul Parikh, Mount Sinai Beth Israel; Mount Sinai Health System, New York, NY*

Background: The association between insurance status and outcome has not been well established for patients with Hodgkin Lymphoma (HL). The purpose of this study was to examine the disparities in overall survival (OS) by insurance status in a large cohort of patients with HL. **Methods:** We used a prospectively collected nationwide database-the National Cancer DataBase (NCDB) to evaluate clinical features and survival outcomes among patients diagnosed with stage I-IV HL from 1998 to 2011. The association between insurance status, co-variables, and outcome was assessed in a multivariate Cox proportional hazards model. Survival was estimated using the Kaplan-Meier method. **Results:** Among the 76,672 patients with HD within the NCDB, a total of 45,777 patients with stage I-IV disease were eligible for this study, with a median follow-up of 6.0 years. The median age was 39 years (range: 18-90). The insurance status was as follows: 3,247(7.1%) uninsured; 7,962 (17.4%) Medicaid; 30,334 (66.3%) private insurance; 3,746 (8.2%) managed care; 488 (1.0%) Medicare. Patients with unfavorable insurance status (uninsured or Medicaid-insured) were found to be older ($>$ 50), more advanced stage at diagnosis, with higher co-morbidity score, more commonly with "B" symptoms, and lower income and education quartiles (all $p < 0.01$). These patients were also less likely to receive radiotherapy, start chemotherapy promptly ($<$ 30 days from diagnosis), and less commonly treated at academic/research centers (all $p < 0.01$). Patients with unfavorable insurance had a 10-year OS of 37% vs. 80% for those with favorable insurance ($p < 0.01$). When adjusting for all co-variates, unfavorable insurance status was associated with a significantly decreased OS (HR = 3.32; 95% CI, 3.02-3.64, $p <$ 0.01). Unfavorable insurance status steadily increased from 22.8% to 28.8% between 1998 and 2011. **Conclusions:** Our study reveals that HL patients with Medicaid or uninsured status have inferior outcomes than patients with more favorable insurance. To our knowledge, this study represents the largest dataset examining the role of insurance status on survival for patients with HL. Targeting this subset of patients with limited access to care may help improve outcomes.

8570 Poster Session (Board #388), Sun, 8:00 AM-11:30 AM

Distinct early response dynamics of circulating tumor DNA and circulating tumor cells during therapy of B-cell NHL. *First Author: David Matthew Kurtz, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Both circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA) have been used for disease monitoring in non-Hodgkin lymphoma (NHL) (Armand BJH 2013; Kurtz ASCO 2014; Roschewski ASH 2014). However, it remains unclear how these compartments compare during induction of active therapy in NHL. Using immunoglobulin high-throughput sequencing (Ig-HTS), we compared the dynamics of ctDNA and CTCs in response to systemic therapy. **Methods:** We performed 206 Ig-HTS assays from 104 serial blood samples in diverse patients with NHL receiving their first cycle of systemic therapy at Stanford University. Tumor samples were used to define tumor specific DNA sequences by Ig-HTS. Identified sequences were used to track ctDNA and CTCs. **Results:** A total of 17 patients with NHL were enrolled (DLBCL = 10, FL = 3, transformed FL = 4). All patients received Rituximab-containing regimens. In patients with high-grade disease, CTCs and ctDNA decreased by a mean of 94% (61%-100%) and 95% (68%-100%) after 1 cycle of therapy respectively. CTCs and ctDNA became undetectable in 7/10 and 5/11 patients by cycle 2. However, a dramatic increase or 'spike' was seen in ctDNA levels within hours of Rituximab (median increase 8.0x, range 0.3x to 264x). In contrast, a dramatic decrease was seen in CTCs (median decrease 72%, range -23% to 93%), indicating their rapid clearance. This ctDNA spike was observed in 6/6 FL/tFL patients, but only 1/5 DLBCL patients ($p =$ 0.02). The size of the ctDNA spike was significantly associated with the burden of pretreatment CTCs ($p < 0.001$) and the magnitude of decrease in CTCs ($p < 0.001$), but was not associated with the pretreatment ctDNA level ($p = 0.88$). Four of eight patients achieving CR and 2/3 patients not achieving CR had a spike in ctDNA ($p = 1.0$). **Conclusions:** While ctDNA and CTCs can be used to monitor NHLs, their dynamics in response to therapy are distinct. Although both clear during therapy, a rapid increase in ctDNA is seen in response to Rituximab, indicating cell death of CTCs. This ctDNA spike is associated with therapeutic effect on CTCs, but not with outcome in this small cohort. Circulating tumor DNA is a potentially useful method to measure cell death in NHL and other malignancies.

8571 Poster Session (Board #389), Sun, 8:00 AM-11:30 AM

Effect of prednisone and rituximab prephase on early toxicity in older DLBCL patients (pts) receiving RCHOP within a NHL specific comprehensive geriatric assessment (CGA) trial. *First Author: Colette Ngozi Owens, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Older pts with DLBCL are increasing in the US and are most vulnerable to treatment related toxicities and mortality (TRM). Effective tools to predict and mitigate toxicity are essential in these pts. The RICOVER-60 trial implemented a "pre-phase" of vincristine and prednisone (Pred) to reduce disease symptoms and improve KPS, reporting decreased early TRM. This prospective pilot study in older DLBCL pts employs a pre-phase of Pred and rituximab (R) as part of a larger CGA validation study in NHL (n = 200; NCT01829958). **Methods:** Eligible pts (n = 30) had de novo DLBCL/tDLBCL, age $\geq$ 70 yrs or $\geq$ 60 yrs with KPS $<$ 80%, and planned RCHOP-like therapy for 2+ cycles. CGA consisted of CARG and CRASH scores as largely self administered assessments. CGA was assessed at baseline, post pre-phase, with each cycle, and at end-of-therapy. Pre-phase included Pred 50-100mg x 5-10 days and R 375mg/m2 x1 day completed in the 14 days pre-RCHOP. The study is powered to show a 15% change in CGA risk score, with secondary endpoints of toxicity, TRM, PFS/OS. **Results:** Of 30 pts: median age 75 (range 65-85), female 59%, DLBCL 87%, Stage III/IV 60%, aaIPI high-int/high 57%, cell of origin GC/non-GC 55%/45%, median ki67 70% (range 60-90%). 97 % completed pre-phase and 2+ cycles of chemotherapy. Median followup is 6m (range 1-18m) with 28/30 pts alive. **Impact of pre-phase:** KPS median increased from 70% to 80% ($p = .057$)post pre-phase; Timed up-and-go was not significantly changed ($p = .484$), but 4/7 normalized post-pre-phase; Pre-phase therapy (n = 29) improved CGA risk scores compared to baseline ($p = .024$). CGA predicted risk of G3+ toxicity was 65%(range 32-89%). Toxicity risk score reduced in 31% (9/29) pts, mean 16% risk reduction for G3+ toxicity. Focusing on early toxicity (C1-C3), actual non-heme grade 3+ events were 41% and heme G4+ events 16%. Hospitalization occurred in 37%. There was no reported TLS or early TRM (n = 30). 1 pt pursued hospice after pre-phase. **Conclusions:** A pre-phase intervention of Pred and R may mitigate early toxicity, resulting in improved KPS and CGA risk score, with no TLS or early TRM in this pilot. Clinical trial information: NCT01829958.

8572 Poster Session (Board #390), Sun, 8:00 AM-11:30 AM

Prognostic value of interim 18F-FDG PET/CT in patients with diffuse large B-cell lymphoma treatment with R-CHOP: SUVmax reduction-based assessment at two cycles of chemotherapy. *First Author: Xu Zhang, Sun Yat-Sen University Cancer Center, Guagnzhou, China*

Background: The prognostic value of interim positron emission tomography/computer tomography (PET/CT) interpreted according to visual criteria is a matter of debate in diffuse large B-cell lymphoma (DLBCL). The purpose of this study was to investigate whether maximal standardized uptake value reduction (△SUVmax) may help to improve the prognostic value of PET/CT, compared with Deauville criteria, after 2 cycles of rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP). **Methods:** To compare the prognostic value of both methods, we analyzed PET/CT done at baseline and after 2 cycles of R-CHOP in 306 DLBCL patients enrolled on this retrospective study. All images were reviewed and interpreted visually according to the Deauville criteria (as negative or positive), and by computing △SUVmax for positive patients. Optimal cutoff to predict progression was 58%. Survival curves were estimated using Kaplan–Meier analysis and compared using the log-rank test. **Results:** By the Deauville criteria, the rate of 2-yearprogression-free survival (PFS) for patients with negative and positive PET/CT was 79.1% and 30.9%, respectively ($p < 0.001$). For positive patients according to Deauville criteria, △SUVmax analysis ($> 58\%$ vs $\leq 58\%$) identified patients with significantly different outcomes (2-year PFS:64.5% vs 15.9%, $p < 0.001$;2-year OS: 83.4% vs. 45.1%, $p < 0.001$). Seventy patients considered as positive by the Deauville criteria could have been reclassified as good responders. **Conclusions:** △SUVmax analysis of interim PET/CT is feasible for DLBCL during first-line chemotherapy and better predicts outcome than Deauville criteria.

8573 Poster Session (Board #391), Sun, 8:00 AM-11:30 AM

A randomized phase II study of bortezomib (Btz)/dexamethasone (dex) with or without elotuzumab (Elo) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). *First Author: Andrzej J. Jakubowiak, University of Chicago Medical Center, Chicago, IL*

Background: Elo, a monoclonal antibody (mAb) targeting Signaling Lymphocytic Activation Molecule F7 (SLAMF7), kills myeloma cells with minimal effects on normal tissue. Elo showed enhanced activity when combined with Btz in a preclinical myeloma model, (van Rhee F, et al. *Mol Cancer Ther* 2009;8:2616–24) and encouraging clinical activity in a Ph 1 study (Jakubowiak A, et al. J Clin Oncol 2012;30:1960–65). This Ph 2 open-label study (NCT01478048, CA204-009) investigated the efficacy and safety of Elo + Btz/dex (Bd) in pts with RRMM. **Methods:** Pts with RRMM, 1–3 prior therapies, were given Elo + Bd (EBd) or Bd in 21-d (Cycles 1–8) or 28-d cycles (9+) to disease progression/unacceptable toxicity. Elo (10 mg/kg IV): wkly Cycles 1–2, D1+11 Cycles 3–8, then D1+15; Btz (1.3 mg/m^2 IV/SC): D1, 4, 8+11 Cycles 1–8, then D1, 8+15; dex 20 mg non-Elo days, 28 mg PO + 8 mg IV Elo days. Primary endpoint: PFS (ITT population). A 2-sided 0.30 significance level was specified (80% power, 103 events) to detect a hazard ratio (HR) of 0.69. **Results:** 152 pts were randomized; 77 EBd, 75 Bd. At data cut-off (12 Sep 2014), 18% (EBd) vs 10% (Bd) of pts remained on therapy. Discontinuation was mainly for disease progression (52%). Median PFS was 9.7 mo (EBd) vs 6.9 mo (Bd) (HR 0.71; 70% CI 0.58, 0.87; $p = 0.08$). PFS HR, adjusting for prognostic factors, was 0.58 (70% CI 0.47, 0.72; $p = 0.01$). ORR was 66% (EBd) vs 63% (Bd). Early overall survival (OS) results revealed a HR of 0.61 (70% CI 0.43, 0.85); 40 deaths (17 EBd, 23 Bd) were observed, mainly from disease. Common ≥ G3 adverse events (EBd, Bd): thrombocytopenia 7 (9%), 13 (17%); infections 14 (19%), 11 (15%). Infusion reactions (IRs; all grade 1–2, none at max 5 mL/min rate) occurred in 7% of pts with EBd. **Conclusions:** This study met the primary endpoint. PFS was longer with EBd than with Bd (HR 0.71). More pts continue on EBd vs Bd and early OS data favor EBd vs Bd. A low rate of IRs was seen with EBd. In patients with RRMM, Elo, an immunotherapeutic mAb, provides clinical benefit with limited added toxicity when combined with Bd vs Bd alone. Clinical trial information: NCT01478048.

8574 Poster Session (Board #392), Sun, 8:00 AM-11:30 AM

A phase I/IIa study of the human anti-CD38 antibody MOR202 (MOR03087) in relapsed or refractory multiple myeloma (rrMM). *First Author: Marc S. Raab, University Hospital Heidelberg, Heidelberg, Germany*

Background: MOR202 is a HuCAL-derived fully human IgG1 anti-CD38 antibody, with high efficacy in preclinical models of MM. **Methods:** This is an open-label, dose-escalation study (3 + 3 design) to evaluate the safety and preliminary efficacy of MOR202 in adult patients (pts) with rrMM. We present the data of pts previously treated with ≥ 2 prior therapies including an immunomodulatory drug and a proteasome inhibitor. Pts received 2-hour IV MOR202 every 2 weeks (q2w) (8 dose levels [DLs] from 0.01–16 mg/kg) without dexamethasone (DEX), or 4 or 8 mg/kg (DLs 6 and 7), weekly (q1w) +/- DEX. MOR202 16 mg/kg (DL 8) q1w +/- DEX and combination cohorts with lenalidomide (LEN)/pomalidomide (POM) + DEX are planned, as well as confirmation cohorts. **Results:** As of December 31st 2014, 38 pts had been treated; 29 and 9 pts in the q2w and q1w DLs, respectively. Median age was 70 (44–80) yrs. The median number of prior treatment lines was 4 (2–10) for all pts. 36 pts (94.7%) developed AEs. The most frequently reported AEs (> 10%) of any grade were anemia (31.6%), fatigue (28.9%), WBC decreased (21.1%), lymphocyte count decreased (LCD) (21.1%), diarrhea (21.1%), nasopharyngitis (18.4%) and leukopenia (13.2%). Grade ≥ 3 hematologic AEs were LCD (15.8%), WBC decreased (7.9%), leukopenia (5.3%), thrombocytopenia (2.6%) and lymphopenia (2.6%). Infusion-related reactions occurred in 13 pts (34%) receiving MOR202 without DEX, mainly during the first infusion. All were grade 1-2 except for 1 pt grade 3. There have been no treatment-related deaths. PK data demonstrate a significant target-mediated drug disposition effect for most pts treated q2w. In 4/6 pts in the q1w 4 mg/kg cohort MOR202 trough levels show the start of target saturation. Only 1 pt (MOR202 0.15 mg/kg q2w) generated a transient anti-drug antibody response to MOR202. **Conclusions:** The MTD has not been reached. MOR202 is safe and well tolerated. PK data show the potential for full target occupancy in the majority of pts receiving 8 and 16 mg/kg q1w. These latter DLs of MOR202 will be tested as monotherapy or in combination with DEX, LEN + DEX and POM + DEX in the upcoming cohorts. Efficacy analyses are ongoing. Clinical trial information: NCT01421186.

8575 Poster Session (Board #393), Sun, 8:00 AM-11:30 AM

Analysis of outcomes based on response for patients with relapsed or relapsed and refractory multiple myeloma in the phase 3 PANORAMA 1 study. *First Author: Vania T.M. Hungria, Irmandade da Santa Casa de Misericordia de São Paulo, São Paulo, Brazil*

Background: Panobinostat (PAN) is the first pan-deacetylase inhibitor (pan-DACi) to demonstrate a statistically significant and clinically relevant increase in median progression-free survival (PFS) in patients (pts) with relapsed or relapsed and refractory multiple myeloma (MM) in a phase 3 clinical trial. In the PANORAMA 1 trial, pts randomized to receive PAN + bortezomib (BTZ) and dexamethasone (Dex; PAN-BTZ-Dex) demonstrated a median PFS of 12.0 months vs 8.1 months for pts who received placebo + BTZ and Dex (Pbo-BTZ-Dex; HR, 0.63; $P < .0001$). Here, we present a detailed analysis of the effect of response on clinical outcomes. **Methods:** Response outcomes, including rate of near complete/complete response (nCR/CR) and duration of response (DOR), were analyzed. A landmarkanalysis at 6, 12, 18, and 24 weeks using a Cox regression model was conducted to determine PFS in pts who achieved nCR/CR or partial response (PR) per mEBMT and IMWG criteria. **Results:** The nCR/CR rate was significantly higher with PAN-BTZ-Dex vs Pbo-BTZ-Dex (27.6% vs 15.7%; $P = .00006$ post hoc testing).The DOR for pts with nCR/CR and PR was 18.4 and 9.0 months, respectively, in the PAN-BTZ-Dex arm and 14.5 and 8.8 months, respectively, in the Pbo-BTZ-Dex arm. The landmark analysis by mEBMT criteria at 12 weeks demonstrated a median PFS of 16.5 months for pts with CR/nCR and 10.3 months for pts with PR in the PAN-BTZ-Dex arm (HR, 0.40; 95%CI, 0.25-0.65) and a median PFS of 14.1 months for pts with CR/nCR and 9.7 months for pts with PR in the Pbo-BTZ-Dex arm (HR, 0.62; 95%CI, 0.36-1.07). By IMWG criteria, the landmark analysis at 12 weeks demonstrated a median PFS of 15.9 months for pts with ≥ very good PR (VGPR) and 8.1 months for pts with PR in the PAN-BTZ-Dex arm (HR, 0.36; 95%CI, 0.21-0.62) and a median PFS of 14.4 months for pts with ≥ VGPR and 7.6 months for pts with PR in the Pbo-BTZ-Dex arm (HR, 0.39; 95% CI, 0.22-0.68). Similar results were observed the other landmarks tested. **Conclusions:** A higher proportion of pts in the PAN-BTZ-Dex arm achieved higher-quality responses, which are associated with longer PFS. Overall, these data support achievement of higher-quality responses as a treatment goal in relapsed/refractory MM. Clinical trial information: NCT01023308.

8576 Poster Session (Board #394), Sun, 8:00 AM-11:30 AM

Phase I interim safety and efficacy of venetoclax (ABT-199/GDC-0199) monotherapy for relapsed/refractory (R/R) multiple myeloma (MM). *First Author: Shaji Kumar, Mayo Clinic, Rochester, MN*

Background: The anti-apoptotic protein BCL-2 has been implicated in mediating the survival of MM cells. Venetoclax (VEN) is a potent, selective, orally bioavailable small-molecule BCL-2 inhibitor. VEN induces cell death in MM cell lines and primary samples in vitro, especially in t(11;14)-positive (pos) cells, which express a high ratio of *BCL2* to *MCL1*(VEN resistance factor). The current Ph 1 study evaluates safety and efficacy of VEN in pts with R/R MM. **Methods:** Primary objectives are to evaluate safety, PK, and RPTD; other objectives include preliminary efficacy and impact of chromosomal abnormalities. In dose-escalation cohorts, VEN was given PO daily at 300, 600, 900, or 1200 mg after a 2-week dose ramp-up. Pts were monitored for tumor lysis syndrome (TLS). **Results:** As of 12/19/2014, there were 28 pts with median age 65 (12/16 F/M); 9 ISS stage I, 11 stage II, 6 stage III. Median (range) prior therapies: 6 (1–13). 23 had prior bortezomib (15 refractory), 26 lenalidomide (12 refractory), and 13 auto-HSCT. 10 pts were t(11;14)-pos. AEs in ≥20% pts: diarrhea (32%), nausea (32%), neutropenia (21%), fatigue (21%). Grade 3/4 AEs (≥10%): thrombocytopenia (18%), anemia (14%), neutropenia (14%). 7 pts had SAEs, with 1 (epigastric pain) possibly related to VEN. 17 pts have discontinued (D/C): 14 due to PD, 2 for AEs (worsening shortness of breath, hypokalemia), and 1 withdrew consent; 11 still receiving therapy. 2 deaths occurred (both PD). 2 DLTs were seen at 600 mg (cohort was expanded): epigastric pain, nausea with abdominal pain. No pt had TLS. Preliminary PK (n=11; 300 and 600 mg): mean C_{max} and AUC_{24} were ~dose-proportional with high intra-dose variability. 21 of 28 pts were evaluable for preliminary efficacy. Best response by t(11;14) status shown in Table. **Conclusions:** VEN monotherapy was well tolerated in heavily-pretreated R/R MM. Responses (including CR) and longer ToS were observed in t(11;14)-pos pts. RPTD was achieved; study is now enrolling in the safety expansion cohort at 1200 mg (with 2-week ramp-up). Clinical trial information: NCT01794520.

n (%)	t(11;14)-pos (n=7)	t(11;14)-neg (n=14)

8577 Poster Session (Board #395), Sun, 8:00 AM-11:30 AM

The prognostic significance of CD45 expression by clonal bone marrow plasma cells in multiple myeloma. *First Author: Wilson I. Gonsalves, Mayo Clinic, Rochester, MN, Rochester, MN*

Background: Evaluation of clonal plasma cells (cPCs) in the bone marrow (BM) of multiple myeloma (MM) patients (pts) reveals two distinct cPC populations based on CD45 expression, i.e. CD45- and CD45+. We explored the prognostic significance of CD45 expression by cPCs in the BM of MM pts using flow cytometry. **Methods:** All MM pts seen at the Mayo Clinic, Rochester from 2009 to 2011 who had BM PCs evaluated by flow cytometry were included. For flow cytometry, a 6-color method was used with each sample stained with antibodies to CD45, CD19, CD38, CD138 and cytoplasmic Kappa and Lambda Ig light chains. Samples where > 20% of the cPCs detected expressed CD45 were classified as CD45+ and the rest were CD45-. Survival analysis was performed by the Kaplan-Meier method and differences assessed using the log rank test. **Results:** There were 604 consecutive MM pts who had their BM PCs evaluated by flow cytometry. Of these pts, 156 were newly diagnosed and 448 were previously treated with systemic therapy. Among newly diagnosed pts, the median follow up was 42 mos and 41 pts (27%) had high risk disease by FISH. The median time to next therapy (TTNT) for pts in the CD45+ group was 12 mos (n = 26, 17%) versus 29 mos for pts in the CD45- group (n = 130, 83%) (P = 0.002). The median overall survival (OS) for pts in the CD45+ group was 23 mos versus not reached for the CD45- group (P < 0.001). Among previously treated pts, the median follow up was 44 mos and 45% had a prior ASCT. There were 240 previously treated pts that were actively relapsing at the time of their bone marrow analysis. The median OS for actively relapsing pts classified as CD45+ was 11 mos (n = 61, 14%) versus 29 mos (n = 386, 86%) for CD45- (P < 0.001). In a multivariable analysis, CD45+ status and PCLI > 3 were independent predictors of worse OS among the newly diagnosed and actively relapsing pts. Increasing age and elevated LDH were independent predictors of worse OS in newly diagnosed and actively relapsing pts, respectively. **Conclusions:** The presence of > 20% cPCs in the BM expressing CD45 appears to bear negative prognostic value in newly diagnosed and actively relapsing MM pts. This may be a surrogate for a more aggressive phenotype of MM.

8578 Poster Session (Board #396), Sun, 8:00 AM-11:30 AM

Outcome at first relapse after frontline RVD regimen plus lenalidomide maintenance in transplant eligible MM patients. *First Author: Murielle Roussel, Hematology Department, IUCT Oncopole- CHU Purpan, Toulouse, France*

Background: The IFM 2009 trial recruited 700 MM pts between 2010-2012. Pts were randomly assigned to received RVD (5-8 cycles) and 1-yr Len maintenance +/- upfront ASCT. More than 250 pts relapsed. We aimed to analyze response rates (RR) and survival outcomes after salvage therapy. **Methods:** Pts who relapsed during RVD cycles or first 2 months of maintenance (group 1) were considered Relapsed and Double Refractory and were likely to receive CVAD or DCEP regimen. Pts who relapsed during or early after maintenance (Group 2) were considered Relapsed and Len Refractory and were likely to receive VCD, CPAD or pomalidomide based regimen (PCD). Pts who relapsed during FU (Group 3) were standard Relapsed. Eligible pts could receive SCT (auto and/or allo). **Results:** 83 pts were retrospectively analyzed. Median age was 56 years (28-65), ISS 2/3=37/22. 27 pts had High Risk (HR) cytogenetics. Group 1 comprised 15 pts (10 relapsed during RVD induction/consolidation). Eight pts received CVAD, 3 DCEP and 1 PD. Three pts died before any tx. Group 2 comprised 40 pts; 14 received VCD, 8 CPAD, 4 DCEP and 11 PCD. Group 3 comprised 28 pts; 12 received VCD, 3 CPAD and 11 PCD. RR and survival outcomes are listed in table 1. ORR was 40, 67.5 and 75% in groups 1,2,3, respectively. 46 pts proceeded to SCT (allo, n = 5). Median FU is 42 months from initial therapy: 64% pts relapsed again and 29% died. Median PFS2 is 11 months and 3-year OS 74%. Pts from group 1 had the poorest prognosis with 60% death, median OS 11.7 months. Median PFS2 was 3.5 months. **Conclusions:** Relapsed pts within 1 year after RVD induction/consolidation have impaired prognosis after salvage therapy.

	Salvage Tx	n	ISS 2/3	PFS 1 mos	BRA	SCT	Relapse 2	PFS 2 mos	Death	3-y OS

Preliminary safety and efficacy of evofosfamide (TH-302), an investigational hypoxia-activated prodrug, combined with bortezomib and dexamethasone in patients with relapsed/refractory multiple myeloma (RR MM). *First Author: Jacob Laubach, Dana-Farber Cancer Institute, Boston, MA*

Background: The presence of hypoxia in the diseased bone marrow presents a new therapeutic target for multiple myeloma (MM) (Colla, *Leukemia* 2010). Evofosfamide (EVO; formerly TH-302) is a novel 2-nitroimidazole prodrug of the DNA alkylator bromo-isophosphoramide mustard that is selectively activated under hypoxia and is investigated in multiple Phase 1-3 trials. Synergistic induction of apoptosis in MM cells by EVO and bortezomib (Bor) was shown *in vivo* and *in vitro* (Hu et al, *Mol Cancer Ther*2013). An ongoing phase 1/2 study investigates EVO in combination with Bor and dexamethasone (D) in RR MM (NCT01522872). **Methods:** This phase 1/2 open-label multicenter study investigates IV EVO (240-480 mg/m^2), IV or SC Bor (1.3 mg/m^2), plus PO D (40 mg) on Days 1, 4, 8 and 11 of a 21-day cycle. At the maximum tolerated dose, a Simon two-stage optimal design was implemented to pursue a regimen with ≥ 50% response rate or discontinue if ≤ 25% (85% power, 10% alpha). **Results:** Nine patients (pts; 4 male, 5 female) have been reported (3 at 240 mg/m^2 EVO and 6 at 340 mg/m^2 EVO). Pts were heavily pre-treated; median number of prior therapies was 8 (4 – 12). Median age was 57 years (45 – 68). All had previously received Bor and lenalidomide or thalidomide. No pt had a dose limiting toxicity and the recommended phase 2 dose (RP2D) was established at 340 mg/m^2 EVO. The most common ≥ Gr 3 adverse events (AEs) were thrombocytopenia (5 pts), lymphopenia (2 pts), leukopenia (2 pts) and anemia (2 pts). Limited skin toxicity has been observed (2 pts, grade 2 rash or skin lesions). Four pts had SAEs; one SAE of thrombocytopenia was related to EVO. Seven pts discontinued for progressive disease; no pts have discontinued due to an AE. IMWG assessments were 1 CR, 2 PR, 4 SD and 2 PD (1 CR and 2 PRs out of 6 pts at 340 mg/m^2 EVO). Two pts with a CR and PR continue on study. To date, 17 of 24 pts have been enrolled to evaluate safety and efficacy at the RP2D. **Conclusions:** EVO can be administered at 340 mg/m^2 twice a week with Bor and D. Preliminary clinical activity has been noted in pts with heavily pre-treated RR MM. Data from pts treated at the RP2D will be updated and presented at the meeting. Clinical trial information: NCT01522872.

8580 Poster Session (Board #398), Sun, 8:00 AM-11:30 AM

Phase 1b interim results: Venetoclax (ABT-199/GDC-0199) in combination with bortezomib (BTZ) and dexamethasone (Dex) in relapsed/refractory (R/R) multiple myeloma (MM). *First Author: Cyrille Touzeau, CHU de Nantes, Hotel Dieu—HME, Nantes, France*

Background: The anti-apoptotic proteins BCL-2 and MCL-1 promote MM cell survival. BTZ can inhibit MCL-1 activity by elevating the MCL-1 antagonist, NOXA. Venetoclax (VEN) is a selective, orally bioavailable, small-molecule BCL-2 inhibitor, which enhances BTZ efficacy in MM xenograft models. This Ph 1 study evaluates VEN with BTZ and Dex in patients (pts) with R/R MM. **Methods:** Objectives include safety, PK, preliminary efficacy, and MTD of VEN with BTZ and Dex. Pts received VEN (50-500 mg PO daily) in cycles (C) 1-11 per designated dose escalation (DE) cohorts (continual reassessment); BTZ (1.3 mg/m^{2}SC, days [D] 1, 4, 8, 11) and Dex (20 mg PO, D1, 4, 5, 8, 9, 11, 12) in C1-8 (21D), BTZ+Dex D1, 8, 15, 22 in C9-11 (35D), and VEN alone ≥ C12. **Results:** 32 pts were enrolled as of 12/18/2014: median age 65; 12/20 F/M. 12 were ISS stage I, 7 stage II, 10 stage III. Median (range) prior therapies: 5 (1–15). 26 pts received prior BTZ (10 refractory), 26 had prior lenalidomide, and 20 auto-HSCT. AEs in ≥ 20% pts: constipation (41%), diarrhea (38%), peripheral edema (28%), thrombocytopenia (31%), peripheral neuropathy (28%), insomnia (28%), dyspnea (25%), anemia (22%). Grade 3/4 AEs (≥10%): thrombocytopenia (25%), anemia (13%). 14 pts had SAE: none VEN-related. Reason for discontinuation (D/C; n = 17): PD (n = 14), AEs (n = 2: adenocarcinoma, cardiac and respiratory decompensation), consent withdrawal (n = 1). 3 deaths occurred (due to PD); 1 DLT at 300 mg (cardiac decompensation attributed to Dex). No TLS occurred. Dose-normalized exposure when given with BTZ+Dex (n = 30) was similar to VEN alone. Preliminary efficacy (best response) by BTZ status. **Conclusions:** Venetoclax with BTZ and Dex has an acceptable safety profile in heavily pretreated MM. This combination targeting BCL-2 and MCL-1 resulted in anti-tumor activity and longer ToS in pts naïve or sensitive to prior BTZ. DE continues at 600 mg. Clinical trial information: NCT01794507.

Total marrow irradiation (TMI) with helical tomotherapy and peripheral blood progenitor cell rescue (PBPC) following high-dose melphalan (Mel) and PBPC as part of tandem autologous transplant (TAT) for patients with multiple myeloma. *First Author: George Somlo, City of Hope, Duarte, CA*

Background: Ablative dose total body irradiation (TBI) of 800 cGy in combination with high-dose melphalan (MEL) was found to be too toxic. TMI, an image-guided targeted TBI using TomoTherapy intensity modulated radiotherapy , given as the sole ablative regimen for the second cycle (C) of TAT was tested in patients (pts) with stable (SD)/responsive MM, in a phase I-II trial. Here we provide long-term update on outcome. **Methods:** We enrolled pts with Durie-Salmon stages (DS) I-III MM in response or with SD, who were ≤ 70 years old and ≤ 18 months from diagnosis. Pts received MEL 200 mg/m^2 and AT (C 1), and, after recovery, TMI (MTD : 1600 cGy) and AT (C 2) followed by maintenance with dexamethasone and an IMiD. **Results:** 54 pts started treatment (23 F/31M). The median age was 54 years (31-67). DS stages were:I (N = 4), II (N = 18), III (N = 32). 44 of the 54 pts received TMI (28 of 36 pts enrolled at the MTD received TMI). 10 pts did not receive TMI due to post-MEL toxicities or pt or doctor's choice. The median time between MEL and TMI was 65 days (range 47-125). All pts engrafted. 9/54 (17%) experienced febrile neutropenia (FN) following MEL, and 8/44 (18%) experienced FN after TMI; less frequent grade 3 or 4 non-hematologic toxicities were similar between MEL and TMI. Best responses included CR (N = 22, of which 3 were in CR prior to MEL), very good partial response (VGPR, N = 8, of which 2 were in VGPR prior to MEL) and PR or SD (N = 14). Median follow-up of alive pts is 73 months (27-117). Second malignancies included 2 skin, 1 breast, 1 thyroid carcinoma, and 1 acute myeloid leukemia. In intent-to-treat analysis median PFS for the 54 pts is 52 months (95% CI 34.4-NR), and median OS is not reached. PFS and OS at 5 years is 43% (95% CI 31-59) and 66% (95% CI 54-81), respectively. For pts enrolled at 1600cGy, the PFS and OS at 5 years were 48% (34-69) and 73% (59-90). **Conclusions:** TMI of 1600 cGy is feasible following MEL in MM patients. The long-term safety and PFS/OS are encouraging, and further assessment of TMI is warranted. Clinical trial information: NCT00112827.

8582 Poster Session (Board #400), Sun, 8:00 AM-11:30 AM

Overall survival in newly diagnosed MM patients with del(17p): A report from the Connect MM Registry. *First Author: Jatin J. Shah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Del(17p) is detected in 10%-15% of patients (pts) with MM and is associated with early relapse and short survival. There are limited data, no uniform or optimal treatment (Tx) approach, and questions on role of autologous stem cell transplant (ASCT). Connect MM, a prospective, observational, US, multicenter disease registry, contains the largest cohort of pts with newly diagnosed MM (NDMM) and del(17p). Disease characteristics and OS were analyzed in this cohort. **Methods:** Connect MM was initiated in Sep 2009. Data from pts (diagnosed ≤ 2 mo before study entry) enrolled up to Dec 2011 (N = 1493) at 234 sites were collected at baseline and quarterly thereafter. Outcomes data through Jun 30, 2014 for 1450 treated pts were analyzed. Survival analysis was adjusted for sex, race, therapy received, and ASCT. OS was estimated using Kaplan-Meier methods and comparisons were assessed using the log-rank test. **Results:** Del(17p) was detected (mainly by FISH) in 108 of the 1450 pts (7.4%). Median age was 69 y (range 27-89), 58% were male, 82% were Caucasian, and 33.3% had ISS stage III MM. Median follow-up was 33.5 mo (0.03-55.9 mo). Pts with del(17p) had lower median survival (38.6 mo vs not reached [NR], $P < 0.001$). Of pts initially treated with transplant intent, 44% (19/43) with del(17p) and 45% (274/615) without del(17p) received ASCT during first-line therapy. ASCT vs no ASCT was associated with a higher median OS in pts with del(17p) (NR vs 31.3 mo, $P = 0.0177$). By multivariate analysis of various baseline characteristics and therapy modalities, front-line ASCT was associated with a lower risk of death (HR 0.14, $P = 0.008$); hypercalcemia was associated with a higher risk of death (HR 3.06, $P < 0.01$) in pts with del(17p). **Conclusions:** Among pts with NDMM across a range of clinical practices, del(17p) was associated with inferior OS. Hypercalcemia may be a negative prognostic factor. Pts with del(17p) seem to benefit from ASCT. Analyses of the impact of novel combination therapies are being done and will be reported, as there is clear need to improve outcomes in this pt segment.

8583 Poster Session (Board #401), Sun, 8:00 AM-11:30 AM

Outcomes of high, t(11;14), and standard cytogenetic risk multiple myeloma following early high dose therapy and autologous hematopoietic cell transplantation (SCT). *First Author: Gregory Peter Kaufman, Mayo Clinic, Rochester, MN*

Background: Current cytogenetic risk stratification in newly diagnosed multiple myeloma (NDMM) is not derived from recent patients (pts) treated with novel agents. High dose melphalan and SCT is a preferred management strategy for transplant eligible NDMM pts following novel agent induction. We investigated outcomes of high cytogenetic risk (HR), t(11;14), and standard cytogenetic risk (SR) NDMM treated with early SCT. **Methods:** Following Mayo Clinic IRB approval and in accordance with the Declaration of Helsinki, all pts treated at Mayo Clinic Rochester with SCT for NDMM between 2003 and 2012 were identified (n = 941). We excluded pts without FISH cytogenetics from diagnosis (dx) and those who did not undergo SCT within 12 months of dx. HR was defined as a composite of mSMART high and intermediate risk abnormalities including del(17p), t(4;14), t(14;20) or t(14;16). Response and progression were defined per IMWG criteria. Overall survival (OS) and progression free survival (PFS) were calculated from dx. **Results:** The study cohort had 409 pts [SR = 244, t(11;14) = 69, HR = 96], with a median estimated follow up of 43 months from dx. Novel agents (IMiDs or proteasome inhibitors) were used in 95% of pts prior to SCT, and 80% of pts achieved partial response. Median PFS for HR, t(11;14), and SR pts was 24.9 (23,30), 28.1 (21,31), and 30.4 (28-34) months respectively (p = 0.034). Median OS for HR, t(11;14), and SR pts was 60.5 (46,71), 73.4 (54,89), and 103 (98,113) months respectively (log rank < 0.0001). When only pts who received post-transplant maintenance therapy were evaluated (IMiDs or proteasome inhibitors), there was no difference in OS at 5 years from diagnosis between HR and SR pts treated with early SCT (p = 0.19). **Conclusions:** Following novel agent induction and early SCT, pts with t(11;14) NDMM have inferior OS compared to a SR cohort of similarly treated pts. This is contrary to the current classification scheme. HR pts have similar OS at 5 years from diagnosis compared to SR pts with the use of early SCT and maintenance therapy.

8584 Poster Session (Board #402), Sun, 8:00 AM-11:30 AM

A phase I/II trial of very low to low-dose continuous azacitidine in combination with standard doses of lenalidomide and low-dose dexamethasone in patients with relapsed or refractory multiple myeloma. *First Author: Frederic J. Reu, Cleveland Clinic, Cleveland, OH*

Background: Azacitidine (AZA) may overcome drug resistance of relapsed or refractory multiple myeloma (RRMM).Continuous administration should maximize epigenetic effects and safety. **Methods:** Lenalidomide (len) 25mg (10mg if GFR 30-59 ml/min) d1-21 every 28d and dexamethasone (dex) 40mg weekly (len-dex) were combined with escalating doses of AZA from 30mg/m^2 SC weekly to 50mg/m^{2}SC twice a week. Dose limiting toxicity (DLT) was assessed during cycle 1. IMWG uniform response criteria (partial response, PR) and adapted EBMT criteria (minor response, MR) were used. Plasma activity of the AZA inactivating enzyme cytidine deaminase (CDA) was measured by HPLC at Zymo Research Corp., CA. **Results:** Forty patients (pts) with relapsed (n = 3) or refractory (n = 37) MM were enrolled after a median of 4 prior regimens (range 1-10). Their disease was refractory to len (n = 32), bortezomib and / or carfilzomib (n = 32), or both len and proteasome inhibitors (n = 28). The target phase II dose of 50mg/m2 SC twice a wk was reached. One DLT (neutropenic fever without documented infection) occurred in 1 of 6 pts treated with 40mg/m2 AZA twice a week);. Grade 3/ 4 toxicities possibly drug related were seen in 23 pts (58%), neutropenia (13), thrombocytopenia (5), fatigue (3), infection (2), anemia (2), pleural effusion (1), fever (1), and atrial fibrillation (1). Twelve pts achieved > MR, 9 > PR (3 VGPR) yielding 30% clinical benefit response (CBR) and 22.5% response rates. Median time on study was 90 days. Responses lasted between 3 months and 2 years. Five pts remain on study. Plasma CDA activity at screening and during the study (q wk x4, then q 28d) inversely correlated with achieving > MR ($p < 0.03$, $p < 0.01$, respectively, Wilcoxon exact test) and varied by median 17%. Pts with screening CDA activity < 1000 mU/mL had 50% CBR, vs. 21% if > 1000mU/mL. **Conclusions:** AZA was well tolerated up to target 50mg/m^2 SC twice a week in combination with len-dex . Inverse correlation of CDA activity with response suggests AZA contributed to benefit and supports development of the HPLC assay to select patients for aza nucleoside treatment and guide development of CDA inhibitors. Clinical trial information: NCT01155583.

8585 Poster Session (Board #403), Sun, 8:00 AM-11:30 AM

The therapeutic benefit and toxicity from multiple myeloma phase I trials, 2004 through 2014. *First Author: Ehsan Malek, Division of Hematology and Oncology, University of Cincinnati, Cincinnati, OH*

Background: Despite the therapeutic benefit of novel agents, majority of multiple myeloma (MM) patients inevitably relapse leading to poor clinical outcomes. During the past decade, there has been an unprecedented pace of new anti-myeloma compound discovery tested through phase I trials, mostly in relapse/refractory setting. In the same period of time, at least 9 agents have been FDA approved for relapse MM that makes the decision making between standard therapy vs. recruitment on phase I trial poorly defined and occasionally ethically challenged. Further, the current perception of low therapeutic benefit from participation in phase I trials is the main obstacle for patient recruitment and make the phase I trial as a "last resort" in overall therapeutic plan. Here, we present a global assessment of therapeutic benefit and toxicity of all MM phase I studies over the past decade that may lead to optimal timing of patients recruitment on phase I trials. **Methods:** We reviewed 43 phase I trials from 2004 until 2014 in a systematic fashion. Quality and rate of response, adverse effects and mortality from single agents as well as combination of the experimental agents with immunomodulators (IMiDs) and proteasome inhibitors (PIs) are reported. **Results:** 41 trials with total of 946 participants were analyzed. 21 were single agents and the reminder tested a combined regimens. Overall response rate (ORR), i.e., partial response or better, was observed in 34% of all patients, 16% with single agents and 42% with combination therapy. Patients participated in trials with combination therapies had more grade III-IV toxicity than single agents (HR: 1.35, p-value: 0.04). There were only 5 patients (less than 1% of all participants) who have therapy-related death. Single agents with anti-CD38 agent, daratumumab and oral PI, ixazomib, had the best single agent response rate, 45% and 36%, respectively. **Conclusions:** Median ORR from MM phase I trials even with single agents is higher than reported response rate from classic chemotherapy phase I trials (i.e. 5%), therefore phase I participation should not count as the "last resort" and MM patients should be offered the opportunity to participate in these trial at any stage after failure on IMiDs and PIs.

8586 Poster Session (Board #404), Sun, 8:00 AM-11:30 AM

Impact of total therapies on clinical outcome of myeloma stratified by risk and molecular subgroups. *First Author: Christoph Johann Heuck, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Despite the introduction of new agents multiple myeloma (MM) is a disease with unpredictable clinical course consistent with it being composed of a variety of subtypes with distinct molecular features. In order to shed light on the impact of this molecular heterogeneity on treatment response we examined clinical outcomes in our series of Total Therapy (TT) trials, stratified by risk status and molecular subgroup. **Methods:** We included 1318 patients with available baseline gene expression profiling (GEP) data enrolled on Total Therapy 2–5, stratified by GEP70-defined risk and molecular subgroup. We analyzed their effect on outcomes and timing of treatment failure in relation to protocol phase. **Results:** For GEP70-defined low risk (LR) MM, PFS and OS has incrementally improved with addition of thalidomide in TT2 and bortezomib (Bz) in TT3a and 3b. While Bz improved outcomes for LRMM within the MS molecular subgroup, it had no significant impact on MF cases. Outcomes for patients treated on TT4 designed for LRMM were similar to TT3a/b. The lower intensity treatment arm TT4-L had inferior outcomes compared to the standard arm. However patients with adverse cytogenetics had improved outcomes on TT4-L. Treatment failures in LRMM were rare and not correlated to treatment phase. CR rates in high-risk (HR) MM are similar to LRMM. Yet a more dose-dense chemotherapy in Total Therapy (TT) 5 failed to improve survival in HRMM. For HRMM treated on TT2 and 3, treatment failures occurred early in the inter-transplant or consolidation phases. Interestingly with dose dense therapy in TT5 treatment failure was not seen until the maintenance phase. **Conclusions:** HRMM has a distinct clinical course with high rates of primary refractory disease and early relapse. Changing therapy for HRMM from dose intense to dose dense has shifted treatment failure from the inter-transplant to the maintenance phase, which is now a setting where novel approaches can be used. For LRMM we can define distinct clinical response and outcome patterns dependent upon GEP-defined molecular subgroups. This differential response dependent upon treatment used at induction opens the potential for adjusting maintenance to take account of the disease subtype. Clinical trial information: NCT00869232.

8587 Poster Session (Board #405), Sun, 8:00 AM-11:30 AM

Pre-clinical translational studies of daratumumab in patients with myeloma or AL amyloidosis undergoing autologous hematopoietic stem cell transplantation (SCT). *First Author: Chakra Pani Chaulagain, Cleveland Clinic Florida, Weston, FL*

Background: Daratumumab (DARA) is a human IgG1 that binds to CD38 and kills tumor cells expressing CD38 through immune-mediated cytotoxicity. CD38 is expressed on plasma cells in multiple myeloma (MM), AL amyloidosis (AL) and on myeloid progenitor cells. Since SCT remains a standard therapy for MM and AL the effect of DARA on progenitor cells was evaluated. Ability of DARA to induce complement dependent cytotoxicity (CDC) of progenitor cells was assessed in progenitor cell assay (PCA). DARA-mediated antibody-dependent cytotoxicity (ADCC) of progenitor cells, its correlation with FcγRIIIA polymorphism and stem cell potential were examined using NK-cells from post-SCT patients (n = 10, n = 6 MM and n = 4 AL) as effectors against a MM target cell line. **Methods:** ADCC was performed with post-SCT NK cells and MM.1S cells in the presence of 100 ng/ml DARA or isotype control (ICA). DARA-mediated CDC was evaluated in PCA: unselected or CD34-selected mobilized cells were incubated in complement-rich serum with no antibodies, or DARA or anti-CD59 (BRIC 229) or both. The effects of these antibodies on CFU-GM and BFU-E were evaluated two weeks later. The results were analyzed by two-tailed paired t tests with $P < 0.05$ as significance level. **Results:** MedianADCC of MM.1S target cells by primary post-SCT NK cells was 39% and 7% using DARA or ICA, respectively ($P < 0.05$). Of the 10 NK donors, 6 were V/F or V/V and lysed 60% of targets, while 4 F/F lysed 17% ($P< 0.05$). In the PCA, there was no decrease in CFU-GM or BFU-E: with unselected mobilized cells, with CD34-selected cells with DARA, or with CD34-selected cells incubated with DARA (500 or 1000 ng/ml) +/- BRIC 229 indicating that DARA did not induce CDC on the CD34-selected progenitor cells. **Conclusions:** DARA is active in ADCC assays with post-SCT NK cells from patients with MM or AL and its activity correlates with *FCGR3A-158V/F* polymorphism. DARA did not inhibit progenitor cell growth by CDC in unselected or CD34-selected cells suggesting that administration of DARA may not cause undue harm to the progenitor cells after SCT. These findings support consideration of clinical trials of DARA consolidation post-SCT in MM and AL. CPC: MMRF fellow.

8588 Poster Session (Board #406), Sun, 8:00 AM-11:30 AM

Effect of IMiD compounds on CD38 expression on multiple myeloma cells: MOR202, a human CD38 antibody in combination with pomalidomide. *First Author: Rainer Boxhammer, MorphoSys AG, Martinsried/Planegg, Germany*

Background: MOR202 (MOR03087), a human CD38 antibody currently under evaluation in a phase I/IIa trial, mediates antibody-dependent cell-mediated cytotoxicity/phagocytosis (ADCC/ADCP) of multiple myeloma (MM) patient-derived cells with high potency (EC50 ~200 pM). IMiD compounds such as lenalidomide (LEN) or pomalidomide (POM), both approved in MM, were evaluated *in vitro* for their ability to modulate CD38 expression and enhance the cytotoxicity of MOR202. **Methods:** CD38 expression +/- LEN and +/- POM on MM cell lines was analyzed by flow cytometry. The antitumor activity of POM combined with MOR202 was evaluated *in vitro*; analyses included the induction of direct cytotoxicity of MM cells and the activation of immune effector cells. On a functional level, the combinatorial effects of MOR202 with POM were assessed in ADCC assays. Different incubation schemes were used to separate the effect of POM on target and effector cells, as well as in the evaluation of the combined effects. The observed combination effects were analyzed for synergistic potential using the fractional product concept. **Results:** POM and LEN mediated a substantial CD38 upregulation on MM cell lines. POM as a single agent showed activation of effector cells and with high potency (EC50 ~150 nM), cytotoxic effects on MM cell lines. Additionally, POM dose-dependently induced an up to 3-fold CD38 upregulation (EC50 ~20 nM) on CD38-expressing MM cell lines. POM-mediated effects were time-dependent, with the most pronounced effects after 72 h incubation. Combining MOR202 with POM led to a synergistic enhancement of cytotoxic activity. The synergy benefit ranged between 1.2–3.1-fold above theoretical additivity, depending on the cell line used, and was most prominent in the case of strong CD38 upregulation. **Conclusions:** Upregulation of CD38 was mediated by both LEN and POM and may represent a class effect of IMiD compounds. The cytotoxic activity of MOR202 on MM cells was enhanced by POM via multiple mechanisms: direct cytotoxicity, CD38 upregulation and activation of effector cells. These results provide a mechanistic rationale for the combination of MOR202 with IMiD compounds and warrant further clinical evaluation.

8589 Poster Session (Board #407), Sun, 8:00 AM-11:30 AM

Patterns of AKT, mTOR, ERK, and STAT3 pathway activation in MGUS, smoldering multiple myeloma, and multiple myeloma. *First Author: Jeremy Todd Larsen, Mayo Clinic, Rochester, MN*

Background: Constitutive activation of key signaling pathways supports proliferation in multiple myeloma (MM). However, pathway activation in MGUS and smoldering multiple myeloma (SMM) compared to MM has not been characterized. We examined the levels of phosphorylated Akt, mTOR, ERK, and STAT3 expression by immunohistochemistry (IHC) in MGUS, SMM, and MM and assessed their impact on clinical outcomes. **Methods:** FFPE bone marrow biopsy samples were obtained during routine clinical care. Primary antibodies used were p-Akt (S473), p-mTOR(Ser2448), p-ERK1/2(Thr202/Tyr204), and p-STAT3 (Tyr705). Staining intensity was scored as: 0 (no staining), 1 ($<$ 50% of cells), 2 ($>$ 50%) and 3 (dark staining of all cells). Nominal variables were compared with Fisher's exact test and time to progression (TTP) was calculated with Kaplan Meier analysis. **Results:** Twenty-one MGUS, 20 SMM, and 18 MM patients were reviewed. Strong expression of p-Akt (2-3+ IHC score) was present in 15% of MGUS cases versus 62% of SMM and 61% of MM patients ($p = 0.037$). Strong p-mTOR expression was observed in SMM and MM patients compared to MGUS patients (100% and 94% versus 45%; $p = 0.001$). 61% of MM cases exhibited strong p-ERK expression versus 34% in SMM and 15% in MGUS ($p = 0.042$). There was non-significant trend toward higher p-STAT3 expression in MM versus SMM/MGUS (39% in MM versus 12% and 10% in SMM and MGUS; $p = 0.15$). Increased p-mTOR activity correlated with high expression of p-Akt(S473) in all patients ($p = 0.023$). TTP in SMM patients with high versus low p-ERK activity was significantly shorter (76 months vs 16 months; $P = 0.046$). No other signaling pathways demonstrated statistical differences in TTP or overall survival. **Conclusions:** Comprehensive IHC analysis across the spectrum from MGUS to SMM and MM demonstrated increased activity of multiple key signaling pathways as disease progression occurs. Expression of p-Akt(S473) and p-mTOR in SMM and MM is significantly higher than MGUS patients, suggesting an upregulation of these pathways is an early event in pathogenesis. Activation of p-ERK and p-STAT3 was more frequent in MM versus MGUS/SMM, suggesting they may be more active in advanced disease.

8590 Poster Session (Board #408), Sun, 8:00 AM-11:30 AM

Assessing clinical response in multiple myeloma (MM) patients treated with monoclonal antibodies (mAbs): Validation of a daratumumab IFE reflex assay (DIRA) to distinguish malignant M-protein from therapeutic antibody. *First Author: Christopher McCudden, Dept. of Pathology & Lab. Medicine, The Ottawa Hospital University of Ottawa, Ottawa, ON, Canada*

Background: Residual therapeutic mAbs can be detected by assays intended to monitor clonal myeloma protein (M-protein). Daratumumab, a human anti-CD38 IgG1k mAb in MM clinical trials, has been detected on serum protein electrophoresis (SPE) and immunofixation (IFE) gels, interfering with IMWG response criteria requiring negative SPE/IFE for CR/sCR. As new therapeutics emerge that induce very deep responses a method is needed to confirm CR/sCR. Validation and use in clinical studies of an assay that distinguishes daratumumab from M-protein is presented. **Methods:** Mouse anti-daratumumab antibody is used to shift daratumumab's IFE migration away from M-protein. Commercial and daratumumab-treated MM patient samples were evaluated to assess specificity, reproducibility and concordance. Detection of M-protein depletion by DIRA triggered additional clinical testing to confirm CR/sCR. **Results:** Daratumumab was identified on IFE in 10/10 samples when added to commercial MM serum in a 1:1 ratio with anti-daratumumab. Reproducibility was tested in 3 independent DIRA runs on 10 samples from daratumumab treated patients (16 mg/kg). 2 independent reviewers assessed daratumumab and M-protein levels and observed 100% concordance. Specificity was evaluated in commercial ($n = 16$) and daratumumab-treated patient samples ($n = 36$) by scoring whether the malignant M-protein was shifted with the anti-idiotype antibody. 94.4% (34/36) of samples had no shift in M-protein with anti-daratumumab. 33 daratumumab patient samples (from single-agent or combination studies) were DIRA tested and clinical responses assessed; 13 (39%) had no M-protein (DIRA -ve) and 10 were confirmed as CR. 20 patients had malignant M-protein remaining (DIRA +ve) and monitoring continued. **Conclusions:** DIRA, a robust and reproducible tool, determines if residual IgGk on IFE is caused by the mAb daratumumab or actual M-protein. DIRA results can trigger further assessments to confirm clinical CR. This first approach to distinguish therapeutic mAb from M-protein in MM will be needed for clinical research and eventually MM treatment.

8591 Poster Session (Board #409), Sun, 8:00 AM-11:30 AM

Safety and efficacy of pomalidomide (POM), dexamethasone (DEX), and pegylated liposomal doxorubicin (PLD) for patients with relapsed/refractory multiple myeloma (RRMM). *First Author: James R. Berenson, Institute for Myeloma & Bone Cancer Research, Los Angeles, CA*

Background: Treatment with POM and DEX has shown efficacy in RRMM patients (pts), even in those refractory to lenalidomide (LEN). In this phase (Ph) 1/2 trial, we investigated the POM-DEX-PLD combination using a modified dose and schedule (28-days) for RRMM pts. **Methods:** Ph1 pts had progressive MM at study entry. Ph2 pts were refractory to LEN (progressive disease (PD) while receiving LEN or relapsed within 8 weeks of last dose). POM was administered orally on days 1-21 of a 28-day cycle, while DEX (40 mg) and PLD (5 mg/m^2) were infused on days 1, 4, 8, and 11. The maximum tolerated dose (MTD) of POM was established at 4 mg; however, because 58.8% of the pts enrolled in Ph2 developed $\geq$ grade 3 (Gr3) neutropenia, the dose of POM was reduced to 3 mg. **Results:** As of December 1st 2014, 56 pts were enrolled, 44 of them in Ph2 and 45 pts had discontinued treatment. Pts had received a median of 4 prior treatments (range, 1-18). Median number of cycles for all pts and those enrolled in Ph2 was 3 (range, 1-8). Median follow-up time for all pts was 4 months (range, 0.2-22 months), whereas that of Ph2 pts was 3.8 months (range, 0.2-12 months). Overall response (ORR) and clinical benefit rates (CBR) were 35%and 47%, respectively. Nine pts (16%) showed stable disease (SD) while 13 (24%) pts exhibited PD. For LEN refractory pts ($N = 44$), ORR and CBR were 32 % and 48%, respectively, with 6 pts (14%) showing SD and 15 pts (34%) displaying PD.Ph2 pts receiving POM at 3 mg ($N = 28$) showed an ORR and CBR of 43% and 61%, respectively. Progression-free survival was 5.23 months. Common $\geq$ Gr3 adverse events were neutropenia (38.2%), lymphopenia (20.0%), hyponatremia (9.1%), and thrombocytopenia (5.5%). One pt died of Gr5 sepsis. **Conclusions:** The combination of POM at 3 mg, PLD and DEX given in 28-day cycles is safe and effective for the treatment of MM pts refractory to LEN. Clinical trial information: NCT01541332.

8592 Poster Session (Board #410), Sun, 8:00 AM-11:30 AM

Clinical outcomes in t(11;14) multiple myeloma. *First Author: Muhamad Alhaj Moustafa, Mayo Clinic, Rochester, MN*

Background: Chromosomal translocations involving the immunoglobulin heavy chain region on chromosome 14 are common abnormalities in multiple myeloma (MM); with translocation t(11;14) being the most common (15-20%). Our study focuses on the outcomes of this group and response to different therapies. **Methods:** We identified 254 patients with MM, who had fluorescence in situ hybridization (FISH) performed between 2004 and 2012 for MM and had t(11;14) abnormality. We included 199 patients who had FISH studies before MM diagnosis or within 2 years of diagnosis. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method. **Results:** The median age at diagnosis was 63 years (range, 22-95) and 129 (65%) were male. The estimated median follow up for the whole cohort was 69 months; 100 (50%) patients are alive. The PFS for the whole cohort was 15 months (95% CI; 11, 18) and the OS was 68 months (95% CI; 54, 88). Twenty-seven (14%) patients received conventional therapies for induction, whereas 172 (86%) received novel agents (116 IMiDs, 33 proteasome inhibitors, 23 both); 115 had stem cell transplant (SCT). Partial response (PR) or a better response to induction was seen in 55%. Median OS was similar for patients receiving conventional drugs or novel agents for initial therapy; 68 months vs. 70.5 months, p= 0.53. Median OS for those receiving an SCT was 72 months compared with 35 months for the remainder. The median OS for 33 patients with a 17p deletion was 26 months vs. 73 months for the remainder, p< 0.01. The OS for the 91 patients diagnosed before 2009 was similar to the 108 patients diagnosed later; p= 0.2. **Conclusions:** The median survival of patients with t(11;14) abnormality is 5-6 years, and does not appear to have changed significantly within the last decade.

8593 Poster Session (Board #411), Sun, 8:00 AM-11:30 AM

Analyzing the relationship of response and survival in patients with refractory or relapsed and refractory multiple myeloma (RRMM) treated with pomalidomide plus low-dose dexamethasone (POM + LoDEX) in the MM-003 trial. *First Author: Katja Weisel, University Hospital of Tuebingen, Tuebingen, Germany*

Background: RRMM patients (pts) previously exposed to bortezomib (BORT) and lenalidomide (LEN) have short overall survival (OS). The phase 3 MM-003 trial (NCT01311687) demonstrated significantly longer OS in RRMM pts treated with POM + LoDEX vs HiDEX (HR, 0.74 [95% CI, 0.56-0.97], P = .0285). This post hoc analysis investigated OS based on the response status of pts at different cycles. **Methods:** Landmark analyses at the start of cycles (C) 3, 5, and 7 were performed using Kaplan-Meier methods and unadjusted Cox regression models. Time-dependent survival analyses captured response status over time. For both approaches, survival of ptswith stable disease (SD) was compared to that of pts with progressive disease (PD) or overall response (OR; ≥ partial response). **Results:** At C3, 38.4% of pts (116/302) randomized to POM + LoDEX attained SD, 14.6% PD, and 19.2% OR; 28% had no response data, most due to early discontinuation. The median OS from randomization by response status at C3 was 15.3 mos for SD, 6.3 for PD, and 17.5 for OR. The difference in OS at C3 between pts with PD or SD was significant (P < .001); that between pts with OR or SD was not (P = .32). A similar pattern was observed at C5 and C7. The time-dependent survival model showed a lower risk of death for pts with SD or OR vs PD (HR, 0.27 [95% CI, 0.17-0.44] and HR, 0.06 [95% CI, 0.02-0.16], respectively). For the HiDEX arm, small pt numbers per group (due to the lower response rate, 2:1 randomization, and shorter OS vs POM + LoDEX) made interpretation challenging. **Conclusions:** In the POM + LoDEX group, pts with SD at C3, C5, and C7 had OS comparable to pts who achieved a response by those times. Pts with either SD or OR had a longer OS than those with PD at the same time points. Clinical trial information: NCT01311687.

Outcomes and treatment of patients with POEMS syndrome experiencing progression or relapse after first line treatment. *First Author: Taxiarchis Kourelis, Mayo Clinic, Rochester, MN*

Background: While clinical improvement is almost universal with first line chemotherapy and/or radiation therapy in patients with POEMS syndrome, outcomes and management of patients who relapse or progress (R/P) after first line treatment have not been described. **Methods:** We identified 291 patients with POEMS syndrome treated at the Mayo Clinic from 1974-2014. Median follow-up for survival and R/P were 68 months and 51 months, respectively. **Results:** For the 78 documented R/P patients (27%), 2ndline treatments included: novel agents, n = 16 (21%), chemotherapy, n = 23 (30%), radiation, n = 15 (19%), ASCT, n = 12 (15%), other, n = 5 (6%) and uncertain type of therapy, n = 5 (6%). The 5 year PFS for the 291 patients was 68%. For patients with documented R/P, median time to R/P was 42 months (range 3-327 months). The 5 year OS for patients with and without an R/P was 85% vs 77%, p = NS. Excluding 9 patients with refractory disease, 47 (60%) patients experienced a clinical R/P and 22 (28%) R/Ps were identified by a combination of worsening VEGF, hematologic or radiographic evaluations. Eighteen (23%) patients relapsed with symptoms that were not present at diagnosis. Outcomes after second line treatment are shown in the table. Thirty patients (30%) went on to experience a second R/P (R/P-2) at a median of 17 months from the end of second line treatment/diagnosis of the first R/P (range 0-96 months). **Conclusions:** One quarter of patients with POEMS had a documented R/P after first line chemo-or radiation therapy, some of whom with symptoms not present at initial diagnosis. The vast majority of patients with R/P responded to subsequent therapy.

Phase III trial of stem cell transplantation compared to melphalan and dexamethasone in the treatment of immunoglobulin light chain amyloidosis (AL). *First Author: Morie A. Gertz, Mayo Clinic, Rochester, MN*

Background: Autologous stem cell transplant is widely performed for the management of select patients with AL amyloidosis in the United States. There are no phase III trials that document improved overall survival. This phase III trial allowed patients to select between melphalan and dexamethasone or autologous stem cell transplantation. **Methods:** Eighty-nine patients with biopsy-proven AL amyloidosis elected to receive melphalan and dexamethasone (n = 34) or stem cell transplantation (n = 54). Patients were selected to exclude those for whom cardiac involvement would not have permitted safe autologous stem cell transplantation. **Results:** Allowing patients to select their preferred treatment resulted in an imbalance of patients between the two arms. Patients that selected melphalan and dexamethasone were younger, were more likely to be ECOG performance status less than 2, and had a higher amyloid stage defined by increasing degrees of cardiac amyloidosis. Patients receiving melphalan and dexamethasone had a three-year progression-free survival of 29% and overall survival of 58.8%. Patients receiving stem cell transplant had a three-year progression-free survival of 51.7% and overall survival of 83.6%. An attempt to match patients between the two arms, in terms of risk, produced 24 matched triplets with no difference in hematologic response. **Conclusions:** This trial, which did not meet its accrual goals, failed to demonstrate a survival advantage for matched patients undergoing autologous stem cell transplantation. Clinical trial information: NCT00477971.

Survival trends in young patients with Waldenstrom macroglobulinemia (WM). *First Author: Nishanth Vallumsetla, Mayo Clinic, Rochester, MN*

Background: Data in young patients (pts) with WM are sparse and the few available studies utilizing SEER database have yielded inconsistent results, possibly overestimating survival, in part related to inclusion of asymptomatic pts. Herein, we investigate trends in overall survival (OS), including the Rituximab era, in a cohort of young symptomatic WM pts, seen at Mayo Clinic over 5 decades. **Methods:** Of 1181 pts with WM seen consecutively between 1960 and 2013, 127 (11%) were ≤ 50 years (y) at diagnosis, and 123 of those received therapy. Pts were categorized into 3 equal year groups based on the timing of initiation of therapy: Group 1 (1960-77), Group 2 (1978-95) and Group 3 (1996-2013), and their OS was analyzed using the Kaplan Meier method. We also compared their outcomes with a cohort of pts, ≥ 65 y and matched (1:1) by the timing of diagnosis. **Results:** Follow-up from initiation of therapy was similar in the 2 cohorts (median: 10.8 y in young vs 10.4 y in control arm). The median OS from initial therapy was 15 y (95% CI 13-18) for the young compared to 7.3 y (CI 5-8) for the control arm. In the young pts, 92% of deaths with known causes were WM related compared to 59% in control arm (p = 0.0004). While there was no significant OS difference observed with the use of Rituximab-based initial therapy in the young [median 11.4 y (CI 6–NR*) versus 15.6 y (CI 13-21) for all other therapies; p = 0.13], the control arm showed superior OS for pts who received Rituximab based initial therapy [median 9.1 y (CI 7-NR) vs 5.8 y (CI 5-8) for other therapies; p = 0.03]. Among young pts, there was no OS improvement from initial therapy across the 3 groups (p = 0.47) while the OS trends for the controls showed improvement across the 3 groups (p = 0.002; Table). **Conclusions:** Survival of young pts with WM remains unchanged over the past 5 decades. In contrast to the patients aged ≥ 65,Rituximab use did not translate to improved survival in young pts.

Parameter	Young Pts	Control
Median Age (Range)	44 y (30-50)	73 y (65-85)

Outcomes of primary plasmacytoma (PP) in United States (US). *First Author: Guru Subramanian Guru Murthy, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Studies on multiple myeloma demonstrate an improvement in overall survival (OS) and increased risk of second primary malignancy (SPM); Population level data on OS and the risk of SPM in primary plasmacytoma (PP) is sparse. Hence, we aimed to determine the trends in OS and SPM in patients with PP in US. **Methods:** The Surveillance, Epidemiology and End Results (SEER-13) database was used to identify patients with age > 20, diagnosed with solitary plasmacytoma of bone (SPB) or extramedullary plasmacytoma (EMP) (ICD-O-3 codes –9731, 9734) as the first primary malignancy between 1992 to 2011. OS analysis was performed using Kaplan-Meier method and compared by log rank test. SPM was identified using SEERstat software (version 8.1.5) with a latency period of 6 months from radiotherapy (RT). Multivariate analysis of OS was performed using Cox proportional hazard regression method. **Results:** 2064 patients with SPB/EMP had a median age of 62 years (range 20-96). Baseline characteristics included 63.6% males, 54.2% with age > 60, 79.2% Whites, 14% African americans and 6.8% other races. About 48.4% of patients received RT alone, 23.5% had surgery and RT, 10.5% had surgery and 17.6% did not receive surgery or RT. OS at 10 years was higher in patients with age < 60 vs. age > 60 (62.5% vs. 22.2%, p < 0.01) and for other races vs. Whites vs. African americans (51.1% vs. 40.1% vs. 34.5% respectively, p = 0.01). Use of RT and surgery resulted in better 10-year OS (51.2%) than surgery alone (44.1%), RT alone (39.8%) or no RT/surgery (21.2%) (p < 0.01).On multivariate analysis, age > 60 (HR 3.01, 95% CI 2.61-3.46; p < 0.01), Whites vs. other races (HR 1.35, 95% CI 1.02-1.77; p = 0.03) and African americans vs. other races (HR 1.52, 95% CI 1.11-2.08; p < 0.01) predicted worse OS, whereas the use of RT along with surgery Vs. RT alone (HR 0.82, 95% CI 0.70-0.97; p = 0.02) predicted better OS. Patients treated with RT had more SPM as compared to general population- all sites standardized incidence ratio (SIR) 1.49, with more leukemia/lymphoma (SIR 6.37) and bone tumors (SIR 19.93) (p < 0.05). **Conclusions:** Our study demonstrates that the use of RT and surgery for PP significantly improves the OS, despite an increased risk of SPM with RT. Our study also shows a significant racial disparity in the long-term OS of PP.

8598 Poster Session (Board #417), Sun, 8:00 AM-11:30 AM

A national study on conditional survival and excess mortality after high dose therapy with autologous stem cell transplantation for non-Hodgkin lymphoma. *First Author: Knut BjÃ„ro Smeland, National Advisory Unit on Late Effects, Department of Oncology, Oslo University Hospital, Oslo, Norway*

Background: The aim of this study was to investigate conditional survival and standardized mortality ratios (SMR) after high-dose therapy with autologous stem-cell transplantation (HDT) for non-Hodgkin lymphoma (NHL) in a national population-based cohort, and to analyse cause of death and incidence of second malignancies. **Methods:** All patients ≥ 18 years treated with HDT for NHL in Norway 1987-2008 were included (n =578). Information about cause of death from Statistics Norway and second malignancies from Cancer Registry of Norway were linked with clinical data. Treatment related mortality (TRM) was defined as death from a complication to HDT in tumour free patients. Observation time was estimated from HDT to death or cut-off at June 30th 2014 (median 6.7 years, range 0-27). Data on second cancer was available until end of 2012. **Results:** The 10- and 15-year overall survival (OS) was 52% (95%CI 48%-56%) and 49% (95%CI 44%-53%). Conditional 5-year OS are shown in the table. SMR was 12.3 (95% CI 11.0-13.9) for the entire cohort and 4.9 (95% CI 4.1-5.9), 2.4 (95% CI 1.8-3.2) and 1.0 (95% CI 0.6-1.8) for patients having survived 2, 5 and 10 years after HDT respectively. Among 281 deaths the underlying causes were NHL (n = 216, 77% of deaths), TRM (n = 21, 7%), second cancers (n = 20, 7%), cardiovascular disease (n = 8, 3%), infections (n = 6, 2%), pulmonary disease (n = 5, 2%) and others/missing (n = 5). Second malignancy after HDT was diagnosed in 38 (6.6%) (non-melanoma skin excluded), including 15 leukaemia/myelodysplastic syndrome. **Conclusions:** The conditional OS improved for each additional year survived after HDT. NHL-patients undergoing HDT had 12-fold increased mortality compared to the general population, but only 2-fold conditioned on having survived 5-years. After 10 years the mortality risk was no longer elevated. TRM and second cancers are the most common non-relapse related causes of death.

TPS8599 Poster Session (Board #418a), Sun, 8:00 AM-11:30 AM

A randomized, double-blind, placebo-controlled, phase 3 study of rituximab with or without ibrutinib for Waldenstrom's macroglobulinemia (PCYC-1127-CA). *First Author: Meletios A. Dimopoulos, Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece*

Background: Current treatments for Waldenstrom's macroglobulinemia (WM) are not curative, and a standard of care does not exist. A highly recurrent somatic mutation in WM, *MYD88 L265P*, signals through interleukin-1 receptor-associated kinase 1 and Bruton's tyrosine kinase (BTK) to mediate the constitutive activation of the NF-κB pathway (Yang, 2013). Ibrutinib (ibr), an oral inhibitor of BTK, impairs crosstalk between MYD88 and BTK, and blocks BTK dependent downstream signaling within the B-cell receptor pathway inducing apoptosis of WM cells (Treon, 2012).Thus, ibr offers a novel therapeutic approach for pts with WM. Pts with previously treated WM receiving different ibr doses achieved durable responses in a phase (Ph) 1 study (Advani, 2013). This was confirmed in a Ph 2 trial of ibr 420 mg daily (overall response rate [ORR] of 87%; Treon, 2014) leading to the first FDA approval in WM. Ibr + rituximab (rtx) showed activity and tolerability in high-risk CLL and MCL. This Ph 3 study evaluates the safety and efficacy of ibr + rtx vs. placebo + rtx in pts with WM. **Methods**: Approximately 150 pts will be randomized in a 1:1 ratio to receive rtx 375 mg/m^2 IV weekly for 4 weeks, followed by a second 4-weekly rtx course 3-months later, and either ibr 420 mg daily or matching placebo until progressive disease (PD) or unacceptable toxicity. Key inclusion criteria include WM with documented PD or no response (stable disease) to last treatment if previously treated; symptomatic disease requiring treatment per the 2nd International Workshop on WM; and adequate hematologic, hepatic, and renal function. Exclusion criteria include CNS involvement and clinically significant cardiovascular disease. Pts refractory to the last rtx-containing therapy excluded from the randomized study are eligible for the open-label single-agent ibr substudy (n = 30). The primary endpoint is progression-free survival assessed by an independent review committee. Secondary endpoints are ORR, overall survival, hematologic improvement, time to next treatment, and safety. Pts in the control arm may receive single-agent ibr after confirmation of PD. Enrollment began in July 2014 (NCT02165397). Clinical trial information: NCT02165397.

TPS8600 Poster Session (Board #418b), Sun, 8:00 AM-11:30 AM

Randomized, phase III trial of the efficacy and safety of lenalidomide plus R-CHOP vs R-CHOP in patients with untreated ABC-type diffuse large B-cell lymphoma. *First Author: Grzegorz S. Nowakowski, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: The activated B-cell like subtype (ABC) of diffuse large B-cell lymphoma (DLBCL) is associated with inferior PFS and OS with R-CHOP-based chemotherapy. Lenalidomide demonstrated significant single agent activity in relapsed/refractory DLBCL, predominantly in ABC-type DLBCL. In first line therapy, lenalidomide + R-CHOP (R2-CHOP) showed improved efficacy over R-CHOP historical controls in two independent single arm phase II trials from Mayo Clinic and Fondazione Italiana Linfomi groups. R2-CHOP appears primarily to improve outcomes in ABC-type DLBCL. The objective of this multicenter, international trial is to compare the efficacy and safety of lenalidomide–R-CHOP (R2-CHOP) vs placebo–R-CHOP in patients with previously untreated ABC-type DLBCL. **Methods**: In this phase III placebo-controlled, double-blinded trial (DLC002; NCT02285062), patients with ABC-type DLBCL are randomized 1:1 to oral lenalidomide (15 mg, days 1-14/21-day cycle) plus standard-dose R-CHOP or placebo–R-CHOP, every 21 days for 6 cycles $\pm$ 2 additional doses of rituximab until PD, intolerability, inadequate response, or withdrawal of consent. Key eligibility criteria include previously untreated, histologically confirmed ABC-type CD20+ DLBCL (WHO classification), age 18-80 years, IPI score $\geq$ 2, Ann Arbor stage II-IV, and adequate organ function. ABC type will be determined by central pathology lab within 3 days by real-time gene expression profiling (GEP) using the NanoString nCounter Analysis System (Scott et al. *Blood.* 2014;123:1214-1217) on FFPE biopsy samples. Primary endpoint is PFS; secondary endpoints are EFS, OS, ORR, CR, duration of CR, time to next lymphoma therapy, and health-related QOL. Additional biological analyses for MRD detection are planned. Responses will be measured by 2007 IWG criteria with PET. Approximately 560 patients will be randomized during the estimated 34 month-accrual period. Enrollment began in January 2015, with expected accrual completion in October, 2017. To our knowledge, this is the first phase III trial in DLBCL using real time GEP to assess patient eligibility, thus allowing precision therapy of patients with DLBCL. Clinical trial information: NCT02285062.

TPS8601 Poster Session (Board #419a), Sun, 8:00 AM-11:30 AM

A phase III study of ibrutinib in combination with either bendamustine and rituximab (BR) or rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) in patients with previously treated follicular lymphoma or marginal zone lymphoma. *First Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Follicular lymphoma (FL) and marginal zone lymphoma (MZL) are indolent non-Hodgkin lymphomas (iNHL) and account for approximately 22% and 10%, respectively, of all NHLs. Although patients (pts) often respond to initial therapy, most relapse and suffer substantial morbidity and mortality related to persistence/recurrence of disease. For pts with relapsed iNHL, the most common chemoimmunotherapy regimens are BR and R-CHOP; however, outcomes in the relapsed setting remain suboptimal. Ibrutinib is an oral Bruton's tyrosine kinase (BTK) inhibitor that has demonstrated activity in a phase 1 study in pts with various B-cell malignancies, including iNHL. A phase 2 monotherapy study in chemoimmunotherapy-resistant FL is ongoing. Other studies have demonstrated that ibrutinib can be safely combined with BR or R-CHOP. Based on these observations, this phase 3 trial has been designed to investigate the combination of ibrutinib with BR or R-CHOP in pts with iNHL. **Methods:** The SELENE study, PCI32765FLR3001, is a randomized, double-blind, placebo-controlled, multicenter phase 3 study of ibrutinib combined with either BR or R-CHOP for previously treated FL or MZL. The study aims to enroll approximately 400 pts with disease that has relapsed, or was refractory to, prior chemoimmunotherapy. All pts will receive 6 cycles of BR or R-CHOP (based on prior treatment) and either daily oral 560 mg ibrutinib or placebo continued up to progression. The primary objective is to evaluate whether the addition of ibrutinib to BR or R-CHOP will prolong progression-free survival; secondary objectives were evaluation of OS, CR rate, ORR, patient-reported lymphoma symptoms, and safety. Exploratory objectives include minimal residual disease negative rate in FL pts, patient-reported outcomes related to general health status, and the pharmacokinetics of ibrutinib. Approximately 145 sites in Europe, Asia, Australia, USA and South America will participate. Enrollment began in Q1 2014. As of January 8, 2015, 163 pts have been randomized across 76 sites in 16 countries. Clinical trial information: NCT01974440.

TPS8602 Poster Session (Board #419b), Sun, 8:00 AM-11:30 AM

A phase I study with an expansion cohort of the combination of ipilimumab and brentuximab vedotin in patients with relapsed/refractory Hodgkin lymphoma: A trial of the ECOG-ACRIN Cancer Research Group (E4412). *First Author: Catherine S. Magid Diefenbach, New York University Perlmutter Cancer Center/New York University School of Medicine, New York, NY*

Background: E4412 is a phase 1 study with an expansion cohort of the combination of brentuximab vedotin (BV) and ipilumumab in patients with relapsed and refractory Hodgkin lymphoma (HL). Despite advances in chemotherapy, relapsed HL remains a significant problem, with over 1,000 lives lost annually. HL has a unique biology in which a small number of malignant Hodgkin Reed-Sternberg (HRS) cells propagate an immunosuppressive microenvironment. In E4412 the peri-tumoral T cells are primed with ipilimumab and the HRS cells targeted with the CD30 specific antibody-drug conjugate BV. We hypothesize that this immuno-chemotherapy approach may overcome tumor cell resistance and deepen clinical response. E4412 is the first clinical trial targeting the HL tumor microenvironment in conjunction with HRS tumor cell targeting. **Methods:** E4412 is currently open at 7 sites within ECOG. A modified 3+3 dose escalation design is used; 6 patients are tested at each dose level if no more than one DLT is observed in the first 3 patients. All DLT are evaluated within the first cycle (1 cycle = 21 days). The primary endpoint is the maximum tolerated dose (MTD) of the combination. Secondary endpoints include complete response (CR) rate, partial response (PR) rate, overall response (ORR) rate, duration of response (DOR), overall survival (OS) and progression-free survival (PFS). Response rates are reported along 95% confidence intervals. DOR, PFS and OS are estimated using Kaplan-Meier methodology. BV is given at 1.8mg/kg and ipilimumab at 1mg/kg (cohort 1) and 3mg/kg (cohort 2) every 21 days for 4 cycles. From cycle 5 BV is given q 21 days, and ipilimumab on cycles 8, 12, and 16. Once the MTD is established, 9 patients are treated in an expansion cohort with BV at 1.8mg/kg and ipilumumab at MTD. Eligibility Criteria include: age $>$ 18, relapsed HL, measurable disease, no prior relapse on BV, no active GVHD or immunosuppressive therapy, ECOG 0-2, FEV1/FVC $>$ 60%, hematology and chemistry labs within standard parameters, no uncontrolled systemic illness. Cohorts I and II have been completed. Expansion cohort enrollment opened on February 3rd, 2015. Clinical trial information: NCT01896999.

TPS8603 Poster Session (Board #420a), Sun, 8:00 AM-11:30 AM

AUGMENT: A randomized, phase 3 trial in patients with relapsed/refractory (R/R) indolent non-Hodgkin lymphoma (iNHL) to compare efficacy and safety of lenalidomide plus rituximab (R^2) versus placebo plus rituximab. *First Author: John Leonard, Weill Cornell Medical College - New York Presbyterian Hospital, New York, NY*

Background: The immunomodulatory drug, lenalidomide (Revlimid), has both anti-inflammatory and antiangiogenic properties. In preclinical studies, the immunological function of tumor-infiltrating lymphocytes is reduced in patients with follicular lymphoma (FL); lenalidomide can restore this response (Ramsay, *Blood*, 2009). In a phase 2 trial of frontline lenalidomide + rituximab (R^2), the overall response rate (ORR) reached 90% (Fowler, *Lancet Oncol*, 2014) in iNHL patients; in a second study, patients with FL achieved 93% ORR (Martin, ICML, 2013). After treatment with R^2 in phase 2 investigations, patients with R/R iNHL achieved clinical responses: ORRs of 73% (36% complete response [CR]) in R/R FL (Leonard, ASCO 2012 oral presentation), and 80% (55% CR) in marginal zone lymphoma (MZL; Raderer, EHA 2014 oral presentation) patients. Based on the results of these preclinical and phase 2 studies, further investigation of R^2 in iNHL is warranted. **Methods:** This multicenter, double-blind, phase 3, randomized study (AUGMENT) is designed to evaluate the efficacy and safety of R^2 versus placebo + rituximab (P+R) in patients with R/R iNHL. Eligibility criteria for patients include: grade 1, 2, or 3a FL or MZL; previous treatment with systemic therapy; considered refractory to or relapsed after last treatment; rituximab-sensitivity if prior rituximab therapy was administered; presentation of $\geq$ 1 measurable lesion; and adequate function in bone marrow, liver, and kidneys. An estimated 350 patients will be randomized 1:1 to either experimental or control groups. Patients enrolled in the R^2 experimental study arm will receive lenalidomide (20 mg/day; days 1 to 21 up to 12 cycles) + rituximab (375 mg/m^2; days 1, 8, 15, 22 of cycle 1 and day 1 of cycles 2 to 5) in 28-day cycles. Patients in the control study arm will receive P+R (375 mg/m^2) following the same schedule. Progression-free survival is the primary endpoint, and key secondary endpoints will include rate of durable CR, overall survival, ORR, safety, and time to next anti-lymphoma treatment. Patients are currently being enrolled for this trial (NCT01938001). Clinical trial information: NCT01938001.

TPS8604 **Poster Session (Board #420b), Sun, 8:00 AM-11:30 AM**

Phase I/II study of intratumoral injection of SD-101, an immunostimulatory CpG, and intratumoral injection of ipillumumab, an anti-CTLA-4 monoclonal antibody, in combination with local radiation in low-grade B-cell lymphomas. *First Author: Michael Siavash Khodadoust, Stanford University, Stanford, CA*

Background: Immunotherapy is a promising treatment modality for low grade non-Hodgkin's lymphomas. SD-101 (Dynavax Technologies) is an immunostimulatory synthetic CpG molecule that activates toll-like receptor 9. Intratumoral CpG injection produced local and abscopal anti-lymphoma immune responses with minimal systemic toxicity in an early phase clinical trial (Brody J et al. J Clin Oncol. 2010). Resistance to CpG is thought to be due to the induction of immune tolerance following an initial immune stimulation. Ipilimumab (Bristol-Myers Squibb) is a monoclonal anti-CTLA-4 antibody that interrupts inhibitory signaling on the surface of T cells, thus blocking the development of immune tolerance. Preclinical models show intratumoral injection of anti-CTLA-4 antibodies can produce systemic anti-tumor immune responses at a fraction of the standard systemic dose, thereby limiting adverse autoimmune side effects. This trial proposes a local low-dose immunomodulation strategy combining intratumoral CpG, intratumoral ipilimumab, and local radiation to produce systemic immune responses with minimal toxicity. **Methods:** Up to 12 patients will be enrolled in the phase 1 dose escalation design to determine maximum tolerated dose of intratumoral ipilimumab with a set dose of SD-101, and an additional 15 patients will be enrolled in the phase II expanded cohort at the chosen ipilimumab dose. All patients initially receive two fractions of 2 Gy radiation. After radiation, patients receive intratumoral SD-101 (1mg) and ipilimumab (10mg or 25mg depending on dose cohort). Weekly SD-101 intratumoral injections continue for a total of 5 doses. The primary objective is to determine the safety and tolerability of increasing dose levels of intratumoral ipilimumab with SD-101. Eligible patients must have relapsed/refractory low grade B-cell lymphoma with a disease site amenable to intratumoral injection and a second measurable disease site to assess abscopal effects. This study is currently accruing and is supported by a grant from the NIH (CA188005). Clinical trial information: NCT02254772. Clinical trial information: NCT02254772.

TPS8605 **Poster Session (Board #421a), Sun, 8:00 AM-11:30 AM**

Phase III trial of brentuximab vedotin and CHP versus CHOP in the frontline treatment of patients (pts) with CD30+ mature T-cell lymphomas (MTCL). *First Author: Owen A. O'Connor, Columbia University Medical Center, New York Presbyterian Hospital, New York, NY*

Background: MTCL including systemic anaplastic large cell lymphoma (sALCL) are aggressive neoplasms. Anthracycline-based multiagent chemotherapy regimens have demonstrated response rates ranging from 76 to 88%. Five-year overall survival rates range from 12 to 49% depending on the histologic subtype. Brentuximab vedotin is an antibody drug conjugate that has shown efficacy in a pivotal phase II study as a single agent in relapsed sALCL (Pro et al., J Clin Oncol, 2012) and evidence of clinical activity in combination with CHP in the frontline treatment of MTCL including sALCL in a phase I study (Fanale et al., ASH 2012). **Methods:** This randomized, double-blind, placebo-controlled, multicenter, phase III study (NCT01777152) is evaluating the safety and efficacy of 1.8 mg/kg brentuximab vedotin with CHP (A+CHP) vs CHOP for frontline treatment of CD30+ MTCL. Pts must have FDG-avid disease by PET and measureable disease of at least 1.5 cm by CT. Approximately 300 pts will be randomized 1:1 to receive A+CHP or CHOP for 6–8 cycles (q3wk). Randomization will be stratified by ALK+ sALCL vs other histologic subtypes and IPI score (0–1, 2–3, or 4–5). The target proportion of pts with a diagnosis of sALCL will be 75%. The primary objective is to compare progression-free survival (PFS) between the 2 treatment arms as determined by an independent review facility (IRF). Secondary objectives include comparisons of PFS per IRF in sALCL patients, safety, overall survival, and complete remission rate between the 2 arms. After completion of treatment, pts will be followed for disease progression, medical resource utilization, quality of life, and survival. Post-treatment stem cell transplant is permitted. Efficacy assessments will use the Revised Response Criteria for Malignant Lymphoma (Cheson 2007). CT and PET scans will be performed at baseline, after Cycle 4, and after the completion of treatment. CT scans will also be performed at regular intervals during follow-up until disease progression, death, or analysis of the primary endpoint. Safety assessments will occur throughout the study until 30 days after last dose of study treatment. Enrollment for this global trial began in early 2013. Clinical trial information: NCT01777152.

TPS8606 **Poster Session (Board #421b), Sun, 8:00 AM-11:30 AM**

MAGNIFY: A randomized, phase 3b trial in patients with relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL) investigating lenalidomide plus rituximab (R^2) induction followed by maintenance R^2 followed by lenalidomide versus R^2 induction followed by rituximab (R) maintenance. *First Author: David Jacob Andorsky, Rocky Mountain Cancer Centers, Boulder, CO*

Background: Combination of the immunomodulatory agent lenalidomide (Revlimid) with rituximab (R^2) is a promising therapeutic option for patients with R/R NHL. As frontline therapy, R^2 provided a 90% overall response rate (ORR) in patients with follicular lymphoma (FL), marginal zone lymphoma (MZL) and small lymphocytic lymphoma (Fowler, *Lancet Oncol*, 2014) and 89% ORR in MCL patients (Ruan, ASH, 2014). In phase 2 trials of R^2, patients with R/R MZL, FL, and MCL achieved ORRs of 80% (55% complete response [CR]), 73% (36% CR), and 57% (36% CR), respectively (Raderer, EHA, 2014; Leonard, ASCO, 2012; Wang, *Lancet Oncol*, 2012). These trials support further investigation of R^2 therapy in R/R NHL. **Methods:** The efficacy and safety of 12 cycles of combination R^2 for induction with randomization to R^2 (Arm A) vs R (Arm B) maintenance will be compared in R/R FL, MCL, or MZL patients as part of the phase 3b MAGNIFY trial. Approximately 500 patients will be randomized 1:1 to 28-day (d) treatment cycles (C). Both patient groups will receive R^2 induction with lenalidomide (20 mg/d on d 1-21; 12 C) + R (375 mg/m^2 on d 1, 8, 15, 22 in C1; d1 of C 3, 5, 7, 9, 11). Patients in Arm A will receive R^2 maintenance with lenalidomide (10 mg/d on d 1-21; C 13-30) + R (375 mg/m^2 on d1 of every other C from 13 to 29), followed by lenalidomide (10 mg/d on d 1-21) until progression. Following 12 cycles of induction with R^2, patients in Arm B will receive maintenance R (375 mg/m^2 on d1 of every other C from 13 to 29). Eligibility criteria include R/R FL grades 1-3b, transformed FL, MZL, or MCL; previous systemic therapy; $\geq$ 1 measurable lesion; and adequate bone marrow, liver, and renal function. Progression-free survival is the primary endpoint. Secondary endpoints include rate of CR/CR unconfirmed (CRu), overall survival, ORR, duration of response, duration of CR/CRu, and safety. An exploratory endpoint, health-related quality of life will be measured using the FACT-Lym questionnaire. The MAGNIFY trial is currently enrolling; 38 patients have been enrolled as of January 30, 2015 (NCT01996865). Clinical trial information: NCT01996865.

TPS8607 **Poster Session (Board #422a), Sun, 8:00 AM-11:30 AM**

A phase 2 trial of INCB040093 alone or in combination with INCB039110 in patients (pts) with relapsed or refractory (r/r) classical Hodgkin lymphoma (cHL). *First Author: Paul M. Barr, University of Rochester Medical Center, Rochester, NY*

Background: In vitro data suggest that both the PI3K and JAK-STAT pathways contribute to tumor growth and survival in HL. Therapies that block both pathways may prove more beneficial in pts with r/r cHL, where treatment options are limited. INCB040093 is an oral PI3Kδ inhibitor and INCB039110 is an oral JAK1-selective inhibitor. **Methods:** This ongoing, nonrandomized, open-label trial has a planned enrollment of 122 pts (61 per treatment arm). Eligible pts are $\geq$ 18 years of age with r/r cHL after autologous stem cell transplant (SCT) and/or after $\geq$ 2 prior chemotherapy-containing regimens who are not candidates for autologous SCT; have fluorodeoxyglucose-avid disease; ECOG performance status 0 to 2; prior brentuximab vedotin (BV) treatment (or not a candidate for BV). Pts who received prior treatment with an immune checkpoint inhibitor are eligible if disease progression or relapse is confirmed with a second assessment $\geq$ 28 days later. Pts must have adequate ANC, platelet count, hemoglobin, total bilirubin, AST and ALT levels. Before first dose of study drug, pts must not have investigational agents within 28 days or 5 half-lives (whichever is greater); autologous SCT within 28 days or allogeneic SCT within 3 months; or radiation treatment within 3 weeks. Pts will receive INCB040093 100 mg bid monotherapy or INCB040093 100 mg bid with INCB039110 300 mg qd. Pts receiving benefit may continue on therapy until they meet treatment discontinuation criteria. Pts receiving INCB040093 monotherapy who experience disease progression or relapse on study may be eligible for crossover to combination therapy. The primary endpoint is objective response rate per the Lugano Classification (Cheson et al. J Clin Oncol 2014) determined by an independent review committee. Secondary endpoints include duration of response and progression-free survival. Overall survival is an exploratory endpoint. Final analysis is planned when all pts reach at least the Week 36 disease evaluation. Clinical trial information: EudraCT 2014-005631-13.

TPS8608 Poster Session (Board #422b), Sun, 8:00 AM-11:30 AM

A randomized open-label study of bortezomib, melphalan, and prednisone (VMP) versus daratumumab (DARA) plus VMP in patients with previously untreated multiple myeloma (MM) who are ineligible for high-dose therapy: 54767414MMY3007 (Alcyone). *First Author: María-Victoria Mateos, University Hospital of Salamanca/IBSAL, Salamanca, Spain*

Background: Based on the results of the VISTA study (San Miguel JF et al. NEJM 2008), VMP is considered a standard of care for newly diagnosed patients with MM not considered suitable for high-dose chemotherapy and stem cell transplantation (SCT). DARA is a human anti-CD38 IgG1κ monoclonal antibody in clinical development for MM. DARA has shown promising efficacy and a favorable safety profile in ongoing phase I/II studies as monotherapy and in combination with chemotherapy (lenalidomide/dexamethasone) in patients with relapsed or relapsed, refractory MM (Lokhorst HM et al. ASCO 2014; Plesner T et al. ASH 2014) as well as in combination with VMP in newly diagnosed MM (Moreau P et al. ASH 2014). **Methods:** This is a phase III randomized, open-label, multicenter study of VMP versus DARA + VMP in patients aged $\geq$ 18 y with previously untreated MM who are ineligible for high-dose therapy. Main inclusion criteria are documented MM satisfying the CRAB criteria, measurable disease, and newly diagnosed and not considered a candidate for high-dose chemotherapy with SCT. Approximately 700 eligible patients will be stratified by International Scoring System, region (Europe vs others), and age ($<$ 75 vs $\geq$ 75 y) and randomized in a 1:1 ratio to VMP or DARA + VMP. All patients will receive up to 9 cycles (1 cycle = 6 wk) of VMP (bortezomib 1.3 mg/m^2 SC twice weekly [Weeks 1, 2, 4, and 5] in Cycle 1, then once weekly [Weeks 1, 2, 4, and 5] in Cycles 2-9; melphalan 9 mg/m^2 and prednisone 60 mg/m^2 PO Day 1-4 of each cycle). Patients in the DARA + VMP arm will receive DARA 16 mg/kg IV weekly x 6 wk (Cycle 1), then every 3 wk for Cycles 2-9; patients will then continue to receive DARA every 4 wk until progression. The primary endpoint is progression-free survival (PFS). An Independent Data Monitoring Committee will conduct reviews of the efficacy and safety data. The primary analysis will occur when approximately 360 PFS events have been observed. Approximately 200 sites in 24 countries will participate. The first patient was enrolled in January 2015. Clinical trial information: NCT02195479.

TPS8609 Poster Session (Board #423a), Sun, 8:00 AM-11:30 AM

Twin randomized studies of daratumumab (DARA; D) plus standard of care (lenalidomide/dexamethasone or bortezomib/dexamethasone [DRd or DVd]) versus Rd or Vd alone in relapsed or refractory multiple myeloma (MM): 54767414MMY3003 (Pollux) and 54767414MMY3004 (Castor). *First Author: Antonio Palumbo, Department of Hematology, University of Torino, Torino, Italy*

Background: Lenalidomide or bortezomib plus low-dose dexamethasone are considered standard of care for relapsed/refractory MM patients. DARA is a human anti-CD38 IgG1κ monoclonal antibody. In ongoing phase I/II studies, DARA (16 mg/kg) has shown promising efficacy and safety as a single agent (overall response rate (ORR) 35%; Lokhorst HM et al. ASCO 2014), in combination with Rd (ORR 87%; Plesner T et al. ASH 2014), as well as in combination with Vd (ORR 100 %; Moreau P et al. ASH 2014). **Methods:** MMY3003 and MMY3004 are phase III randomized, open-label, multicenter studies for patients with relapsed/refractory MM. For both studies, the main inclusion criteria are documented MM after one or more prior line of therapy, and documented evidence of progressive disease. In MMY3003, approximately 560 patients will be randomized in a 1:1 ratio to DRd (DARA 16 mg/kg IV weekly x 8 wk, every 2 wk x 16 wk, every 4 wk thereafter; lenalidomide 25 mg PO Days 1-21 of each 28-day cycle; dexamethasone 40 mg weekly) or Rd and stratified by International Staging System (ISS), number of prior lines (1 vs 2 or 3 vs $>$ 3), and prior lenalidomide exposure. In MMY3004, approximately 480 subjects will be randomized in a 1:1 ratio to DVd (DARA 16 mg/kg IV weekly x 3 cycles, Day 1 of Cycles 4-9, every 4 wk thereafter; bortezomib 1.3 mg/m^2 SC Days 1, 4, 8, and 11 of each 21-day cycle; dexamethasone 80 mg weekly) or Vd and stratified by ISS, number of prior lines (1 vs 2 or 3 vs $>$ 3), and prior bortezomib exposure. The primary endpoints for MMY3003 and MMY3004 are progression-free survival (PFS). An Independent Data Monitoring Committee (IDMC) will review data every 6 months for safety and at 2 predetermined interim analyses for both studies. First patients were dosed June/September 2014 (MMY3003/MMY3004). The primary analysis in each study will occur after 295 PFS events have been observed. Clinical trial information: NCT02076009 and NCT02136134.

TPS8610 Poster Session (Board #423b), Sun, 8:00 AM-11:30 AM

MM-007: A phase 3 trial comparing the efficacy and safety of pomalidomide (POM), bortezomib (BORT), and low-dose dexamethasone (LoDEX [PVD]) versus BORT and LoDEX (VD) in subjects with relapsed or refractory multiple myeloma (RRMM). *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: Combination treatment (Tx) with immunomodulatory agents and proteasome inhibitors can provide deep and durable responses in patients (pts) with RRMM (Richardson, *Blood,* 2013). PVD showed promising activity and was well tolerated in a Ph 1 dose-escalation study (Richardson, ASCO, 2014). MM-007 is a global, multicenter, randomized, open-label Ph 3 trial designed to compare efficacy and safety of PVD vs VD in pts with RRMM (target enrollment: 782 pts; NCT01734928). **Methods:** Pts must have received 1-3 prior lines of anti-MM Tx, including $\geq$ 2 consecutive cycles (C) of a lenalidomide-containing regimen. Exclusion criteria include refractory to prior BORT 1.3 mg/m^2 twice weekly, ANC $<$ 1000/μL, platelet count $<$ 75,000/μL ($<$ 30,000/μL for pts with $\geq$ 50% bone marrow plasma cells), CrCl $<$ 30 mL/min requiring dialysis, hemoglobin $<$ 8 g/dL, and peripheral neuropathy $\geq$ grade 2. Pts will be randomized 1:1 to continuous Tx with PVD or VD q3w until progression or unacceptable toxicity. PVD (arm A): POM 4 mg on D1-14; BORT SC 1.3 mg/m^2 on D1, 4, 8, 11 for C1-8, D1, 8 for C9+; and D 20 mg (10 mg for pts $>$ 75 y) on D1, 2, 4, 5, 8, 9, 11, 12 for C1-8, D1, 2, 8, 9 for C9+. VD (arm B): BORT and D same as arm A. Thromboprophylaxis with low-dose aspirin or equivalent is required for pts treated with PVD (VD if prior history of deep vein thrombosis or pulmonary embolism). The primary endpoint is progression-free survival (PFS). Secondary endpoints are overall survival (OS), safety, overall response rate by modified IMWG criteria, and duration of response. Exploratory endpoints include evaluation of PFS2, clinical benefit rate, PK, and HRQOL. Minimal residual disease, genomic, molecular/mechanistic, and immune biomarkers will be evaluated. Upon Tx discontinuation, follow-up will continue for subsequent anti-MM Tx, OS, and second primary malignancies. As of Jan 2015, 62 sites have opened in the US and 53 pts have been enrolled. Top enrolling US sites include Dana-Farber Cancer Inst, MA; UT SW Medical Ctr, TX; Gabrail Cancer Ctr, OH; and NW Georgia Oncology Ctr, GA. Sites are planned for Italy, Spain, France, and the rest of the world. Clinical trial information: NCT01734928.

TPS8611 Poster Session (Board #424a), Sun, 8:00 AM-11:30 AM

Denosumab compared with zoledronic acid for the treatment of bone disease in adults with newly diagnosed multiple myeloma: An international, randomized, double-blind trial. *First Author: Noopur S. Raje, Massachusetts General Hospital, Boston, MA*

Background: A characteristic feature of multiple myeloma (MM) is osteoclast-mediated breakdown of the bone. Patients with MM and bone lesions often experience debilitating pain and skeletal complications including pathologic fractures, need for radiotherapy or surgery to bone, and spinal cord compression, collectively termed skeletal-related events (SREs). RANKL is the key mediator of osteoclast activity. Denosumab, a fully human monoclonal antibody specific to RANKL, inhibits the formation, function, and survival of osteoclasts, thus decreasing cancer-mediated bone destruction. The primary endpoint of this trial is to determine whether denosumab is noninferior to zoledronic acid (ZA) in delaying the time to 1st on-study SRE in patients with MM. Secondary endpoints include superiority of denosumab vs ZA in delaying the time to 1st on-study SRE and time to 1st-and-subsequent SRE and overall survival. Safety endpoints will be assessed. This trial is registered (ClinicalTrials.gov NCT01345019) and sponsored by Amgen Inc. **Methods:** Targeted enrollment is ~1520 adults with newly diagnosed MM and $\geq$ 1 bone lesion receiving first-line treatment. Patients with $\leq$ 30 days of anti-myeloma therapy, $\leq$ 1 prior dose of IV bisphosphonate, an ECOG status $\leq$ 2, and adequate organ function are eligible. Use of any approved anti-myeloma treatment is permitted. Enrolled patients are stratified by whether they intend to undergo autologous stem cell transplant; use of novel vs non-novel anti-myeloma agents as first-line therapy; stage at diagnosis per the International Staging System (I, II, or III); SRE at time of presentation; and geographic region. Randomized (1:1) patients receive either SC denosumab 120 mg + IV placebo *or* IV ZA 4 mg (adjusted for CrCl) + SC placebo once every 4 weeks. Daily calcium ($\geq$ 500 mg) and vitamin D ($\geq$ 400 IU) supplements are strongly recommended. The primary analysis is planned when ~800 patients experience an on-study SRE. Enrollment is currently ongoing and enrollment rates are as planned.

TPS8612 Poster Session (Board #424b), Sun, 8:00 AM-11:30 AM

A multicenter, randomized, open-label, phase 2 study of carfilzomib with or without ARRY-520 (filanesib) in patients with advanced multiple myeloma. *First Author: Jeffrey A. Zonder, Karmanos Cancer Institute, Detroit, MI*

Background: Immunomodulatory agent (IMiD)/bortezomib (BTZ) combinations are common frontline therapy in patients with multiple myeloma (MM). Despite high initial objective response rates (ORR) and prolonged progression-free survival (PFS), almost all patients eventually relapse. Treatment for relapsed or refractory disease typically includes regimens that maintain IMiDs and/or proteasome inhibitors (PIs) as a foundation. Filanesib is a highly selective, targeted kinesin spindle protein (KSP) inhibitor that has shown promising preliminary activity and manageable toxicity as a single agent and in combination with dexamethasone, BTZ and carfilzomib (CFZ). Due to a distinct mechanism of action, filanesib demonstrates activity in patients with myeloma that has become resistant to IMiDs and PIs, potentially addressing a significant unmet medical need. **Methods:** This multicenter, randomized (2:1), open-label Phase 2 study is designed to assess the efficacy, safety and pharmacokinetics (PK) of CFZ ± filanesib in 75 patients with measurable MM who have received at least 2 prior treatment regimens (including BTZ and an IMiD) and have disease refractory to their last myeloma therapy (NCT01989325). Patients at community and academic centers in the United States are stratified by BTZ-refractory disease status and randomized to receive CFZ + filanesib (~50 patients) or single-agent CFZ (~25 patients) in continuous 28-day cycles until disease progression or unacceptable toxicity. CFZ (20/27 mg/m^2) is administered intravenously (IV) on Days 1, 2, 8, 9, 15 and 16. Filanesib is administered as 1.25 mg/m^2/day IV on Days 1, 2, 15 and 16 with prophylactic filgrastim. Crossover from single-agent CFZ to combination treatment is permitted upon confirmed disease progression. The primary endpoint is PFS; secondary endpoints include PFS rate at 6 months, ORR, duration of response, time to best response, clinical benefit rate, disease control rate, safety, and PK. No formal comparisons will be made between treatment arms. Exploratory measurements of alpha 1-acid glycoprotein (AAG), a potential predictive biomarker for filanesib treatment, will be performed. Clinical trial information: NCT01989325.

TPS8613 Poster Session (Board #425a), Sun, 8:00 AM-11:30 AM

The AfFIRM Study: A multicenter phase 2 study of single-agent filanesib (ARRY-520) in patients with advanced multiple myeloma. *First Author: Sagar Lonial, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA*

Background: An unmet medical need exists for patients (pts) with multiple myeloma (MM) whose disease has progressed despite prior exposure to immunomodulatory agents (IMiDs) and proteasome inhibitors (PIs), particularly if their disease has become refractory to carfilzomib (CFZ) and/or pomalidomide (POM). Filanesib is a highly selective, targeted kinesin spindle protein (KSP) inhibitor that has shown promising activity and a manageable safety profile as a single agent in heavily pretreated pts with MM. Due to a distinct mechanism of action, filanesib is expected to be active in cells that have become resistant to IMiDs and PIs, potentially addressing a significant unmet need in the treatment of patients with refractory MM. Nonclinical and prior clinical data have suggested that pts with high serum levels of α 1-acid glycoprotein (AAG) may not obtain therapeutic benefit from filanesib as a result of decreased unbound fraction of drug and ineffective therapeutic exposure. The correlation between Baseline AAG and clinical response to single-agent filanesib will be evaluated. **Methods:** This single-arm Phase 2 study is designed to assess the efficacy and safety of single-agent filanesib in ~160 pts with MM at centers in North America and Europe (NCT02092922). Eligible pts have received at least 2 prior lines of therapy; have received prior bortezomib and lenalidomide; and have disease refractory to CFZ and/or POM. Filanesib (1.50 mg/m^2/day) is administered intravenously on Days 1, 2, 15 and 16 in continuous 28-day cycles with prophylactic filgrastim until disease progression or unacceptable toxicity. Objective response is assessed by independent central review and classified per International Myeloma Working Group (IMWG) criteria. AAG is measured by a central laboratory using a validated immunoturbidimetric assay. The primary endpoint is objective response rate (ORR) in pts with low Baseline AAG. Secondary endpoints are ORR in pts with high Baseline AAG, duration of response, time to best response, clinical benefit rate, disease control rate, progression-free survival, time to next treatment, overall survival and safety. The study includes a 25-pt pharmacokinetics/QT substudy. Clinical trial information: NCT02092922.

TPS8614 Poster Session (Board #425b), Sun, 8:00 AM-11:30 AM

The VITAL study: A randomized, double-blind, placebo-controlled, global, phase III study of NEOD001 in patients with AL amyloidosis and cardiac dysfunction. *First Author: Michaela Liedtke, Stanford Comprehensive Cancer Center, Stanford, CA*

Background: Light chain (AL) amyloidosis is a rare disease caused by the deposition of misfolded proteins that cause dysfunction of vital organs (eg, heart and kidneys). There are no approved therapies. Current therapeutic approaches target the plasma cells that produce the pathogenic light chain proteins and are typically associated with significant adverse effects. Therefore, there is a substantial need for a safe and effective therapy that specifically targets the misfolded light chain proteins responsible for the underlying organ dysfunction. NEOD001 is a monoclonal antibody that targets these misfolded proteins, and it is hypothesized to neutralize circulating soluble protein aggregates and clear insoluble aggregates from organs. In an ongoing phase I/II study in 27 patients with AL amyloidosis and persistent organ dysfunction, NEOD001 was safe and well tolerated, with monthly infusions producing meaningful decreases in cardiac and renal biomarkers by best response. Supported by these positive results, the current study (VITAL; NCT02312206) is a randomized, double-blind, placebo-controlled, phase III trial of NEOD001 in patients with AL amyloidosis and cardiac dysfunction. **Methods:** Eligible patients with a diagnosis of AL amyloidosis (newly diagnosed and treatment naive) with cardiac dysfunction (N-terminal pro-brain natriuretic peptide [NT-proBNP] 650-8500 pg/mL) will be randomly assigned to receive NEOD001 (24 mg/kg q28d) or placebo. Concurrent anti-plasma cell therapy will be allowed in both arms. The primary end point is a composite evidence-based measure consisting of all-cause mortality or cardiac hospitalization. Secondary end points include NT-proBNP response, time to cardiac mortality or cardiac hospitalization, change in the 6-minute walk test, change in the Short Form-36 (SF-36) Questionnaire and Kansas City Cardiomyopathy Questionnaire (KCCQ), and renal and hepatic response. The study has 90% power to detect a $\geq$ 30% difference in events between treatment groups. An interim analysis for efficacy or futility is planned. Estimated enrollment is 236 patients. The VITAL phase III trial has commenced. Clinical trial information: NCT02312206.

9000 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Oral nicotinamide to reduce actinic cancer: A phase 3 double-blind randomized controlled trial. *First Author: Andrew James Martin, NHMRC Clinical Trials Centre, University of Sydney, Sydney, Australia*

Background: Nicotinamide (vitamin B3) enhances DNA repair and prevents cutaneous immune suppression after ultraviolet (UV) radiation exposure. It reduces photocarcinogenesis in mice, and human non-melanoma skin cancers (NMSC) in Phase 2 clinical trials. We report the outcomes of the Phase 3 Oral Nicotinamide to Reduce Actinic Cancer (ONTRAC) Study. **Methods:** ONTRAC was a double-blind RCT conducted in two tertiary treatment centers in Sydney, Australia from 2012-2014. 386 immune competent participants with ≥ 2 histologically-confirmed NMSC in the past 5 years were randomized (1:1) to oral nicotinamide 500mg bd (NIC) or matched placebo (PBO) for 12 months. The primary endpoint was the number of new NMSCs to 12 months. Secondary endpoints included number of squamous cell carcinomas (SCCs), basal cell carcinomas (BCCs), and actinic keratoses (AKs) to 12 months. Skin reviews by dermatologists were performed 3 monthly. The sample size provided 90% power to detect a 33% difference in NMSC rates. Analysis was by intention-to-treat. **Results:** The mean age of study population was 66 years, the mean number of NMSC in the past 5 years was 8, and 63% were men. Treatment discontinuation rates were 9% for PBO versus 10% for NIC. 99% of patients underwent at least one post-baseline skin assessment. The average NMSC rate was significantly lower for NIC (1.77) than PBO (2.42). The estimated relative rate reduction (RRR) was 0.23 (95% CI: 0.04 to 0.38, p = 0.02) adjusting for center and NMSC history, and 0.27 (95% CI: 0.05 to 0.44; p = 0.02) with no adjustment. Treatment effects of comparable magnitude were found for both BCCs (RRR = 0.20, 95% CI: -0.06 to 0.39, p = 0.1) and SCCs (RRR = 0.30, 95% CI: 0 to 0.51, p = 0.05). AK counts were reduced for NIC compared to PBO by 11% at 3 months (p = 0.01), 14% at 6 months (p < 0.001), 20% at 9 months (p < 0.0001) and 13% at 12 months (p < 0.005). There were no clinically relevant differences in adverse event rates between the two arms. **Conclusions:** Nicotinamide reduces NMSC formation in high risk patients and is well tolerated. Furthermore, it is widely accessible as an inexpensive over-the-counter vitamin supplement and presents a new chemopreventive opportunity against NMSCs that is readily translatable into clinical practice. Clinical trial information: ACTRN12612000625875.

9001 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Long term follow up of survival in a randomised trial of wide or narrow excision margins in high risk primary melanoma. *First Author: Andrew J Hayes, The Royal Marsden NHS Trust, London, United Kingdom*

Background: Our randomized trial of 1 versus 3 cm clinical excision margins for high risk melanoma showed that narrow margins were associated with an increase in loco-regional relapse, but with no significant difference in melanoma-specific survival (MSS). We now report long-term melanoma-specific and overall survival from that trial. **Methods:** Patients with primary cutaneous melanoma two mm or more in Breslow thickness were randomized to a 1 or 3 cm excision. **Results:** Four hundred and fifty-three patients were randomized to a 1 cm margin and 447 patients to a 3 cm margin. Median age was 58.7 (IQR 47.2-69.2), median tumour thickness and percentage ulceration were similar in both groups (1 cm group: 3.0 mm and 31.8%, 3 cm group: 3.1 mm and 34.5%) . At a median follow-up of 8.8 years (IQR 6.3-11.3), 494 patients have died, with 359 of these deaths from melanoma. There were 194 melanoma deaths in the 1 cm group and 165 in the 3 cm group. Relative rate of melanoma death was estimated to be 24% higher in the 1 cm group than the 3 cm group on univariable analysis (hazard ratio (HR) 1.24; 95% confidence interval (CI) 1.00 to 1.52; p = 0.05). This effect was similar in multivariable analysis, adjusting for known prognostic factors (table).While there was an increase in the number of overall deaths in the 1 cm group compared to the 3 cm group (253 versus 241), this difference was not statistically significant in univariable analysis (HR 1.14: 95% CI 0.96 to 1.36, p = 0.14). **Conclusions:** With longer follow up, the previously reported increase in loco-regional relapse associated with narrow excision margins has translated into a significant increase in melanoma specific mortality.

			Overall Survival	Melanoma-Specific Survival
		N (%)	HR (95% CI) p value	HR (95% CI) p value
Margin	3cm	387 (50.2)	1.00	1.00
	1cm	384 (49.8)	1.19 (0.99-1.45) 0.07	1.27 (1.02-1.59) 0.036

Survival of SLNB-positive melanoma patients with and without complete lymph node dissection: A multicenter, randomized DECOG trial. *First Author: Ulrike Leiter, Department of Dermatooncology, University of Tuebingen, Tuebingen, Germany*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.

9003 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Surveillance imaging with FDG-PET in the follow-up of melanoma patients at high risk of relapse. *First Author: Jeremy Howard Lewin, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Background: In the modern era of melanoma treatment, approaches to imaging surveillance following surgery require reconsideration. The aim of this study was to evaluate disease sub-stage specific schedules of positron emission tomography (PET) surveillance for resected stage III melanoma. **Methods:** Between 2009-2013, patients at the Peter MacCallum Cancer Centre with fully resected AJCC stage III melanoma underwent serial whole body PET/CT scans according to schedules based on Bayesian disease sub-stage relapse probabilities. Schedules were stage IIIA: 6, 18 months; IIIB: 6, 12, 18, 24, 36, 48, 60 months; IIIC: 6, 12, 18, 24, 36 months. Descriptive statistics and contingency table analyses were used to evaluate outcomes for each schedule. **Results:** Eighty-six patients underwent PET surveillance according to schedule (IIIA: 11; IIIB: 50; IIIC: 25). In total, 232 PET scans were performed over a median follow-up of 28 months after surgery. Relapses were identified in 25 (29%) patients (IIIA: 4%; IIIB: 56%; IIIC: 40%), of which 20 (80%) were asymptomatic at the time of scanning. Incidental secondary malignancies were found in 6 (6.5%) patients. Stage IIIA/B relapses were more likely than stage IIIC to be loco-regional (IIIA/B: 42%; IIIC: 10%; p = NS). Nine (36%) relapsed patients underwent potentially curative resection (IIIA: 1; IIIB: 6; IIIC: 2), with 5 (IIIA: 1; IIIB: 4) free of disease after a median 32 months follow-up. The positive and negative predictive values (PPV, NPV) of an individual PET scan for detecting disease relapse at the same time point were: stage IIIB – PPV 69% (CI: 43-87%) and NPV 99% (CI: 95-100%), stage IIIC – PPV 73% (CI: 39-94%) and NPV 97% (CI: 90-100%). The PPV and NPV of each surveillance protocol for detecting any disease relapse were: stage IIIB – PPV 68% (CI: 43-87%) and NPV 97% (CI: 83-99%), stage IIIC – PPV 73% (CI: 39-94%) and NPV 86% (CI: 57-98%). The sensitivity and specificity of the overall approach of sub-stage specific PET/CT surveillance for detecting disease relapse were 88% (CI: 69-97%) and 84% (CI: 72-92%), respectively. **Conclusions:** FDG-PET is effective in detecting asymptomatic metastases and thus facilitating early treatment in patients who relapse after resection of stage III melanoma.

9004 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Clinical response, progression-free survival (PFS), and safety in patients (pts) with advanced melanoma (MEL) receiving nivolumab (NIVO) combined with ipilimumab (IPI) vs IPI monotherapy in CheckMate 069 study. *First Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

Background: Combined blockade of T-cell checkpoints by NIVO and IPI demonstrated a high objective response rate (ORR), promising overall survival (OS), and a manageable safety profile in pts with advanced MEL in a phase I study, based on which an appropriate dose was selected for registrational trials. We report efficacy and safety of the NIVO + IPI combination vs IPI alone in treatment-naïve pts with advanced MEL, including pts with poor prognostic factors, in a phase II study. **Methods:** Pts (N = 142) with metastatic or unresectable MEL were randomized 2:1 to receive IPI 3 mg/kg combined with either NIVO 1 mg/kg or placebo Q3W × 4, followed by NIVO 3 mg/kg or placebo Q2W until disease progression or unacceptable toxicity. The primary endpoint was ORR in BRAF wild-type (WT) pts. Secondary and exploratory objectives included PFS in BRAF WT pts, ORR and PFS in BRAF V600 mutation-positive (MT) pts, and safety. **Results:** In BRAF WT pts (n = 109), ORR was 60% (43/72) for NIVO + IPI; 11% (4/37) for IPI alone ($P < 0.0001$); complete responses were reported in 12 (17%) and 0 pts, respectively. Median PFS was 8.9 months for the combination vs 4.7 months for IPI alone ($P = 0.0012$). Higher ORR was observed for NIVO + IPI vs IPI in predefined pt subgroups with poor prognostic factors, such as elevated baseline LDH (53% vs 0%) and M1c stage disease (62% vs 25%). Similar ORR and PFS results were observed in 33 BRAF MT pts. Grade 3–4 drug-related adverse events (AEs) were reported in 51% of pts receiving NIVO + IPI vs 20% for IPI alone. The safety profile of NIVO + IPI was similar across pt subgroups, including age. Select AEs related to the combination regimen were consistent with phase I reports and most resolved with immunosuppressive medication (> 83% across organ categories) with the exception of endocrinopathies. Updated results from a planned data analysis in March 2015 will be presented. **Conclusions:** NIVO + IPI significantly improved ORR and PFS compared with IPI alone and had a manageable safety profile. The efficacy and safety of the combination was similar across pt subgroups and provided a favorable risk-benefit ratio in treatment-naïve pts with advanced MEL. Clinical trial information: NCT01927419.

9005 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

Long-term efficacy of pembrolizumab (pembro; MK-3475) in a pooled analysis of 655 patients (pts) with advanced melanoma (MEL) enrolled in KEYNOTE-001. *First Author: Adil Daud, UC San Francisco, San Francisco, CA*

Background: The anti–PD-1 antibody pembro is approved in the US for treating unresectable or metastatic MEL that progressed following ipilimumab (IPI) and, if *BRAF* ^{V600} mutant, a BRAF inhibitor. Pembro has demonstrated robust antitumor activity and manageable toxicity in IPI-treated (IPI-T) and naive (IPI-N) pts. In KEYNOTE-002, pembro significantly prolonged PFS over chemotherapy in IPI-refractory MEL. Here we present long-term follow-up data for all pts with MEL enrolled in KEYNOTE-001 (NCT01295827). **Methods:** IPI-T and IPI-N pts received pembro 2 mg/kg every 3 weeks (Q3W), 10 mg/kg Q3W, or 10 mg/kg Q2W until unacceptable toxicity, disease progression, or investigator decision. Treatment could continue beyond initial radiographic progression in eligible pts. Response was assessed every 12 wks. Pts were followed for survival every 3 mo after discontinuation. Primary end point was ORR per RECIST v1.1 by central review; secondary end points included PFS, OS, and duration of response (DOR). **Results:** 655 pts enrolled: 342 IPI-T, 313 IPI-N. Median-follow-up duration was 14.8 mo (range, 7.5-29). Median duration of exposure was 5.6 mo (range, 0.03-28.3). At the time of analysis, 217 (33%) pts remained on therapy. ORR was 34% (29% IPI-T, 38% IPI-N), with a 6% CR rate. Median time to response was 2.8 mo (range, 1.6-19.3). 80% of responses were ongoing at the time of analysis, and median DOR was not reached (range, 6+ to 98+ wk). Median PFS was 5.2 mo (95% CI 3.6-5.5) (IPI-T, 4.9 mo [3.0-5.5]; IPI-N, 5.4 mo [3.1-6.9]). PFS rates at 6 and 12 mo were 44% and 34% (41% and 32% IPI-T, 47% and 36% IPI-N). The 1-y OS rate was 67% (63% IPI-T, 71% IPI-N); the rate at 2 y was 50% (46% IPI-T, 53% IPI-N). Overall, 14% of pts experienced grade 3-4 treatment-related AEs, and there were no treatment-related deaths. In randomized cohorts, there were no significant differences in efficacy and safety between doses/schedules. **Conclusions:** Pembro provides robust and durable antitumor activity, promising long-term survival data, and a manageable safety profile in pts with IPI-T and IPI-N metastatic MEL. These results support the approved indication for pembro and its further exploration in other MEL populations. Clinical trial information: NCT01295827.

Update of progression-free survival (PFS) and correlative biomarker analysis from coBRIM: Phase III study of cobimetinib (cobi) plus vemurafenib (vem) in advanced *BRAF*-mutated melanoma. *First Author: James M. G. Larkin, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Primary analysis of coBRIM showed significant improvement in PFS and overall response rate (ORR) in *BRAF*^{V600} mutation–positive patients (pts) with advanced melanoma treated with vem + cobi (Table). We report an updated median PFS evaluation and a correlative analysis of clinical response with baseline (BL) oncogenic mutations coexisting with *BRAF*^{V600} mutations. **Methods**: Study methods were previously described.[1] PFS and ORR were updated (cutoff Jan 16, 2015), median follow-up was ~14 months. *BRAF*^{V600} mutation and 528 known activating mutations in 17 oncogenic protein kinases were analyzed using next-generation sequencing (average-read depth > 3000×). Reverse-phase protein array (RPPA) was used to assess oncogenic pathway activation in tumors. Co-mutation data were correlated with PFS and ORR. **Results**: Updated median PFS was 12.3 mo for vem + cobi vs 7.2 mo for vem + placebo (pbo); PFS hazard ratio was 0.58 [95% CI; 0.46-0.72]. ORR data are presented (Table). In 46 of 423 (11%) pt samples, coexisting BL oncogenic mutations were seen in *H-,K-,N-Ras*, non-V600 *BRAF*, or receptor tyrosine kinases (RAS/RAF/RTK), with a median allele frequency of 8%. Co-mutations were not correlated with shorter PFS or lower ORR in pts treated with vem + pbo or vem + cobi, despite the tumors' having higher levels of ERK and MEK activation than those without coexistent mutations (detected by RPPA). **Conclusions:** Longer follow-up confirms the clinical benefit of vem + cobi in pts with advanced *BRAF*^{V600}-mutant melanoma. Co-existence of *BRAF*^{V600} and BL activating RAS/RAF/RTK mutations do not seem to affect disease progression or rate of response to vem + cobi or vem treatment. Clinical trial information: NCT01689519.

9007 **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

A phase Ib/II study of BRAF inhibitor (BRAFi) encorafenib (ENCO) plus MEK inhibitor (MEKi) binimetinib (BINI) in cutaneous melanoma patients naive to BRAFi treatment. *First Author: Ryan J. Sullivan, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: MEKi addition to BRAFi therapy has been reported to increase response rate (RR) and duration of response. The BRAFi ENCO (LGX818) and MEKi BINI (MEK162) have each shown promising single-agent activity in *BRAF*V600–mutant melanoma. **Methods:** Combined ENCO and BINI are being evaluated in this phase (Ph) Ib/II open-label study of patients (pts) with *BRAF*V600–mutant cutaneous melanoma. Based on Ph Ib dose-escalation findings, the safety and efficacy of ENCO 600 mg or 450 mg daily + BINI 45 mg twice daily are being investigated in the Ph II part of the study. **Results:** Fifty-five BRAFi-naive pts were enrolled in Ph Ib (n = 13) or Ph II (n = 42). Median duration of exposure was 9.7 mo; 9 pts received ENCO 400 mg or 450 mg daily (5 in Ph Ib, 4 in Ph II), and 39 pts received ENCO starting at 600 mg daily (1 in Ph Ib, 38 in Ph II), all with BINI. Among all pts starting at ENCO 600 mg, common adverse events (AEs; all grades [Grs] > 30%) were nausea (54%), diarrhea (44%), fatigue and arthralgia (33% each), and vomiting, pyrexia, and increased AST (31% each). At ENCO 400/450 mg, rates of these AEs were: nausea and fatigue (44% each), diarrhea, vomiting, and increased AST (33% each), and arthralgia and pyrexia (11% each). Gr 3/4 AEs occurred in 64% of pts treated with 600 mg, commonly including increased ALT (18%), lipase (15%), AST (13%), and creatine phosphokinase (13%). At 400/450 mg, Gr 3/4 AEs occurred in 67% of pts; increased lipase (22%) was the only event occurring in > 1 pt. Photosensitivity (n = 1, 400 mg; n = 1, 600 mg) and Gr 3/4 pyrexia (n = 2, 600 mg) were rare. The confirmed RR among pts treated at ENCO 400/450 mg was 78% (1 CR + 6 PRs) and at ENCO 600 mg was 72% (3 CRs + 25 PRs). Ph Ib and Ph II combined (all doses) median progression-free survival (95% CI) was 11.3 (7.4-14.6) mo, and in pts with baseline lactate dehydrogenase (LDH) > upper limit of normal (ULN; n = 21) and ≤ ULN (n = 32), was 6.8 (5.0-11.3) mo and 20.0 (11.0-not reached) mo, respectively. **Conclusions:** These data suggest that ENCO + BINI is well tolerated at multiple doses, with promising activity in BRAFi-naive pts with *BRAF*-mutant melanoma. A Ph III trial (COLUMBUS) is underway using ENCO 450 mg daily with BINI. Clinical trial information: NCT01543698.

9008 Oral Abstract Session, Sat, 1:15 PM-4:15 PM

BRAF inhibitor acquired resistance: A multicenter meta-analysis of the spectrum and clinical implications of resistance mechanisms. *First Author: Douglas Buckner Johnson, Vanderbilt Univ, Nashville, TN*

Background: Acquired resistance (AR) to BRAF inhibitors (BRAFi) in melanoma is a near-universal phenomenon driven by numerous genetic and non-genetic alterations. Clinical implications of these AR mechanisms have not been described in a large cohort. We assessed the spectrum of BRAFi AR mechanisms and their associated timing of onset, pattern of disease progression (DP), and clinical outcomes. **Methods:** We compiled clinical and genetic data from 100 patients (pts) with 132 melanoma samples obtained at BRAFi DP from three previously published studies of BRAFi resistance. Whole exome sequencing and/or PCR-based genetic testing were performed on all samples. Associations between AR mechanisms and clinical features/outcomes were assessed with multivariate logistic regression models. **Results:** In 132 DP samples, putative AR mechanisms were identified in 58%, including *NRAS* or *KRAS* mutations (20%), *BRAF* splice variants (16%), $BRAF^{V600E/K}$ amplifications (13%), MEK1/2 mutations (7%), and non-MAPK pathway alterations (11%). Marked heterogeneity was observed within tumors and patients. $BRAF^{V600E/K}$ amplifications and non-MAPK alterations often co-occurred with other genetic changes, whereas *NRAS* mutations, *MEK1/2* mutations, and *BRAF* splice variants largely arose in isolation ($p = 0.02$). Of 19 pts with ≥ 2 DP biopsies, identified AR mechanisms were concordant in only 1 pt (5%). *NRAS* mutations were associated with vemurafenib use ($p = 0.045$) and baseline intracranial metastases ($p = 0.036$). Progression-free survival and patterns of DP were similar across AR mechanisms. The median survival after DP was 6.9 months, and subsequent responses to combined BRAF/MEK inhibition were uncommon (2/15; 13%); no patients responded to ipilimumab (0/24). Post-progression outcomes did not correlate with specific BRAFi AR mechanisms. **Conclusions:** This is the largest study of acquired BRAFi resistance in pts with *BRAF* mutant melanoma. Despite marked heterogeneity of AR mechanisms within pts and tumors, *NRAS* mutations were associated with vemurafenib use and intracranial disease. Further investigation into non-genetic AR mechanisms and immune features of BRAFi progression is warranted.

Safety and activity of pembrolizumab in melanoma patients with untreated brain metastases. *First Author: Harriet M. Kluger, Yale School of Medicine, New Haven, CT*

Background: Brain metastases (BrMs) develop in 40% of metastatic melanoma (MM) patients (pts). Untreated BrMs exclude from most clinical trials. In prior trials, treatment of MM with pembrolizumab (pembro), an IgG4 antagonist of the immune checkpoint PD-1, produced response rates of $> 30\%$. A phase 2 study (NCT02085070) was initiated to assess safety and activity of pembro in pts with previously untreated or progressing BrMs. **Methods:** Pts with BrMs from melanoma (reported here) or lung cancer are eligible if at least 1 asymptomatic 5-20mm BrM not requiring immediate local therapy or systemic steroids is present, and at least 1 BrM is amenable to biopsy or resection. Prior PD-1/PD-L1 inhibitors are excluded. Pembro 10mg/kg is administered every 2 weeks (wks). Brain MRI is repeated at 4 wks to assess safety and restaging is done every 8 wks. Primary endpoint is BrM response by modified RECIST (lesions $\geq$ 5mm are measurable on MRIs with 1mm slices; up to 5 BrMs are used to determine response). **Results:** Between April and December 2014, 17 pts were accrued, 6 with BRAF mutations, 10 previously received ipilimumab. Activity at interim analysis was sufficient to continue. Four were unevaluable for BrM response (3 due to rapid extracerebral disease progression (PD), 1 due to intralesional hemorrhage), and 1 was too early. Among 12 evaluable pts, BrM partial responses (PRs) were observed in 3 pts (1 with prior ipilimumab), stable disease in 2, PD in 7 (2 with a mixed response and 1 with PD by imaging but pseudoprogression on histology). BrM responses are ongoing at 7+, 6+ and 3+ months. One CR and 3 PRs were observed in extra-cerebral metastatic disease, 3 of these 4 with concordant BrM response. The only grade 3 adverse event clearly related to pembro was liver function abnormalities (1 pt). Two pts had seizures, 1 from perilesional edema, 1 from tumor growth, treated with anti-convulsants and a brief course of steroids. **Conclusions:** Early results from this ongoing trial suggest that pembro has promising activity in untreated melanoma BrMs. CNS symptoms were controllable with anti-convulsants and transient use of steroids. Accrual is ongoing and correlative studies from pre-treatment brain and extra-cerebral tumor samples are being conducted. Clinical trial information: NCT02085070.

The use of pembrolizumab for the treatment of metastatic uveal melanoma. *First Author: Lisa A. Kottschade, Mayo Clinic, Rochester, MN*

Background: Uveal melanomas are a rare type of melanoma with only 5-7 cases per 1 million persons diagnosed each year. Patients with metastatic melanoma of uveal origin, tend to have lower response rates on traditional therapies, as well as are usually excluded from clinical trials. Herein we report our experience with 7 patients with metastatic uveal melanoma who received pembrolizumab as part Merck's expanded access program. **Methods:** Patients were considered eligible for treatment on this protocol, if they were $\geq$ 12 years old, diagnosed with unresectable metastatic melanoma, had progressed on prior ipilimumab therapy, and if BRAF mutant had progressed on BRAF inhibition therapy. Patients had to have good performance status (ECOG of 0 or 1) and adequate organ and marrow function. Patients could have CNS disease, but needed to be clinically stable, prior to enrollment and could not be receiving other concurrent therapy for their cancer. Patients were treated with 2 mg/kg of pembrolizumab IV over q3 weeks until disease progression, unacceptable toxicity or for up to 2 years. **Results:** Between 4/15/2014 and 8/6/2014, we enrolled a total of 7 patients with metastatic uveal melanoma onto study MK-3475-030. Median age at enrollment was 64, with 5 patients being female. As of the data cutoff date of 1/27/2014 median progression free survival was 12.2 weeks (range 3.14-41) with 2 patients still currently receiving therapy without progression. There was 1 CR, 1 PR and 1 patient with SD. Three patients had PD and 1 patient was excluded as she discontinued therapy after 1 dose due to grade 4 endocrine toxicity. Other toxicities were as expected and were usually grade 1 or 2 in nature. **Conclusions:** While this cohort of patients was small, to our knowledge this is the first such report of outcomes in uveal melanoma patients being treated with anti-PD1 therapy. Toxicities were acceptable and expected. Patients were all pretreated, most with 2+ regimens. Treatment with pembrolizumab appears to be a viable option for patients with metastatic uveal melanoma. Clinical trial information: NCT02083484.

Response to anti-PD1/PDL1 therapy in patients with metastatic desmoplastic melanoma. *First Author: Zeynep Eroglu, City of Hope, Pasadena, CA*

Background: Higher overall burden of somatic mutations in tumors may be associated with better response rates to immunotherapy. Desmoplastic melanoma (DM) is a rare subtype of melanoma comprising approximately 1% of cases. Since DM has been reported to have a higher mutational load than other sub-types of melanoma, we hypothesized that patients with metastatic DM may respond more frequently to anti-PD1 or anti-PDL1 immunotherapies. **Methods**: A retrospective analysis of over 1000 melanoma patients treated with anti-PD1/PDL1 therapies among seven institutions (UCLA, MD Anderson, UCSF, Memorial Sloan Kettering, Vanderbilt, Melanoma Institute Australia, and Westmead) was conducted to identify patients with DM. We assessed objective response rates (ORR), overall survival (OS), and progression-free survival (PFS). **Results**: We identified 23 patients with stage IV DM (either pure or mixed subtype), 2 with stage M1a, 11 with M1b, and 10 with M1c disease. Eighteen patients had received prior systemic therapy, including 12 whose disease progressed following ipilimumab. Three patients were treated with nivolumab (anti-PD1 antibody, doses 0.1 or 3 mg/kg), 1 with nivolumab (3mg/kg) plus ipilimumab (1 mg/kg), 3 with BMS-936559 (anti-PDL1, 0.1 or 0.3 mg/kg), and 16 with pembrolizumab (anti-PD1, 2 or 10 mg/kg). Patients received a median of 9 cycles of therapy. A RECIST ORR of 70% was observed, including 9 complete responses and 7 partial responses (3 with $> 75\%$ decrease in tumor size per RECIST criteria). Median length of follow-up was 13.4 months. Three patients with eventual isolated progression underwent surgical excision without further disease progression, and only 2 of 23 patients received subsequent systemic therapy. Eighteen patients were alive at last follow-up; Kaplan-Meier median OS (range 2.8 months to 3.5+ years) and median PFS (range 1.4 months to 2.7+ years) were not reached. **Conclusions**: Patients with metastatic DM appear to have higher response rates and favorable clinical outcomes to anti-PD/PDL1 therapy compared to other patients with advanced melanoma. Additional mechanistic studies are ongoing.

Deep profiling of tumor immune microenvironment (TME) with fluorescence activated cell sorting (FACS) in advanced melanoma. *First Author: Kimberly Loo, UC San Francisco, San Francisco, CA*

Background: Tumor PD-L1 expression by immunohistochemistry has limitations in describing the tumor immune microenvironment as it relates to treatment with PD-1/PD-L-1 antibodies. We developed a novel FACS based method to study the tumor immune microenvironment and used it in patients undergoing PD-1/PD-L-1 antibody treatment. **Methods**: Multi -parameter flow cytometry was performed on freshly harvested metastatic melanoma tumor tissue following overnight enzymatic digestion (n = 161). The gating strategy sorted tumor cells, CD4+, CD8+ and myeloid/stromal cells. CD8+ cells were further sorted for PD-1, PD-L1, CTLA-4, and HLA-DR, while CD4+ cells were sorted for FoxP3 in addition to these markers. Tumor associated macrophage and dendritic cell activation markers were also determined in samples. Overall responses were derived from investigator reported data by Response Evaluation Criteria in Solid Tumors (RECIST). Descriptive statistics for responders vs. non-responders to anti-PD-1 therapy were constructed to assess the prognostic utility of these markers. **Results:** TME-FACS was evaluable on 32 unique patients who were evaluable for response. A high percentage (> 35% of total CD8+ cells) of PD-1 and CTLA-4 expressing $CD8^+$TILs is associated with an increased response to anti-PD-1 therapy. Increased mean fluorescence intensity (MFI) of PD-1/CTLA-4 dual expression on CD8+ cells is also associated with response. Myeloid cell markers clearly stratified responders vs. non-responders to anti-PD-1 therapy. **Conclusions:** TME-FACS is a novel method to functionally define the immune microenvironment in melanoma. TME-FACS immunoprofiling revealed that an increased percentage of PD-1/CTLA-4 + CD8+ TIL populations in metastatic lesions correlates with responsiveness to anti-PD-1 therapies. Defined myeloid subsets can also be uncovered by TME-FACS.

Response Assessment	Median PD1 / CTLA4 MFI	Median % PD1+ CTLA4+ CD8 TILs
Complete Response (CR)	238	49 %
Partial Response (PR)	217.5	37.5 %
Stable Disease (SD)	199.5	32.05 %
Progressive Disease (PD)	163	26.1 %

Bim as a predictive T-cell biomarker for response to anti-PD-1 therapy in metastatic melanoma (MM). *First Author: Roxana Stefania Dronca, Mayo Clinic, Rochester, MN*

Background: Given the variability in response to novel immunotherapeutic agents such as anti-PD1/PD-L1 therapies and the desire to extend their long-term benefit to more patients (pts), there is an increased need for the development of biomarkers that can help predict treatment outcomes and ensure that these treatments, which may have significant toxicities, are offered to pts more likely to benefit. We evaluated Bim (BCL-2-interacting mediator of cell death) in peripheral blood (PB) tumor-reactive $CD11a^{high}PD\text{-}1^+CD8^+$cytotoxic T lymphocytes (CTL) as a marker of the status of PD-1 engagement and T-cell reversibility to identify pts with MM who are more likely to benefit from anti-PD-1. **Methods:** MM patients treated with Pembrolizumab (pembro) 2 mg/kg every 3 weeks through an Expanded Access Program (EAP) had PB collected at baseline and at radiographic tumor evaluation through a separate biomarker sub-study. Frequencies of Bim^+ T cells and Bim median fluorescence intensity (MFI) were measured by flow cytometry in gated $CD11a^{high}PD1^+$ $CD8^+$T cells. Non-parametric t-test was used to compare baseline Bim and percent change in Bim levels in pts who had a radiographic response (CR/PR/SD) compared to those who had progressive disease (PD) at 12 wks. **Results:** 29/40 ptsenrolled in the EAP had baseline samples and 14/29 pts had serial samplesavailable. Clinical benefit (CR/PR/SD) was observed in 9/27 evaluable pts at 12 wk; 18/27pts had PD. Two pts discontinued therapy for adrenal insufficiency (attribution to pembro unknown) and were not evaluable. Pts with clinical benefit after 4 cycles had higher frequency of Bim+/PD-1+ CD8 T cells at baseline compared to pts with radiographic PD (mean 60% vs. 49%, P = 0.04). In 9/9 responders who had serial PB samples available, the levels of Bim in PD-1+ CD8 T cells decreased after the first 3 months of treatment, and they increased/did not change in all 5/5 nonresponders with serial samples evaluable (P = 0.003). **Conclusions:** Measurements of Bim levels in tumor-reactive PD-1+ CD8 T cells may select patients likely to benefit from anti-PD-1 therapy, and provide a new non-invasive way to monitor response to anti-PD-1 blockade in MM. These results are being validated on a larger prospective cohort.

Effect of melanoma intrinsic β-catenin signaling on immune exclusion and resistance to immunotherapies. *First Author: Stefani Spranger, University of Chicago, Chicago, IL*

Background: A subset of metastatic melanoma patients shows evidence for a T cell-inflamed tumor microenvironment at baseline, which has prognostic value and is associated with clinical response to immunotherapies including anti-PD-1. However, the molecular mechanisms mediating the absence of T cell infiltration in a major subset of patients have not been defined. **Methods:** Exome sequencing and gene expression profiling of melanoma metastases (TCGA) was combined with mechanistic studies in genetically engineered mouse models. **Results:** Analysis of melanoma metastases samples using gene expression profiling and exome sequencing, revealed activation of Wnt/ß-catenin pathway in a major subset of non-T cell-inflamed tumors. Using genetically engineered mouse melanoma models ($Braf^{V600E}$/$PTEN^{-/-}$± active ß-catenin), we demonstrated a causal effect between tumor-intrinsic ß-catenin signaling and T cell exclusion from the tumor microenvironment. The mechanism was via failed production of the chemokine CCL4, which was associated with failed recruitment of Batf3-lineage dendritic cells. Mice with these non-T cell-inflamed melanomas failed to respond to anti-CTLA-4/anti-PD-L1 mAb therapy. Active Wnt/ß-catenin signature in human melanomas was associated with reduction of Batf3 dendritic cell transcripts. Clinically, a patient who responded to a melanoma vaccine then recurred showed selection for loss of the T cell signature and gain of the ß-catenin phenotype. **Conclusions:** We have for the first time identified an oncogenic pathway that directly mediates immune evasion, which is implicated in examples of both primary and acquired resistance to immunotherapies.

Quantitative assessment of *BRAF* V600 mutant cell-free tumor DNA from plasma as a diagnostic and therapeutic biomarker in pts with *BRAF* V600 mutant melanoma. *First Author: Max Schreuer, Vrije Universiteit Brussel (VUB), Brussels, Belgium*

Background: Analysis of *BRAF* V600 mutant cell-free tumor DNA (ctDNA) from plasma is under consideration as a biomarker in pts with advanced melanoma. **Methods:** Plasma samples were obtained from pts with advanced melanoma who participated in 3 prospective clinical trials. Quantitative allele-specific PCR analysis for *BRAF* V600 E/E2/D/K/R/M mutations was performed on cell-free DNA extracted from 1ml plasma (Idylla, Biocartis). **Results:** From 2/2014 to 12/2014, 232 plasma samples from 41 pts were analyzed. Detection of *BRAF* V600 mutant ctDNA at the time of diagnosis of metastatic disease was concordant with tumor tissue analysis in 100% of pts (*BRAF* mutant 3/10, *BRAF* wt 7/10). In the 3 *BRAF* mutant pts, ctDNA results preceded tissue results with a median of 40 days (14-93). Therapeutic monitoring of *BRAF* mutant ctDNA was performed in 33 pts (median of 7 analyses per pt [range 2-13]; median follow up of 4.8 months [0.5-9]). Treatment consisted of BRAF/MEK targeted therapy (n = 26 pts), ipilimumab (n = 5) or pembrolizumab (n = 9). In the 6 pts who had a detectable *BRAF* mutant ctDNA fraction (range 7-53%) at initiation of BRAF/MEK targeted therapy, the *BRAF* mutant ctDNA fraction became undetectable (n = 5) or < 1% (n = 1) after a median of 14 days (5-40) notwithstanding the absence of radiological CR. During BRAF/MEK targeted therapy, an increase in the *BRAF* mutant ctDNA fraction was detected prior to PD on imaging in 7/12 pts (58%; median interval of 1.1 month [0.8-1.7]) and concomitantly with PD on imaging in 2/12 pts (17%). An increase in *BRAF* mutant ctDNA fraction predicted PD during the following month in 67% of cases (n = 14/21, $p < 0.001$) and in 100% of cases within the following 2 months (n = 21/21, $p < 0.001$). Undetectable *BRAF* mutant ctDNA predicted absence of PD in the following month in 91% of analyses (n = 94/103; $p < 0.001$) and in the following 2 months in 83% of analyses (n = 77/93; $p < 0.001$). **Conclusions:** Analysis of *BRAF* mutant ctDNA from plasma allows for a rapid diagnosis of the *BRAF* status in pts with advanced melanoma. *BRAF* mutant ctDNA likely reflects the *BRAF* mutant proliferative tumor burden and holds promise as a therapeutic monitoring tool for pts with advanced *BRAF* V600 mutant melanoma.

Circulating melanoma cells and recurrence in stage III melanoma patients. *First Author: Anthony Lucci, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There is a need for more sensitive and specific prognostic markers for advanced stage melanoma patients to help improve the risk-benefit ratio of systemic adjuvant therapies. While it has been demonstrated that circulating melanoma cells (CMCs) can be detected in melanoma patients, there is limited data regarding the prognostic significance of CMCs. The aim of this prospective study was to determine if CMCs predicted relapse in stage III melanoma patients. **Methods:** Serial CMC assessments (7.5mL blood) were performed in 101 patients with stage III cutaneous melanoma patients using the CellSearch system (Janssen). CD146+ cells were immunomagnetically enriched; CD146+, HMW-MAA+/, CD45-/, and CD34- nucleated cells were considered CMCs. Relapse-free survival was compared between patients with ≥1 CMC detected at baseline (first presentation to our clinic) or at second blood draw (6 months after baseline), versus those with no CMCs at baseline and at the second blood draw. Log-rank test and Cox regression analysis were applied to establish the association of CMCs with relapse-free survival. **Results:** CMCs were identified in 44 of 101 (44%) patients at either baseline or at second blood draw. Median follow up was 10 months. We observed no significant association between CMC presence and primary tumor factors including Breslow thickness, number of mitotic figures, or ulceration. Relapse was observed in 10 of 44 (23%) patients with ≥ 1 CMC, versus 4 of 57 (7%) of patients with no CMCs at baseline and at second blood draw (log-rank P = 0.04, HR 3.25, 95% CI 1.01 to 10.37; P = 0.04). **Conclusions:** CMCs at baseline or at a six month follow up blood draw predicted relapse in stage III melanoma patients. This data supports larger studies to confirm that presence of CMCs could be used to identify patients at risk for relapse, with an ultimate goal of early systemic intervention.

Plasma-based monitoring of BRAF mutations during therapy for malignant melanoma (MM) using combined exosomal RNA and cell-free DNA analysis. *First Author: Ryan J. Sullivan, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Oncogenic mutations in the *BRAF* gene (V600E/V600K) are present in 40-50% of patients with MM and represent an important therapeutic target (e.g. vemurafenib). Blood-based, serial monitoring of BRAF and other mutations during therapy may be useful to inform time-critical treatment decisions. Plasma contains at least two sources of cell-free nucleic acids (NAs): exosomal RNA (exoRNA) and cell-free DNA (cfDNA). Combining exoRNA and cfDNA maximizes the yield of genetic material from plasma, and may enable monitoring of both biologically important sources to enhance mutation detection sensitivity and help match patients to targeted therapies. **Methods:** Blood was drawn from 10 metastatic MM patients for analysis prior to therapy initiation and up to 8 serial time points. Subsequent purification of high-quality NAs using a novel, spin-column based method (EXO52) to co-isolate all exoRNA and cfDNA allowed analysis of mutations present in both NA fractions by ultra-deep sequencing. A custom next-generation sequencing (NGS) library preparation method, with a novel bioinformatics pipeline to efficiently call the rare mutations, was used to analyze a panel of 9 mutation hotspots from 6 genes, including BRAF. Data were correlated with tissue-based mutational analysis, treatment information, and RECIST-defined response assessments. **Results:** Somatic mutations from MM tumors were readily detected in both exoRNA and cfDNA from plasma. We show that the BRAF mutation signal from patient blood reduces with BRAF inhibitor treatment and is detectable in plasma prior to observed clinical and radiographic progression. Further, mutation signal from exoRNA consistently exceeds that from cfDNA across timepoints, with rate of change during response or relapse also showing differences. Possible clinical relevance of the BRAF exoRNA:cfDNA ratio will be discussed. **Conclusions:** Co-isolation of circulating exoRNA and cfDNA with EXO52 and subsequent NGS using a targeted gene panel provides a highly sensitive approach to monitor for BRAF and other somatic mutations in MM patients over the course of treatment, and has clinical utility.

Safety profile of nivolumab (NIVO) in patients (pts) with advanced melanoma (MEL): A pooled analysis. *First Author: Jeffrey S. Weber, Moffitt Cancer Center, Tampa, FL*

Background: NIVO is a programmed death-1 (PD-1) immune checkpoint inhibitor which has shown durable tumor responses in multiple cancer types and prolongs overall survival in pts with MEL. The objective of the current analysis is to describe the safety profile of NIVO across recent MEL studies, including 4 studies in which guidelines for the management of adverse events (AEs) were utilized. **Methods:** A retrospective safety review was conducted for 4 ongoing phase I–III trials, in which MEL pts received NIVO 3 mg/kg Q2W until disease progression or unacceptable toxicity. Data were included from pts who received at least 1 dose of NIVO, and included assessments of AEs, select AEs (immune-related etiology), time to onset and resolution, and the use as well as impact of immune modulating agents (IMs). **Results:** A total of 576 patients received NIVO for a median of 3.7 months; 312 (54%) had received prior ipilimumab (IPI). The most frequent drug-related AEs of any grade were fatigue (25%), pruritus (17%), diarrhea (13%), and rash (13%); grade 3–4 drug-related AEs occurred in 10% of all pts, and in 8% of pts with prior IPI. No drug-related deaths were reported. Drug-related select AEs of any grade were most frequent in the skin (34%), GI tract (13%), endocrine glands (8%) and liver (4%); grade 3–4 select AEs occurred in 4% of pts. Median time to onset of drug-related select AEs ranged from 5 wks for skin AEs to 15 wks for renal AEs. IMs were administered to 166/474 pts (35%) in phase III studies to manage AEs; 114 pts (24%) received systemic corticosteroids. Among 21 pts with grade 3–4 drug-related select AEs, all but 1 pt with a skin AE resolved with IMs. Median time to resolution ranged from 3 wks for hepatic AEs to 29 wks for skin AEs. The objective response rate was 44% in pts who received an IM and 36% in those who did not; time to response was similar (median 9 wks), and the median duration of response was not reached for either pt subgroup. **Conclusions:** In this pooled analysis, drug-related AEs with NIVO monotherapy were primarily low grade and the incidence of grade 3–4 drug-related AEs was not affected by prior IPI. Nearly all drug-related grade 3–4 select AEs resolved with use of IMs, which did not appear to impact on tumor response.

Ipilimumab in metastatic melanoma patients with pre-existing autoimmune disorders. *First Author: Douglas Buckner Johnson, Vanderbilt Univ, Nashville, TN*

Background: Ipilimumab (Ipi) is a cornerstone of metastatic melanoma therapeutics. Since Ipi toxicities are largely immune-related, clinicians may withhold therapy in patients (pts) with pre-existing autoimmune disorders (AD). We assessed whether pts with AD treated with Ipi experienced exacerbation of their AD, excessive immune-related adverse events (irAEs), and optimal clinical activity. **Methods:** We retrospectively reviewed records from 12 pts with metastatic melanoma and pre-existing AD treated with Ipi from 4 centers. We characterized baseline AD symptoms, prior management, and disease course on therapy. We also assessed rates of classical Ipi-related irAEs, and subsequent clinical outcomes, including objective response rate (ORR), overall survival (OS), and progression-free survival (PFS). **Results:** Of 12 pts, 5 had baseline rheumatoid arthritis, 3 had psoriasis/psoriatic arthritis, 1 had systemic lupus erythematosus, 1 had Crohn's disease, 1 had transverse myelitis, and 1 had sarcoidosis. Ten (83%) had previously received corticosteroids or other systemic therapy for their AD, including 5 ongoing at the time of Ipi initiation (low-dose prednisone in 2 pts and hydroxychloroquine in 3). Following Ipi, 6 pts (50%) had symptomatic worsening or flares of their AD; all resolved with short courses of corticosteroids and none required additional immune suppression. Grade 3-5 irAEs were observed in 5 pts (42%) including colitis (n = 2), hypophysitis (n = 2), and acute angle glaucoma (n = 1). One treatment-related death occurred, presumably from colitis and possibly hypophysitis (no laboratory confirmation) following dose 3 of Ipi. ORR was 17% (2/12 pts); median OS and PFS were and 22.0 and 3.0 months, respectively. One pt experienced a durable complete response. **Conclusions:** This is the largest study of Ipi in pts with autoimmune disorders. Ipi was associated with moderate tolerability and clinical activity in this cohort of pts with mild to moderate pre-existing AD. Clinicians should monitor pts closely for irAEs and AD flares. Larger retrospective and prospective studies are ongoing to characterize this cohort further.

9020 Poster Session (Board #263), Mon, 1:15 PM-4:45 PM

Extended follow-up results of phase Ib study (BRIM7) of vemurafenib (VEM) with cobimetinib (COBI) in *BRAF*-mutant melanoma. *First Author: Anna C. Pavlick, New York University Cancer Center, New York, NY*

Background: BRIM7 formed the basis for development of the VEM + COBI regimen, which, in a randomized phase III trial, confirmed the statistically significant and clinically meaningful progression-free survival (PFS) improvement of VEM + COBI over VEM. Results of BRIM7 with extended follow-up are presented. **Methods:** Eligible patients (pts) had advanced $BRAF^{V600}$-mutated melanoma, ECOG PS 0-1, and could either have progressed on VEM (VEM-PD) or be BRAF inhibitor (BRAFi) naive. Dose escalation pts received VEM 720 mg or 960 mg twice daily (BID) continuously + COBI 60 mg, 80 mg, or 100 mg once daily (QD) 14 days on/14 days off (14/14); 21 days on/7 days off (21/7); or continuously. Two dose levels were expanded: VEM (720 mg and 960 mg BID) + COBI 60 mg QD 21/7. **Results:** Previously, we reported the 129 VEM + COBI treated pts with the following characteristics: BRAFi naive: 49%; stage M1c: 70% and 82%; LDH > ULN: 46% and 62%; and median follow-up: 13 months and 6 months, for BRAFi-naive and VEM-PD pts, respectively (Ribas A. *Lancet Oncol* 2014; 15:954-965). In this update, the median follow-up in BRAFi-naive and VEM-PD pts was 21 months and 8 months, respectively. Adverse event (AE) frequency and severity remained stable with extended follow-up. The frequencies of symptomatic MEK inhibitor AEs (serous retinopathy and cardiomyopathy) and BRAFi AEs (skin squamous carcinoma) were also unchanged. Confirmed response rate in BRAFi-naive pts remained at 87%. Four additional pts attained complete response (CR) at Cycles 16-25, increasing CR rate from 10% (6 pts) to 16% (10 pts). Median PFS was unchanged at 13.8 months. With extended follow-up, median overall survival (OS) was reached at 28.5 months and 2-year OS was 61%. Confirmed response rate in VEM-PD pts remained at 15%, 1 pt attained CR at Cycle 22. CR was not observed previously in VEM-PD pts. Median PFS and OS were unchanged at 2.8 months and 8.4 months, respectively. The 2-year OS was 15% with extended follow-up. **Conclusions:** VEM + COBI continues to show robust efficacy in BRAFi-naive pts, with a manageable and tolerable safety profile without new safety signals. Median OS in BRAFi-naive pts was > 2 years. Late CR conversions indicate persistent activity with continued therapy. Clinical trial information: NCT01271803.

9021 Poster Session (Board #264), Mon, 1:15 PM-4:45 PM

Quality-of-life (QOL) assessment in patients (pts) with metastatic melanoma receiving vemurafenib (V) and cobimetinib (C). *First Author: Brigitte Dréno, Nantes University, Nantes, France*

Background: The phase 3 coBRIM study showed significant improvement in progression-free survival in pts with metastatic melanoma on V + C compared with those on V and placebo (P) (HR, 0.51; 95% CI, 0.39-0.68, $P< 0.001$ (Larkin et al. *N Engl J Med* 2014;371:1867-1876). We report the evaluation of health-related QOL in coBRIM for V + C versus V + P, as measured by the European Organization for Research and Cancer (EORTC) Quality of Life Questionnaire (QLQ-C30). **Methods:** The EORTC QLQ-C30 was evaluated in pts with baseline (BL) and ≥ 1 post-BL assessment. Assessments were conducted on Days (D) 1 and 15 in cycles (C) 1 and 2 (each C = 28 days), and every other cycle thereafter until pt withdrawal or end of study. The analysis includes assessments up to C8D1. Each domain score, assessing global health status and QOL, and symptom scales were examined at BL and for each time point (change from BL) by treatment arm descriptively; formal statistical comparisons were not conducted. Clinically meaningful (CM) change was defined as a ≥ 10-point increase or decrease from BL. **Results:** The completion rate at BL for both treatment arms was 96.7% and was consistently high (≥ 88%). Across all functioning domains (cognitive, emotional, social, role, and physical) and symptoms (appetite loss, constipation, nausea and vomiting, dyspnea, pain, and fatigue), pts in the V + C arm reported better scores at 1 or more post-BL time points evaluated versus those in the V + P arm, but mean score change did not reach CM criteria. However, pts in the V + C arm experienced a CM or marginal improvement in insomnia (C2D15, C4D1, C6D1, C8D11), while no V + P pts showed CM change from BL in insomnia. The V + C arm experienced CM worsening of diarrhea from BL only at C1D15 and C2D15; no CM change from BL for diarrhea was observed in the V + P arm. Responder analysis showed that a higher percentage of pts in the V + C arm had CM score improvements from BL for all EORTC domains; the greatest differences were observed in insomnia (16%), social functioning (11%), fatigue (9%), and pain (7%). **Conclusions:** In pts with metastatic melanoma, V + C provided superior efficacy compared with V +P and symptom improvement for insomnia, social functioning, fatigue, and pain with similar QOL. Clinical trial information: NCT01689519.

9022 Poster Session (Board #265), Mon, 1:15 PM-4:45 PM

Determination of locally advanced basal cell carcinoma (BCC) in the first 285 patients enrolled in the RegiSONIC disease registry study. *First Author: Simon S. Yoo, Northwestern University, Chicago, IL*

Background: Advanced BCC (aBCC), including metastatic (mBCC) or locally advanced BCC (laBCC), is rare, and a broadly accepted diagnostic definition of aBCC is lacking. The RegiSONIC disease registry (ClinicalTrials.gov identifier: NCT01604252) is designed to evaluate how clinicians diagnose and treat aBCC in real-world practice. **Methods:** RegiSONIC is an ongoing, multicenter, prospective observational cohort study in 3 BCC patient (pt) populations, treated according to clinician's standard of care: newly diagnosed pts with vismodegib-naive aBCC (cohort 1), pts with aBCC who previously received vismodegib in a Genentech-sponsored study (cohort 2), or pts with BCCNS who have aBCC or multiple BCCs of any stage (cohort 3). Determination of aBCC was at the clinician's discretion and not dictated by the protocol. This summary describes determination of laBCC in the first 285 pts enrolled to cohort 1 as of September 12, 2014. **Results:** Median time from initial diagnosis of the current BCC lesion to enrollment was 1.64 months and from determination of laBCC to enrollment was 0.43 months. Determination of laBCC was based on the following (sums to > 100%): lesion size (78%), histopathology (55%), location (53%), extent of disease (51%), recurrence (30%), curative resection unlikely (29%), radiotherapy contraindicated (21%), surgery contraindicated (16%), and other (8%). All pts had clinically visible locally advanced lesions; 72% had a single lesion, and 28% had multiple lesions (median, 3.0 lesions). The median size of target lesions was 20 mm; among 220 pts diagnosed on the basis of lesion size, 65% had lesions measuring ≥ 20 mm. Among 84 pts diagnosed on the basis of recurrence, 40% had ≥ 2 recurrences. Clinical/histopathologic subtype of the target lesion (sums to > 100%) was nodular (64%), morpheiform/infiltrative (29%), superficial (13%), micronodular (3%), basosquamous (3%), and other (11%). Target lesions were predominantly located on the head, including the nose (22.4%), forehead (12.6%), ear (8.3%), cheek (8.3%), and scalp (7.6%). **Conclusions:** Data from RegiSONIC will provide real-world clinical practice insight to help improve the diagnosis and care of pts with aBCC. Clinical trial information: NCT01604252.

9023 Poster Session (Board #266), Mon, 1:15 PM-4:45 PM

The RegiSONIC disease registry: Preliminary effectiveness and safety in the first 66 newly diagnosed locally advanced basal cell carcinoma (BCC) patients treated with vismodegib. *First Author: Mario E. Lacouture, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Treatment of advanced BCC (aBCC), including metastatic or locally advanced (la) BCC, is challenging, with approaches ranging from surgery to recently approved targeted Hedgehog pathway inhibitor vismodegib (VISMO). RegiSONIC (NCT01604252) is an ongoing, multicenter prospective observational cohort study designed to collect real-world data on the diagnosis and treatment of patients (pts) with aBCC and/or BCC nevus syndrome (BCCNS). Here we present preliminary effectiveness and safety results in the first 66 non-BCCNS newly diagnosed laBCC pts treated with VISMO. **Methods:** Pts are enrolling into 3 cohorts (C): newly diagnosed (VISMO-naive) aBCC pts (C1), aBCC pts who previously received VISMO in a Genentech-sponsored study (C2), or pts with BCCNS who have aBCC or multiple BCCs of any stage (C3). Determinations of disease response were investigator assessed. Pt follow-up is every ~3 months. **Results:** By Sept 12, 2014, 285 non-BCCNS newly diagnosed laBCC pts had been enrolled: median age, 68 years; male, 63%. 66 (23%) pts were treated with VISMO (received VISMO within 90 days of determination of laBCC). Median (range) of follow-up: 13.2 (0.16-26.8) months. Results are in the Table. All AEs leading to treatment discontinuation and 1 SAE (acute renal failure) were considered related to VISMO; the 4 deaths (6%) were not. **Conclusions:** Preliminary data from the RegiSONIC study demonstrate effectiveness of VISMO in non-BCCNS newly diagnosed laBCC pts, with a safety profile consistent with previous studies. Real-world data may provide clinical insights to improve the treatment of aBCC pts. Clinical trial information: NCT01604252.

Impact of treatment breaks on vismodegib patient outcomes: Exploratory analysis of the STEVIE study. *First Author: Reinhard Dummer, University Hospital Zurich, Zurich, Switzerland*

Background: Vismodegib (VISMO) is the first Hh pathway inhibitor approved for use in adults with advanced BCC (aBCC) that is inappropriate for surgery or radiotherapy. While most VISMO-related adverse events (AEs) are mild to moderate, the presence of multiple chronic AEs may lead to treatment interruption or discontinuation. Treatment breaks are allowed in the STEVIE study (NCT01367665) for the management of toxicity, among other reasons. Herein we present an exploratory analysis assessing the safety and efficacy profile in patients (pts) with treatment breaks on study. **Methods:** STEVIE is an ongoing study focusing on safety of VISMO in pts with aBCC. Pts receive VISMO 150 mg once daily until progressive disease, unacceptable toxicity, or withdrawal. The primary objective is safety; efficacy is a secondary end point. Tumor response assessments are performed using RECIST 1.1 as assessed by the investigator. Exploratory analyses were performed using data from a planned interim analysis (data cutoff Nov 6, 2013). **Results:** 499 pts were included in the safety population and analyzed according to number of treatment breaks received. The median duration of treatment was 223.5, 299.0, 399.0, and 454.0 days in pts with 0, 1, 2, or ≥ 3 treatment breaks, respectively. Median dose intensity was 97%, 89%, 86%, and 81%, respectively. Median treatment break duration was 22 days (SD 13.92). Safety and efficacy results are presented in the Table. Patients with more treatment-emergent AEs (TEAEs) including those experiencing more grade ≥ 3 TEAEs had more treatment breaks. These were AEs known to be commonly associated with VISMO use. The most common grade ≥ 3 TEAE was muscle spasm. **Conclusions:** Increased number of treatment breaks was associated with longer median duration of VISMO treatment and did not appear to compromise efficacy. Clinical trial information: NCT01367665.

De novo versus nevus-associated melanomas: Differences in associations with prognostic indicators and survival. *First Author: Rachel M. Cymerman, NYU School of Medicine, New York, NY*

Background: Although 20%-30% of melanomas may be histopathologically "nevus-associated," implying direct transformation of a nevus into melanoma, the majority of melanomas arise in clinically normal skin with no detectable precursor lesion. We aimed to determine whether nevus-associated and de novo melanomas differ in their associations with histopathologic features and survival. **Methods:** 1,048 melanoma patients prospectively enrolled in the NYU Melanoma Cooperative Group registry between 1972 and 1982 (NYU1) were analyzed to detect associations between type of melanoma (de novo vs nevus-associated) and age, anatomic site, ulceration, thickness, mitotic index, histological type, stage, and survival. We tested the significant associations in a replication cohort of 1,202 melanoma patients prospectively enrolled between 2002 and 2009 in the NYU Interdisciplinary Melanoma Cooperative Group registry (NYU2). **Results:** In the NYU1 dataset, de novo melanomas were more likely to be associated with older age (54 vs 47 years, $p < 0.01$), non-axial location (OR 1.53, $p < 0.01$), tumor thickness > 1.0mm (OR 1.95, $p < 0.01$), ulceration (OR 1.61, $p = .026$), nodular subtype (OR 2.79, $p < 0.01$), stage > 1 (OR 2.35, $p < 0.01$), and shorter overall survival ($p < 0.01$). In the NYU2 replication dataset, de novo melanoma was again significantly associated with older age (61 vs 54 years, $p < 0.01$), non-axial location (OR 2.29, $p < 0.01$), tumor thickness > 1.0mm (OR 2.22, $p < 0.01$), ulceration (OR 2.92 $p < 0.01$), nodular subtype (OR 2.23, $p < 0.01$), stage > 1 (OR 2.43, $p < 0.01$), and shorter overall survival ($p < 0.01$). In multivariate analysis, de novo histopathology was an independent, poor prognostic indicator in the NYU2 cohort only (HR = 1.69, $p < 0.01$). The NYU2 cohort has patients with thinner tumors (56.2% have tumors < 1.0mm) compared to the NYU1 cohort (41.8% have tumors < 1.0mm), which may contribute to the differing impact of the de novo histopathology on the survival models for these cohorts. **Conclusions:** These data suggest that de novo melanomas may be more aggressive than nevus-associated melanomas, and may differ in their molecular pathogenesis. These findings may also have implications for early detection programs.

9026 Poster Session (Board #269), Mon, 1:15 PM-4:45 PM

PD1/PDL-1 and VEGF expression in lymph node microenvironment and relation with tumor burden and survival in cutaneous melanomas. *First Author: Vinicius L Vazquez, Barretos Cancer Hospital, Barretos, Brazil*

Background: The regional lymph nodes are the most common site for melanoma metastasis. The understanding of lymph node microenvironment may lead to the comprehension of the metastasis development and factors related to tumour progression. The aims of this study are to characterize the PD1 (programmed cell death-1), VEGF (Vascular endothelial growth factor) A and C expression in the regional lymph nodes of melanoma patients with and without metastasis; PDL-1 (PD1 ligand) in the lymph node metastasis; and their relation to tumour burden and survival. **Methods:** We retrospectively researched the sentinel nodes, both negative, (pn0) positive (pN1+), and the negative nodes retrieved from the lymph node dissection of the sentinel positive patients (pN1-); Immunohistochemistry was performed looking for the expression of PD-1, VEGFA and C in the lymph node normal/surrounding tumor tissue and their correlation to clinical findings. **Results:** 20 negative sentinel lymph nodes (pN0), 20 positive sentinel nodes (pN1+) and 18 negative lymph nodes from patients with lymph node metastasis (pN1-) were analysed. Follow up ranged from 5.91 to 85.45 months; mean 38.77 (SD 16.13). PD-1 was expressed in 94.7% of pN0, 77.8% of pN1- and 47.1% of pN1+ ($p = 0.006$). PDL-1 was expressed in 68.7% of the tumor cases. VEGF A was expressed in 6.7% of pN0, 16.7% of pN1- and 72,2% of pN1+ ($p < 0.001$). VEGF C expression was present in 89.5% of pN0, 55.6% of pN1- and 80% of pN1+ ($p = 0.101$). Five years survival of PD1 negative patients was 42.9% and PD1 positive 77.1% ($p = 0.034$). PDL1 (only N1+) Five years survival was 33.3% in positive cases versus 24.2% in negative ones ($p = 0.566$). VEGF A five years survival was 78.4% for negative cases and 43.4% for positive ones ($p = 0.008$). VEGF C was 68.6% for negative cases and 66.9% for positive ($p = 0.746$) **Conclusions:** PD-1 expression in the regional lymph node is associated to absence or low tumour burden what is related to higher survival rates. VEGFA expression in the regional lymph node is associated to presence or high tumour burden what is related to low survival. Further studies should be performed to confirm this data and look at their clinical implications. Supported by *CNPQ grant #447590/2014-6*

9027 Poster Session (Board #270), Mon, 1:15 PM-4:45 PM

Effect of nivolumab (NIVO) on quality of life (QoL) in patients (pts) with treatment-naïve advanced melanoma (MEL): Results of a phase III study (CheckMate 066). *First Author: Georgina V. Long, Melanoma Institute Australia, North Sydney, NSW, Australia*

Background: While treatments exist that extend survival in advanced MEL, the quality of that survival is not often evaluated. There is a need for treatments that demonstrate increased survival while preserving long-term QoL. In a phase III, randomized, double-blind study, NIVO (a PD-1 immune checkpoint inhibitor; 3 mg/kg every 2 weeks [wks; Q2W]) improved overall survival compared with dacarbazine (DTIC; 1,000 mg/m^2 Q3W) in treatment-naïve pts with advanced MEL. **Methods:** In this study, QoL measured by European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30) and the EuroQol-five dimension questionnaire (EQ-5D) was evaluated at baseline (BL) and at treatment cycles Q6W. Mean changes and non-parametric comparisons are reported. Further analyses are planned to examine longitudinal QoL and the relationship between clinical and pt outcomes. **Results:** A total of 418 pts were randomized to NIVO (n = 210) or DTIC (n = 208). Adjusted completion rates at BL for EQ-5D utilities were 69.5% with NIVO and 64.9% with DTIC, and those for EORTC QLQ-C30 were 70.0% with NIVO and 64.9% with DTIC. While rates remained similar throughout the study, analysis of QoL involving DTIC was not feasible after wk 13 due to a high attrition rate in the DTIC arm (n ≤ 41). Mean BL QoL scores were similar for NIVO versus DTIC (EQ-5D utilities: 0.778 vs 0.711; EQ-5D visual analog scale [VAS] scores: 70.9 vs 69.1; EORTC Global Health: 68.9 vs 66.2). No QoL change was noted for DTIC prior to study dropout. For NIVO, improvements from BL were noted in EQ-5D utilities from wk 7 (0.027; n = 132; P= 0.011) through wk 49 (0.045; n = 38; P= 0.034), and in EQ-5D VAS scores at wks 25, 31, 37, 49 and 61 (P≤ 0.03). EORTC subscale scores did not change over time. **Conclusions:** These results demonstrate that NIVO does not impair QoL and may enhance it compared with BL, while also conferring survival benefits, in treatment-naïve pts with advanced MEL. Dropout rates with DTIC after wk 13 limited QoL data interpretation for this treatment group. Clinical trial information: NCT01721772.

Nivolumab in resected and unresectable melanoma: Immune-related adverse events and association with survival outcomes. *First Author: Morganna L Freeman-Keller, Moffitt Cancer Center, Tampa, FL*

Background: In metastatic melanoma, immune checkpoint blockade has generated excellent response rates and prolonged survival. As the depth of immune activation may correlate with occurrence of immune related adverse events (irAEs), an association between irAEs and disease outcomes might also exist. We describe herein the irAE toxicity profile of 148 patients with resected and unresectable melanoma treated with nivolumab at our institution, and the association of irAEs with progression-free (PFS) and overall survival (OS). **Methods:** Data was pooled from 148 patients (33 resected, 115 unresectable) treated at 1-, 3-, or 10mg/kg doses (with or without peptide vaccine) every 2 weeks for 12 weeks, then an additional 12 weeks if stable or better, and up to 2 additional years if stable or better. Frequency, grade, and irAE characteristics were analyzed, including kinetics of onset, resolution, and need for steroid therapy. We conducted a 12-week landmark OS analysis, with a multivariate time-dependent Cox proportional hazard model to assess differences in PFS (for 115 unresectable patients) and OS (all 148 patients) in the presence or absence of irAEs. **Results:** IrAEs of any grade were observed in 68.2% of patients (101/148). Grade III/IV irAEs were infrequent: 3 patients (2%) had Grade III rash, 2 (1.4%) had asymptomatic Grade III amylase/lipase elevation, and 2 (1.4%) had Grade III colitis. Of the irAEs, colitis and pneumonitis required steroids (median duration = 5 wks). Statistically significant PFS and OS differences were seen in patients who experienced any grade of irAE ($p = < 0.001$ and $p = 0.078$, respectively). Improved PFS was associated with rash ($p = < 0.001$ [HR 0.237, 95% CI 0.098 to 0.573]) and vitiligo ($p = 0.005$ [HR 0.121, 95% CI 0.024 to 0.62]). Rash was associated with improved OS ($p = 0.005$ [HR 0.098, 95% CI 0.006 to 1.711]), with non-significant association between vitiligo and OS ($p = 0.081$ [HR 0.146, 95% CI 0.009 to 2.488]. No survival differences were seen with other irAEs (endocrinopathies, diarrhea, or pneumonitis). **Conclusions:** Rash and vitiligo are associated with prolonged PFS and OS in melanoma patients treated with nivolumab, which should be validated in subsequent prospective analyses.

9029 Poster Session (Board #272), Mon, 1:15 PM-4:45 PM

Effect of nivolumab (NIVO) in combination with ipilimumab (IPI) versus IPI alone on quality of life (QoL) in patients (pts) with treatment-naïve advanced melanoma (MEL): Results of a phase II study (CheckMate 069). *First Author: Amy Pickar Abernethy, Duke Cancer Institute, Durham, NC*

Background: New therapies in advanced MEL improve survival, but QoL preservation is uncertain. NIVO (a PD-1 immune checkpoint inhibitor) and IPI are each approved as monotherapy for advanced MEL. In a phase II, randomized, double-blind study, NIVO (1 mg/kg every 3 weeks [wks; Q3W]; 4 doses) combined with IPI (3 mg/kg Q3W; 4 doses) followed by NIVO (3 mg/kg Q2W) significantly improved response rate and progression-free survival (PFS) versus IPI (3 mg/kg Q3W; 4 doses), with a manageable safety profile, in treatment-naïve pts with advanced MEL. **Methods:** In this study, QoL measured by EORTC QLQ-C30 and EQ-5D was evaluated at baseline (BL) and Q6W treatment cycles for the first 6 months. Mean changes and non-parametric comparisons are reported. Further analyses are planned to examine longitudinal QoL and the relationship between clinical and pt outcomes. **Results:** Pts received NIVO + IPI (n = 95) or IPI (n = 47). Adjusted completion rates at BL for EQ-5D utilities and EORTC QLQ-C30, respectively, were 64% and 65% with NIVO + IPI and 77% and 79% with IPI; rates remained stable throughout the study except a notable reduction at wk 13 in NIVO + IPI (48%). While completion rates remained similar to BL in the 2 arms after wk 13, pt numbers for IPI were substantially reduced after wk 13 ($n \leq 14$) due to disease progression (median PFS: 3.7 months) or toxicity. NIVO + IPI and IPI had similar mean EORTC QLQ-C30 global health scores at BL (76.9 vs 80.9), wk 7 (69.2 vs 74.5) and wk 13 (78.5 vs 72.2), and similar mean EQ-5D utility index scores at BL (0.861 vs 0.847), wk 7 (0.788 vs 0.789) and wk 13 (0.894 vs 0.834). A transient deterioration in EQ-5D utilities was noted at wk 7 for NIVO + IPI (−0.071; n = 53; *P*= 0.023) and IPI (−0.055; n = 35; *P*= 0.140), but scores returned to BL levels at wk 13 and were maintained with NIVO + IPI beyond wk 13 after the switch to NIVO alone. Similar results were noted with EORTC QLQ-C30 scales. **Conclusions:** NIVO + IPI and IPI alone maintained QoL to a similar level in treatment-naïve pts with advanced MEL, with NIVO + IPI providing superior tumor response and PFS. Studies with increased follow up and pt numbers are needed to confirm these results. Clinical trial information: NCT01927419.

9030 Poster Session (Board #273), Mon, 1:15 PM-4:45 PM

Final data from CALM: A phase II study of Coxsackievirus A21 (CVA21) oncolytic virus immunotherapy in patients with advanced melanoma. *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: CVA21 (CAVATAK) is a novel bio-selected oncolytic and immunotherapeutic strain of Coxsackievirus A21. Intratumoral (i.t) CVA21 injection initiates preferential tumor cell infection, cell lysis and enhancement of a systemic anti-tumor immune response. Presented are the final data of the open-label, multicenter Phase II CALM (***CA***VATAK in ***L***ate stage ***M***elanoma) study. **Methods:** The CALM study investigated the efficacy and safety of i.t CVA21 in 57 patients with treated or untreated unresectable Stage IIIC-IVM1c melanoma. Pts received up to 3×10^8 $TCID_{50}$CVA21 i.t on study days 1,3,5, 8 and 22, and then every three weeks for a further 6 injections. Pts displaying immune-related progression-free survival (irPFS) or better at 6 mos were eligible for 9 additional injections. Key eligibility criteria were ≥ 18 yrs old, ECOG PS 0-1, and at least 1 injectable cutaneous, subcutaneous, or nodal melanoma metastasis ≥ 1.0 cm. The primary endpoint was to achieve > 9 of 54 evaluable pts with irPFS at 6 mos. Secondary endpoints included irRECIST overall response rate, durable response rate (continuous response ≥ 6mos), median time to response and 1-year survival. **Results:** The primary endpoint of the study was achieved with 21 of 57 (38.6%) evaluable pts displaying irPFS at 6 mos with a median irPFS of 4.2 mos. The overall response rate (irRECIST) was 28.1% (16 of 57 evaluable pts) with a ≥ 6 mos durable response rate of 19.3 % (11 of 57 pts). The median time to response was 2.8 mos, and the 1-year survival rate 75.4% (43 of 57 pts). After a median follow-up of ~16.5 mos, median duration of response in responders and median OS for all pts was not reached. The most common AE's were Grade 1 fatigue, chills, local injection site reactions and fever. No Grade 3 or 4 product-related AE's were observed. **Conclusions:** Intralesional CVA21 is a promising novel oncolytic immunotherapeutic agent for the treatment of unresectable Stage IIIC-IVM1c melanoma and the CALM study met its primary endpoint of irPFS at 6 mos. CVA21 was well tolerated and exhibited both local and distant durable tumor responses. Further clinical studies using CVA21 in combination with other immunotherapies are underway. Clinical trial information: NCT01227551.

9031 Poster Session (Board #274), Mon, 1:15 PM-4:45 PM

Clinical characteristics predictive of response to pembrolizumab in advanced melanoma. *First Author: Katy K. Tsai, UC San Francisco, San Francisco, CA*

Background: Anti-PD-1 therapy has shown significant clinical activity in advanced melanoma and in other cancers. Factors predictive of response remain vaguely defined. We report on clinical characteristics correlated with higher response rates to therapy in a phase I trial of pembrolizumab. **Methods:** Advanced melanoma patients (n = 110, enrolled Dec 2011 to Oct 2013, data analysis July 2014) received pembrolizumab in 1 of 3 dosing regimens: 2Q3W, 10Q3W, or 10Q2W. Tumor responses were evaluated by RECIST 1.1 criteria. Sites of metastases were determined based on CT imaging, and this analysis was not limited to RECIST target lesions. The overall response rate (ORR) and exact two-sided 95% CI were calculated. Demographic and clinical variables were compared between responders and progressors. **Results:** In this cohort, ORR to pembrolizumab was 40%. Factors correlated with significantly higher ORR were: LDH ≤ normal (ORR 52.2%), no previous ipilimumab (ORR 48.3%), and presence of lung metastasis (ORR 52.8%). Patients with liver metastasis had worse response (ORR 18.4%), as did those with liver and lung metastases (ORR 31.3%). Data for associations of subgroup variables with ORR in univariate analyses are shown (Table). **Conclusions:** Normal LDH, no previous ipilimumab, and presence of lung metastasis are correlated with better response to pembrolizumab in advanced melanoma patients. The presence of liver metastasis is correlated with lower response to pembrolizumab, both in the presence and absence of lung metastasis. These correlations were observed regardless of BRAF status, presence of brain metastasis, or site of primary melanoma (cutaneous vs. uveal). Clinical trial information: NCT01295827.

Clinical characteristic	ORR, % (95% CI)	p-value
All patients	40 (30.7-49.3)	
Age <65	36.2 (23.5-49)	0.39
ECOG 0	41.1 (29.5-52.7)	0.741
LDH ≤ normal	52.2 (40-64.5)	0.009
BRAF WT	40.7 (30.1-51.3)	0.416
No previous ipilimumab	48.3 (35.3-61.4)	0.0049
Brain metastasis (met)	38.9 (13.9-63.8)	0.916
Lung met	52.8 (38.9-66.7)	0.008
Liver met	18.4 (5.5-31.3)	0.001
Lung met, no liver met	62.2 (45.8-78.6)	0.001
Lung met and liver met	31.3 (5.7-56.8)	0.001
Liver mets, no lung mets	9.1 (4-22.1)	0.001

9032 Poster Session (Board #275), Mon, 1:15 PM-4:45 PM

A single-arm, open-label, phase II study to evaluate the safety of vemurafenib (VEM) followed by ipilimumab (IPI) in BRAF V600-mutated metastatic melanoma (MM). *First Author: Asim Amin, Levine Cancer Institute, Carolinas Healthcare System, Charlotte, NC*

Background: There is much interest in determining how to incorporate BRAF inhibitors with immune checkpoint inhibitors in the treatment of patients (pts) with BRAF-mutant MM. A phase I study showed that concurrent administration of IPI, an antibody that blocks cytotoxic T-lymphocyte antigen-4, and VEM, an inhibitor of BRAF V600-mutated kinase, caused significant dose-limiting hepatotoxicity in BRAF-mutant MM pts. An alternate strategy is to use these agents sequentially in order to minimize toxicities observed with concurrent administration and to improve efficacy over either agent alone. **Methods:** This single-arm, open-label, phase II study evaluated the safety of VEM followed by IPI in treatment-naïve MM pts harboring a BRAF V600 mutation. Pts initially received VEM for 6 weeks (960 mg twice daily) followed by IPI at 10 mg/kg (Q3W x 4 doses, then Q12W beginning at week 24 until disease progression or unacceptable toxicity) [VEM1-IPI phase]; VEM was then restarted. The primary objective was to estimate the incidence of grade 3–4 drug-related skin adverse events (AEs) during the VEM1-IPI phase. **Results:** Among 46 pts treated in the VEM1-IPI phase, 80% were male, 52% had stage M1c, and 54% had ≥ 5 sites involved. Grade 3–4 drug-related skin AEs occurred in 15 (33%) pts during the VEM1-IPI phase, the most common of which was rash in 9 (20%) pts. Grade 3–4 drug-related gastrointestinal AEs occurred in 10 (22%) pts (diarrhea in 5 [11%]) and hepatobiliary AEs in 2 (4%) pts (hepatitis; hyperbilirubinemia). There were no deaths due to study drug toxicity. At a median follow-up of 10.5 mo, the objective response rate was 30% (95% CI, 18%–46%) during the VEM1-IPI phase. Median progression-free survival was 4.4 mo (95% CI, 4.2–5.9). Interim median overall survival was 20.3 mo (95% CI, 11.1–NE). **Conclusions:** VEM followed by IPI at 10 mg/kg has a manageable safety profile with no significant signals of hepatobiliary toxicity, as seen with concurrent VEM and IPI; the incidence of grade 3–4 skin AEs was higher than with either agent alone. The benefit/risk of this sequence needs to be evaluated further based on individual patient characteristics and new treatment options. Clinical trial information: NCT01673854.

9033 Poster Session (Board #276), Mon, 1:15 PM-4:45 PM

Clinical features of cobimetinib (COBI)–associated serous retinopathy (SR) in *BRAF*-mutated melanoma patients (pts) treated in the coBRIM study. *First Author: Luis De La Cruz-Merino, Hospital Universitario Virgen Macarena, Seville, Spain*

Background: Various ocular adverse events (AE) have been described with targeted agents. MEK inhibitors (MEKi) are associated with SR. We describe the clinical features of SR observed with COBI in the coBRIM study. **Methods:** coBRIM is a multicenter phase 3 study that evaluated the efficacy and safety of COBI + vemurafenib (VEM) in advanced $BRAF^{V600}$-mutated melanoma pts (Larkin et al. *N Engl J Med* 2014;371:1867-76). Ophthalmic examinations, including optical coherence tomography, were performed at baseline, day 28 and every 3 cycles thereafter (84 days). SR cases were identified in the study database using a group of relevant and synonymous AE terms. Corresponding clinical data were abstracted. **Results:** 495 advanced $BRAF^{V600}$-mutated melanoma pts were randomly assigned to receive COBI + VEM or placebo (PB) + VEM. No pt had retinal abnormalities at baseline. A total of 83 SR events were reported in 63 pts (26%) in the COBI + VEM arm (median age: 59 yr, male: 59%) and 7 SR events in 7 pts (3%) in the PB + VEM arm (median age: 62 yr, male: 29%). Highest severity grade of SR observed in the COBI + VEM arm were NCI-CTCAE grade 1 (asymptomatic/mild symptoms) – 33 pts (52%), 2 – 23 (37%), 3 – 6 (10%) and 4 – 1 (2%). All pts in the PB + VEM arm had grade 1 SR, except 1 pt with grade 2 SR. Median time to first onset of SR was 1 month in both arms. In the COBI + VEM arm, the majority of grade ≥ 2 SR (52%) occurred before study day 12 and most grade 1 SRs were identified during surveillance ophthalmic examination. No other concurrent ocular abnormalities (cornea, conjunctiva, anterior chamber or vitreous) were reported. Most (74%) grade 1 SR events were followed clinically without modification of COBI doses, while grade 2 and 3 SR events were commonly managed with interruption or reduction of COBI. After dose interruption, reduction, or permanent discontinuation of COBI, 75% of SR events resolved or were resolving. **Conclusions:** COBI-related SR occurred in 26% of COBI + VEM treated pts. The majority of SR observed with COBI was of low severity grade and was managed with dose modification of COBI. Surveillance ophthalmic examination identified mostly asymptomatic low severity grade SR, for which clinical significance is uncertain. Clinical trial information: NCT01689519.

9034 Poster Session (Board #277), Mon, 1:15 PM-4:45 PM

Prognostic relevance of baseline neutrophils and derived neutrophil to lymphocyte ratio for ipilimumab-treated advanced melanoma patients. *First Author: Pier Francesco Ferrucci, European Institute of Oncology, Milan, Italy*

Background: Clinical responses to ipilimumab are variable in terms of onset, magnitude and duration. Upfront identification of patients who are more likely to benefit from treatment is a major need. The prognostic value of baseline neutrophils and derived neutrophil to lymphocyte ratio (dNLR) has been addressed in different malignancies with interesting but contrasting data. **Methods:** Data from 720 metastatic melanoma patients treated with ipilimumab 3 mg/kg within the Italian expanded access programme were analyzed. Patients were stratified according to baseline neutrophilia (ANC ≥ 7500) and derived neutrophil to lymphocyte ratio (dNLR). The optimal cut-off value of baseline dNLR for survival was determined by the receiver operating characteristics curve analysis. Overall survival and progression free survival were estimated using the Kaplan-Meier method. The prognostic values of ANC and dNLR were assessed using multivariate Cox proportional hazard models. **Results:** The median follow-up was 16.5 months. Both baseline neutrophilia and dNLR were significantly associated with the outcome of melanoma patients treated with ipilimumab, in terms of disease progression and death ($P< 0.0001$ for all). When the two indexes were combined, we found that patients with both elevated ANC and dNLR had a significantly increased risk of death (HR = 6.25; 95%CI: 4.73-8.25) and of progression (HR = 4.60; 95%CI: 3.51-6.03) when compared to patients with both low ANC and dNLR. The 1-year and 2-years survival rates were 2% and 0%, respectively, for patients with both elevated ANC and dNLR, and 43% and 24%, respectively, for patients with both low ANC and dNLR. **Conclusions:** By analyzing a large cohort of ipilimumab-treated advanced melanoma patients, we identified a subpopulation of patients that is very unlikely to benefit from this treatment. Based on these data responders could be easily selected from general population, allowing for an upfront screening that could spare toxicity to non responder ones.

9035 Poster Session (Board #278), Mon, 1:15 PM-4:45 PM

An adjuvant clinical trial of SCIB1, a DNA vaccine that targets dendritic cells *in vivo*, in fully resected melanoma patients. *First Author: Poulam M. Patel, University of Nottingham, Nottingham, United Kingdom*

Background: SCIB1 is a DNA vaccine encoding a human IgG1 antibody, with T cell epitopes from gp100 and TRP-2 antigens engineered into its CDRs. It targets dendritic cells *in vivo* via the high affinity Fc receptor. A clinical trial in stage III/IV melanoma patients showed that doses of 2-8 mg could induce T cell responses in 7/9 patients with no associated toxicity. Overall median survival was 24 months. In this study SCIB1 is used as an adjuvant therapy. **Methods:** 16 patients with fully resected stage III (9) or stage IV (7) melanoma, were immunised with SCIB1 by Intramuscular electroporation at 0, 3, 6, 12 and 24 weeks. Patients tolerating treatment were allowed to continue treatment for up to 5 years. **Results:** Thirteen patients received 4mg doses of SCIB1 on 5 occasions and one received 4 doses of 4mg followed by one dose of 2mg. One patient only tolerated administration of three 2mg doses of SCIB1. One patient received three 2mg doses and then two 4mg doses. Seven patients received additional doses of SCIB1. One patient received 3 doses prior to withdrawal due to disease progression and one patient received 5 doses. The other six patients remain on continuation: three have received 5 doses and two have received 6 doses of SCIB1. Apart from soreness at the injection site, there have been no significant toxicities. All sixteen patients showed an epitope specific proliferation response *ex vivo* and an γIFN Elispot response *in-vitro*after T cell expansion. Eleven patients responded to all 4 epitopes, three patients to 3 epitopes, one patients to 2 epitopes and one patients to 1 epitope. All patients with continued treatment showed strong T cell memory responses. Currently patients have a median survival time from trial entry of 29.5 months and from diagnosis of metastases of 34 months. Progression free survival is 78% and 72% for stage III and IV respectively and overall survival is 100% for both groups. Only 4 patients have relapsed at 4, 14, 18 and 18 months, since the last relapse there have been no further recurrences for 23 months. **Conclusions:** These results suggest that SCIB1 may confer protection from recurrence of melanoma with little associated toxicity. This vaccine deserves further evaluation as an adjuvant therapy. Clinical trial information: 2009-017355-10.

9036 Poster Session (Board #279), Mon, 1:15 PM-4:45 PM

Updated overall survival (OS) results for BRF113220, a phase I–II study of dabrafenib alone versus combined dabrafenib and trametinib in patients with *BRAF* V600 metastatic melanoma (MM). *First Author: Adil Daud, UC San Francisco, San Francisco, CA*

Background: This Phase I—II study evaluated the safety and efficacy of the combination of dabrafenib and trametinib (the combination) compared with dabrafenib alone (monotherapy) in patients (pts) with *BRAF* V600 MM. **Methods:** *BRAF* V600E/K MM pts naive to BRAF and MEK inhibitors were enrolled. Part B (Ph I, n = 77 BRAFi-naive) pts enrolled into escalating dose (mg) cohorts of dabrafenib twice daily (BID)/trametinib once daily (QD) as follows: 75/1, 150/1, 150/1.5 and 150/2. Part C (Ph II, n=162) pts were randomized 1:1:1 to dabrafenib 150 mg monotherapy, 150/1 and 150/2. Crossover from monotherapy to 150/2 combination was allowed post-progression of disease. Primary endpoints were progression-free survival, response rate, duration of response, and safety; secondary endpoints were OS and pharmacokinetics. **Results:** Previously reported landmark 2-year OS results for pts in Parts B and C with median follow-up of 35 and 34 mo is presented in Table 1.In Part C, median OS rate for 150/2 combination pts was 25 mo (HR = 0.79 vs monotherapy; p = 0.3341). OS rate for monotherapy was confounded by crossover to the 150/2 arm; 45 (83%) pts crossed over at time of analysis. In the 150/2 arm, 16 (30%) pts continued to receive combination beyond progressive disease. Subsequent systemic therapies were similar across arms; 39 (24%) pts received ipilimumab, 17 (10%) received anti-PD-1/PD-L1 therapies, and 21 (13%) received vemurafenib. **Conclusions:** Landmark 2-year OS rate was 51% for Part C 150/2. Further follow-up is ongoing. Landmark 3-year OS rate and safety data with 12 mo additional follow-up will be presented. NCT01072175 Clinical trial information: NCT01072175.

Treatment	Deaths, n (%)	Med. OS, mo (95% CI)	HR (95% CI) p-value	12-mo OS rate (%)	24-mo OS rate (%)
Part B 150/2 combination (n = 24)	10 (42)	27.4 (12.9, NR)	NA	72	60
Part C dabrafenib monotherapy (n = 54)	36 (67)	20.2 (14.5, 27.1)	NA	70	44
Part C 150/2 combination (n = 54)	32 (59)	25.0 (17.5, NR)	0.79 (0.49, 1.27) 0.3341	80	51

9037 Poster Session (Board #280), Mon, 1:15 PM-4:45 PM

Prognostic value of *BRAF^{V600}* mutations in American Joint Committee on Cancer (AJCC) stage 3 cutaneous melanoma patients in the MelanCohort prospective cohort. *First Author: Philippe Saiag, Hospital Ambroise Pare, Boulogne-Billancourt, France*

Background: Prognosis of AJCC stage 3 melanoma pts is heterogeneous. The prognostic value of *BRAF^{V600}* mutations in melanoma is debated. In a retrospective study of 105 stage 3 pts with a nodal deposit of > 2 mm, we showed that *BRAF^{V600}*mutation was an independent factor of decreased both overall and distant metastasis free survivals (DMFS). We aimed to validate this finding in an independent prospective data set and to expand it to the entire AJCC stage 3 spectrum. **Methods:** We selected all pts with AJCC stage 3 cutaneous melanoma at inclusion or during follow-up that were included in Melancohort (NCT00839410), which recruited prospectively during 2003-8. *BRAF^{V600}*mutations were detected by pyrosequencing of DNA in nodal or in transit met samples with > 60 %melanoma cells. Melanoma was considered mutated when > 10% of DNA was mutated. Endpoints were melanoma-specific survival (MSS) and DMFS. Kaplan-Meier curves and multivariate Cox PH regression model were used. 9 pts receiving targeted therapy were censored at first dose given. A sample of 155 pts gave 89% power to detect an HR of 2 for survival, with α risks set at 0.05. **Results:** Median follow-up for stage 3 pts was 56 months. *BRAF* status was assessed in 158 melanomas. *BRAF^{V600mut}* (V600E & V600K in 89 and 9 % of cases, respectively) were detected in 50.6 % of melanomas. The only significant differences according to BRAF at entry in AJCC stage 3 were histological subtypes and age (younger for *BRAF^{V600mut}*). The only characteristics associated with worst MSS in multivariate model were higher AJCC stage (P = 10^{-5}, HR: 2.74, 95%CI: 1.69-4.43), age > 50 (P = 0.02, HR: 1.86, 95%CI: 1.1-3.14), *BRAF^{V600mut}* (P = 0.02, HR: 1.9, 95%CI: 1.1-2.78), male sex (P = 0.02, HR 1.71, 95%CI 1.06-2.75), and mitosis in primary melanoma (P = 0.04, HR 1.6, 95%CI 1.01-2.54). Worst DMFS was associated with higher AJCC stage (P = 0.003, HR: 1.9, 95%CI: 1.27-2.85), age > 50 (P = 0.0007, HR: 2.11, 95%CI: 1.34-3.33), and *BRAF^{V600mut}* (P = 0.02, HR: 1.59, 95%CI: 1.05-2.38). **Conclusions:** *BRAF^{V600mut}* was an independent prognostic criteria in stage 3 pts. This may help to better characterize this stage. Results of adjuvant trials in *BRAF^{V600mut}* stage 3 pts are urgently needed. Clinical trial information: NCT00839410.

9038 Poster Session (Board #281), Mon, 1:15 PM-4:45 PM

***XPC, XPF, TP53* and *GSTP1* polymorphisms in prognosis of cutaneous melanoma patients.** *First Author: Carmen Silvia Passos Lima, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil*

Background: *XPC*, *XPF*, *TP53* and *GSTP1* genes act on repair and detoxification of ultraviolet (UV) radiation-induced DNA damage, which are related to cutaneous melanoma (CM) development and progression. The DNA repair ability is variable in humans, since the genes enrolled in the process are polymorphic. This study aimed to evaluate whether *XPC* c.2815A > C, *XPF* c.2505T > C, *TP53* c.215G > C and *GSTP1* c.313A > G polymorphisms are associated with survival of CM patients. **Methods**: We analyzed 237 CM patients diagnosed from 2000 to 2014 at the University of Campinas. Genomic DNA of patients was analyzed by polymerase chain reaction and restriction fragment length polymorphism assays, for discrimination of pertinent genotypes. Relapse-free survival (RFS) and overall survival (OS) times were calculated using Kaplan-Meier estimate probabilities and differences between survival curves were analyzed by the log-rank test. The prognostic impact of genotypes was examined using univariate and multivariate Cox regression analyses. **Results**: The median follow-up time of all patients enrolled in this study was 52 months (range: 0.9-175.1 months). At 60 months of follow-up, patients with *XPC* CC genotype presented shorter RFS (59.6% vs. 74.0%, *P*= 0.03), and patients with *XPF* CC genotype presented a tendency for short RFS (48.0% vs. 73.5%, *P*= 0.06) and a shorter OS (71.8% vs. 85.6%, *P*< 0.001) than those with other genotypes (Kaplan-Meier estimates). Patients with *XPC* CC genotype (HR: 1.85, *P* = 0.03) and *XPF* CC genotype (HR: 3.59, *P*= 0.01) had more chance to recurrence than those with other genotypes in univariate and multivariate Cox regression analyses, respectively. Patients with *XPF* CC (HR: 3.52, *P*= 0.001) and *XPF* TC+CC (HR: 9.40, *P*= 0.02) genotypes were associated with greater risk of progressing to death than other genotypes in univariate and multivariate Cox regression analyses, respectively. **Conclusions**: The data suggest, for the first time, that inherited abnormality in DNA repair pathway related to *XPC* and *XPF* polymorphisms influence prognosis of CM patients. These findings, once validated in additional studies, will contribute to individualize high-risk patients, who deserve to receive a closer follow-up and/or adjuvant therapy.

9039 Poster Session (Board #282), Mon, 1:15 PM-4:45 PM

A global genomic and small molecule inhibitor interrogation of KIT mutant melanoma to reveal underlying biology and novel molecular targets. *First Author: Junna Oba, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Activating mutations in *KIT* are present in 15-20% of acral lentiginous (AL), mucosal (MM) and chronic sun-damaged melanomas. Functional studies in *KIT* mutant melanoma have been hampered by a paucity of cell lines with recurrent mutations, and limited information about the molecular context in which they occur. This study analyzes the co-mutation status of a large set of cancer-related genes that could influence cell signaling programs in *KIT* mutant melanomas. Further, we perform first-to-date functional studies on a melanoma cell line with a common (10%) recurrent *KIT* mutation at amino acid position 822. **Methods:** Results of a CLIA-certified clinical next-generation sequencing (NGS) platform that interrogates regions of recurrent mutations in 46 cancer-related genes for 1430 melanoma patients were reviewed to identify tumors with mutations in *KIT* (n = 116). Those tumors were analyzed for associated clinical and molecular characteristics. A novel *KIT* mutant (N822Y) melanoma cell line was generated from an AL tumor, upon which global copy number, protein activation and high-throughput small molecule inhibitor testing were performed. **Results:** Among patients with clinical NGS results, 116 tumors with *KIT* mutations were identified (46 non-acral cutaneous [CM], 26 AL and 44 MM). Unlike *KIT* mutant CMs, AL and MM tumors harbored few non-redundant *KIT* missense mutations or mutations in known oncogenes (*BRAF, N/H-RAS*), and when present, mutations in tumor suppressor genes were more frequent in CM tumors by the technique employed. Low frequency hotspot mutations in *CTNNB1* were present in all *KIT* mutant subtypes (2-12%). A bioactive 1,161 compound screen of an AL KIT N822Y cell line revealed a selective set of compound classes (KIT, RAF, PI3K-MTOR, CDK inhibitors) to meet threshold efficacy. **Conclusions:** AL and MM *KIT* mutant melanomas lack co-mutations frequently present in CMs. High-throughput compound screening test of KIT (N822Y) melanoma cell line suggests a small set of compound classes for combinatorial screening.

9040 Poster Session (Board #283), Mon, 1:15 PM-4:45 PM

Patient-reported outcomes (PROs) in KEYNOTE-002, a randomized study of pembrolizumab vs chemotherapy in patients (pts) with ipilimumab-refractory (IPI-R) metastatic melanoma (MEL). *First Author: Dirk Schadendorf, University Hospital Essen, Essen, Germany*

Background: Pembrolizumab is approved for treating advanced MEL that progressed following IPI and, if *BRAF*^{V600} mutant, a BRAF inhibitor. In KEYNOTE-002 (NCT01704287), pembrolizumab significantly prolonged PFS compared with chemotherapy in IPI-R advanced MEL ($P < .0001$) and was associated with a lower rate of grade 3-5 AEs. Herein, we present the PRO analysis. **Methods:** Pts with advanced MEL that progressed within 6 mo after ≥2 IPI doses and, if *BRAF*^{V600} mutant, following a BRAF/MEK inhibitor, were randomized 1:1:1 to pembrolizumab 2 or 10 mg/kg every 3 wk or investigator's choice of chemotherapy. Primary end points were PFS and OS. PROs were an exploratory end point with prespecified analysis. The EORTC QLQ-C30 was collected at baseline, wk 3, 6, 12, 24, 36, treatment discontinuation, and safety follow-up. The key PRO end points are the score change from baseline and the proportions of improvement/deterioration at wk 12 of the global health status score. A constrained longitudinal data analysis model assessed between-arm differences in all pts with ≥1 PRO assessment. **Results:** 520 of 540 enrolled pts were included in the PRO analysis. Baseline global health status scores were similar across treatment arms. Pembrolizumab-treated pts had significantly lesser decreases from baseline in the global health status scale score compared with control (Table). At wk 12, the proportion of pts with a ≥10-point decrease in global health status was 38% for control, 32% for pembrolizumab 2 mg/kg, and 27% for pembrolizumab 10 mg/kg. Pembrolizumab-treated pts had consistently lesser score changes from baseline for the different function and symptoms scales. **Conclusions:** In KEYNOTE-002, quality of life was maintained to a greater degree with pembrolizumab versus chemotherapy in IPI-R MEL. Clinical trial information: NCT01704287.

	Global Health Status Scale Score				
	Baseline		Wk 12		Change From Baseline, Least Squares Mean (95% CI)
	Mean	SD	Mean	SD	
Control (n = 167)	64.0	21.9	59.0	23.2	–9.1 (–12.9, –5.4)
Pembro 2 mg/kg (n = 176)	66.2	22.1	66.3	23.0	–2.6 (–6.2, 1.0)*
Pembro 10 mg/kg (n = 177)	63.0	23.6	64.3	22.9	–2.6 (–6.0, 0.9)*

*P = .01 versus control.

9041 Poster Session (Board #284), Mon, 1:15 PM-4:45 PM

Melanoma-specific MHC-II expression to predict response to α-PD-1 therapy. *First Author: Justin M. Balko, Vanderbilt Univ Medcl Ctr, Nashville, TN*

Background: αPD-1 therapy yields objective clinical responses in 30-40% of advanced melanoma (MEL) patients (pts). While promising, many pts do not benefit clinically. Predictive biomarkers to guide pt selection are needed. We hypothesized that tumor antigen presentation (MHC-I or MHC-II expression) is a requirement of αPD-1 benefit, and presence of these cell surface markers would predict benefit. **Methods:** We profiled MHC-I/II mRNA across 60 MEL cell lines. The transcriptional characteristics of MHC-II+ cell lines were analyzed by Gene Set Analysis. Cell surface expression of MHC-I and MHC-II was confirmed by flow cytometry (FC) in a subset of cell lines under basal and stimulated (IFNγ) conditions. In 26 tumor samples from αPD-1 treated MEL pts, immunohistochemistry (IHC) was performed for HLA-DR (MHC-II) or HLA-A (MHC-I), SOX10, CD4 and CD8. IHC results were correlated with response and progression-free survival (PFS). **Results:** MHC-I mRNA was expressed in all cell lines while MHC-II expression was bimodal (60% positive). MHC-II$^+$ cell lines had transcriptional signatures of the PD-1 signaling, allograft rejection, and T-cell receptor signaling. By FC, MHC-II$^+$ (mRNA) cell lines were constitutive and inducible (IFNγ stimulation) for HLA-DR while MHC-II$^-$ cells did not express or induce HLA-DR. In contrast, all tested cell lines significantly upregulated PD-L1 with IFNγ stimulation. Of 26 pts treated with αPD-1, 10 were MHC-II$^+$. All 10 MHC-II$^+$ (100%) pts had partial, complete, or mixed responses (MR), while only 7/16 (44%) of MHC-II$^-$ pts benefited (Fisher's exact p = 0.004). Excluding MR pts (n = 2), median PFS for MHC-II$^+$ was 728 days (d), while the median PFS for MHC-II$^-$ tumors was 98d (log-rank p = 0.01) . MHC-II$^+$tumors had enhanced CD4 and CD8 infiltrate (Pearson's correlation p = 0.000002 and p = 0.03, respectively). MHC-I positivity was ubiquitous and not associated with response. **Conclusions:** A subset of MEL demonstrates an MHC-II signature that correlates with αPD-1 response and enhanced CD4/CD8 T-cell infiltrate. MHC-II+ tumors can be robustly identified by routine melanoma-specific IHC for HLA-DR to guide pt selection. Combining HLA-DR IHC with other biomarkers, including PD-L1 expression may further improve pt selection.

9042 Poster Session (Board #285), Mon, 1:15 PM-4:45 PM

Multiplatform biomarker analysis on non-sun exposed mucosal melanoma. *First Author: Alan H. Bryce, Mayo Clinic, Scottsdale, AZ, Scottsdale, AZ*

Background: Mucosal melanoma is a rare malignancy, notoriously resistant to conventional chemotherapy, with few treatment options. Because of their origin, they do not receive screening and, hence, are detected in advanced stages where prognosis and curative rates are poor. The purpose of this study is to identify novel, potential targets and therapeutic options for this disease, utilizing a multiplatform approach. **Methods:** In total, 93 mucosal melanoma specimenswere tested via a multiplatform profiling service (Caris Life Sciences, Phoenix, AZ) consisting of gene sequencing (Sanger or next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]) and/or gene amplification (CISH or FISH). Conjunctival melanoma was excluded. **Results:** Notable protein overexpression rates included co-expression of PD-1 and PD-L1 (71.4%, 5/7) and cKIT (42.4%, 14/33). Percent agreement between c-KIT by IHC and sequencing was 62% (16/26). Overall, sequencing revealed the highest mutation rates in TP53 (17%, 4/23), cKIT (18.2%, 14/77), BRAF (12.0%, 10/83), and NRAS (10.0%, 4/40). A sub-analysis of BRAF, cKIT, and NRAS (BRAF/cKIT/NRAS) based on the anatomic location of the melanoma revealed the following: sinonasal (5.3%, 0.0%, 27.0%), vulvovaginal (21.2%, 27.3%, 7.1%), and anorectal (5.0%, 18.0%, 0.0%). Details on the TP53-mutated specimens (n=4) are shown in the table below. **Conclusions:** Multiplatform tumor profiling identified multiple, potentially actionable targets. Given the high rate of PD-1 and PD-L1 co-expression, new immunotherapies should be strongly considered in advanced stages of this disease. In addition, mutations detected may provide further guidance in this rare malignancy. The highest rates of NRAS mutations occurred in the sinonasal melanomas. Meanwhile, cKIT mutations were highest in vulvovaginal and anorectal mucosal melanomas. This variability in mutation rates of BRAF, cKIT, and NRAS based on the primary site's location should be further elucidated in larger studies for potential diagnostic and theranostic purposes.

Specimen Primary Site	TP53 Mutation(s)
Sinonasal	H179R (c.536A>G)
Nasopharyngeal	V272L (c.814G>T), R248W (c.742C>T)
Vaginal	R337C (c.1009C>T), R273C (c.817C>T)
Rectal	N268fs

9043 Poster Session (Board #286), Mon, 1:15 PM-4:45 PM

Analysis of CTLA4 expression on T regulatory cells in patients with advanced stage melanoma in the setting of high dose IL-2 (HDIL-2). *First Author: Maggie L. Diller, Emory University, Atlanta, GA*

Background: HDIL-2 is associated with long-term remissions in stage IV melanoma, but in less than 10% of patients. Combination therapy with HDIL-2 and agents immunomodulating CTLA-4 have been undertaken. We investigated the effect of HDIL-2 on CTLA4 expression on T cell subsets in patients with melanoma. **Methods:** Peripheral blood was collected at baseline and serially post-treatment at 24, 48, 72, and 96 hours from 6 patients with advanced stage melanoma undergoing HDIL-2. All patients were treatment naïve with regard to anti-CTLA4 therapy. PBMCs were isolated and restimulated ex vivo for 4 hours using PMA/ionomycin. Fluorophore conjugated anti-CTLA4 antibody was added at time of restimulation and incubated with cells for 4 hours. Intracellular and extracellular cytokine staining was then performed and co-signaling molecule expression was quantified via flow cytometry and measured on a continuous scale. Statistical analysis was performed using paired *t* tests via Prism 6.0e software. **Results:** HDIL-2 resulted in increased frequencies of T regulatory cells ($T_{reg;}$ CD25+FoxP3+CD4+) on day 4 of therapy (24% +/- 12% on day 4 compared to 12% +/- 7% at baseline; p = 0.03; 95% CI [1.5,22]). Importantly, CTLA4 expression on T_{reg} cells was increased on day 4 post-treatment relative to baseline (51% +/- 19% on day 4 compared to 35% +/- 19% at baseline; p = 0.02; 95% CI [2.5,28]). CTLA4 expression was not statistically different within other CD4+ T cell compartments or within the CD8+ T cell compartments. **Conclusions:** These results demonstrate that HDIL-2 is associated with an increase in the expression of CTLA4 onT_{reg} cells in patients with advanced melanoma. HDIL-2 effect on the T_{reg} population provides a potential rationale for the lack of efficacy of HDIL-2 in most patients and implies potential synergy between HDIL-2 and CTLA4 blockade. Together, these findings provide justification for testing the combination of HDIL-2 and anti-CTLA4 therapy in patients with advanced melanoma and that timing of anti-CTLA4 therapy with HDIL2 will be crucial.

9044 Poster Session (Board #287), Mon, 1:15 PM-4:45 PM

Association of PD-L1 expression in melanoma with response and prognosis to ipilimumab. *First Author: Caroline Brueggemann, Department of Dermatology, University Hospital Erlangen, Erlangen, Germany*

Background: Immunotherapy with ipilimumab demonstrated a statistically significant survival benefit. In two large phase III trials responses were observed in 10-15% of patients. However, 64% of patients exhibited significant and 20% of the patients severe grade 3 and 4 side effects. Identifying predictive biomarker profiles could enable better treatment allocation. **Methods:** In this multicenter study 176 tumor samples from 125 patients with metastatic melanoma were analyzed for PD-L1 gene expression, thereof 78 patients had received ipilimumab (30 responders and 48 non-responders). mRNA was extracted from formalin-fixed paraffin embedded (FFPE) tumor tissue by a fully automated method and measured by quantitative RT-PCR. Differences of survival and PD-L1 expression between patient groups were assessed using the Mann-Whitney U test, the logrank test and the Kaplan-Meier technique. **Results:** Patients with low PD-L1 expression showed a significantly better survival than those with high expression of PD-L1 ($p = 0.002$) not considering the subsequent therapy. No statistical difference in PD-L1 expression between responders ($n = 30$) and non-responders ($n = 48$; $p = 0.458$) to ipilimumab was observed. **Conclusions:** Our results suggest that PD-L1 expression is not predictive for response to therapy with ipilimumab but is a positive prognostic marker for survival of melanoma patients.

9045 Poster Session (Board #288), Mon, 1:15 PM-4:45 PM

Evaluation of the impact of infliximab use for the treatment of ipilimumab related diarrhoea on the outcome of patients with advanced melanoma. *First Author: Edurne Arriola, University of Southampton, Southampton, United Kingdom*

Background: The use of immunosuppressants for the treatment of immune related (IR) toxicities from immunoregulatory antibodies, such as ipilimumab is intended to dampen harmful adaptive immune responses. It is uncertain whether this also results in reduction of anti-tumour immunity and adversely affects disease specific outcome. The aim of our study was to evaluate the impact on overall survival (OS) of infliximab use for the treatment of immune related diarrhoea from ipilimumab in patients with metastatic melanoma. **Methods:** We retrospectively evaluated 90 patients with advanced melanoma treated with ipilimumab (3mg/kg) with assessment of response during and following treatment. We recorded clinical characteristics, toxicity data and outcome. Kaplan Meier and Log rank tests were used to assess outcome differences. **Results:** Fifty-one percent of patients were male, the median age was 64 years; sixty-nine (77%) patients has cutaneous primaries, 11(12%) uveal and 2(2%) mucosal. Sixty-five patients (72%) had M1c disease. *BRAF*assessment was available in 77% of tumours and 32% cases harboured a V600E mutation. Ipilimumab was administered as second line treatment and 60% completed four cycles. Thirty percent ($n = 27$) of patients developed ipilimumab-related diarrhoea of any grade. Twenty-one (80%) required oral steroids for management, escalated to iv methylprednisolone (1-2mg/kg/24hrs) in 12 cases. In seven patients (25%) infliximab was required to control G3/4 colitis. Median follow up was 8 months for the whole population. M1c disease, poor performance status at treatment initiation and progression at the week 12 response assessment were associated with shorter survival (all p-values < 0.05). Patients who developed diarrhoea had improved OS when compared to those who did not (8.8m vs 5.4m; $p = 0.041$). Within patients with diarrhoea, the median OS of those treated with infliximab compared to those without was 8.8m vs 6.8 ($p = 0.16$), respectively. **Conclusions:** In our series infliximab does not negatively affect the outcome of patients with advanced melanoma treated with ipilimumab and early switch in order to spare steroid toxicity appears warranted and safe.

9046 Poster Session (Board #289), Mon, 1:15 PM-4:45 PM

Safety of infusing ipilimumab (ipi) over 30 minutes (min). *First Author: Parisa Momtaz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The approved dose of ipi is 3mg/kg infused over 90 min. In clinical trials, however, 10mg/kg has also been infused over 90 min. At 10mg/kg, patients (pts) receive 3mg/kg within the first 27 min of treatment. We sought to determine if the standard 3mg/kg dose could be safely infused over 30 min. **Methods:** We first retrospectively reviewed the incidence of infusion-related reactions (IRRs) to ipi at our institution in melanoma pts receiving either 3mg/kg or 10mg/kg doses infused over 90 min. Our findings led to a change in institutional guidelines for ipi infusion time from 90 min to 30 min. We then prospectively reviewed the 30 min infusion of ipi. **Results:** Between 4/1/08 and 6/30/13, 595 pts received ipi infused at either 3mg/kg ($n = 457$) or 10mg/kg ($n = 138$) over 90 min. There was no significant difference in the incidence of IRRs between pts receiving 10mg/kg (4.3%) vs. 3mg/kg (2.2%) of ipi over 90 min ($p = 0.22$). 120 pts were then treated prospectively with 3 mg/kg ipi infused over 30 min. 7 pts (5.8%) had an IRR ($p = 0.06$ compared to 10/457 (2.2%) in the 3 mg/kg 90 minute infusions). All IRRs occurred at dose 2; 6 were grade 2, one was grade 3. Five IRRs occurred during the infusion, two occurred after (one 30 min after and the second immediately after completion of infusion). All 7 pts received subsequent doses of ipi safely administered over a range of 30-90 min. 5/7 pts received subsequent doses with pre-medication (diphenhydramine, steroids) without incident. One of the 2 pts who did not receive pre-medication at dose 3, experienced an IRR at dose 3, received pre-medication for dose 4, and did not experience an IRR at dose 4. **Conclusions:** Ipi at 3mg/kg can be infused safely over 30 min with an acceptably low incidence of IRRs. Dose 2 is most commonly associated with an IRR. After an IRR, patients can safely receive additional doses of ipi with premedication. It is unclear from our data whether subsequent infusions need to be administered more slowly. It may be reasonable to observe patients for a short period of time after the infusion. A 30 min infusion time enhances patient convenience and allows more efficient use of outpatient infusion facilities.

9047 Poster Session (Board #290), Mon, 1:15 PM-4:45 PM

Efficacy of high-dose adjuvant interferon therapy in high-risk melanoma harboring gene mutations. *First Author: Xuan Wang, Peking University Cancer Hospital & Institute, Beijing, China*

Background: BRAF/NRAS mutations are predictors of poor prognosis in melanoma. High-dose interferon (HDI) is the only drug approved by FDA as adjuvant therapy in high risk resected melanomas. However, efficacy of HDI in high-risk melanomas harboring BRAF/NRAS mutations has not been evaluated systemically. This study aimed to clarify whether there is beneficial effect of HDI in these patients. **Methods:** Melanoma patients, after melanoma resection, with BRAF mutation (Exon 15) or NRAS mutation (Exon 2) in melanoma of high risk (Stage IIB to Stage IIIC) were enrolled in this study. Patients were randomized (ratio of 2:1) into 1-year adjuvant HDI therapy group ($n = 88$) and observation group ($n = 52$). The endpoint was disease-free survival (DFS). The median follow-up is 16 months till Dec. 2014. Somatic mutations were detected by DNA sequencing. All the statistical analyses were performed using SPSS 16.0 software. **Results:** The proportion of stage IIB/IIC and III disease were 55.0% and 45.0%, respectively. 53.6% patients were acral melanomas. Primary ulceration was found in 52.9% lesions. Of the 140 patients, 108 cases harbored BRAF mutation, and 32 cases with NRAS mutations. At the end of follow-up, 55% patients had metastatic or local recurrence. The overall median DFS was 19.0 months. DFS in HDI group was significantly longer than observation group (21.0 months vs. 10.0 months, $p = 0.002$). DFS of HDI vs. observation group were 19.0 vs. 9.0 months ($p = 0.021$) in BRAF-mutated patients. But stratified analysis did not show significantly DFS improvement of HDI in acral or stage IIB/IIC subgroups in BRAF-mutated patients. NRAS-mutated patients did not get significantly benefit from HDI therapy (DFS: 24.0 months vs. 20.0 months, $p = 0.21$). Stratified analysis did not show significantly different in DFS between two groups either in different stages (stage IIB/IIC vs. III) or in different subtypes (Non-CSD/CSD vs. acral). **Conclusions:** In the BRAF-mutated high-risk melanoma, HDI may provide beneficial effect in the resected patients. However, more powerful adjuvant therapy should be explored for NRAS-mutated melanoma patients.

9048 Poster Session (Board #291), Mon, 1:15 PM-4:45 PM

Evaluation of genetic heterogeneity in paired lymph node metastases from melanoma patients using next-generation sequencing (NGS) approaches. *First Author: Giuseppe Palmieri, ICB-CNR, Cancer Genetics Unit, Sassari, Italy*

Background: In our previous experience (*JCO 2012;30:2522-9*), we demonstrated a high consistency of *BRAF* and *NRAS* mutations between primary tumors and lymph node metastases in melanoma patients. A subset of paired samples of multiple asynchronous lymph node metastases from that series was here screened mainly using NGS technologies in order to better elucidate the existence of a real genetic homogeneity during clonal expansion to lymph node sites. **Methods:** Genomic DNA was isolated from frozen tissues of paired asynchronous lymph nodes, ascertained for presence of melanoma metastases (at least 80% of metastatic cells), using standard methods. Specimens from 12 patients were analyzed for mutations in 50 most common cancer genes with the Ion Torrent AmpliSeq Cancer Panel HotSpot.V2 (CHPv2) on the Ion PGM sequencer. All variants detected by NGS were confirmed through PCR-based Sanger sequencing. Paraffin-embedded tumor tissues from the same series were evaluated by fluorescence *in situ* hybridization (FISH) assays, using probes specific for *CyclinD1*/*EGFR* genes or 9p21 locus and correspondent control centromeres. **Results:** Overall, only one (8%) of the 12 analyzed patients presented discrepancies in mutation patterns between the two distinct lymph nodal metastases developed in different times. In particular, the differences were represented by the BRAF-V600E and the CDKN2A-R80X mutations, suggesting that changes, when occur (though in a limited fraction of cases), they affect the main genes controlling cell proliferation and survival involved in melanomagenesis. No discrepancy was observed by FISH analysis into the same series. Considering the total number of analyzed samples, we detected the following mutations: BRAF-V600E (54% of cases), KDR-Q472H (50%), TP53-P72R (42%), cKIT-M541L (25%), NRAS-Q61R/K (25%). **Conclusions:** Our findings indicated a very low genetic heterogeneity during lymph node dissemination in melanoma patients, confirming the previously published data. Mutations in *BRAF*, *NRAS*, and *cKIT* genes were further confirmed to play a predominant role in melanoma pathogenesis.

9049 Poster Session (Board #292), Mon, 1:15 PM-4:45 PM

Analysis of mTOR Mutations in Chinese Melanoma Patients and Evaluation of Their Sensitivity to PI3K-AKT-mTOR Pathway Inhibitors. *First Author: Yan Kong, Peking University Cancer Hospital & Institute, Beijing, China*

Background: mTOR is a validated target in cancer treatment. *mTOR* mutations are estimated to be 2.46% of all cancers and 5.76% of cutaneous melanoma. However, *mTOR* mutations in other types of melanoma have not been reported. **Methods:** This study involved tumor samples from 412 Chinese melanoma patients, including 210 acral melanomas, 105 mucosal melanomas, 30 melanomas on skin with chronic sun-induced damage and 58 melanomas on skin without chronic sun-induced damage. Tissue samples were analyzed for mutations in all exons of *mTOR* gene in genomic DNA by Sanger sequencing. Mutation status was confirmed using Agilent's sureselect target enrichment system. HEK293T cells stably expressing mutant mTOR were constructed by TALEN (Transcription Activator-like Effector Nucleases). Function of mTOR mutants in these cells and in vitro sensitivity of *mTOR* gain-of-function mutations to PI3K-AKT-mTOR pathway inhibitors were analyzed. **Results:** The overall incidence of somatic mutations within the *mTOR* gene was 10.4% (43/412). Increased *mTOR* mutations were relatively more frequent in acral (11.0%) and mucosal (14.4%) melanomas than in CSD (6.7%) and Non-CSD (3.4%) melanomas. Of the 43 cases with *mTOR* mutations, 41 different mutations were detected, affecting 25 different exons. Point mutations resulting in single amino acid substitutions (totaling 40 mutations detected in 43 patients) were the most common type of *mTOR* mutation. The median survival time for melanoma patients with *mTOR* mutation was significantly shorter than that for patients without *mTOR* mutation ($P = 0.028$). Transient expression of several mTOR mutants in HEK293 cells strongly activated the mTOR/p70S6K pathway. In HEK293 cells with stable expression of H1968Yor P2213S mTOR mutants, LY294002 and AZD5363 showed higher potency than Temsirolimus or BYL719 in inhibiting the mTOR/p70S6K pathway. **Conclusions:** These data demonstrate that *mTOR* mutations are more frequent in Chinese melanoma patients than in Caucasian melanoma patients. *mTOR* mutations is a worse prognostic factor in Chinese melanoma patients. Clinical trials with PI3K-AKT-mTOR pathway inhibitors may be beneficial for melanoma patients with *mTOR* mutations.

9050 Poster Session (Board #293), Mon, 1:15 PM-4:45 PM

Association of immune-related thyroid disorders with pembrolizumab (pembro, MK-3475) in patients (pts) with advanced melanoma treated in KEYNOTE-001. *First Author: Caroline Robert, Gustave Roussy, Villejuif, France*

Background: The anti–PD-1 antibody pembro is approved in the US for treating advanced MEL that progressed following IPI and, if $BRAF^{V600}$ mutant, a BRAF inhibitor. Immune-related AEs (irAEs) are of interest for immunotherapies such as pembro. Among the first 411 MEL pts treated with pembro in the phase 1 KEYNOTE-001 study (NCT01295827), 18% experienced irAEs (4% gr 3/4). We describe the incidence and treatment of thyroid disorders, the most common irAEs observed in KEYNOTE-001. **Methods:** AEs were monitored throughout treatment and for 30 d thereafter (serious AEs and potential irAEs for up to 90 d). AEs were graded per CTCAE v4.0. Thyroid disorders included hypothyroidism, hyperthyroidism, thyroiditis, and related terms. TSH and free T4 (FT4) levels were measured at baseline and once per treatment cycle. **Results:** Thyroid disorders occurred in 39 (9.5%) pts: hypothyroidism in 33 (8.0%), hyperthyroidism in 6 (1.5%), and thyroiditis in 3 (0.7%); 2 pts experienced both hypo- and hyperthyroidism, and 1 pt experienced hypothyroidism and thyroiditis. 2 events were of gr 3 severity: 1 hypo- and 1 hyperthyroidism. Hypothyroidism was managed with long-term hormone replacement therapy, with no permanent discontinuation required; only 4 pts required temporary pembro interruption. 2 pts with hyperthyroidism required corticosteroids, and 2 permanently discontinued pembro. Hyperthyroidism resolved in 83% of pts. Thyroiditis resolved in 67% of pts; no cases required treatment interruption, discontinuation, or corticosteroid use. Median time to onset and duration are shown in the Table. 111 (33.9%) pts had ≥1 abnormal postbaseline TSH or FT4 value, with subclinical hypo- and hyperthyroidism most common (20.5% and 19.3%, respectively). **Conclusions:** Thyroid disorders are the most frequent irAEs associated with pembro. Most events are of gr 1 or 2 severity and can be managed with supportive care and temporary treatment interruption. These findings support regular assessment of thyroid function in pembro recipients. Clinical trial information: NCT01295827.

	Median (range), d	
	Time to Onset	Duration
Hypothyroidism	106 (5-576)	385 (14-740)
Hyperthyroidism	47 (15-665)	84 (29-201)
Thyroiditis	29 (20-64)	57 (43-108)

9051 Poster Session (Board #294), Mon, 1:15 PM-4:45 PM

Utility of PET/CT for surveillance of asymptomatic patients with resected stage III or IV melanoma. *First Author: Roberto Antonio Leon-Ferre, Mayo Clinic, Rochester, MN*

Background: Evidence-based guidelines for the use of surveillance imaging in melanoma patients are lacking. Here, we present a retrospective review of the Mayo Clinic experience using PET/CT (PET) for surveillance of asymptomatic patients with resected stage III-IV melanoma. **Methods:** A search of our radiologic database identified 601 melanoma patients seen at Mayo Clinic who underwent PET between 1/1/2008 and 6/30/2009. 153 met the inclusion criteria of having a resected cutaneous or mucosal stage III-IV melanoma, and at least 2 PETs performed < 1 year apart for surveillance. **Results:** 95(62%) were male and 58(38%) were female. 120(78%) had resected stage III [IIIA: 49(32%), IIIB: 51(33%), IIIC: 20(13%)], while 33(22%) had resected stage IV. Primary was cutaneous in 128(84%), mucosal in 8(5%) and MUP in 17(11%). Mean age at diagnosis of stage III or IV was 54. Of all patients, 80(52%) developed a first recurrence. 39(49%) were asymptomatic, not apparent on exam and detected by PET, 7(9%) were asymptomatic and detected by other imaging techniques, while 27(33%) were symptomatic and 7(9%) were detected on exam. Treatment to no evidence of disease (NED) with resection, radiation or ablation was possible in 26(67%) recurrences detected by PET and in 25(74%) symptomatic or exam-detected recurrences ($p = 0.64$). Median survival was superior among patients whose first recurrence was successfully treated to NED compared to patients in whom treatment to NED was not possible (7.08 vs 2.92 years, $p = 0.0002$). However, median survival was similar regardless of method of detection of first recurrence (5.04 in the PET group vs 5.18 years in the symptomatic group, $p = 0.87$). Median time to detection of first recurrence was 12 months by PET vs 10.7 months by symptoms/exam ($p = 0.93$). Median number of PET per patient was 9. **Conclusions:** Survival was superior among patients with resected stage III or IV melanoma whose first recurrence was amenable treatment to NED. Use of PET, however, did not appear to increase the proportion of patients that benefited from treatment to NED of first recurrence. Survival did not appear to be different among asymptomatic recurrences detected by PET compared to recurrences that were symptomatic or detectable on exam.

9052 Poster Session (Board #295), Mon, 1:15 PM-4:45 PM

Identification of a predictive signature based on immunohistochemical (IHC), RNA-seq and epigenetic profiling of melanoma metastases for response to ipilimumab-based immunotherapy. *First Author: Teofila Seremet, Universitair Ziekenhuis Brussel, Brussels, Belgium*

Background: Ipilimumab (Ipi) improves the survival of patients (pts) with advanced melanoma. Combination of Ipi with an autologous monocyte-derived DC therapy (TriMixDC-MEL) may further improve patient outcome (Neyns et al., 2014 ASCO AM). A predictive melanoma tissue signature for the clinical efficacy of Ipi and TriMixDC is needed to optimize individualized treatment strategies. **Methods:** Between 01/2011 and 05/2013 freshly frozen melanoma metastases were collected from pts treated with Ipi (n: 9), TriMixDC-MEL (n: 2), or TriMixDC-MEL plus Ipi (n: 14). Samples were profiled by IHC (incl. CD3, CD8, PanMel, MCSP, CD20, CD163, DC-LAMP, Casp-3, Ki-67, PHH3, HLA class I, vWF), RNA-seq and MBD-seq (genome-wide DNA methylation profiling). Tumor response was assessed according to the irRC. **Results:** Five pts obtained a complete response (CR), 6 obtained a mixed response (MR), and there was no evidence of tumor response in 14 pts (NR). A total of 26 metastases (15 obtained prior to and 11 post therapy) were profiled by IHC and 18 were additionally profiled by RNA and MBD-seq. Intra-tumor CD3 and CD8 T cell infiltration was observed in 23/26 samples, with variable pattern and extent of infiltration. None of the 3 pts with absent CD3/CD8 infiltration in their tumor core regions responded to Ipi-based immunotherapy. The differential analysis of the RNA-seq data resulted in a list of 195 genes with a statistically significant difference in expression between CR and NR (false discovery rate < 0.05). A gene ontology enrichment analysis revealed that the differentially expressed genes were enriched for immune-related ontologies. The MR expression profiles clustered together with the NR group. MBD-seq revealed differences in methylation status between CR and NR pts. These differences in methylation status were not linked to the observed differences in RNA expression. **Conclusions:** Comprehensive analysis of melanoma metastases with gene expression and methylation status provides a distinct profile that identifies long-term responders to Ipi-based immunotherapy. Prospective validation is warranted.

9053 Poster Session (Board #296), Mon, 1:15 PM-4:45 PM

A multi-center phase II study of high dose IL-2 (HD IL-2) sequenced with vemurafenib in patients with BRAF-V600E mutation positive advanced melanoma. *First Author: Joseph Clark, Loyola Univ Medical Center, Maywood, IL*

Background: Durable unmaintained remissions are consistently observed in a small percentage of patients with metastatic melanoma (mM) treated with HD IL-2. Vemurafenib therapy gives rise to a high response rate in BRAF-V600 (BRAF) mutated melanoma patients, but these are relatively short-lived; thus using both drugs in sequence may complement the individual strengths of each therapy. We report the early efficacy and safety results for the PROCLIVITY01 clinical trial of sequenced vemurafenib and HD IL-2. **Methods:** The primary objective is to assess the CR rate at 10 wks $\pm$3 (assessment 1) and 26 wks $\pm$ 3 (assessment 2) from start of HD IL-2. Trial patients were IL-2 eligible and BRAF mutant positive. Cohort 1 patients were treatment naïve and on trial received vemurafenib 960 mg BID for 6 weeks prior to HD IL-2. Cohort 2 patients received vemurafenib for 7-18 weeks prior to enrollment. Both cohorts received HD IL-2 at 600,000 IU/kg every 8 hours for up to 14 doses on days 1-5 and days 15-19. Vemurafenib was held during HD IL-2 treatment. **Results:** A total of 53 patients received vemurafenib (cohort 1, N = 38); cohort 2 (N = 15). Of these, 40 had assessment 1 and 15 had assessment 2. The overall response rate is14.8% and disease control rate is 51.9% for cohort 1, assessment 1 (n = 27), and 15.4 and 69.2% for cohort 2 (n = 13), respectively. An independent safety committee did not raise safety concerns with the sequencing of these two drugs and patients experienced toxicities as anticipated for IL-2 or vemurafenib. There were no treatment-related deaths. A shift in the melanoma treatment landscape during this trial adversely affected accrual, and led to early trial closure. **Conclusions:** Vemurafenib given in sequence with HD IL-2 did not change the known toxicity profile for either drug. Early efficacy results reveal low response rates for vemurafenib. Durability of response and long term survival will be reported as patients continue to be followed in the PROCLAIM IL-2 database. Clinical trial information: NCT01683188.

9054 Poster Session (Board #297), Mon, 1:15 PM-4:45 PM

Triple wild type melanoma profiling in the Caris Molecular Intelligence registry. *First Author: Krisztian Homicsko, University Hospital Lausanne, CHUV, Lausanne, Switzerland*

Background: Malignant melanoma is a genetically diverse disease. The most frequent mutation is BRAF, followed by NRAS and cKIT mutations. While BRAF, NRAS and cKIT mutations represent the largest fraction of patients, there is also an important group of triple wild type patients (3xWT) in dire need for potential targeted therapies. We compared mutational and PD-L1 profiles of 3xWT tumors using the database of the Caris Molecular Intelligence. **Methods:** We analyzed 541 patient samples for immunohistochemistry (IHC) and next generation sequencing (NGS) data available from the Caris database. Out of the 541 samples 89 samples also had PD-L1 expression data available. Samples were grouped in 4 subtypes: $BRAF^{mut}$ (n = 169), $NRAS^{mut}$ (n = 151), $cKIT^{mut}$(n = 25) and 3xWT (n = 197). **Results:** The database is skewed with an underrepresentation of $BRAF^{mut}$ patients and enrichment of 3xWT tumors. $BRAF^{mut}$, $NRAS^{mut}$, $cKIT^{mut}$and 3xWT patient were 30%, 26%, 3.7% and 40% of the total population, respectively. $BRAF^{mut}$ and 3xWT subgroups have more frequent cMET expression (p = 0.002). While $NRAS^{mut}$ tumors show lack of ERCC1 expression, $cKIT^{mut}$ tumors lack PGP expression. All mutation subtypes present equally frequent expression of MGMT, SPARC, TOP2A, TOPO1, TS, TUBB3 and RRM1 suggestive of multiple chemoresistance pathways. TP53 mutations are recurrent (~15%) in all mutation subgroups. In 3xWT tumors a different spectrum of mutations arise with low frequency ($<$ 10%). Mutant KRAS, JAK3, cMET, GNA11, GNAQ, APC, KDR, BRCA1, ERBB4, represent actionable alterations in up to 40% of that subgroup. None of the 541 tumors presented mutation in Akt, BRCA2, IDH1, CSF1R, GNAS, Notch1, Smo, STK11, VHL, MLH1, MPL, MPM1 A PD-L1 subanalyzes showed an overall 75% positivity. 3xWT tumors were more frequently PD-L1 negative as compared to $BRAF^{mut}$(p = 0.077) **Conclusions:** To our knowledge,the Caris database provides one of the largest profiling of 3xWT. In contrast to $BRAF^{mut}$, $NRAS^{mut}$ and $cKIT^{mut}$ tumors, 3xWT melanoma harbor a more complex mutational landscape. Low frequency mutations can identify targets in up to 40% of these patients. 3xWT are less frequently PD-L1 positive. Overall 3xWT patients should be tested for multiple markers in order to identify low frequency mutations

9055 Poster Session (Board #298), Mon, 1:15 PM-4:45 PM

Survival, biomarker, and toxicity analysis of nivolumab (NIVO) in patients that progressed on ipilimumab (IPI). *First Author: Jeffrey S. Weber, Moffitt Cancer Center, Tampa, FL*

Background: PD-1 antibodynivolumab was administered with/without a multi-peptide vaccine to 126 patients (pts) with unresectable melanoma that failed at least one regimen and were IPI naïve (34), or progressed after IPI (92). We assess its toxicity especially in those with prior dose limiting immune related adverse events (irAEs) to IPI, update survival and response duration data, and characterize myeloid derived suppressor cell (MDSC) and T cell subsets in IPI refractory pts. **Methods:** Pts refractory to IPI received NIVO at 3 mg/kg: two cohorts of pts were A*0201 positive and had either grade 2 or less IPI-related irAE (10 pts), or grade 3-4 dose limiting irAE (21 pts); 61 pts had grade 2 or less irAE, were not HLA restricted and received NIVO alone. Pre- and 12 week post-treatment peripheral blood was analyzed. **Results:** Median follow-up for IPI refractory pts was 18.7 months (mos);the response ratewas 29% by mWHO; 44% had clinical benefit with confirmed partial and complete response or stable disease at 24 weeks (CR+PR+SD).Median duration of response was 14.3 mos. Median progression-free survival (PFS) was 5.4 mos, and estimated median overall survival (OS) was 20.1 mos (95% CI: 17.0, not reached) with 1 and 2 year OS of 69.2% (95% CI: 57.9-78.0%) and 39.1% (95% CI 26.0-52.0%). Of 14 pts that have completed all therapy or stopped due to toxicity while stable or in response, all remain in remission. Of 21 pts with prior IPI-induced grades 3-4 irAEs, only 2 had a subsequent dose limiting (and different) irAE with NIVO, with 8 PR and 5 SD seen; all 8 PR and 3 SD are without progression. Biomarker studies showed that circulating pre-treatment HLA-DR lo/CD14+/CD11b+ myeloid-derived suppressor cells (MDSC) were associated with progression and worse OS (p = 0.0001 and 0.0009). Pre-treatment, MDSC suppressed T cell reactivity (p = 0.006) which was overcome by PD-1 blockade ex vivo, and had high levels of VISTA, CD244 and BTLA. Low PD-L1 and Tim3 expression on MDSC was associated with response. **Conclusions:** This is the first survival assessment in IPI refractory NIVO treated melanoma pts, with median OS of 20.1 mos and PFS of 5.4 mos. Prior irAEs to IPI were not replicated with NIVO. Novel biomarkers of outcome were found on circulating MDSC. Clinical trial information: NCT01176461.

9056 Poster Session (Board #299), Mon, 1:15 PM-4:45 PM

A phase I study of vemurafenib and decitabine in metastatic melanoma. *First Author: Sneha Deepak Phadke, University of Iowa Hospitals and Clinics, Iowa City, IA*

Background: Targeted therapy in metastatic melanoma has shown unprecented response rates. However, this effect is usually short lived, with a median progression free survival of 5.3 months with the use of vemurafenib. This phase I study explored the novel combination of vemurafenib and decitabine. **Methods:** Patients with BRAF V600E mutated metastatic melanoma were eligible for participation. Dosing of decitabine was modified for each cohort, which is detailed in the Table. The primary objective was safety while the secondary objective was response rate. **Results:** There were 4 patients were enrolled in cohort 1, 3 in cohort 2, 4 in cohort 3, and 3 in cohort 4. Seven patients had previously been exposed to vemurafenib. The most common adverse events included hyperbilirubinemia, hypophosphatemia, leukopenia, arthralgia, and rash. Most were grade 1-2. Ten patients required a dose reduction of vemurafenib. Maximum tolerated dose of decitabine was not reached, and there were no dose limiting toxicities. Six patients (43%) had a response to therapy with three (21%) achieving a complete response (CR). Five patients (36%) achieved stable disease while 3 (21%) had progressive disease. Two of the 3 patients with partial response had previously progressed on single agent vemurafenib. Of the 6 patients that had a response, 3 were in cohort 1. **Conclusions:** This study demonstrated that the combination of vemurafenib and decitabine in BRAF V600E mutated metastatic melanoma is safe and resulted in an overall response rate of 43%. In comparison to the BRIM-3 trial, this trial had a significantly higher rate of patients achieving CR with the combined treatment (21% vs $< 1\%$, $p < 0.01$). As half the patients that responded were enrolled in cohort 1, a similar phase I trial is planned which explores the effect of decitabine given at a low dose for a longer duration to ensure maximal depletion of DNA methyltransferase, the enzyme to which decitabine binds. Table. Clinical trial information: NCT01876641.

Cohort	Dose of decitabine	Duration of decitabine treatment	Dose of vemurafenib
1	0.1 mg/kg SQ three times weekly	2 weeks	960 mg BID continuous
2	0.2 mg/kg SQ three times weekly	2 weeks	960 mg BID continuous
3	0.3 mg/kg SQ three times weekly	1 week	960 mg BID continuous
4	0.3 mg/kg SQ three times weekly	2 weeks	960 mg BID continuous

9057 Poster Session (Board #300), Mon, 1:15 PM-4:45 PM

Demographics, tumor characteristics, and clinical outcomes associated with somatic mutations in 201 cancer-related genes in advanced melanoma patients (pts). *First Author: Michael A. Davies, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cutaneous melanomas (CM) have a high rate of somatic mutations. We analyzed the prevalence and correlations of mutations in 201 cancer-related genes to identify clinically significant molecular events in a cohort of pts with advanced melanoma. **Methods:** Next generation sequencing (NGS) of all exons of 201 cancer-associated genes was performed on tumor and germline DNA from pts with a known primary non-acral CM enrolled in an IRB-approved research protocol. Demographics, primary tumor characteristics, date of diagnosis of stage IV disease, and overall survival (OS) were collected for all pts. The significance of associations between these characteristics and somatic mutations was analyzed by a variety of statistical methods. **Results:** NGS was performed on 106 advanced melanoma pts with a known non-acral primary CM. Genes with a mutation rate $> 10\%$ ($n = 74$) were assessed for clinical associations. NF1 (OR 12.9, $p = 0.002$) and PCLO (OR 3.1, $p = 0.01$) mutations were associated with male gender, while BRAF V600 mutations were more common in women (OR 0.38, $p = 0.03$). BRAF mutations were associated with younger age at diagnosis ($p < 0.0001$), and 12 genes were associated with older age. Mutations in 5 genes were associated with increased primary tumor Breslow thickness, most significantly MET (mean 8.3 vs 3.5 mm, $p = 0.005$). Among all pts with NGS data with distant metastases ($n = 88$), NRAS mutation was associated with significantly shorter OS from the diagnosis of stage IV (HR 3.2, $p = 0.007$), while mutations in BRAF (HR 0.35, $p = 0.02$) and 12 other genes were associated with significantly longer OS (HR 0.12 to 0.40). Among stage IV pts without BRAF V600 mutations ($n = 52$), NRAS mutation was again a significant predictor of shorter OS (HR 2.8, $p = 0.04$), and mutations in 12 other genes correlated with increased OS (HR 0.11 to 0.37). **Conclusions:** Somatic mutations in several genes in advanced non-acral CM pts were significantly associated with disease characteristics and clinical outcomes, and merit analysis in additional cohorts of pts. Analysis of copy number variations will be included in the final report for the cohort.

9058 Poster Session (Board #301), Mon, 1:15 PM-4:45 PM

Trends in demographics, incidence, and survival in children, adolescents and young adults (AYA) with melanoma: A Surveillance, Epidemiology and End Results (SEER) population-based analysis. *First Author: Demytra Krista Lee Mitsis, Roswell Park Cancer Institute, Buffalo, NY*

Background: Whilemelanoma incidence continues to rise in the United States, trends in children and AYA groups are poorly defined.Understanding the burden in these groups is critical in developing effective prevention strategies to ↓ risk. **Methods:** Data from 9 registries that have contributed to the SEER program since 1973 were used to assess descriptive epidemiology & time-trends in incidence & overall survival (OS) of melanoma in children (0-14 yrs) & AYA (15-39 yrs) from 1973-2011. 4 time quartiles (1973-80, 1981-90, 1991-2000 & 2001-11) were used. OS was compared using univariate & multivariate proportional hazards methods controlling for age, gender, race, ethnicity, stage, site & time period of diagnosis. Analyses were done using SAS v9.4. **Results:** 35,726 cases of melanoma in < 40 yrs old were reported from 1973-2011; median age 32 yrs; 98.9% cases in AYA. There were 13,616 males (38%) & 22,110 females (62%) with ↑ incidence in both genders over time ($p < 0.001$). The incidence rate per 100,000 ↑ from 13.26 to 46.79 ($p < 0.001$); similar significant trends were noted in both age groups across time quartiles (children: 0.45 → 1.51; AYA 22.28 →74.36; all $p < 0.001$). An ↑ female/male incidence rate ratio over time was noted; females comprised 57% of cases from 1973-80 but 65.2% of cases from 2001-11 ($p < 0.001$). The incidence was significantly higher in whites (94.8%) than other races. Most cases were cutaneous (98.6%) & localized; the incidence of in-situ melanoma rose from 4.1% to 30.4% over time ($p < 0.001$). OS has ↑ over all time quartiles (ref 1973-80; HR = 0.86, 0.65, 0.38; all $p < 0.001$) with 5 & 10-yr OS of 0.93 and 0.90 respectively. No difference in OS was seen between children & AYA (HR = 0.79; 95% CI, 0.6, 1.05; $p = 0.1$) or between blacks & whites (HR = 1.02; 0.70, 1.49; $p = 0.907$). Ocular melanoma was associated with ↓ OS (HR = 1.75; 1.48, 2.08; $p < 0.001$). **Conclusions:** Since 1973, the incidence of melanoma in children and AYA has increased by 253% with white female young adults at particular risk. There is a trend in diagnosis at earlier disease stage. Potential causes must be explored to devise intervention strategies.

9059 Poster Session (Board #302), Mon, 1:15 PM-4:45 PM

Efficacy and toxicity of treatment with the anti-CTLA-4 antibody Ipilimumab in patients with metastatic melanoma who have progressed on anti-PD-1 therapy. *First Author: Prashanth Prithviraj, Medical Oncology Unit, Austin Health, Heidelberg, Australia*

Background: Immunotherapy with anti-CTLA-4 and anti-PD-1 antibodies has demonstrated overall survival benefits in patients (pts) with metastatic melanoma (MM) compared to standard therapy. An early phase clinical trial suggests that combination therapy with an anti-CTLA-4 and anti-PD-1 antibody increases the response rate compared to single agent treatment however is associated with increased toxicity. Anti-PD-1 therapy demonstrated equal efficacy and toxicity in pts that progressed on or were naive to treatment with the anti-CTLA-4 antibody Ipilimumab. So far only very limited evidence exists regarding the efficacy and toxicity of Ipilimumab in pts that have progressed on treatment with an anti-PD-1 agent. **Methods:** We retrospectively identified ten pts with MM who received anti-PD-1 therapy (Nivolumab/Pembrolizumab) in a clinical trial and were subsequently treated with Ipilimumab. Ipilimumab was administered at a dose of 3mg/kg every three weeks for four cycles and response has been assessed by CT scan 4-6 weeks after the last dose. **Results:** The median time between the last dose of anti-PD-1 therapy and the commencement of Ipilimumab was 7 months. The median age of the patient cohort was 58 years with all pts having stage IV C disease and 4/10 pts had an elevated LDH on commencement of Ipilimumab therapy. 1/10 of pts achieved a partial remission as their best response to anti-PD-1 therapy with an additional 5/10 having stable disease. 4/10 of pts received all four doses of Ipilimumab. The follow up after the last dose of Ipilimumab has been more than three months. 1/10 of pts achieved a response to ipilimumab with another 1/10 having prolonged stable disease. 3/10 pts experienced grade3/4 immune related adverse events (irAE). **Conclusions:** Ipilimumab therapy can induce responses in pts who have failed treatment with an anti-PD-1 antibody. The response rate and clinical benefit rate appears similar compared to pts that have not received prior anti-PD-1 antibody therapy. Although cases of severe and unusual irAEs (eg pneumonitis) have been observed in our pts, an analysis of a larger patient cohort will be required to test the significance of these observations.

9060 Poster Session (Board #303), Mon, 1:15 PM-4:45 PM

Adoptive Cell Therapy for metastatic melanoma: A UK centre experience. *First Author: Manon Rhys Pillai, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Adoptive cell therapy (ACT) with tumour infiltrating lymphocytes (TIL) has consistently demonstrated impressive clinical results in several international studies in the management of metastatic melanoma. We describe our experience as the only UK cancer centre providing TIL therapy. **Methods:** TIL are cultured from resected tumour samples as previously described. Infusion is preceded by non-myeloablative lymphodepleting chemotherapy (high dose cyclophosphamide and fludarabine) and followed by intravenous high dose interleukin 2 (HD-IL2). **Results:** Eleven patients have been treated to date: eight with cutaneous melanoma, two with ocular melanoma and one patient with mucosal melanoma. All patients had metastatic disease and were heavily pre-treated with a combination of targeted agents and immunotherapies (anti-CTLA4 and anti-PD1 antibodies). In the ten patients currently evaluable, 60% achieved an objective clinical response according to the response evaluation criteria in solid tumours. Five of eight patients with cutaneous melanoma achieved a response, including one ongoing complete response (30+ months) and four partial responses. All other patients showed disease stabilisation. One patient with ocular melanoma achieved a short lived partial response. Of eight patients with significant symptomatic progressive disease, six obtained clear symptomatic benefit. Treatment is well tolerated. All patients experienced anticipated toxicities associated with pre-conditioning chemotherapy and HD-IL2, which were short lived and manageable on the medical ward. **Conclusions:** We show that at our centre lympho-depleting chemotherapy followed by transfer of TIL and HD-IL2 is feasible and clinically effective, demonstrating tumour regression in over 60% of patients with metastatic cutaneous melanoma. Short lived responses were additionally seen in patients with ocular melanoma, where treatment options are limited, suggesting a potential role for TIL therapy in this group of patients also. Significant toxicities are attributable to HD-IL2 and further evaluation of TIL followed by low dose IL2 should be conducted to decrease treatment related complications and expand clinical participation in ACT.

9061 Poster Session (Board #304), Mon, 1:15 PM-4:45 PM

The expression quantitative trait loci (eQTLs) and their association with melanoma clinical outcomes. *First Author: Matjaz Vogelsang, New York University School of Medicine, New York, NY*

Background: Prognosis of cutaneous melanoma (CM) is modulated by tumor immunogenicity, which varies on the individual level. While this suggests a contributing role of germline genetic factors, current approaches suffer from difficulties in identifying biologically relevant germline prognostic biomarkers. Recent whole-genome scans have established comprehensive maps of eQTLs (i.e. gene expression correlating germline genetic variants) across different populations and human tissues. We hypothesize that the interrogation of inherited eQTLs in cells of the immune system may reveal biologically important germline markers of CM immunogenicity and clinical outcomes. **Methods:** Based on our computational analyses of publicly available eQTL data, we selected 43 genetic variants most significantly correlating with expression of 41 immune-modulating genes in lymphoblastoid cell lines derived from 857 healthy female twins from Multiple Tissue Human Expression Resource. Variants were genotyped in a prospective cohort of 1022 CM patients and analysed for their association with overall and recurrence-free survival using Cox regression model, adjusted by demographic and clinical covariates. **Results:** We have discovered novel and highly significant association of rs6673928, an *IL19* eQTL variant, with favorable CM overall survival (OS)(HR 0.54, 95% CI 0.37 to 0.79; P= 0.00087). Associations with melanoma OS were also observed for other significant eQTLs: rs6695772 (HR 1.76, 95% CI 1.21 to 2.55; P= 0.002), rs11569345 (HR 0.35, 95% CI 0.14 to 0.91; P= 0.014) and rs841718 (HR 1.75, 95% CI 1.12 to 2.72; P= 0.018) strongly correlating with expression of *BATF3*, *CD40* and *STAT6*, respectively. **Conclusions:** Our unique approach of interrogating lymphocyte-specific eQTLs from healthy twins was notably powerful in identifying several immunomodulatory eQTL variants as novel biologically relevant predictors of CM prognosis. These data suggest that eQTL-based strategy proposed here will be highly efficient in discovering the missing germline genetic component associated with risk, outcome or therapy response in other human cancers driven by specific molecular pathways.

9062 Poster Session (Board #305), Mon, 1:15 PM-4:45 PM

One-year overall survival (OS) and biomarker correlates from a phase II study of ipilimumab (IPI) with carboplatin and paclitaxel (CP) in patients with unresectable stage III or IV metastatic melanoma (MM). *First Author: Rahima Jamal, Hopital Notre-Dame, Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada*

Background: Pivotal studies with IPI demonstrated increased OS both as single agent (10.1 months) and with DTIC (11.2 months). We've previously reported an encouraging safety profile with IPI plus CP and early efficacy results. We now report updated 1-year OS and biomarker correlates of patient response. **Methods:** 30 patients were randomized in a 1:2 ratio to arm A (C (AUC = 6) and P (175mg/m2) every 3 weeks x 5 and IPI (3mg/kg) every 3 weeks x 4 starting at week 4) or arm B (similar dosing to arm A except IPI was given on week after CP). Tumor biopsies were collected at screening and week 8, and immune monitoring bloods were collected throughout. **Results:** Median OS was 16.1 months, with a 1-year OS of 56.5% for all patients with no differences between arms. Overall median follow-up was 23.2 months. Best overall response rate (BORR) and disease control rate (DCR) were 26.7% and 56.7% by irRC. BORR in patients whose tumors were wild type for BRAF and NRAS was 44%, compared to 8% in patients with a mutation in BRAF or NRAS. Clinical responses correlated with the abundance of peri and intratumoral CD3+ inflammatory cells in the pretreatment biopsy, but not with CD4/CD8 ratios or CD20 infiltrate. Circulating levels of some chemokines were elevated in non-responders compared to responders. While IPI influenced B cells and monocyte differentiation, this did not correlate with clinical outcome. Although all patients had an increase in $ICOS^+$ T cells after IPI treatment, a pre-existing low proportion of $ICOS^+$ T cells before treatment was associated with a more favorable clinical outcome. Lower levels of PD-1 on CD4 and CD8 T cells were observed in responders compared to non-responders. **Conclusions:** Median OS and 1-year OS compared favorably to previous pivotal trials. Patients whose tumors were wild type for BRAF/NRAS had a higher rate of objective response. High baseline level of CD3 infiltrate was associated with a positive clinical response to IPI/CP. A low activation state (ICOS) before treatment and maintenance of low levels of PD-1 on T cells during treatment correlated to a favorable clinical response to IPI. Clinical trial information: NCT01676649.

9063 Poster Session (Board #306), Mon, 1:15 PM-4:45 PM

Survival, safety, and response patterns in a phase 1b multicenter trial of talimogene laherparepvec (T-VEC) and ipilimumab (ipi) in previously untreated, unresected stage IIIB-IV melanoma. *First Author: Igor Puzanov, Vanderbilt University Medical Center, Nashville, TN*

Background: T-VEC is an HSV-derived oncolytic immunotherapy designed to induce systemic antitumor immunity. In a phase 3 melanoma study, T-VEC monotherapy significantly improved durable response rate (DRR, ≥ 6 month response) vs GM-CSF (16% vs 2%, $P < 0.0001$; Andtbacka et al. ASCO 2013), and median OS was 4.4 months longer for T-VEC vs GM-CSF (23.3 vs 18.9 months; HR = 0.79, 95% CI: 0.62-1.00; P= 0.051; Kaufman et al, ASCO 2014). Combining T-VEC to promote tumor-derived antigen release with an immune checkpoint inhibitor may enhance efficacy compared to either agent alone. The phase 1b portion of this phase 1b/2 combination study (NCT01740297) completed enrollment and met its primary objective with no dose-limiting toxicities (DLTs) and an objective response rate (ORR) of 56% (Puzanov et al. ASCO 2014). **Methods:** Key inclusion criteria included stage IIIB-IV melanoma; no prior systemic treatment; measurable disease; and ≥ 1 injectable cutaneous, subcutaneous, or nodal lesion. T-VEC was given intralesionally at ≤ 4 mL of 10^6 PFU/mL at week 1, then 10^8 PFU/mL at week 4, and then Q2W. Ipi 3 mg/kg Q3W was given as 4 infusions starting week 6. T-VEC continued until DLT, intolerance, all injectable tumors disappeared, or disease progression (PD) per immune-related response criteria (irRC). **Results:** The data cutoff was Dec 22, 2014 with all patients at least 17 months from start of treatment. 18 patients received T-VEC+ipi; grade 3/4 treatment-emergent AEs occurred in 32% and grade 3/4 immune-related AEs occurred in 2 patients with no treatment-related deaths. Per irRC, ORR was 56% (33% CR) and DRR was 44%. Median time to response was 5.3 months (range 2.6-5.7). Median progression-free survival (PFS) was 10.6 months (2.6-19.3+). Median overall survival (OS) was not reached; 12-month and 18-month survival were 72.2% and 67%. On a lesion level, 24 and 11 of 35 injected index lesions and 8 and 5 of 16 uninjected index lesions regressed ≥ 50% and 100%, respectively. **Conclusions:** At > 17 months, T-VEC+ipi continued to demonstrate durable responses with 2/3 of patients alive at 18 months and no new safety signals. Phase 2 (ipi vs T-VEC+ipi) is ongoing. Clinical trial information: NCT01740297.

9064 Poster Session (Board #307), Mon, 1:15 PM-4:45 PM

Identification of potentially actionable mutations in RTKs in melanoma detected by next generation sequencing (NGS). *First Author: Jan Kemnade, Baylor College of Medicine, Houston, TX*

Background: The success of personalized cancer therapies targeting patients with specific actionable mutations underscores the need to expand the search for relevant mutations with functional and/or clinical consequences. Cutaneous melanomas have a high mutation burden due to ultraviolet radiation exposure, thus necessitating approaches to distinguish driver versus passenger mutations. Here we report the analysis of the nature and location of somatic mutations in 16 receptor tyrosine kinases (RTKs) in a cutaneous melanoma cohort analyzed by next generation sequencing (NGS). **Methods:** NGS for all exons of 201 cancer-related genes was performed on tumor and germline DNA from pts with non-acral cutaneous melanoma (n = 108). Somatic mutations in RTKs (MET, PDGFRA, PDGFRB, KIT, EGFR, ERBB2, ERBB3, RET, IGF1R, EPHA3, DDR1, DDR2, ALK, JAK1, JAK2, JAK3) were mapped to the tyrosine kinase domain (TKD), other functional regions (i.e. transmembrane domains, binding domains) or conserved protein domains (ORD), or regions of unknown significance (RUS) in each gene. The COSMIC database was analyzed for presence of the same mutations in other tumors. **Results:** Missense mutations were detected in all 16 RTKs. The number of mutations identified in each RTK ranged from 2 (IGF1R) to 24 (EPHA3), with a median of 7.5 mutations per RTK. The average incidence of mutations found in the TKD region for each RTK was 29% and ranged from 0% (ERBB2, ERBB3) to 80% (JAK2). For the ORD regions the average was 34%, ranging from 0% (ERBB2, ERBB3, RET, DDR2) to 61.5% (MET). For the RUS regions the average was 37%, ranging from 0% (PDGFRB, DDR1) to 100% (ERRB2, ERRB3). Mutations detected in 11 of the RTKs were also identified in cancer sequencing datasets available on COSMIC. **Conclusions:** The prevalence of mutations in the TKD, ORD, and RUS regions varied significantly among the 16 RTKs in the cutaneous melanoma cohort. Overall ~62% of the mutations mapped to regions with potential functional significance, and ~16% have been reported previously in other cancers. Integration of these analyses with predicted structural and functional consequences may be used to prioritize candidate actionable mutations for in-depth characterization.

9065 Poster Session (Board #308), Mon, 1:15 PM-4:45 PM

The effect of ipilimumab on natural killer cells identifies the subset of advanced melanoma patients with clinical response. *First Author: Ines Esteves Domingues Pires Da Silva, New York Univ Langone Medcl Ctr, New York, NY*

Background: The concept of immune cell exhaustion in the context of metastatic melanoma has been reinforced by the success of immunotherapies targeting the exhaustion markers CTLA-4 and PD-1. Natural Killer (NK) cell exhaustion, characterized by an up-regulation of inhibitory receptors and loss of function, was described in the context of melanoma. Ipilimumab (IPI - anti-CTLA-4) improves the anti-tumor T cell activity and achieves response rates of 15-20%, however the effect of IPI on NK cells is unknown. In this project, we studied the effect of IPI on the phenotype of NK cells from melanoma patients and how it relates with clinical response. **Methods:** NK cells were purified from the peripheral blood of 10 advanced melanoma patients treated with IPI. Blood samples were collected at baseline, after the 2nd and 4th cycles of IPI. NK cells were characterized acccording to the expression of activating (NKG2D) and inhibitory (KIRB1) receptors, function (cytotoxicity, IFN-γ production), levels of the IL-2R α chain and response to IL-2 stimulation. We analyzed the effect of IPI on NK cells as it relates to clinical response. **Results:** IPI induces an upregulation of 50% in the IL-2R α chain levels on NK cells ($p = 0.03$). There was no significant difference in other receptors or function ($p > 0.05$). We then checked the phenotype and function of these NK cells after 48 hours of IL-2 stimulation and in 4 patients out of 10 there was an improvement of cytotoxicity and higher levels of IL-2R α chain. Remarkably, this better response to IL-2 was observed in patients with clinical response to IPI (partial/complete response) compared with non-responders, with higher cytotoxicity ($p = 0.05$) and levels of IL-2R α chain ($p = 0.02$). **Conclusions:** CTLA-4 is expressed mainly on T cells, including regulatory T cells, with no expression on NK cells. Nevertheless, we have shown an effect of IPI on the phenotype of NK cells, with an increase of IL-2R expression. More importantly, the effect of IPI on NK cells (better response to IL-2 stimulation and cytotoxicity) is associated with a good clinical response. The mechanism behind this effect is not clear yet, however this may be indirect through the action of IPI on other immune cells.

9066 Poster Session (Board #309), Mon, 1:15 PM-4:45 PM

Continued evaluation of a 31-gene expression profile test (GEP) for prediction of distant metastasis (DM) in cutaneous melanoma (CM). *First Author: David H. Lawson, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: A GEP has been validated as an independent predictor of DM, distant metastasis free survival (DMFS) and overall survival (OS) (Gerami, CCR 2015; Gerami JAAD, 2015). This abstract combines the third validation cohort study with the two prior studies for analysis by T factor subgroups.**Methods:** 555 patients (pts) were enrolled in a multi-center IRB approved archival tissue study with a primary endpoint of DMFS. 492 CMs had T-factors available for analysis. Quantitative RT-PCR and Radial Basis Machine modeling classified CM tumors as low risk Class 1 vs. high risk Class 2. Results are reported for thin (T1), intermediate (T2/T3) and thick (T4) lesions. Most patients were node negative clinically or by sentinel node biopsy.**Results:** GEP Class 1 vs 2 was found to be a significant predictor of DMFS and OS (log-Rank $p<0.0001$), and GEP, Breslow's thickness, and ulceration were independent predictors in Cox multivariate analysis (DMFS HR=2.7, p=0.0003; 2.2, p=0.03; 3.3, $p<0.0001$, respectively and OS HR=2.8, p=0.0002, 2.5, p=0.01, 1.7, p=0.01, respectively). In the T2/T3 N0 cohort (n=180) frequency of class 2 signature increases with depth [T2:35/78 (45%) Class 2; T3:75/102 (74%) Class 2] and ulceration [nonulcerated: 54/108 (50%) Class 2; ulcerated: 53/63 (84%) Class 2]. The table reflects survival analysis in this cohort. In the T1 group (median followup for non-DM group = 7.4 yrs) 14/173 (8%) reported DM. For T4 group: 42/80 (53%) developed DM. Data not considered adequate for further analysis of either group.**Conclusions:** GEP offers prognostic information that complements conventional staging at least in patients with T2/T3 CM. Ongoing studies will further define the role of GEP in evaluating these patients.

T2/T3 N0 group (n=180)

	DM	all cause deaths
Total events	51/180 (28%)	47/180 (26%)
Class 1	7/70 (10%)	7/70 (10%)
Class 2	44/110 (40%)	40/110 (36%)

9067 Poster Session (Board #310), Mon, 1:15 PM-4:45 PM

Long-term results of ultrasound (US)-guided fine needle aspiration cytology (FNAC) in conjunction with sentinel node biopsy (SNB) to support step-wise approach in melanoma. *First Author: Alexander Christopher Jonathan Van Akkooi, Netherlands Cancer Institute – Antoni van Leeuwenhoek, Amsterdam, Netherlands*

Background: Ultrasound (US) guided Fine Needle Aspiration Cytology (FNAC) is a common diagnostic tool in the work-up of other cancers, i.e. breast and thyroid. The results in melanoma (mel) were poor (sensitivity 20-40%). Introduction of the Berlin Morphology criteria has recently shown potential improvements up to 65 – 80% in selected patients (pts). **Methods:** Between 2001 and 2010 over 1000 stage I/II consecutive mel pts prospectively underwent US-FNAC prior to Sentinel Node (SN). All pts underwent lymphoscintigraphy prior to US-FNAC. The Berlin US morphology criteria: Peripheral perfusion (PP), loss of central echoes (LCE) and balloon shaped (BS) were registered and FNAC was performed if any factor was present. SN tumor burden was measured according to the Rotterdam criteria. All pts underwent SN or lymph node dissection in case of positive FNAC. **Results:** Mean/median Breslow thickness was 2.58/1.57 mm. Mean/median follow-up was 69/63 months (IQR 42 - 98). SN positivity rate was 21%. US-FNAC Sensitivity was 71% (US only) and 51% (US-FNAC). Sensitivity of US-FNAC was highest for T4 (76%) and ulcerated melanomas (63%). PP, LCE and BS had sensitivity of 69%, 24% and 24% respectively. Sensitivity of US-FNAC increased with increasing SN tumor burden. PP was an early sign of metastasis (58% in < 0.1 mm metastases). Threshold size of a metastasis for FNAC was 0.3 mm. Survival analyses for different end-points (Melanoma Specific, Disease-Free, Distant-Metastasis-Free) demonstrated that pts with pos FNAC and/or BS/LCE had poor survival. Pts with PP and with neg FNAC had a slightly worse survival (HR 1.61 (P = 0.025), 1.45 (P = 0.034) and 1.72 (P = 0.007) compared to completely neg pts (regardless of SN result). **Conclusions:** The long-term results support the step-wise approach to melanoma patients. In case of positive FNAC and/or clearly malignant US (BS and/or LCE) patients have larger amounts of SN tumor burden and poor survival, they can be spared a SNB. In case of PP and negative FNAC, patients should proceed to undergo a SNB to detect microscopic occult disease. Completely US-FNAC negative patients might only require follow-up and no SN staging.

9068 Poster Session (Board #311), Mon, 1:15 PM-4:45 PM

Phase II trial of trametinib in combination with the AKT inhibitor GSK 2141795 in BRAF wild-type melanoma. *First Author: Alain Patrick Algazi, University of California, San Francisco, San Francisco, CA*

Background: There is currently a lack of effective targeted therapies for BRAF wild type (WT) melanoma. We explored the combination of the MEK inhibitor trametinib with the AKT inhibitor GSK2141795 in BRAF/NRAS WT and BRAF WT/NRAS mutant (MT) melanoma. **Methods:** Study accrual goal was 24 patients (pts) with metastatic BRAF WT/NRAS WT melanoma and 24 pts with BRAF WT/NRAS MT melanoma. Eligibility criteria included: unresectable stage III or IV disease, ECOG status 0-2, stable CNS disease, and adequate cardiac function (LVEF $\geq$ 50%, QTc $>$ 480). For each cohort, an interim analysis was pre-specified after 10 pts. If no responses were seen, the cohort would be closed. If one or more responses were seen, an additional 14 pts would be accrued. Pts received trametinib (1.5 mg) and GSK 2141795 (50 mg) orally, once daily for each cycle lasting 28 days. ORR was assessed by RECIST 1.1 with restaging performed every 8 weeks (2 cycles). **Results:** Twenty pts were enrolled from October 2013 to October 2014: 10 pts in each NRAS cohort. Rash (70%) and diarrhea (50%) were the most common drug-related adverse events (AE's) for all grades; mucositis occurred in 40% of pts. The best overall response was stable disease in 65%: 80% of BRAF WT/NRAS WT patients and 50% of BRAF WT/NRAS MT patients. No RECIST-confirmed partial or complete responses were observed. As a result, both cohorts were closed to further accrual. Median progression-free survival was 2.75 months (IQR: 1.7 to 3.7 mos), with no difference between the NRAS cohorts ($p = 0.46$). **Conclusions:** The combination of trametinib and GSK2141795 is safe, but at these doses and schedules, is ineffective in the BRAF WT population, regardless of NRAS status. Clinically significant adverse events were common at the doses tested. Pharmacodynamic studies are ongoing to determine the extent of pathway inhibition achieved. Clinical trial information: NCT01941927.

9069 Poster Session (Board #312), Mon, 1:15 PM-4:45 PM

Changes in blood eosinophilia during anti-PD1 therapy as a predictor of long term disease control in metastatic melanoma. *First Author: Lydia Gaba, Hospital Clinic de Barcelona, Barcelona, Spain*

Background: The anti-PD1 antibody (Ab) Nivolumab (Nivo) has demonstrated to improve the overall survival (OS) in patients (pts) with metastatic melanoma (MM) compared to DTIC. Pembrolizumab (Pembro), another anti-PD1, showed durable antitumor activity in pts with MM and has been approved in the US for the treatment (tmt) of MM that progressed on ipilimumab and, if *BRAF*V600 mutant, a BRAF inhibitor. To date, no lab test has been identified to predict clinical benefit (CB) to anti-PD1 Abs. **Methods:** This retrospective observational study included pts with MM who received anti-PD1 tmt in a single institution. The objective was to identify whether an increase of at least 100/mm3 at 3 weeks over the baseline or increase $>$ 400/mm3 at 12 weeks in the absolute eosinophil counts (AEC) could predict CB. Blood tests were performed before every administration. Response to tmt according immune-related response criteria, progression free survival (PFS) and OS were evaluated. Descriptive statistics were used to analyze patient baseline characteristics. Response rates (RR) were compared by exact Fisher test. PFS and OS were estimated by the Kaplan-Meier method. **Results:** From March 2013 to December 2014, 29 pts were treated with anti-PD1 Abs (3 pts with Nivo and 26 pts with Pembro). Median age was 57 years (range 30-83) with 10.3% stage M1a, 24.1% M1b and 65.5% M1c, and 51.7% had elevated LDH. Pts who experienced an increase in AEC over the baseline $>$ 100/mm3 at 3 weeks demonstrated better outcomes in terms of RR (55.6% vs 9.1%, $p = 0.190$), PFS (9.9 [95% CI: 5.8-14.0] vs 2.6 [95% CI: 1.0-4.2] months, $p = 0.008$) and OS (18.8 [95% CI: 15.5-22.1] vs 6.9 [95% CI: 3.5-10.3] months, $p = 0.001$) compared with those who did not. Moreover, pts with an AEC $>$ 400/mm3 at 12 weeks responded to tmt (100% vs 18.2%, $p = 0.002$) and showed more benefit regarding PFS (18.6 vs 3.6 months, $p < 0.0001$) and OS (not reached vs 11.4 months, $p = 0.017$) compared to those who did not. **Conclusions:** An increase in AEC of 100/mm3 over baseline at week 3 and an absolute AEC $>$ 400/mm3 at week 12 during anti-PD1 tmt might identify pts with MM most likely to experience long-term disease control with anti-PD1 Abs.

9070 Poster Session (Board #313), Mon, 1:15 PM-4:45 PM

Immunologic profile of melanoma brain metastases (MBM) in patients (pts) with prolonged survival. *First Author: Kevin P. Lui, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

Background: Median survival of MBM pts is significantly shorter than pts with extra-cranial metastases. However, a subset of MBM pts exhibit extended survival. Radiation therapy (RT - radiosurgery and whole-brain radiation) is used to treat MBM pts and recent data by several groups including ours demonstrate that RT may potentiate response to immunotherapies by inducing an immunological tumor cell death. In this study, we investigate the immunomodulator effect of RT on MBM tissue and attempt to identify an immunological profile associated with improved post-MBM survival. **Methods:** Expression of 560 immunoregulatory genes was assessed in 32 MBM tissues (10 post radiation and 22 no radiation) using a customized NCounter GX Human Immunology Kit (Nanostring) comprising of 24 immunology-related gene networks compiled from the Gene Ontology Consortium List of immunologically important genes. We also compared expression of the immunoregulatory genes in long term survivors ($>$ 1 year) compared to short term survivors ($<$ 1 year). We then verified the data using RT-PCR and IHC in an expanded cohort of 47 MBM tissues. **Results:** Irradiated MBM had higher expression of genes involved in: (1) autophagy/apoptosis (ATG12, BCL2L11 and CASP8); (2) adhesion (CD209, ICAM2; ITGA4 , ITGB1 and PECAM-1); (3) immune cell development and activation (IFNAR2, IKZF2, MAP4K2, NFATC3, POU2F2 and TCF4) ($p < 0.05$). In addition, RT induced upregulation of PD-L1 (transmembrane protein involved in immunoinhibitory signals) and TGF-b (immunosuppressive cytokine and cell cycle regulator) at the gene expression level, as determined by Nanostring and confirmed by RT-PCR, and protein level of PD-L1 by IHC. Genes involved in lymphocyte activation such as CD44, CD81 and IL16 were significantly overexpressed in long term survivors ($p < 0.05$). **Conclusions:** Our data demonstrate that RT induces both lymphocyte activation and upregulation of immunosuppressive signals. Our data also suggest that MBM pts with prolonged survival host an immunologically distinct subset of tumors with upregulated lymphocyte activating genes. Identification of MBM pts with enhanced immunogenicity may aid in prognostication and prediction of response to immunotherapy.

9071 Poster Session (Board #314), Mon, 1:15 PM-4:45 PM

A novel algorithm applicable to cancer next-generation sequencing panels to predict total tumor mutation load and correlation with clinical outcomes in melanoma. *First Author: Jason Roszik, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Next-generation sequencing (NGS) panels of cancer-related genes are increasingly utilized in oncology. We developed an algorithm to estimate total tumor mutation burden in melanoma using genes present in local and commercial NGS panels. The algorithm was validated using independent datasets and analyzed for clinical significance in two cohorts of advanced melanoma patients (pts). **Methods:** Overlapping genes ($n = 170$) from two NGS panels were used for algorithm development. Publicly available whole exome sequencing (WES) data ($n = 345$) from the cutaneous melanoma TCGA was employed to develop a mutation score for each gene in the panel. The summation of the mutation scores yields the Predicted Total Mutation Load (PTML) of the tumor. The algorithm was applied to 3 independent melanoma WES datasets to test the correlation of predicted with actual mutation burden. The PTML was then determined for cohorts of melanoma pts treated with immune-therapy regimens (e.g., adoptive cell transfer (ACT)), and associations with clinical outcomes were determined. **Results:** The PTML correlated strongly with the actual WES mutation load of each tumor in all 3 tested melanoma WES datasets (Set 1, $n = 121$, $r2 = 0.58$; Set 2, $n = 64$, $r2 = 0.84$; Set 3, $n = 127$, $r2 = 0.93$). For subsequent analyses low PTML was defined as $\leq$ 100, and high as $>$ 100 based on observed distributions. High PTML predicted both increased PFS ($n = 36$, $p < 0.05$) and OS ($n = 35$, $p < 0.05$) among pts treated with ACT. Pts with high PTML also had a longer interval from stage III to stage IV ($n = 55$, $p < 0.05$) and improved OS from stage IV ($n = 62$, $p < 0.01$) in a large cohort of MDACC patients with NGS data. Further testing demonstrated that accurate disease-specific PTML algorithms for other cancers (e.g., lung) are feasible. **Conclusions:** In this proof of concept study, a novel algorithm applied to NGS panels accurately predicted total mutation burden in cutaneous melanoma pts. High PTML ($>$ 100 mutations) correlated with improved OS in two cohorts of melanoma pts, including pts treated with immunotherapy. These results support further testing of the PTML algorithm in risk assessment and management of melanoma pts.

9072 Poster Session (Board #315), Mon, 1:15 PM-4:45 PM

Low vemurafenib plasma exposure as a short-term predictive parameter of progression disease in metastatic *BRAFV600^{mut}* melanoma. *First Author: Lauriane Goldwirt, AP-HP, Hôpital Saint-Louis, Department of Pharmacology, Paris, France*

Background: The BRAF inhibitor Vemurafenib (V) improves survival in *BRAFV600* mutated metastatic melanoma patients, with a 59% response rate (BRIM-3). The aim of this retrospective study is to explore the potential relationship between V plasma concentration ($_{pl}$VC) and progression disease (PD). **Methods:** Patients with AJCC stage IIIb/c (n = 9) or IV (n = 39) *BRAFV600^{E}* melanoma treated with V in monotherapy were retrospectively included according a signed informed consent. Blood samples were collected monthly. Response evaluation (RECIST 1.1) and toxicity evaluation were performed monthly after V initiation. $_{pl}$VC were quantified using a routine HPLC-UV method. All samples were included in the response-concentration analysis. Regression analysis was performed with R- software. $_{pl}$VC cut-off to predict progression was determined with ROC curve analysis (pROC R Package). Progression-free survival (PFS) was assessed with multivariate Cox analysis (survival R package). **Results:** $_{pl}$VC obtained in 48 patients (148 blood collections) displayed a wide inter- and intra-individual variability (5.3 to 135.2μg/mL, median 66.8). All patients declared high compliance to treatment. Eleven patients (23%) experienced PD during V treatment. With a median follow-up of 12 months (1 to 50), progression on V occurred after a median 5 months treatment duration (14$\pm$9). Median $_{pl}$VC tended to be lower in patients experiencing PD (51$\pm$22μg/mL) compared to complete, partial or stable responders (67$\pm$24 μg/mL, p = 0.06). Maximal concentrations were higher in responding patients (67 vs 51 μg/mL, p = 0.01). Patients with at least one value reaching 65 μg/mL tended to have a lower risk of disease progression than other patients (p = 0.11). This threshold value of 65 μg/mL predicted progression with 78% specificity and 82% sensibility. Interestingly, this effect appeared to be more significant before 6 month (PFS6). **Conclusions:** $_{pl}$VC was confirmed highly variable at steady state. As low exposure was associated to higher progression risk and lower PFS6, therapeutic drug monitoring should be performed at least for 6 months from treatment initiation of V that is now used in combination to the MEK inhibitor cobimetinib.

9073 Poster Session (Board #316), Mon, 1:15 PM-4:45 PM

Patterns of response to anti-PD1 treatment: Comparison of three radiological response criteria and effect on overall survival (OS) in metastatic melanoma patients (MM). *First Author: Minnie Kibiro, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Radiological assessment of patterns of response (R) to checkpoint inhibitors remain imperfect. irRC accounts for pseudoprogression but does not evaluate change in density. We aimed to evaluate individual lesion and inter patient R by RECIST 1.1, irRC, CHOI and modified CHOI (mCHOI) and correlate R with OS. **Methods:** 37 patients (pts) with 567 measurable lesions treated with pembrolizumab in a phase 1 trial were studied. Bidimensional tumor diameter and density measurements were obtained at baseline and serial assessment CT scans. Overall R was assigned as per final CT scan assessment. Association of each criterion with OS was determined. **Results:** R varied according to site of metastases; lung lesions had the highest rate of complete response (CR) compared to other sites (69/163 (42%) lesions vs 71/404 (18%) p < .0001) and R varied at first assessment by RECIST compared to irRC (table). Delayed R post first scan were seen in 2/37 (5%) deemed PD by RECIST and 2/14 (14%) pts deemed PD by irRC at 1st assessment. 1/6 pts deemed to have PD by irRC at second assessment also had delayed R. 24 (65%) pts met CHOI density and size criteria for R at first follow-up. mCHOI criteria (> 15% density decrease and decrease in tumor size > 10%) showed R of 38% (14/37). Change in tumor size and density on 1st follow-up assessment was associated with OS with each 1000 mm^2 increase in tumor size from baseline increasing the hazard of dying by 25.9% (HR = 1.259, [95% CI = 1.116-1.420], p = 0.0002). Similarly each 100HU increase in density increased the HR by 99% (HR = 1.99, [95% CI 1.246-3.176], p = 0.0039). R defined by any criteria had superior OS (CHOI, p = 0.0084; mCHOI, p = 0.0183; irRC, p < 0.0001 and RECIST, p = 0.0003). **Conclusions:** R by any criteria was prognostic and pseudoprogression was seen. The novel patterns of R and changes on treatment in tumor density suggest complex anti-tumor R of immunotherapy and require further validation.

9074 Poster Session (Board #317), Mon, 1:15 PM-4:45 PM

Tumor size and clinical outcomes in melanoma patients (MEL pts) treated with talimogene laherparepvec (T-VEC). *First Author: Howard Kaufman, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: T-VEC is an HSV-1 derived oncolytic immunotherapy designed to selectively replicate in tumors, produce GM-CSF, and enhance systemic antitumor immune responses. We describe factors associated with clinical outcomes in 436 pts with previously treated or untreated, unresected stage IIIB-IV MEL in OPTiM, a randomized (2:1) phase 3 trial of intralesional T-VEC vs subcutaneous GM-CSF. **Methods:** Multivariate analyses (MVAs) and Cox regression were used to evaluate association of BTB (sum of products of 2 largest perpendicular diameters [per investigator] of measurable lesions at baseline), stage (IIIB/C/IVM1a vs IVM1b/c), treatment (tx) line (TL; 1st vs ≥ 2nd), and ECOG PS (0 vs 1), previously reported to be associated with clinical outcomes, with overall response rate (ORR), durable response rate (DRR; continuous PR or CR ≥ 6 months), and overall survival (OS). **Results:** 288 T-VEC and 126 GM-CSF pts had available BTB; all received tx as randomized. Median BTB: 14.8 cm^2 (interquartile range, 5.8-39.3) for T-VEC, 14.1 cm^2 (5.7-31.0) for GM-CSF (P = 0.50). Median BTB was higher with advanced stage (IVM1b/c: 23.6 [11.5-53.1]; IIIB/C/IVM1a: 8.6 [3.2-23.2], P < 0.001) and later TLs (≥ 2nd: 18.0 [7.0-45.9]; 1st: 12.9 [5.3-25.6], P < 0.001). In MVA of T-VEC pts (Table), BTB < median, stages IIIB/C/IVM1a, and 1st TL were associated with improved ORR and DRR; BTB < median and stages IIIB/C/IVM1a were associated with better OS. In MVA of all OPTiM pts, T-VEC tx (vs GM-CSF; HR 0.74, 95% CI 0.58-0.96, P = 0.023), BTB < median (HR 0.42, 95% CI 0.32-0.54, P < 0.001), stages IIIB/C/IVM1a (HR 0.54, 95% CI 0.42-0.69, P < 0.001), and ECOG 0 (HR 0.63, 95% CI 0.49-0.82, P < 0.001) were associated with better OS. **Conclusions:** Based on these exploratory analyses, BTB was prognostic for OS and achieving a DR and OR with T-VEC in OPTiM. BTB should be further evaluated as a prognostic factor in future MEL trials.

	ORR		DRR		OS

Investigation of intrapatient heterogeneity in the tumor infiltrating T cell repertoire in patients with metastatic melanoma treated with pembrolizumab. *First Author: Rodrigo Ramella Munhoz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Blockade of the programmed death-1 (PD-1) receptor results in impressive activity in patients (pts) with metastatic melanoma (MM). Mechanisms of antitumor effect are not fully understood but may be associated with the degree of T cell receptor (TCR) repertoire clonality in tumor infiltrating lymphocytes (TIL). We hypothesized that differences among multiple tumors in the same patient may be reflected in heterogeneity of TCR repertoire clonality in TIL. We tested this hypothesis using TCR sequencing in pts with MM treated with pembrolizumab. **Methods:** Post-treatment samples were obtained from different lesions at the same time points. TCR repertoire quantification was performed using high-throughput sequencing of the rearranged TCR β-chain genes; these were amplified and sequenced using the survey ImmunoSeq assay in a multiplexed PCR method using primers to TCR Vβ and Jβ gene segments. Productive TCR sequences were used to obtain a clonality metric, and frequency of each T cell clone was obtained by comparing the number of reads generated by each unique CDR3 sequence. The proportion of TIL was determined using quantitative immunohistochemistry. Variations in proportion of TIL and clonality between samples were analyzed using ANOVA test. Tests were performed in duplicate. **Results:** Eight tumors from two pts receiving pembrolizumab (Four from pt A and four from pt B, obtained 2 and 4 months after treatment initiation, respectively) were analyzed. Significant intrapatient intertumoral heterogeneity in TCR repertoire was observed (pt A: p = 0.000153 and p = 0.013/pt B: p = 0.00083 and p = 9.01E-07 for differences in proportion of TIL and clonality, respectively). There was a high correlation between duplicates (r^2 = 0.86- > 0.99), suggesting these findings were not the result of experimental variation. **Conclusions:** Our data suggest significant intrapatient intertumoral heterogeneity in the proportion of TIL and clonality of the TCR repertoire at the same post-treatment timepoint. Caution should be exercised in interpreting the results of TCR analyses from single tumor biopsies in patients treated with checkpoint blockade.

9076 Poster Session (Board #319), Mon, 1:15 PM-4:45 PM

Phase I trial of the CDK 4/6 inhibitor, P1446A-05 (voruciclib) in combination with the BRAF inhibitor (BRAFi), vemurafenib in advanced, BRAF-mutant melanoma. *First Author: Adi Diab, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: P1446A-05 is a potent, selective CDK 4/6 inhibitor with activity in multiple BRAF-mutant and wild type cell lines. The BRAFi have been transformative in the therapy of BRAF-mutant melanoma. However, resistance does develop frequently, often in only a few months. The addition of a CDK 4/6 inhibitor to BRAF inhibitors is supported by extensive preclinical data. **Methods:** A prospective, multicenter Phase I trial was conducted to determine the safety, maximum tolerated dose (MTD) and dose limiting toxicity of P1446A-05 in combination with Vemurafenib. The Phase I, "dose escalation" part of the trial is reported here. A total of 4 cohorts were planned in the Vemurafenib-arm of this phase in the trial. Vemurafenib was escalated from 720 mg PO BID to 960 mg PO BID and P1446A-05 was planned to be escalated from 150 mg up to 350 mg PO QD. In each cohort, 3 to 6 patients were planned to be enrolled. Extensive PK analysis was conducted. Eligible patients could be BRAFi-naïve or resistant, ECOG PS 0-1, and QTc $<$ 480 at baseline. **Results:** A total of 9 patients have been accrued to date. The combination has been well tolerated and no significant drug-drug interactions have been seen. Adverse events include fatigue (n = 3), headache (n = 3) and constipation (n = 3); no DLTs have been observed. C_{max} for P1446A-05 in combination was observed to be 796 ng/ml on D1 and $AUC_{0\text{-}24}$was 14451 ng.hr/ml, similar to that achieved with the single agent, P1446A-05. Nine patients were assessable for clinical response (3 BRAFi-naïve, 6 refractory). Responses were seen in 3/3 BRAFi-naive patients [1 complete response (CR) and 2 partial responses (PR)]. **Conclusions:** The combination of P1446A-05 and Vemurafenib is well tolerated. This trial was stopped by the Sponsor after accrual of 9 patients (2 dose escalation cohorts) for non-medical reasons. The MTD was not reached in the trial. Based on the available data, the recommended dose for further testing of this combination is Vemurafenib 960 mg PO BID with 150 mg PO QD of P1446A-05. No drug-drug interactions were observed and the PK parameters for the combination were acceptable. Preliminary evidence of efficacy in the treatment-naïve patients was seen. Clinical trial information: NCT01841463.

9077 Poster Session (Board #320), Mon, 1:15 PM-4:45 PM

Next generation sequencing of solid tumor and circulating tumor DNA (ctDNA) in metastatic melanoma. *First Author: Erica L. Carpenter, Division of Hematology/Oncology University of Pennsylvania School of Medicine, Philadelphia, PA*

Background: Capture and molecular analysis of ctDNA represents a promising strategy for noninvasive detection of circulating tumor material. This approach is particularly promising for melanoma, in which detection of intact circulating tumor cells has low sensitivity. We conducted a pilot study using ultra-deep sequencing ctDNA in melanoma patients. **Methods:** Plasma samples ranging from 1-5ml were obtained from 9 metastatic melanoma patients. DNA was extracted using Qiagen Circulating Nucleic Acid Kit. Ultra-deep sequencing of ctDNA was conducted using the Illumina Melanoma Gene Panel to detect variants in a panel of 38 genes. Matched tumor tissue samples were obtained for 5 of these patients; next generation sequencing in the tumor tissue DNA was conducted using a separate assay, the Illumina TrueSeq Cancer Amplicon panel of 47 genes. **Results:** Nonsynonymous variants of known significance were detected in ctDNA from 8 of 9 patients. 13 mutations were detected in 6 genes, including *BRAF, KIT, TSC2, MET, FGFR3, and AKT3*. More than one mutation was detected in 5/9 patients. *BRAF* mutations were detected in 5 of 9 patient ctDNA samples. For 5 patients with matched solid tumor data, 11 variants were detected by either the ctDNA panel, the solid tumor panel, or both panels. Among these 11 variants, 7 were covered by both panels, 2 by the ctDNA panel only, and 2 by the solid tumor panel only. Among the 7 covered by both panels, 3/7 variants were identified identically on both panels and were therefore deemed concordant, while 2/7 variants were only detected on the ctDNA panel and not the solid tumor panel, and the remaining 2/7 variants were only detected on the solid tumor panel and not the ctDNA panel. Possible reasons for these 4/7 discordant calls include tumor heterogeneity over time, with solid tumor tissue collected earlier in the disease course and/or the higher sensitivity of the ctDNA panel. **Conclusions:** Non-invasive monitoring for ctDNA via plasma detection of mutational variants is feasible in metastatic melanoma. Comparison of tumor DNA and plasma ctDNA yields a discordance that underscores the need to validate ctDNA assays in clinical trials, while accounting for assay sensitivity and tumor heterogeneity.

9078 Poster Session (Board #321), Mon, 1:15 PM-4:45 PM

Factors associated with worse outcome for patients with AJCC stage IIC relative to stage IIIA melanoma. *First Author: Caroline C. Kim, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA*

Background: Sentinel lymph node (SLN) status is used in melanoma AJCC staging to distinguish between stage I or II and stage III disease. However patients (pts) with stage IIC (Breslow $>$ 4 mm, ulcerated, SLN -, T4bN0) have worse survival than pts with stage IIIA (any Breslow, nonulcerated, SLN +, Txa,N1a or N2a) disease. We sought to identify factors beyond stage criteria associated with worse outcomes for Stage IIC pts and to compare a matched IIIB population (T4bN1a or N2a). **Methods:** We performed a retrospective chart review of pts diagnosed with T4b (stage IIC and IIIB) or IIIA melanoma in the BIDMC Cutaneous Oncology Program between 1998-2011. Demographics, risk factors, tumor characteristics and outcomes were collected. Groups were compared using a Wilcoxon rank sum test or Fisher's exact test. Log-rank testing and Cox regression modeling were performed. **Results:** 162 pts with stage IIC (56), IIIA (80) and matched Stage IIIB (26) melanoma were identified. Median follow-up time was 5.6 years. The estimated 5-year survival rate for pts with IIC vs IIIA disease was 56% (38-70, 95% CI) vs. 79% (67-87, 95% CI). Besides stage criteria, significant differences between IIC vs. IIIA cohorts included: age at diagnosis (62 vs. 51, $p < 0.001$), amelanotic tumors (45% vs. 22%, $p = 0.03$), mitotic rate (10 mits/mm^2 vs. 2 mits/mm^2, $p < 0.001$), nodular subtype (71% vs. 24%, $p < 0.001$), radial growth (23% vs. 55%, $p < 0.001$) and presence of precursor lesion (6% vs. 22%, $p = 0.02$). Regression modeling revealed that older age at diagnosis ($>$ 55, $p < 0.001$) and higher mitotic rate ($>$ 5 mits/mm^2, $p = 0.001$) were associated with worse survival in pts with stage IIC disease. Of note, pts with matched stage IIIB disease had similar 5-yr survival (52% [29-74, 95% CI])) to pts with IIC disease. **Conclusions:** Our study suggests that aside from stage criteria, there are inherent differences between the IIC and IIIA melanoma population, and older age and higher mitotic rates are associated with worse prognosis for IIC vs. IIIA pts. Further, the similar survival for IIC pts with matched IIIB (T4bN1a or N2a) pts calls into question the value of SLN biopsy as a staging tool in this population. These factors merit consideration in the management of pts with T4b primary lesions.

TPS9079 Poster Session (Board #322a), Mon, 1:15 PM-4:45 PM

A randomized phase II study of ipilimumab induction in patients with melanoma brain metastases receiving stereotactic radiosurgery. *First Author: Ann W. Silk, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Despite recent advances in the treatment of metastatic melanoma, survival remains poor in patients who develop brain metastases. Radiation therapy continues to be the backbone of treatment of brain metastases. Stereotactic radiosurgery (SRS) is a type of external radiation therapy that uses multiple beams to deliver a large dose of radiation to a tumor in a single session. The use of immunotherapy may complement radiation therapy because the latter damages the blood brain barrier (BBB), alters the tumor microenvironment, and increases immunogenicity of tumors. Ipilimumab, an immune checkpoint inhibitor, improves survival in patients with metastatic melanoma. The time to best response after ipilimumab is often several months, emphasizing the need for early initiation of treatment. Ipilimumab has a 16% response rate in patients with brain metastases who are neurologically asymptomatic. Previous studies have suggested that treatment with SRS and ipilimumab was associated with a 16-month prolongation in overall survival as compared to SRS alone. The optimal combination schedule to induce effective antitumor immunity is unknown. We hypothesize that "induction" with ipilimumab prior to SRS will improve control of the irradiated metastases. The trial will explore the use of dynamic contrast-enhanced (DCE) MRI as a potential imaging biomarker for predicting tumor response. DCE MRI is a functional imaging technique that can quantitatively map the spatial distribution of physiologic vascular parameters in the brain, such as regional cerebral blood volume and gadolinium-DTPA transfer constant, which is a measure of "leakiness" across the BBB. **Methods**: This is a randomized phase II "pick the winner" selection study. Forty subjects with 1-4 asymptomatic brain metastases will be randomized to one of two sequences of therapy: either ipilimumab (3 mg/kg IV every 3 weeks x 2 doses) bracketing SRS (Induction arm), or SRS followed by ipilimumab (3 mg/kg IV every 3 weeks x 4 doses; No Induction arm). The primary endpoint is the rate of control of the irradiated metastases at 6 months assessed by MRI. DCE-MRI and various immune parameters will be explored as potential biomarkers. Clinical trial information: NCT02097732.

TPS9080 **Poster Session (Board #322b), Mon, 1:15 PM-4:45 PM**

A multi-center phase II open-label study (CheckMate 204) to evaluate safety and efficacy of nivolumab (NIVO) in combination with ipilimumab (IPI) followed by NIVO monotherapy in patients (pts) with melanoma (MEL) metastatic to the brain. *First Author: Kim Allyson Margolin, Stanford University Medical Center and the Cytokine Working Group (CWG), Stanford, CA*

Background: Brain metastasis develops in approximately 50% of pts with metastatic MEL. In these pts, progressive brain disease is the major cause of tumor-related death (median overall survival [OS] after diagnosis, 4 months). NIVO (a fully human IgG4 PD-1 immune checkpoint inhibitor antibody) and IPI (a fully human IgG1 CTLA-4 immune checkpoint inhibitor antibody) are each approved as monotherapy for advanced MEL. In a phase II study, IPI showed activity in some pts with advanced MEL and brain metastases. Building upon the success of that study, this open-label, multi-site, US, phase II study is the first to evaluate NIVO combined with IPI followed by NIVO monotherapy for pts with MEL metastatic to the brain. It is anticipated that approximately 50% of enrolled pts will have had prior stereotactic radiotherapy (SRT). **Methods:** Pts ≥ 18 years of age with MEL measurable in extracranial sites and with asymptomatic brain metastases are eligible. Pts with a history of leptomeningeal involvement, a history of whole brain irradiation, autoimmune disease or corticosteroid use will be excluded. Pts will receive NIVO 1 mg/kg combined with IPI 3 mg/kg every three weeks (Q3W; 4 doses), followed by NIVO monotherapy 3 mg/kg Q2W until progression or unacceptable toxicity. SRT for progression of a single central nervous system (CNS) lesion will be permitted. The primary objective is to assess the CNS clinical benefit rate (CBR; complete response + partial response + stable disease [SD] ≥ 6 months) per protocol-defined response criteria; this endpoint was selected based on its relevance in this population and ability to capture both objective response and durable SD. Secondary objectives are to assess extracranial CBR per RECIST v1.1; global CBR (CNS plus extracranial) per RECIST v1.1 with modifications; CNS, extracranial and global CBR per immune-related response criteria; OS and safety. Exploratory correlates are also planned. An estimated 110 pts will be enrolled. Clinical trial registration number: NCT02320058. Clinical trial information: NCT02320058.

TPS9081 **Poster Session (Board #323a), Mon, 1:15 PM-4:45 PM**

A multicenter, open-label trial of talimogene laherparepvec (T-VEC) plus pembrolizumab vs pembrolizumab monotherapy in previously untreated, unresected, stage IIIB-IV melanoma. *First Author: Antoni Ribas, David Geffen School of Medicine at the University of California, Los Angeles, Los Angeles, CA*

Background: T-VEC is a herpes simplex virus-1-based oncolytic immunotherapy designed to preferentially replicate in tumors, produce GM-CSF and stimulate an anti-tumor immune response. OPTiM, a phase III trial of T-VEC vs GM-CSF in unresected stage IIIB-IV melanoma (n = 436), met the primary endpoint of improved durable response rate (DRR) in the T-VEC arm (16 vs 2%; Andtbacka et al ASCO 2013). Pembrolizumab is a human programmed death receptor-1 (PD-1)-blocking antibody indicated in the U.S. for the treatment of patients with unresectable or metastatic melanoma and disease progression following ipilimumab and, if BRAF V600 mutation positive, a BRAF inhibitor. Combining T-VEC with pembrolizumab may enhance the anti-tumor immune response vs either therapy alone. Here, we describe a study (NCT02263508) assessing safety and efficacy of T-VEC + pembrolizumab in previously untreated, unresected stage IIIB-IV melanoma. Phase 1b enrolment began 12/2014. **Methods: 1º objectives:** Phase 1b: assess dose-limiting toxicities of T-VEC + pembrolizumab. Phase 2: compare confirmed ORR by immune-related response criteria (irRC) at Wk 24 for T-VEC + pembrolizumab vs pembrolizumab alone **2º objectives:** Best OR, DRR, duration of response (DOR), PFS, OS, treatment-emergent/related AEs **Treatment:** T-VEC is injected into cutaneous, subcutaneous or nodal lesions at up to 4 mL of 10^6 plaque forming units (PFU)/mL Day 1, then at up to 4 mL of 10^8 PFU/mL Day 22 and Q2W (phases 1b and 2). Pembrolizumab is given at 200 mg IV Q2W from Day 36 in phase 1b (n = 20) and Day 1 in phase 2 (n = 90). Treatment with both therapies will continue until (whichever comes first): CR or PD per irRC, intolerance, for up to 2 yrs or, for T-VEC only, when there are no longer injectable lesions. Pts in phase 2 will be randomized 1:1 to T-VEC + pembrolizumab vs pembrolizumab alone. **Key eligibility:** Stage IIIB-IV melanoma naïve to systemic treatment (except adjuvant), injectable lesions, ECOG PS 0-1, no active cerebral metastases, no autoimmunity/immunosuppression, no active herpetic infection. Clinical trial information: NCT02263508.

TPS9082 **Poster Session (Board #323b), Mon, 1:15 PM-4:45 PM**

Phase III multicenter trial of eltrapuldencel-T: Autologous dendritic cells loaded with irradiated autologous tumor cells (DC-TC) in granulocyte-macrophage colony stimulating factor (GM-CSF) in patients with metastatic melanoma (INTUS trial). *First Author: Robert O. Dillman, NeoStem, Newport Beach, CA*

Background: Melanomas harbor non-synonymous mutations that can result in unique, immunogenic tumor associated antigens (TAA). Recognition of TAA can be induced or enhanced by vaccination. The best source of TAA for this purpose may be proliferating, self-renewing, autologous tumor cells (patient-specific tumor stem cells). Patients with stage IV and recurrent stage III melanoma were treated with repeated s.c. injections of autologous dendritic cells loaded with antigens from irradiated tumor cells derived from autologous melanoma cell lines (DC-TC), and suspended in GM-CSF. In a single arm Phase II trial (n = 54) 5-year survival was 50%. In a randomized Phase II trial (n = 42), 2-year survival was 72% for DC-TC vs. 31% for control patients (HR = 0.27, p = 0.007). Toxicities associated with DC-TC were minimal (n = 72). Improvements in manufacturing have increased the probability of establishing a tumor cell line and decreased the time needed to manufacture DC-TC. Eltrapuldencel-T (DC-TC) was granted special protocol assessment (SPA) and fast track designation by the U.S. Food and Drug Administration in association with approval of this pivotal trial. **Methods:** INTUS is a Phase III, double-blind, randomized, placebo-controlled trial. Eligible patients have stage IV or recurrent stage III melanoma with at least one lesion amenable to surgical resection. Resected tumor is transferred to a manufacturing facility to grow the cell line. After successful establishment of a cell line and referral for treatment, 250 patients with good performance status (ECOG 0-1) will be stratified by whether they have no evidence of disease, non-measurable disease by RECIST, or measureable disease with elevated LDH or without elevated LDH, then randomized 2:1 to receive either DC-TC or autologous mononuclear cells. Patients undergo leukapheresis to obtain mononuclear cells for each arm. Both products are suspended in 500 micrograms of GM-CSF and injected weekly for 3 weeks, and then monthly for 5 months. The endpoint is overall survival (death from any cause) [NCT01875653]. Clinical trial information: NCT01875653.

TPS9083 **Poster Session (Board #324a), Mon, 1:15 PM-4:45 PM**

A single-arm, open-label, multicenter phase II trial (CheckMate 172) of nivolumab (NIVO) safety in European patients (pts) with advanced melanoma (MEL) who have progressed after ipilimumab therapy (IPI). *First Author: Dirk Schadendorf, University Hospital Essen, Essen, Germany*

Background: In recent years, the treatment landscape for advanced MEL has evolved with approval of an anti-CTLA-4 antibody (IPI), BRAF/MEK inhibitors and anti-programmed death-1 (PD-1) antibodies (NIVO and pembrolizumab). In a phase III study with pts previously treated with IPI, NIVO had an objective response rate of 32% (vs 11% with chemotherapy) and a manageable safety profile. Anti-PD-1 antibodies have been associated with select adverse events (AEs; i.e., those with a potential immunologic etiology), most of which resolve using established safety management guidelines. However, further safety information would be desirable in pts who progressed after prior IPI, particularly in pt subgroups that were under-represented in previous studies. Consequently, this phase II trial will assess the safety of NIVO in a large population of European pts with stage III or IV MEL progressing after prior IPI treatment, including a separate prospective cohort of pts with ECOG performance status (PS) 2. **Methods:** Eligible pts are ≥ 18 years of age, have histologically confirmed malignant stage III (unresectable) or stage IV MEL, have ECOG PS 0–1 (Cohort 1) or 2 (Cohort 2), were previously treated regardless of BRAF mutation status and have evaluable RECIST v1.1-defined disease progression. Pts will be treated with NIVO 3 mg/kg every 2 weeks (Q2W) until progression or unacceptable toxicities for a maximum of 24 months. Safety assessments will be performed Q2W in Cohort 1 and Q1W in Cohort 2. Tumor assessments will begin at week 12. The primary objectives are to determine the rate and frequency of high-grade (CTCAE v4.0 grade 3 or higher), treatment-related, select AEs. Secondary objectives are to characterize the outcome (grade of resolution; duration of AE-specific treatment) of high-grade, select AEs and to estimate overall survival and investigator-assessed best overall response. Approximately 1,800 pts will be enrolled across Europe, including a maximum of 300 pts with ECOG PS 2. Clinical trial registration number: NCT02156804. Clinical trial information: NCT02156804.

TPS9084 Poster Session (Board #324b), Mon, 1:15 PM-4:45 PM

Phase 1 dose escalation and expansion safety study of BLZ-100 in subjects with skin cancer. *First Author: Dennis Michael Miller, Blaze Bioscience Inc, Seattle, WA*

Background: BLZ-100 is an intraoperative, fluorescent imaging agent designed to specifically label malignant tissue and enable more complete surgical resection of tumor tissue. BLZ-100 achieves tumor targeting through the peptide portion of the molecule, a modified chlorotoxin (CTX) peptide, and its imaging properties from the coupled near-infrared fluorescent dye, indocyanine green. Tumor-specific uptake of BLZ-100 has been shown in multiple mouse tumor models and in dogs with spontaneous cancers. **Methods:** In order to characterize the safety of BLZ-100, a first-in-human, phase 1 dose escalation and expansion study in subjects with suspected skin cancer is being conducted. BLZ-100 is administered via a 15-minute IV infusion to subjects approximately 2 days before planned excision of their skin tumor. Subjects with known or suspected non-melanotic skin cancer (e.g., basal cell carcinoma) are included in the dose escalation. Subjects with known or suspected melanoma are included in the dose expansion. Subjects must have adequate bone marrow, liver and kidney function to participate. Dose escalation is being conducted according to a traditional "3+3" design. Dose limiting toxicity is defined as any related adverse event (AE) of ≥ Grade 3 severity occurring within 7 days of BLZ-100 administration. Measures of safety include patient or physician reported adverse events, laboratory measures of hematology, liver and kidney function, and coagulation parameters and changes in vital signs and electrocardiograms (ECG). Blood samples are collected over the 7-day DLT period to measure BLZ-100 serum concentrations via a LC/MS method. Serial fluorescence imaging of suspected skin tumors in situ is conducted over 48 hours using the Fluobeam 800 device. Portions of the excised skin specimens from the dose escalation were also subjected to fluorescent image analysis using an Odyssey scanner and immunohistochemistry analysis for the presence of Annexin A2 (presumed target of BLZ-100). Dose escalation in the 5 pre-specified dose levels has been completed without DLT. Enrollment of the expansion cohorts is on-going as of December 16, 2014. Clinical trial information: NCT02097875.

TPS9085 Poster Session (Board #325a), Mon, 1:15 PM-4:45 PM

SWOG S1404: A phase III randomized trial comparing high dose interferon to pembrolizumab in patients with high risk resected melanoma. *First Author: Kenneth F. Grossmann, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Current adjuvant treatment for patients with a surgically resected stage III-IV melanoma is limited to high dose Interferon (HDI) and pegylated interferon (pegIFN), which have shown limited but consistent benefits in RFS (HDI and pegIFN) and OS (HDI) in high-risk melanoma, while no other agents have been proven superior in randomized trials. Anti-PD-1 antibodies such as pembrolizumab (MK-3475) have shown unprecedented rates of durable tumor response in patients with metastatic melanoma with low rates of adverse events. S1404 is a Phase III randomized trial comparing the standard of care HDI to pembrolizumab in patients at high risk for recurrence and death after surgery. **Methods:** Patients age 15 or greater with Stages IIIA(N2), IIIB, IIIC and IV (M1a, b and c) are eligible. Patients with brain metastasis will be excluded. At entry, patients must have had complete staging and adequate surgery to render them free of melanoma including completion lymph node dissection for those with sentinel lymph node positive disease. Prior therapy with PD-1 blockade or interferon are not allowed. Two treatment arms are assigned based on stratification by stage and PD-L1 staining status (positive vs negative vs unknown). Patients (n = 1,378) will be randomized 1:1 to either 1) interferon Alfa-2b 20 MU/m2/days 1-5 weeks 1-4, followed by Interferon Alfa-2b 10 MU/m2/d SC days 1,3,5weeks 5 -52, or 2) pembrolizumab 200 mg day 1, q 3 weeks for 52 weeks. Efficacy will be measured in terms of both overall survival and relapse free survival, with interim analyses planned for both endpoints at 50% OS information. Safety, pharmacokinetics, and quality of life data will also be studied.

TPS9086 Poster Session (Board #325b), Mon, 1:15 PM-4:45 PM

A phase II, open-label, multicenter trial to investigate the clinical activity and safety of avelumab (MSB0010718C) in patients with metastatic Merkel cell carcinoma. *First Author: Howard Kaufman, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: The programmed death-1 receptor (PD-1) and its ligand (PD-L1) are key therapeutic targets in the reactivation of the immune response against multiple cancers. Avelumab* (MSB0010718C) is a fully human anti-PD-L1 IgG1 antibody currently being investigated in clinical trials. Merkel cell carcinoma (MCC) is a rare, aggressive, Merkel cell polyomavirus (MCPyV)-induced skin cancer with suboptimal therapeutic options. Cytotoxic chemotherapy is commonly used to treat metastatic MCC, although responses are seldom durable. There is a strong rationale for investigating PD-1/PD-L1 blockade in MCC. Despite their immunogenicity, MCC tumors are able to evade the host immune system through multiple mechanisms that include exhaustion of tumor virus-specific T cells via expression of PD-L1 on the tumor cells and adjacent immune-cell infiltrates. **Methods**: This is a multicenter, international, single-arm, open-label, phase II trial to evaluate the efficacy and safety of avelumab in patients (pts) with metastatic MCC who have received ≥ 1 prior line of chemotherapy. Up to 84 eligible pts will receive avelumab at a dose of 10 mg/kg as a 1h intravenous (IV) infusion Q2W. Treatment will continue until disease progression, unacceptable toxicity, or if criterion for treatment withdrawal is met. Primary objective is to assess the clinical activity of avelumab as determined by the objective response rate (ORR) according to RECIST 1.1 by an Independent Endpoint Review Committee. Secondary objectives include assessment of the duration of response, progression-free survival time (PFS), overall survival (OS), and safety. The pharmacokinetic (PK) profile of avelumab will also be evaluated. Exploratory objectives include assessment of immune-related responses and evaluation of PD-L1 expression and its potential association with response rate. This study will also explore the quality of life of pts with MCC who have been treated with avelumab. The trial is in progress: 19 of a planned 84 patients have been recruited (trial start June 2014, estimate end January 2017). NCT02155647. *Proposed INN. Clinical trial information: NCT02155647.

TPS9087 Poster Session (Board #326a), Mon, 1:15 PM-4:45 PM

Randomized phase II study comparing the MET inhibitor cabozantinib to temozolomide (TMZ) or dacarbazine (DTIC) in ocular melanoma: A091201. *First Author: Jason John Luke, University of Chicago, Chicago, IL*

Background: Ocular melanoma has been described to express the receptor tyrosine kinase MET in up to 80% of specimens and preclinical data suggests that MET inhibitors reduce proliferation and metastatic potential in cell lines and murine xenografts. Cabozantinib is a receptor tyrosine kinase inhibitor with significant inhibitory activity against MET and VEGFR2 (among other targets). Cabozantinib was associated with a median progression-free survival (mPFS) of 4.8 months in final follow up of the ocular melanoma cohort of the cabozantinib randomized discontinuation clinical trial. Notably, the MEK inhibitor selumetinib was determined to deliver mPFS of 3.9 months in a randomized phase II study. **Methods:** This is a national (Alliance for Clinical Trials in Oncology, Eastern Cooperative Oncology Group, NCIC Clinical Trials Group) open-label phase II study comparing cabozantinib with TMZ/DTIC in advanced ocular melanoma (clinicaltrials.gov: NCT01835145). The study randomizes patients 2:1 to cabozantinib and facilitates cross-over from the chemotherapy arm to cabozantinib at progression of disease. Eligibility is for any line of therapy and allows for prior treatment with MEK inhibitor or immunotherapy. Other eligibility includes biopsy proven metastatic ocular melanoma, ECOG 0-1 and adequate organ function (modified for elevated liver function tests related to hepatic metastases). The primary endpoint is PFS at 4 months with secondary endpoints evaluating RECIST response rate, PFS, overall survival and correlation of the primary endpoint with pre-treatment tumor tissue MET expression by IHC. The study is open to accrual via the Cancer Trials Support Unit (CTSU) of NCI to any cooperative group member site. Recruitment is on-going (target 69 patients). Clinical trial information: NCT01835145 or Alliance for Clinical Trials in Oncology # A091201. Clinical trial information: NCT01835145.

TPS9088 Poster Session (Board #326b), Mon, 1:15 PM-4:45 PM

Phase 2 study of cobimetinib in combination with vemurafenib in active melanoma brain metastases (coBRIM-B). *First Author: Melissa K. Yee, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Significant advances in the management of melanoma have improved the prognosis and overall survival of patients (pts) with metastatic disease. However, pts with active melanoma brain metastases (MBM) have been excluded from large Phase III trials and overall prognosis remains poor. Resistance to BRAF inhibitors (BRAFi) has been associated with reactivation of MAPK pathway and combination with MEK inhibitors (MEKi) has shown synergy and delays resistance. Cobimetinib is a potent MEK 1/2 inhibitor. In pts without MBM, the combination of vemurafenib + cobimetinib has improved response rates and PFS as compared to vemurafenib. Single agents BRAFi are safe to administer in pts with MBM resulting in objective intracranial responses. We aim to improve the outcomes of pts with MBM by assessing the clinical benefit of combination BRAFi/MEKi (vemurafenib + cobimetinib) in this population. **Methods:** This is a multi-center single arm, open label, Simon 2-stage Phase 2 study to determine the safety and efficacy of the combination of cobimetinib and vemurafenib in patients with BRAF-mutated melanoma with active MBM. Pts must have histologically confirmed BRAF V600-mutated metastatic melanoma and $>$ 1 measurable intracranial target lesion. Prior BRAFi or MEKi is not allowed. Subjects will be given vemurafenib 960 mg PO BID and cobimetinib 60 mg PO QD for 21 days (28-day cycle). The primary objective is to determine the investigator-assessed objective intracranial response rate (OIRR) as measured by modified RECIST. The primary efficacy analysis is based on pts with BRAF V600E mutations and the study will accrue 29 pts in the 1st stage. If $>$ 6 pts experience an OIRR, acrrual to the 2nd stage will proceed to a total of 72 pts. Pts with non-V600E mutation are allowed but will not enter into the primary efficacy analysis. Secondary objectives include safety/tolerability, ORR (intracranial + extracranial), PFS, OS, duration of response, changes in relative apparent diffusion coefficient by MRI, volumetric response using 3D-MRI in a subset of pts, immune modulation and early markers of progression in peripheral blood, and health-related quality of life (by FACT-Br). The trial is open for enrollement. NCT02230306 Clinical trial information: NCT02230306.

TPS9089 Poster Session (Board #327a), Mon, 1:15 PM-4:45 PM

A Phase 2 biomarker-enriched study of evofosfamide (TH-302) in patients with advanced melanoma. *First Author: Elaine McWhirter, Juravinski Cancer Centre, Hamilton, ON, Canada*

Background: In melanoma, tumor hypoxia is associated with invasion, angiogenesis, and metastasis formation, as well as treatment resistance such as immune evasion. Evofosfamide (EVO, TH-302) is a hypoxia-activated prodrug designed to release the bis-alkylating DNA crosslinker bromo-isophosphoramide mustard (Br-IPM) when reduced in severe hypoxia. In the Phase 1 study (NCT00495144) of EVO monotherapy, 7 of 36 (19%) patients with advanced melanoma had partial responses and 12 of 36 (33%) stable disease. Dose limiting adverse events included skin and mucosal toxicities. A Phase 2 biomarker-enriched trial was initiated to further evaluate the efficacy of EVO in melanoma, and identify hypoxia and other biomarkers predictive of response. **Methods:** This Phase 2 trial is a single-arm, multi-center, study investigating the efficacy and safety of EVO monotherapy (NCT01864538). The primary endpoint is 3-mo PFS. The study incorporates a Simon two-stage design (alpha = 0.15; beta = 0.15) based on 3-mo PFS with level of disinterest of 20% and level of interest of 35%. Secondary endpoints include response rate, overall survival, pharmacokinetics, safety, and evaluation of imaging, serum, and tissue biomarkers that may be associated with tumor response and predict for efficacy and safety of EVO. EVO (480 mg/m^2) is given by IV infusion over 30 - 60 minutes on Days 1, 8 and 15 of a 28-day cycle. Hypoxia PET imaging using [^{18}F]HX4 or [^{18}F]FAZA, *in vivo* hypoxia detection using pimonidazole, hypoxia biomarkers such as CA-IX, HIF1-alpha, OPN, and VEGF; DNA damage markers such as gamma-H2AX, as well as tumor immune monitoring are included. Up to 40 patients will be enrolled with histologically confirmed recurrent or metastatic melanoma, measureable disease by RECIST 1.1, and ECOG 0-1. There are no limits on the number of prior targeted therapies or immunotherapies; however, patients may not have received more than one prior chemotherapy. Patients with brain metastases are eligible, if treated and stable for 2 months. Eligible patients must also have adequate tumor tissue available for pre-therapy and post-therapy biopsies. The first patient was treated in August 2013; recruitment is ongoing. Clinical trial information: NCT01864538.

TPS9090 Poster Session (Board #327b), Mon, 1:15 PM-4:45 PM

A randomized, phase III study of fotemustine versus the combination of fotemustine and ipilimumab or the combination of ipilimumab and nivolumab in patients with metastatic melanoma with brain metastasis: the NIBIT-M2 trial. *First Author: Anna Maria Di Giacomo, Medical Oncology and Immunotherapy, University Hospital of Siena, Siena, Italy*

Background: The anti-CTLA-4 monoclonal antibody (mAb), ipilimumab (Ipi) significantly improves the survival of metastatic melanoma (MM) patients (pts). In spite of their poor prognosis, initial studies have evaluated the therapeutic potential of Ipi also in MM pts with brain metastasis (BM), providing preliminary evidences of efficacy. Among these, the multicentric, phase 2, Italian Network for Tumor Biotherapy (NIBIT)-M1 trial, combining Ipi with fotemustine, showed initial signs of activity in a subset of 20 MM subjects with active BM, regardless of prior radiotherapy. Though limited by the number of pts enrolled, disease control in the brain was long lasting achieving a 3-year survival rate of 28% (Di Giacomo et al, *Annals Oncol*, 2014). Based these results and on the highly promising efficacy of Ipi in combination with nivolumab (Nivo) in MM patients without BM, the NIBIT-M2 study will further explore the efficacy of immunotherapy with check-point blocking mAb in MM pts with BM. **Methods:** The NIBIT-M2 is a randomized, phase 3, open-label, study that will enroll 168 MM pts with untreated, asymptomatic BM, ECOG performance status of 0 or 1, BRAF W/T or mutant disease. Pts will be randomized to receive fotemustine i.v. at 100 mg/m2 weekly for 3 weeks (wk), and q3 wk from week 9 (ARM A) or Ipi i.v. at 10 mg/kg q3 wk for 4 doses and once q12 wk from week 24 in combination with fotemustine (ARM B) or Ipi i.v. at 3 mg/kg q3 wk for 4 doses in combination with Nivo at 1 mg/kg q3 wk for 4 doses and then Nivo at 3 mg/kg q2 wk (ARM C). Primary objective is Overall Survival; secondary are safety, Disease Control Rate in and outside the brain, Objective Response Rate and Duration of Response evaluated using both the modified-WHO response criteria and the immune-related response criteria; progression Free Survival (PFS), 3- and 6-months Brain-PFS rate and Quality of Life will also be evaluated. Phenotypic and functional cellular and humoral translational studies will correlate the immunomodulatory activity of treatment with clinical outcomes. Seventeen pts have been enrolled to date. (EUDRACT # 2012-004301-27) Clinical trial information: 2012-004301-27.

TPS9091 Poster Session (Board #328a), Mon, 1:15 PM-4:45 PM

Neoadjuvant BRAF (dabrafenib) and MEK (trametinib) inhibition for high-risk resectable stage III and IV melanoma. *First Author: Jennifer Ann Wargo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Significant advances have been made in the treatment of melanoma through the use of mitogen -activated protein kinase pathway (MAPK)-targeted therapies, with several agents now FDA-approved for patients (pts) with BRAF V600 mutations with stage IV or unresectable stage III disease. Based on the efficacy of BRAF inhibitors and combined BRAF/MEK inhibitors in patients with stage IV melanoma, these agents are being investigated as adjuvant therapy in patients with resectable stage III melanoma as part of multi-national phase 3 trials, where the current standard of care is upfront surgery. Mature results from these trials, however, will not be available for some time. A critical question to consider is whether neoadjuvant treatment with MAPK-targeted therapy will improve outcomes in a subset of these patients with significant burden of disease. **Methods:** Here we report 2 current phase II trials -- at MD Anderson Cancer Center (MD Anderson) and Melanoma Institute Australia (MIA) -- of neoadjuvant combined BRAF inhibition (dabrafenib, at 150 mg by mouth twice a day) and MEK inhibition (trametinib, at 2 mg by mouth once a day) for high risk resectable metastatic melanoma (stage IIIB-C; MIA and MD Anderson) and oligometastatic stage IV (MD Anderson)). Both trials incorporate serial biopsies during the course of treatment for translational research on molecular and immune biomarkers. At MD Anderson, eligible patients are randomized in a 2:1 fashion to neoadjuvant BRAF/MEK x 8 weeks with adjuvant BRAF/MEK x 44 weeks versus upfront surgery and SOC adjuvant therapy (target accrual 84 patients). Endpoints include RECIST response (RR), relapse-free survival (RFS), overall survival (OS), pathologic CR rate, and toxicity. At MIA, all patients receive neoadjuvant BRAF/MEK x 12 weeks, followed by adjuvant BRAF/MEK for 40 weeks (target accrual 35 patients). The primary endpoint is pathologic CR rate, secondary endpoints include RFS, OS, toxicity, and translational endpoints correlated with outcome. This neoadjuvant approach has the potential to establish a new treatment paradigm for patients with high-risk resectable metastatic melanoma harboring a BRAF mutation. Clinical trial information: NCT01972347, NCT02231775.

TPS9092 Poster Session (Board #328b), Mon, 1:15 PM-4:45 PM

A pilot study of neoadjuvant cetuximab in locally advanced squamous cell carcinomas of skin (SCCS). *First Author: Kristen Renee Spencer, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: The incidence of SCCS has increased over the past two decades, including a high risk subset with aggressive behavior. Due to a lack of high-quality clinical trials in this population, there is no standard systemic therapy for advanced SCCS. The epidermal growth factor receptor (EGFR), often highly expressed in SCCS, is implicated in UV-induced skin carcinogenesis and SCCS development. Cetuximab, a monoclonal antibody that competitively inhibits EGFR, improved disease control as first line therapy in unresectable SCCS in a single arm phase II trial. Despite impressive responses with cetuximab in some, most treated SCCS patients do not respond, and there is a need for predictive biomarkers. We hypothesize that the use of cetuximab will improve clinical outcomes in patients with advanced SCCS in the neoadjuvant setting, and that measures of antibody dependent cytotoxicity (ADCC) in tumor and/or specific genomic features of the tumor may predict response to therapy. **Methods:** In this pilot trial (NCT 02324608), we will enroll 20 patients with relapsed locally advanced SCCS or SCCS unamenable to definitive local therapy. The primary endpoint will measure response rate to cetuximab by RECIST criteria with secondary endpoints of progression free and overall survival, and conversion to resectability. Molecular tumor correlates include analyzing DNA mutations and measuring downstream activation of EGFR signaling and ADCC, correlating these with clinical benefit. Patients will receive cetuximab at 400mg/m^2 X 1 followed by weekly doses of 250mg/m^2 for 8 weeks prior to surgery. Patients will be evaluated for subsequent definitive surgical resection, or definitive radiotherapy if surgical resection is not possible. Postoperative adjuvant radiotherapy will be permitted. Patients will undergo pretreatment biopsies, and post-treatment tissue will be harvested at surgery or through a biopsy at the conclusion of cetuximab. Paired skin and tumor samples will be evaluated through partial DNA (FoundationOne™) and RNA sequencing, IHC analysis of EGFR signaling components, and measurement of ADCC. The trial is currently screening eligible subjects. Clinical trial information: 02324608.

TPS9093 Poster Session (Board #329a), Mon, 1:15 PM-4:45 PM

SWOG S1320: A randomized phase II trial of intermittent versus continuous dosing of dabrafenib and trametinib in BRAF$^{V600E/k}$ mutant melanoma. *First Author: Alain Patrick Algazi, University of California, San Francisco, San Francisco, CA*

Background: Combined BRAF and MEK inhibition yields improved response rates and overall survival compared with BRAF inhibitor monotherapy in BRAF mutant melanoma patients(Robert et al., 2015), but the median progression-free survival is less than one year. Recent preclinical data suggest that resistant BRAF mutant melanoma cells adapt to the presence of BRAF inhibitors, but these adaptations may be disadvantageous in the absence of drug(Das Thakur et al., 2013; Moriceau et al., 2015). Further *in vitro* and *in vivo* studies suggest that intermittent dosing of BRAF inhibitors and especially BRAF + MEK inhibitor combinations may extend disease control in BRAF mutant melanoma. Based on these findings, S1320, an intergroup SWOG/ECOG randomized phase 2 clinical trial, was designed to determine whether an intermittent dosing schedule of dabrafenib and trametinib improves progression-free survival (PFS) in BRAF mutant melanoma patients treated with a standard, continuous dosing regimen. **Methods:** ELIGIBILITY: Patients with unresectable or metastatic BRAF$^{V600E/K}$ melanoma who have not been treated previously with BRAF or MEK inhibitors are eligible. Patients must have adequate end organ function and any known brain metastases must be treated prior to enrollment. DESIGN: Patients will be treated with dabrafenib at 150 mg twice daily and trametinib 2 mg twice daily during an 8 week lead in period. Patients without disease progression at the end of the lead in period will be randomized 1:1 to either continuous dosing or intermittent dosing according to a 5 weeks on, 3 weeks off schedule. Reimaging will be performed once every 8 weeks. ENDPOINTS: The primary endpoint of this study is the PFS in the continuous versus intermittent dosing arms. Secondary endpoints include the toxicity, best overall response rate, and overall survival. Early and late molecular events associated with disease progression will also be assessed using serial biopsies in a subset of patients in each arm. Support: NIH/NCI/NCTN grants CA180888, CA180819, CA180820 Clinical trial information: NCT02196181.

TPS9094 Poster Session (Board #329b), Mon, 1:15 PM-4:45 PM

Phase 2, multicenter, randomized, open-label trial assessing efficacy and safety of talimogene laherparepvec (T-VEC) neoadjuvant treatment (tx) plus surgery vs surgery for resectable stage IIIB/C and IVM1a melanoma (MEL). *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Risk of recurrence and death after resection of stage IIIB/C and IVM1a MEL is high. T-VEC is an HSV-1-derived oncolytic immunotherapy designed to selectively replicate in tumors, produce GM-CSF, and enhance systemic antitumor immune responses. In OPTiM, a randomized phase 3 trial of T-VEC vs GM-CSF in patients (pts) with unresected stage IIIB/C and IVM1a MEL, T-VEC improved the primary endpoint (EP) of durable response rate (continuous PR/CR for $\geq$ 6 mos) from 2% to 16%, $P <$ 0.0001. Median overall survival (OS, secondary EP) was 23.3 mos with T-VEC vs 18.9 mos with GM-CSF; HR = 0.79, 95% CI: 0.62-1.00; $P =$ 0.051. We hypothesize that neoadjuvant T-VEC will improve local control rates and decrease distant metastases (DM) in pts with resectable stage IIIB/C and IVM1a MEL. **Methods:** 150 pts with resectable stage IIIB/C and IVM1a cutaneous MEL with $\geq$ 1 injectable cutaneous, subcutaneous, or nodal lesion will be randomized 1:1 to immediate surgical resection vs 6 doses of neoadjuvant T-VEC for up to 12 wks, followed by surgical resection. T-VEC is administered as $\leq$ 4 mL x 10^6 pfu/mL, then after 3 wks $\leq$ 4 mL x 10^8 pfu/mL q2w until all injectable tumors have disappeared, intolerance to tx, or alternative tx initiated. Eligible pts are $\geq$ 18 y old, ECOG PS 0-1, with adequate hematologic, hepatic, and renal function; prior systemic, regional, radiation therapies for MEL were completed $\geq$ 3 mos before randomization; history or evidence of symptomatic autoimmune disease, immunodeficiency, active herpes, prior HSV-1 complications, systemic tx with antiherpetic drugs, and prior tumor vaccines are not allowed. Primary EP is recurrence-free survival (RFS); key secondary EPs are 2 y, 3 y, and 5 y RFS, OS, overall tumor response, R0 resection, pathological CR, local RFS, DM-free survival, and safety. Blood and tumor biomarkers for response to T-VEC will be explored. Primary analysis of RFS will be at the later of 2 y after the end of randomization (EOR) or 64 events. Additional analyses will occur 3 and 5 y after EOR. The trial is planned at ~50 sites in Australia, Brazil, Europe, and USA. Accrual began in February 2015. Clinical trial information: NCT02211131.

9500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III trials of anamorelin in patients with advanced non-small cell lung cancer (NSCLC) and cachexia (ROMANA 1 and 2). *First Author: Jennifer S. Temel, Massachusetts General Hospital, Boston, MA*

Background: Patients with advanced cancers frequently experience anorexia and cachexia, which is associated with decreased functional status and poor tolerance of chemotherapy. ROMANA 1 and 2 were two randomized, double blind trials evaluating the effect of anamorelin, a ghrelin receptor agonist, on cachexia in patients with advanced NSCLC. **Methods:** We randomly assigned 484 patients (ROMANA 1) and 495 patients (ROMANA 2) with inoperable stage III or stage IV NSCLC and cachexia ($\geq$ 5% weight loss within prior 6 months or BMI $<$ 20 kg/m^2) to placebo or anamorelin 100 mg orally once daily. Co-primary efficacy endpoints were the change in lean body mass and handgrip strength from baseline over 12 weeks. Secondary endpoints included change in body weight and symptom burden over 12 weeks and pooled survival from ROMANA 1 and ROMANA 2. Exploratory analyses evaluated change in total body mass and fat mass from baseline to 12 weeks. **Results:** Patients assigned to anamorelin experienced an increase in lean body mass compared to those assigned to placebo in ROMANA 1 (1.10 vs -0.44 kg, $p < 0.001$) and ROMANA 2 (0.75 vs -0.96 kg, $p < 0.001$), but no difference in handgrip strength. Patients assigned to anamorelin also had a significant increase in body weight (2.2 vs 0.14 kg, $p < 0.001$) and (0.95 vs -0.57 kg, $p < 0.001$) and improvement in their anorexia/cachexia symptoms (4.12 vs 1.92, $p < 0.001$) and (3.48 vs 1.34, $p = 0.002$) in ROMANA 1 and 2, respectively. Exploratory analysis demonstrated an increase in total body mass (2.87 vs 0.07 kg, $p < 0.001$) and (2.04 vs -0.59 kg, $p < 0.001$), and fat mass (1.21 vs -0.13 kg, $p < 0.001$) and (0.77 vs 0.09 kg, $p = 0.012$) for anamorelin versus placebo in the two studies, respectively. Anamorelin was well tolerated with hyperglycemia and diabetes as the most frequent drug-related adverse events ($\leq$ 5%). Median 1-year survival was not different between study arms. **Conclusions:** Anamorelin increased lean body mass, body weight, total body mass and fat mass indicating anabolic activity and restoration of energy balance in patients with advanced NSCLC. Patients also experienced significant improvement in anorexia/cachexia symptoms. Anamorelin was well tolerated, with similar pooled survival between study arms. Clinical trial information: NCT01387269 and NCT01387282.

9501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

CALGB 70604 (Alliance): A randomized phase III study of standard dosing vs. longer interval dosing of zoledronic acid in metastatic cancer. *First Author: Andrew Louis Himelstein, Helen F. Graham Cancer Center & Research Institute, Newark, DE*

Background: Zoledronic acid (ZA) given monthly for 24 months (mo) reduces bone pain and skeletal-related events (SRE) in patients (pts) with bone metastases. We tested whether ZA every 3 mo would be non-inferior to monthly for 24 mo, with less toxicity, in a randomized trial in 1822 pts: breast (n = 833), prostate (n = 674), myeloma (n = 270), and other (n = 45). **Methods:** SRE were defined as radiation therapy (RT) to bone, fractures, spinal cord compression or surgery to bone within 24 mo. ZA doses were adjusted for creatinine clearance. The primary endpoint was the proportion of pts in each group who had $\geq$ 1 SRE; secondary endpoints included skeletal morbidity rates, performance status, pain using the Brief Pain Inventory, and incidences of jaw osteonecrosis and renal dysfunction. The trial design was non-inferiority (NI) with stratification and pre-planned analyses by disease. The NI margin was 7% absolute difference. With 1,230 pts (planned sample size 1758 with 30% allowance for inevaluable pts), the power was $>$ 82% when the NI margin was $<$ 0 using a 1-sided test at a 5% significance level. **Results:** Between May 1, 2009 and April 13, 2012, 1822 pts were randomized. Baseline characteristics of the 2 groups were comparable. Dose delays were more common with ZA monthly. The 2-year cumulative incidences of SRE and selected toxicities are presented in the Table. The proportions of SRE were 29.5% vs 28.6% (95% CI for margin: -3.3% to 5.1%, Cochran-Maentel-Hanzel p = 0.79) for monthly and every 3 mo, respectively. **Conclusions:** ZA administered every 3 mo is non-inferior to ZA administered monthly for 24 mo in breast cancer, prostate cancer and multiple myeloma. Bone turnover markers in a subset of pts and a cost analysis will be presented. Clinical trial information: NCT00869206.

	Q Month N = 911	Q 3 Months N = 911	HR (P-value)
Total ZA dose (median)	56 mg	24 mg	— ($<$ 0.01)
Dose delays	62%	37%	— ($<$ 0.01)
Any SRE	260	253	1.05 (0.60)
Any SRE – breast pts (N = 820)	113	119	0.90 (0.43)
Any SRE – prostate pts (N = 660)	107	101	1.15 (0.31)
Any SRE – myeloma pts (N = 265)	35	30	1.30 (0.29)
Bone RT	185	163	1.16 (0.18)
Bone fractures	62	79	0.78 (0.13)

Grade 2-4 creatinine increase	11	5	— (0.46)

9502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Olanzapine versus fosaprepitant for the prevention of nausea and vomiting in patients receiving concurrent chemoradiation treatment. *First Author: Rudolph M. Navari, Indiana Univ School of Medcn South Bend, Mishawaka, IN*

Background: The purpose of the study was to compare the effectiveness of olanzapine (OLN) and fosaprepitant (FOS) for the prevention of nausea and vomiting in patients receiving concurrent highly emetogenic chemotherapy (HEC) and radiation therapy for head and neck and esophageal cancer. **Methods:** A randomized, double-blind, phase III trial was performed in chemo and radiation therapy naïve patients receiving concurrent local radiation and cisplatin, $>$ 70 mg/m^2, based chemotherapy comparing OLN to FOS in combination with palonosetron (PAL) and dexamethasone (DEX). The OLN, PAL, DEX (OPD) regimen was 10 mg of oral OLN, 0.25 mg of intravenous PAL, and DEX 20 mg intravenous pre-chemotherapy, day 1, and 10 mg/day of oral OLN alone on days 2-4 post-chemotherapy. The FOS, PAL, DEX (FPD) regimen was 150 mg of intravenous FOS, 0.25 mg intravenous PAL, and 12 mg intravenous DEX, day 1, and 4 mg DEX twice a day, days 2 and 3. Distribution of patients to different groups were similar in gender, types of cancer, and radiotherapy regimens. **Results:** One hundred and nine patients consented to the protocol and were randomized. One hundred patients were evaluable. Complete response (CR) (no emesis, no rescue) was 88% for the acute period (24 hours post-chemotherapy), 76% for the delayed period (days 2-5 post-chemotherapy), and 76% for the overall period (0-120 hours) for 51 patients receiving the OPD regimen. CR was 84% for the acute period, 73% for the delayed period, and 73% for the overall period in 49 patients receiving the FPD regimen. Patients without nausea (0, scale 0-10, visual analogue scale) were: OPD: 86%, acute; 71%, delayed; and 71%, overall; FPD: 77%, acute; 41%, delayed; and 41%, overall. There were no grade 3 or 4 toxicities. CR and control of nausea in subsequent chemotherapy cycles were equal to or greater than cycle one for both regimens. **Conclusions:** For the overall period, OPD was comparable to FPD in the control of emesis; nausea was significantly ($p < 0.01$) improved with OPD compared to FPD.

9503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Chemotherapy-related cognitive impairment (CRCI), and neurotransmitter signaling, longevity, and inflammation pathways in 366 breast cancer (BC) patients and 366 age-matched cancer-free controls: A prospective, nationwide, longitudinal URCC NCORP study. *First Author: Michelle Christine Janelsins, Department of Surgery, University of Rochester Medical Center, Rochester, NY*

Background: CRCI is a burdensome clinical problem for many BC patients. Large studies are needed to definitively assess CRCI and elucidate its' biological underpinnings. We conducted the largest longitudinal, observational study to date assessing CRCI in BC patients and controls, and assessed whether neurotransmitter signaling, longevity, and inflammation pathways are involved in CRCI. **Methods:** We recruited non-metastatic BC patients (n = 366) without previous chemotherapy (CT) and age-matched controls (n = 366). Cognitive function was assessed within 1 wk pre-CT and within 4 wks post-CT using the FACT-Cog to assess self-reported function and neuropsychological assessment (computerized CANTAB Verbal Memory (VM), paper-based Controlled Oral Word Association (COWA), phone-based word recall (RAVLT) and backward counting) to assess executive function. Controls were assessed at the same time intervals as patients. SNPs involved in neurotransmitter signaling (*COMT*) and longevity (*FOXO3*), and pre- and post-CT cytokines (IL-1β, MCP-1, sTNFR1) were measured in patients. **Results:** BC patients (89% white, mean age = 53) reported more CRCI on the FACT-Cog (total score and all 4 domains) from pre- to post-CT and performed worse on all 4 executive function tests over time via t-tests (all $p < 0.05$).Using ANCOVA, adjusting for age, education, WRAT-4 reading, anxiety (STAI), and pre-CT cognitive score, BC patients performed worse on all measures post-CT compared to controls: FACT-Cog Effect Size (ES) = 0.74, VM ES = 0.27, COWA ES = 0.33, RAVLT ES = 0.27, Backward Count ES = 0.19; all $p < 0.05$. *FOXO3* and *COMT* SNPs predicted level of CRCI on the FACT-Cog (both $p = 0.07$). Decreases in executive function were associated with increases in IL-1β, MCP-1 (both $p < 0.05$) and sTNFR1 ($p = 0.08$). **Conclusions:** This is the largest longitudinal study showing significant CRCI amongBC patients receiving CT compared to cancer-free controls. CRCI in BC patients is influenced by neurotransmitter signaling and longevity genes and leads to increased inflammation. NCI UG1CA18996, K07CA168886.

9504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

EXCAP exercise effects on cognitive impairment and inflammation: A URCC NCORP RCT in 479 cancer patients. *First Author: Karen Michelle Mustian, University of Rochester Medical Center, Rochester, NY*

Background: Cognitive impairment (CI) is one of the most troublesome side effects experienced by patients, arises due to chronic inflammation, and impairs quality of life (QOL). We conducted a nationwide, multi-site, phase III RCT examining the efficacy of exercise for improving CI and inflammation through the URCC NCORP Research Base. **Methods:** Non-metastatic cancer patients receiving chemotherapy were randomized into 2 arms: 1) chemotherapy and 2) chemotherapy plus a 6-week (wk) exercise intervention--Exercise for Cancer Patients (EXCAP): a home-based, personalized prescription of aerobic walking and anaerobic resistance band training. CI and inflammation were assessed via the FACT-Cog and standard serum Luminex assays, respectively, at pre- and post-intervention. **Results:** 479 patients beginning chemotherapy were accrued (94% female, 84% breast cancer, mean age = 54). ANCOVAs controlling for baseline CI and chemotherapy cycle (1 wk, 2 wk, 3 wk) revealed significant differences in CI total score, perceived CI, impact of CI on QOL, and perceived CI by others (all $p < 0.05$) with a trend for differences in perceived cognitive ability ($p < 0.10$) between groups at post-intervention. Follow-up analyses showed exercise participants receiving 2 wk cycles of chemotherapy demonstrated less CI overall and across all domains (all $p < 0.05$) except perceived cognitive ability ($p < 0.10$) than controls at post-intervention. T-tests revealed an exercise-induced anti-inflammatory response with down-regulation of pro-inflammatory cytokines (IFNg, IL-8, IL-1b) and up-regulation of anti-inflammatory cytokines (IL-6, IL-10, sTNFra) in exercisers (all $p < 0.05$). Conversely, t-tests revealed down-regulation of IL-10 and less up-regulation of sTNFra in controls (all $p < 0.05$). Canonical correlations revealed a trend where changes in inflammation predicted changes in CI in exercisers ($r = 0.33$; $p = .06$), but not controls. **Conclusions:** EXCAP exercise improves CI and inflammation in patients receiving chemotherapy, and exercise-induced anti-inflammatory responses may elicit improvements in CI. Clinicians should consider prescribing EXCAP to reduce CI and inflammation. NCI UGCA189961 & K07CA120025. Clinical trial information: NCT00924651.

9505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Randomized trial of exercise on quality of life and fatigue in women diagnosed with ovarian cancer: The Women's Activity and Lifestyle Study in Connecticut (WALC). *First Author: Yang Zhou, Yale Cancer Center, New Haven, CT*

Background: Ovarian cancer survivors experience a wide range of treatment side effects that can affect health-related quality of life (HRQOL). Physical activity has been shown to improve HRQOL for other cancer survivors; however, prior to our study, no large randomized exercise trial (RCT) has been conducted in ovarian cancer. We examined the effect of exercise vs. attention control on HRQOL and fatigue in ovarian cancer survivors. **Methods:** We randomized 144 physically inactive ovarian cancer survivors who had completed initial chemotherapy into a 6 month RCT of exercise vs. attention control. Women in the exercise arm received weekly phone calls from a certified exercise trainer and were counseled on increasing their physical activity to 150 min/wk of aerobic exercise. Women in the attention control arm also received weekly phone calls to discuss a relevant health topic. HRQOL and fatigue were measured via SF-36 and FACT-F questionnaires. Generalized linear models were used to compare baseline to 6-month changes in HRQOL and fatigue between the two arms. **Results:** At baseline, participants were, on average (mean + SD), 1.7 ± 1.0 years post-diagnosis, 54% stage III-IV, 57.3 ± 8.6 years of age, and exercised 31.0 ± 45.8 mins/wk. Baseline physical HRQOL (Physical component summary (PCS) score of the SF-36) (mean = 46.0 ± 9.0) and fatigue scores (mean = 36.3 ± 10.9) were similar for both arms.At 6 months, women in the exercise arm increased exercise by 132.8 ± 108.8 min/wk compared to 59.0 ± 90.4 min/wk in the attention control arm ($P < 0.001$). Women in the exercise arm improved physical HRQOL compared to a decreased physical HRQOL in women in the attention control arm (SF-36 PCS change score of 1.7 ± 1.1 vs. -1.9 ± 1.2, mean ± SE, $P = 0.02$). Borderline significant improvements in fatigue were observed for women randomized to exercise (FACT-F change score of 4.0 ± 1.1) vs. a 1.2 ± 1.2 increase for controls at six months, $P = 0.06$). **Conclusions:** Our results show that ovarian cancer survivors are interested in and able to exercise at recommended levels, with exercise improving physical HRQOL. Exercise programs for ovarian cancer survivors should be implemented in an effort to improve HRQOL. Clinical trial information: NCT02107066.

9506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Results of the exercise and nutrition to enhance recovery and good health for you (ENERGY) trial: A behavioral weight loss intervention in overweight or obese breast cancer survivors. *First Author: Cheryl L Rock, UC San Diego, La Jolla, CA*

Background: Obesity increases risk for all-cause and breast cancer mortality and co-morbidities in women who have been diagnosed and treated for breast cancer. The Exercise and Nutrition to Enhance Recovery and Good Health for You (ENERGY) Study is the largest weight loss intervention trial among breast cancer survivors to date. **Methods:** In this multi-center randomized trial, 692 overweight/obese women, who were on average 2 years post-primary treatment for early stage breast cancer, were randomized to a group-based cognitive-behavioral intervention with telephone counseling and tailored newsletters to support weight loss or a less intensive (control) intervention and followed for 2 years. The primary endpoint for this randomized controlled trial was weight loss measured at both 1- and 2-year follow-up. Secondary aims included the exploration of effect modifiers (such as time since diagnosis and type of tumor and therapy) on weight loss at 24 months. Weight and blood pressure were measured at 6, 12, 18, and 24 months. Longitudinal mixed models were used to analyze change over time. **Results:** At 12 months, mean weight loss was 6.0% of initial weight in the intervention group and 1.5% in the control group ($P < .0001$). At 24 months, mean weight loss in the intervention and control groups was 3.7% and 1.3%, respectively ($P < .0001$). Physical activity increased significantly in intervention vs. control women at 6 and 12 months ($P < .0001$). Blood pressure (diastolic and systolic) was lower in the intervention vs. control groups at follow-up clinic visits ($P < .05$). The weight loss intervention was more effective among women older than 55 years than among younger women. **Conclusions:** A behavioral weight loss intervention can lead to clinically meaningful weight loss in overweight/obese breast cancer survivors. These findings support the need to conduct additional studies to test methods to support sustained weight loss. They also underscore the need for larger, longer-term trials to test the effects of intentional weight loss on breast cancer recurrence and survival. Clinical trial information: NCT01112839.

9507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

The impact of physical activity on fatigue and quality of life in lung cancer patients: A randomised controlled trial (RCT). *First Author: Janette L. Vardy, Concord Cancer Centre, University of Sydney, Sydney, Australia*

Background: Physical activity (PA) has been shown to improve fatigue and quality of life (QOL) in a range of cancer populations. Little research has been done in the advanced lung cancer setting. This RCT evaluated a 2-month PA intervention in patients with unresectable lung cancer. **Methods:** Participants were stratified (disease stage, performance status [PS] 0-1 vs 2, center) and randomized (1:1) to usual care (UC) (general nutrition and PA education materials) or UC plus 2-month program of supervised weekly PA and behaviour change sessions and home-based PA. Assessments were completed at baseline, 2, 4 and 6 months. The primary endpoint was fatigue (FACT-F subscale) at 2-months. Secondary endpoints included: QOL, functional abilities, physical fitness, activity (accelerometers), mood, dyspnea, survival and blood results. Intention-to-treat analysis using linear mixed models was done. **Results:** 111 patients were randomized: male 55%, median age 62 (35-80); 95% NSCLC, 5% SCLC; 95% Stage IV. At baseline 77% were on active treatment. Baseline characteristics, including PA levels, comorbidities and Glasgow Prognostic Score (GPS) were well balanced between groups. Attrition was 22, 36 and 50% at 2, 4 and 6 months respectively; no difference between groups. Adherence to intervention sessions: behavioral 77%, PA 69%. There were no significant differences in fatigue, QOL, symptoms, mood, distress, sleep, dyspnea, activities of daily living, GPS between groups at 2, 4 or 6 months. Patients over report PA levels compared to accelerometer data. Using accelerometer data, PA increased only in the PA group from 0 – 2 months, but the difference in PA between groups was not significant. Median survival (months): PA 13.7 vs UC 12.6 (p= 0.76): 38 participants remain alive. **Conclusion:** Adherence to the 8-week intervention was good but did not increase PA levels compared to education materials alone. No difference was seen in fatigue, QOL, symptom control or functional status. Clinical trial information: ACTRN12609000971235.

9508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Impact of the LIVESTRONG at the YMCA Program on physical activity, fitness, and quality of life in cancer survivors. *First Author: Melinda L Irwin, Yale School of Public Health, New Haven, CT*

Background: Physical activity (PA) has been linke d to cancer risk and outcomes, yet many survivors are inactive. We evaluated the impact of the LIVESTRONG at the YMCA program, an exercise program available for cancer survivors at YMCA's across the USA, on PA, fitness, and quality of life (QOL). **Methods:** Participants were recruited through Yale Cancer Center/Smilow Cancer Hospital and Dana-Farber Cancer Institute. Key eligibility criteria included having a cancer diagnosis and being able to walk. Participants were randomized to immediate participation in a 12-week LIVESTRONG at the YMCA program at a participating YMCA in CT or MA, or to a wait-list control group. Study measures were collected at baseline and 12-weeks. Intervention effects were evaluated using chi-square tests and generalized linear models, with change at 12-weeks in PA and fitness (assessed through the 6-Minute Walk Test [6MWT]) as primary endpoints. **Results:** A total of 186 participants were randomized (95 to the LIVESTRONG Program and 91 to control). The majority of patients had stage I-II disease and 50% had breast cancer. A majority of participants were inactive at baseline, with only 34% reporting 150+ min/wk of PA. Participants randomized to the LIVESTRONG Program attended on average 83% of scheduled sessions over the 3-month program and experienced significant increases in physical activity (75% exercising at 150+ min/wk vs. 25% of controls, $p < .05$), and improvements in fitness and QOL compared to controls (Table). **Conclusions:** The LIVESTRONG program was effective in increasing PA, fitness and QOL in cancer survivors. Additional work is needed to evaluate sustainability of these effects, but this program could provide a platform to increase physical activity in thousands of cancer survivors across the USA. Clinical trial information: NCT02112149.

9509 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Association between renal function and chemotherapy-related toxicity in older adults with cancer. *First Author: Lindsay Leuthen Peterson, Med Univ of South Carolina, Charleston, SC*

Background: Older adults with cancer are at increased risk for chemotherapy-related toxicity (CRT). Tools are needed to better define their risk and aid in treatment planning. Renal function declines with age and can be calculated with various formulas, although the ideal formula for such calculations is unclear. We therefore evaluated the association between renal function and CRT in older adults and compared the effect of different renal function formulas and body weight measurements on this association. **Methods:** This is a secondary analysis of data from a prospective multicenter study of 500 patients age 65 and older who were starting a new chemotherapy regimen. Renal function was estimated with four formulas (modified Jelliffe [Jelliffe], Cockcroft-Gault [CG], Wright, and Modification of Diet in Renal Disease [MDRD]), using actual, ideal and adjusted body weights. The association between baseline renal function and grade 3-5 CRT was evaluated by unconditional logistic regression. **Results:** Mean age of the 492 evaluable patients was 73 (range 65-91); 40% were aged ≥ 75 years (18% age 80-91); 61% had stage IV disease; 56% were female. Mean estimated renal function ranged from 56 to 78 mL/min, depending on the formula. One or more grade 3-5 toxicities occurred in 53% of patients (26% hematologic; 43% non-hematologic). Decreased creatinine clearance [CrCl] calculated by CG (actual body weight) was associated with increased odds of CRT (OR 1.12, $P < 0.01$ 95% CI 1.04-1.20); for every 10 mL/min decrease in CrCl, the odds of CRT increased 12%. This association is independent of the type of chemotherapy received (renally cleared vs not). Neither primary dose reduction nor chemotherapy duration was associated with CRT. There were no statistically significant associations between decreased renal function with non-CG formulas (Jelliffe, Wright and MDRD) and odds for CRT. Serum creatinine alone was not associated with toxicity risk (OR 0.67, $P = 0.15$ 95% CI 0.37-1.14). **Conclusions:** Decreased CrCl (as measured by CG with actual body weight) is associated with increased odds of chemotherapy-related toxicity and should be considered when treating older adults with cancer. Serum creatinine alone is not adequate for risk assessment.

9510 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

Evaluation of a web-based cognitive rehabilitation programme (CRP) in cancer survivors reporting cognitive symptoms following chemotherapy. *First Author: Victoria J Bray, Liverpool Cancer Centre, Liverpool, Australia*

Background: Self-reported cognitive impairment is frequently seen in cancer survivors. We evaluated a CRP in cancer patients with cognitive symptoms. **Methods:** 243 adult cancer patients who had completed adjuvant chemotherapy within 6-60 months and reported changes in memory and/or concentration on EORTC-QLQ-CF, received a 30 minute phone consultation and were randomized to a 15-week, home-based CRP (Insight) or usual care (UC). Primary endpoint was self-reported cognitive function (FACT-COG Perceived Cognitive Impairment [PCI] subscale). Secondary endpoints included: neuropsychological (NP) testing (CogState), quality of life (QOL) and fatigue (FACT-F), anxiety/depression (GHQ), and stress (PSS). Primary analysis used linear mixed models comparing the difference in FACT-COG PCI between the 2 arms at each post baseline timepoint: post intervention (T2) and 6 months later (T3). **Results:** A total of 243 patients were randomized: median age 53 (range 23-74); 95% female; 89% breast cancer, 5% colorectal cancer. There were no significant differences between the groups at baseline. The CRP group had improvement in all FACT-COG domains including PCI at T2, which were sustained at T3. Individual NP test results were not significantly different at T2 or T3. Anxiety/depression was improved at T2 and T3, and stress at T3, in the CRP group. There were no differences between the groups in fatigue or QOL (global or in domains) at any timepoint. **Conclusions:** The web-based CRP Insight led to improvements in cognitive symptoms that were sustained at 6 months compared to phone consultation alone. Clinical trial information: ACTRN12609000683235.

9511 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM

A clinical score to predict early death at 100 days after a comprehensive geriatric assessment (CGA) in elderly cancer patients: A prospective study with 815 patients. *First Author: Rabia Boulahssass, UCOG PACA EST CHU de Nice, Nice, France*

Background: Trying to predict very early death after a CGA is very difficult in clinical practice. Last year, we presented predictors of early death (Boulahssass et al, 9511, *ASCO 2014*).The aim of this new study was the next step by developing a score to estimate the risk of death at 100 days in order to illuminate the clinical decision-making. **Methods:** This is a multicentric and prospective cohort study approved by an ethics committee. A standardized CGA has been done before the treatment decision at the baseline (MMSE, MNA, Grip strength, ADL, IADL, CIRSg, Charlson, Lee, PS, Gait speed, QLQc30, G8, Balducci score). During the follow up of 100 days, the events (death), the treatments made, and the targeted geriatric interventions were collected. A multivariate logistic regression permits the selection of risk factors. The calibration was assessed with the Hosmer-Lemeshow goodness of fit test. The internal validation of the model was performed by a bootstrap method with 1000 randomized samples. Score points were assigned to each risk factors by using the β coefficient. The accuracy of the score was assessed with the mean c-statistic (0.813). **Results:** 815 patients with a mean age of 82 years joined the study. The predictors were: metastatic cancer (OR 2.5 CI 1.6-3.6 $p < 0,0001$), gait speed < 0.8m/s (OR 1.7 CI 1.1-2.9 $p = 0,025$), MNA <17 (OR 8.8 CI 3.5-22.9 $p < 0.0001$), MNA ≤ 23.5 and ≥ 17 (OR 5.1 CI 2.1-12.2 $p < 0.0001$), PS > 2 (OR 1.9 CI 1.1-3.2 $p = 0.01$), cancers other than breast cancers (OR 2.1 CI 1.3-3.2 $P = 0.001$). We assigned in the score 5 points for MNA < 17, 3 points for MNA ≤ 23.5 and ≥ 17, 2 points for metastatic cancers, 1 point for: lower gait speed, PS > 2, and for cancers other than breast cancers. The risk of death at 100 days after a CGA was 5% for 0 to 5 points, 20% for 6 to 7 points,40% for 8 to 9 points and 60% for 10 points. **Conclusions:** This is the first score that estimates very early death in elderly cancer patients. This score could be useful in treatment decisions in clinical practice in order to choose the best treatment for the patient.

9512 Poster Discussion Session; Displayed in Poster Session (Board #171), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Pilot study of family caregiver burden in home hospice: Stress-induced immune changes. *First Author: Abdullah Ladha, Mayo Clinic Health System Eau Claire, Eau Claire, WI*

Background: In 2012, 1.5-1.6 million patients received hospice care in United States. The majority received care at home. Unfortunately caregiving has been reported as an independent risk factor for mortality. Caregivers of hospice patients comprise a special group, as most patients die within short time span and have diverse trajectories. Therefore, this group deserves study to confirm or negate immune dysregulation as seen in dementia caregivers. **Methods:** Family caregivers were enrolled after providing informed consent. Caregivers were included if they provided minimum of eight hours cares each day, for at least two weeks and had no active inflammation or infection. Participants filled a questionnaire and provided a blood sample. Samples from age and sex matched healthy control subjects were acquired from the Mayo Clinic Biobank. ELISA and flow cytometry were used to run lab tests. Paired t-tests were used to compare biomarker values in two groups. **Results:** Blood samples from 39 caregivers were compared with controls. The following markers were significantly higher in caregivers: IL-1 beta, IL-2, IL-12, CRP, IL-8, CXCL1, CXCL2 and CXCL3. Cell markers with higher values in caregivers were: CD4+, CD8+, CD56+16+, CD69 and CD62L. Regulatory markers like regulatory T cells and TIM-3 were also higher in caregivers. Cytokines and chemokines significantly lower in caregivers were: IL-4, CCL-7, CCL-22, CCL-4, Eotaxin (CCL-11, CCL-24, CCL-26), CX3CL1 and CXCL10. **Conclusions:** Hospice caregivers demonstrated an increased inflammatory state and enhanced cell mediated immune changes as compared to age-matched controls. These changes may reflect immune dysregulation and proliferation, either due to loss of regulatory markers like Eotaxins or inefficient regulatory machinery including TIM-3 and regulatory T-Cells, which is unable to suppress inflammation and potentially result in adverse caregiver health.

Biomarker	Paired Difference Median	P-value
CD16+56+	5.5 (-1.6 , 10.6)	0.003
CD3+CD4+	9.1 (-1.1 , 18.5)	0.001
CD3+CD8+	8.0 (-0.2 , 15.6)	0.003
CD4+TIM3+	3.1 (0.6 , 4.5)	< 0.001
Treg	6.3 (-1.7 , 15.3)	0.005

Quality of life and satisfaction with care in caregivers of patients with advanced cancer: Results from a trial of early palliative care. *First Author: Julie Clare McDonald, Department of Psychosocial Oncology and Palliative Care, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Early palliative care has been shown to improve the quality of life (QOL) and satisfaction with care of patients with advanced cancer, but little is known about its effects on family caregivers. Here we report secondary outcomes of caregiver QOL and satisfaction with care from a cluster-randomized controlled trial of early palliative care. **Methods:** 461 patients with advanced cancer were recruited from 24 medical oncology clinics at Princess Margaret Cancer Center between December 2006 and February 2011 to participate in a cluster-RCT of early palliative care versus standard care (Zimmermann, C et al. Early palliative care for patients with advanced cancer: a cluster-randomized controlled trial. Lancet 2014;383: 1721-30). The primary caregivers identified by these patients were approached for participation if they were ≥ 18 years of age and had sufficient English proficiency. Consenting caregivers (N = 182) completed validated measures at baseline and monthly for 4 months, assessing QOL (Caregiver QOL-Cancer [CQOLC] and Medical Outcomes Study Short Form [SF-36v2]), and satisfaction with care (FAMCARE). A random effect mixed-model was used to evaluate change of QOL and satisfaction with care over time; all analyses were by intention to treat. **Results:** 182 caregivers completed baseline measures (94 intervention, 88 control); 151 completed at least one follow-up assessment. Over the 4-month period of the study, there was no significant improvement in QOL scores in the intervention group compared to the control group for the CQOLC ($p = 0.53$), SF-36 physical component summary ($p = 0.27$), or SF-36 mental component summary ($p = 0.58$). Satisfaction with care improved significantly in the intervention compared to the control group ($p = 0.01$). **Conclusions:** In this study, early palliative care involvement increased caregivers' satisfaction with care but not their QOL. An intervention tailored specifically for caregivers may be required to have a substantial impact on caregiver QOL. Clinical trial information: NCT01248624.

Depression and anxiety among family caregivers of patients with advanced cancer. *First Author: Joel Nathan Fishbein, Massachusetts General Hospital, Boston, MA*

Background: Despite the important role family caregivers (CGs) play in the care of patients with cancer, little is known about their psychological distress. We sought to describe rates and correlates of depression and anxiety in CGs of patients with advanced cancer to determine those at greatest risk for psychological distress. **Methods:** As part of an ongoing trial of early palliative care, we are assessing baseline depression and anxiety in patients within 8 weeks of advanced lung or gastrointestinal cancer diagnosis and their CGs. We are administering the Hospital Anxiety and Depression Scale (HADS), subscale scores >7 denoting clinically significant depression or anxiety. We are assessing patient coping styles with the Brief COPE. We used multiple logistic regression with purposeful selection of covariates to identify correlates of CG depression and anxiety. **Results:** Of 240 CGs (mean age=57 years), 156 (65%) were spouses/partners, 167 (70%) were female, and 131 (55%) were working. 37 (15%) and 102 (43%) CGs reported significant depression and anxiety, respectively. CG age, gender and employment status, as well as patients' anxiety and lack of acceptance coping, were associated with higher rates of CG depression. CG age, gender, marital status and education level, as well as patients' anxiety and presence of brain metastases were associated with higher rates of CG anxiety. **Conclusions:** Younger, female CGs were at greatest risk of both depression and anxiety. Thus, this CG population should be monitored closely and referred for cancer center support services for distress management. We also found that patients' anxiety was associated with higher rates of both CG depression and anxiety, underscoring the importance of interventions that address both patient and CG psychological distress.

Intended and unintended consequences: Ethics, communication, and prognostic disclosure in pediatric oncology. *First Author: Jonathan Michael Marron, Dana-Farber/Boston Children's Cancer and Blood Disorder Center, Boston, MA*

Background: Most patients wish for all available information about their prognosis, but physicians can be hesitant to discuss prognostic information with patients, particularly those with poor prognoses. For some, concerns that this will cause anxiety, depression, or decreased hope outweigh the ethical obligation to provide such information. **Methods:** We surveyed 353 parents of children with newly diagnosed cancer at the Dana-Farber/Boston Children's Cancer and Blood Disorders Center and the Children's Hospital of Philadelphia. We used multivariable logistic regression to assess associations between parental report of elements of discussions of prognosis with the child's oncologist (quality of information, quality of communication, prognostic disclosure) and the intended/unintended outcomes of these discussions (trust, hope, peace of mind, depression, anxiety). Analyses were stratified by the child's prognosis: favorable (≥ 75% likelihood of cure) or less favorable (< 75% likelihood) as reported by the oncologist. **Results:** Among parents of children with less favorable prognoses (n = 140), those who reported receiving high quality information from the oncologist expressed greater peace of mind (odds ratio [OR] 4.44, 95% confidence interval [1.53, 12.90], $p < 0.01$), and those who reported their oncologist to have provided high quality communication endorsed greater trust in the oncologist (OR 3.25 [1.22, 8.70], $p = 0.02$) and feelings of hope (OR 2.96 [1.24, 7.03], $p = 0.01$). Parents who received more information about prognosis were not significantly more anxious ($p = 0.82$), depressed ($p = 0.55$) or less hopeful ($p = 0.86$) than those who received less prognostic information. Similar findings were seen in the more favorable prognosis subset and the overall cohort. **Conclusions:** We find no evidence that greater prognostic disclosure leads to the unintended consequences of increased anxiety, depression, or decreased hope, even in parents of children with less favorable prognoses. Rather, communication processes may increase the intended consequences of peace of mind, trust, and hope, supporting the discussion of prognosis with all parents, even those of children with a lower likelihood of cure.

A randomized, controlled trial of a cardiopulmonary resuscitation (CPR) video decision support tool for seriously ill hospitalized patients with advanced cancer. *First Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

Background: Discussing CPR preferences with patients with advanced cancer who are hospitalized is a critical component of end-of-life decision making. However, these discussions are challenging and often avoided by clinicians. We examined the impact of a CPR video decision tool on patients' choices and knowledge about CPR, and their comfort with watching the video. **Methods:** We conducted a multi-center randomized controlled trial of 116 patients with advanced cancer hospitalized at two academic oncology centers. We randomized patients to either a 3-minute video describing CPR (n = 52) or standard-oncology care (n = 64). The primary outcome was participants' preferences for CPR (immediately after viewing the video in the intervention arm). Secondary outcomes included patients' knowledge (using 5-item questionnaire with higher score reflects greater knowledge), and intervention participants' comfort with watching the video. **Results:** The mean age was 66 years (SD = 12); 50% were women, 84% were white, and 48% had lung or gastrointestinal cancer. Only 47% of study participants reported having a discussion about their CPR preferences at the time of admission to the hospital. At baseline, there were no differences in patients' preferences for not wanting CPR between the intervention and control arms (63% vs. 58%, P = 0.79). After the intervention, participants randomized to the video were more likely not to want CPR (81% vs. 58%, P = 0.03) and were more knowledgeable (mean knowledge score 4.3 vs. 3.2, P < 0.0001) versus control participants. In the intervention arm, 81% of participants found the video helpful, and 94% felt comfortable watching it and would recommend it to others. **Conclusions:** Seriously ill hospitalized patients with advanced cancer who watched a CPR video decision support tool were more likely not to want CPR and were better informed about their options. Participants reported feeling comfortable watching the video and would recommend it to others facing similar decisions. Video decision support tools can facilitate end-of-life decision-making for hospitalized patients with advanced cancer. Clinical trial information: NCT01527331.

Quality of life and mood in patients with advanced cancer: Associations with prognostic understanding and coping style. *First Author: Ryan David Nipp, Dana-Farber / Harvard Cancer Center, Boston, MA*

Background: Patients' prognostic understanding and coping styles influence their treatment decisions, but how these factors relate to their quality of life (QOL) and mood has not been well described. We sought to examine the associations of patients' prognostic understanding and coping style with their QOL and mood. **Methods:** As part of an ongoing trial of early palliative care, we are assessing baseline QOL (Functional Assessment of Cancer Therapy-General), mood (Hospital Anxiety and Depression Scale), coping (Brief Cope), and prognostic understanding in patients within 8 weeks of diagnosis of advanced lung or gastrointestinal (GI) cancer. To determine associations, we used linear and logistic regression, adjusting for patients' age, sex, cancer type, and marital status. **Results:** Of 300 participants (mean age=64.7 years; 138 (46%) female), 132 (44%) had GI cancer and 168 (56%) had lung cancer. Using cutoff score >7 for the HADS, 61 (20%) and 85 (28%) reported depression and anxiety. 138 (49%) reported their prognosis as terminal. A terminal perception of prognosis was associated with lower QOL and higher rates of anxiety. Emotional support, acceptance, and active coping styles were associated with better QOL and mood. Denial and self blame were associated with worse QOL and mood. **Conclusions:** These data demonstrate that acknowledging a terminal prognosis may be associated with greater physical and psychological distress, or conversely, patients with worse QOL and mood may better appreciate the gravity of their illness. Certain coping styles (self blame and denial) are associated with lower QOL and higher distress. Understanding the relationships among patients' prognostic awareness, coping styles, QOL and mood will allow us to develop more effective supportive care interventions.

Clinical performance of the DigniCap system, a scalp hypothermia system, in preventing chemotherapy-induced alopecia. *First Author: Hope S. Rugo, University of California, San Francisco, San Francisco, CA*

Background: Alopecia is an emotionally traumatic side effect for breast cancer (BC) patients (pts) undergoing adjuvant chemotherapy (CTX). The DigniCap System is the first scalp cooling system studied under a clinical trial approved by the Food and Drug Administration (FDA) to minimize alopecia. **Methods:** This prospective trial evaluated the clinical performance of the DigniCap System in women with early stage BC receiving adjuvant CTX. The primary endpoint was efficacy evaluated by pt self-assessment of 5 photographs of the head using the Dean scale to estimate hair loss one month after the end of chemotherapy. A score of 0-2 (≤ 50% hair loss) was defined as treatment success. Tolerability was defined as the percentage of patients who completed all planned CTX cycles using the DigniCap System and by the Patient Symptoms Survey. Eligibility included women with stage I/II BC scheduled to receive adjuvant CTX, excluding sequential anthracycline/taxane regimens. With 100 pts enrolled, there was 90% power to detect the difference between the null hypothesis treatment success proportion of less than 40% versus an alternative proportion of 56%. Pts who chose not to undergo scalp cooling were enrolled in a control group. **Results:** 101 pts used the DigniCap System and were evaluable for the primary endpoint. CTX regimens included docetaxel (D)/ cyclophosphamide (76%), D/carboplatin (12%) & weekly paclitaxel (12%); trastuzumab and pertuzumab were allowed. Treatment success was seen in 71 (70.3%; 95% CI, 60.4 - 79.0%; p < 0.001), compared to 0/16 in the control group. Minimal or no hair loss (Dean score 0-1) was seen in 39 pts (39%). Toxicity included grade 1/2 headache (4), pruritus (1), pain of skin (1) and head discomfort (1). Three pts discontinued cooling, primarily from feeling cold. **Conclusions:** Use of the DigniCap System prevented significant hair loss in 70.3% of pts with breast cancer receiving adjuvant CTX, compared to control where 94% had > 75% hair loss. Treatment was well tolerated and there has been no evidence of scalp metastases. Pts will be followed for long-term safety. The DigniCap System is highly effective in reducing chemotherapy-induced alopecia with a clinically meaningful benefit. Clinical trial information: NCT01831024.

Chronic health conditions (CHCs) following cisplatin-based chemotherapy (CHEM): A multi-institutional study of 680 testicular cancer survivors (TCS). *First Author: Mohammad Issam Abu Zaid, Indiana University School of Medicine, Indianapolis, IN*

Background: Platinating agents are among the most commonly used group of cytotoxic drugs worldwide. Few studies, however, have comprehensively examined the number and range of co-morbidities following CHEM in uniformly treated patients. Given the limited number of CHEM regimens used to cure TC and high long-term survival rates, TCS represent a unique population to provide new knowledge. We examined CHCs in an ongoing North American multi-center study of TCS given CHEM (NCI 1R01 CA157823-02). **Methods:** Eligible TCS were aged < 50 y at diagnosis and treated with only first line cisplatin CHEM after 1990. Questionnaires regarding co-morbidities and prescription drugs were completed. Evaluated CHCs included tinnitus, hearing loss, peripheral neuropathy (PN), balance/vertigo, renal disease, hypertension (HTN), Raynaud's syndrome, diabetes (DM), thyroid disease, hypogonadism, erectile dysfunction (ED), anxiety/depression, pain, and others. For PN, responses of "a little", "quite a bit", or "very much" regarding tingling, numbness or shooting/burning pain were scored as 'yes'. Yes/no variables assessed ototoxicity (i.e., tinnitus, "problems hearing words, sounds, or language in crowds", hearing aid use, and deafness). **Results:** We evaluated 680 consecutively enrolled TCS. Median age at diagnosis was 31 (range, 15-49 y); median time since CHEM completion was 52 mos. (range, 1-30 y). Only 15% of patients reported no CHCs, with 21%, 23%, 17%, and 24% reporting 1, 2, 3, or 4+ CHCs, respectively. 47% reported any ototoxicity including tinnitus in 36% of all TCS. Ten patients reported hearing aid use. 55% reported PN, while 29% had both PN and ototoxicity. Medication use for HTN, hypercholesterolemia, DM, ED, pain, or anxiety/depression was reported by 8%, 11%, 4%, 4%, 7%, and 13% of patients respectively. **Conclusions:** Several years after CHEM, nearly a quarter of TCS in this study reported 4 or more CHCs. We may have overestimated the number of CHCs, since PN included "a little" symptomatology, and ototoxicity was based on limited binary variables without finer gradation of symptoms. Future studies will continue to identify important CHCs following CHEM in TCS.

Comparison between clinician- and patient-reporting of baseline (BL) and post-BL symptomatic toxicities in cancer cooperative group clinical trials (NCCTG N0591 [Alliance]). *First Author: Thomas Michael Atkinson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Reporting of clinician-based toxicity assessment via the Common Terminology Criteria for Adverse Events (CTCAE) commonly does not distinguish between symptoms already present at BL versus those that develop during a trial. Therefore, current estimation of toxicities may include symptoms that predate trial entry. We hypothesize that patient (pts) provide more complete BL symptom reports than clinicians, and that these BL symptoms can be "subtracted" from those reported during a trial at the pt level to better understand which toxicities actually developed during the trial. **Methods:** Data were pooled from Alliance trials where at BL and throughout the trial, (1) clinician-reported symptomatic toxicities were documented with the CTCAE and (2) analogous pt self-reported symptoms were documented via a questionnaire. McNemar's test was used to compare between clinician- and pt-reporting of: 1) BL prevalence, 2) maximum post-BL, and 3) worsening (i.e., BL subtracted) scores. **Results:** Across 26 trials, 24 clinician- and analogous pt-reported symptoms were captured for 2608 pts (median age 60, 62% female, 93% Caucasian, 97% non-Hispanic). For 20/24 (83%) symptoms at BL, pts reported a significantly higher prevalence (grade or score $\geq$ 1) than did clinicians. Prevalence using maximum post-BL was significantly different between clinicians and pts for 21 (88%) symptoms with 16/21 (76%) having a higher prevalence by the pt report. When subtracting BL, a significant difference between clinicians and pts was observed in 16/24 (67%) symptoms, with a lesser number (9/16, 56%) having a higher incidence by pt report. **Conclusions:** Clinicians consistently under-reported prevalence of BL symptoms compared to pts. Change from pt-reported BL assessment appears to more closely match clinician-graded AEs. This method should be considered for future pt-based toxicity assessments in clinical trials as a more accurate appraisal of symptoms attributable to study treatments rather than to pre-existing etiologies.

Long-term safety of fertility preservation by ovarian stimulation and concurrent aromatase inhibitor treatment in women with breast cancer. *First Author: Kutluk Oktay, Institute for Fertility Preservation and New York Medical College, New York, NY*

Background: Cryopreservation of embryos and oocytes after ovarian stimulation (OS) is an established method of fertility preservation (FP). To minimize the elevation of serum estrogen levels, an aromatase inhibitor, letrozole, has been used concurrently with OS. However, long-term safety of this approach is unknown. The objective of this trial was to determine the long-term safety of controlled OS with letrozole supplementation (COSTLES) in women with breast cancer. The impact of BRCA mutations, estrogen-receptor (ER) and operative status on recurrence after COSTLES were also evaluated. **Methods:** A total of 337 women aged 24-45 with a diagnosis of stage $\leq$ 3 breast cancer were enrolled during FP consultations. Of those, 120 elected to undergo COSTLES for FP prior to chemotherapy; the remaining 217 served as controls. **Results:** The baseline characteristics were similar between FP and control groups except for the younger age ($P = 0.03$) and less frequent lymph node involvement ($P = 0.02$) in the former. The mean follow-up after diagnosis was 4.9 years (range 1-13) in the FP and 6.2 years (1-14) in the control group. In the FP group, the hazard ratio for recurrence was 0.77 (95% CI: 0.28, 2.13) and the survival was not compromised compared with controls ($P = 0.61$). Neither BRCA gene mutation status ($P = 0.18$), nor undergoing FP before breast surgery ($P = 0.56$) affected survival . Likewise, none of the tumor characteristics including the receptor status affected the survival following COSTLES. Thirty-three women attempted pregnancy with frozen embryos; 15 using a gestational carrier. Seventeen of those 33 had at least one child (FP rate: 51.5%; livebirth/embryo transfer rate: 45.0%). The livebirth rate was similar to an age-matched control group from a national IVF database. There were no recurrences among women who conceived. **Conclusions:** COSTLES is unlikely to cause substantially increased recurrence risk in breast cancer even in the presence of BRCA gene mutations, and it results in the preservation of fertility in a majority of women. Our data strongly support that FP via COSTLES should be made more widely available for young women with breast cancer even before undergoing breast surgery. Clinical trial information: NCT00504699.

The impact of adjuvant breast cancer (BC) chemotherapy on ovarian reserve and menses. *First Author: Shari Beth Goldfarb, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In prior studies, menses was used as a surrogate for fertility. But, anti-mullerian hormone (AMH) may be a better surrogate for ovarian reserve. The goal of this study is to delineate the extent of ovarian damage from specific treatments by using AMH level and menstrual calendars and to determine if chemo-induced amenorrhea and AMH levels correlate. Here we report results from the largest longitudinal study with a pretreatment evaluation to measure the impact of chemo on ovarian reserve in women with BC. **Methods:** A multi-institutional IRB-approved study was performed in 207 premenopausal women with stage 0-III BC. AMH levels were evaluated at baseline and 1 yr post adjuvant chemo. Menstrual calendars were completed monthly. After the exclusions (failure to f/u, serum sample inadequacy, presumed PCOS, Tam only treatment and consent withdrawal), 104 women ages 26-46 (median 38) were available for analysis at 1 yr post treatment. AMH levels were measured in frozen sera with an ultrasensitive ELISA assay and were log transformed due to non-normal distribution. Results were analyzed with Wilcoxon rank sum test and repeated measures ANOVA to adjust for age, tam use and stage. **Results:** In the104 evaluable women, 95 pts had HR+ and 21 had triple negative BC. 78 pts received anthracycline-based (ddAC-T/EC-T) chemo and 26 non-anthracycline-based chemo (TC/CMF/TH). In the 104 pts who received chemo,compared to baseline (median0.20ng/ml, 0.001-3.9 ng/ml), AMH levels declined significantly (median 0.12 ng/ml, 0.001-4.47 ng/ml; $p < 0.0001$) at 1 yr post chemo. The type of chemo, stage and adjuvant tam use post-chemo did not significantly impact the results. Despite a significant decline in ovarian reserve by AMH, 73% (74/102) of women who received chemo and completed menstrual calendars had return of menses by 1 yr post treatment. There was no difference in AMH levels between the women whose menses returned and those who remained amenorrheic. **Conclusions:** This longitudinal study shows that BC chemo is detrimental to ovarian reserve. The fact that the majority of pts resumed their menses despite a significant decline in their ovarian reserve by AMH indicates that resumption of menses is not a reliable measure of ovarian normalcy/fertility.

Treatment-related amenorrhea among young women one year following diagnosis of early-stage breast cancer. *First Author: Philip Daniel Poorvu, Dana-Farber Cancer Institute, Boston, MA*

Background: Treatment-related amenorrhea (TRA) is common among premenopausal women treated for early-stage breast cancer and is associated with important reproductive, sexual, and metabolic side effects. Few prior studies have prospectively evaluated factors associated with TRA among young women receiving modern treatment regimens. **Methods:** As part of a prospective cohort study of women age $\leq$ 40 diagnosed with breast cancer, participants were surveyed at enrollment and one year following diagnosis (dx) regarding sociodemographics, medical history, menstrual status, and treatment. TRA at one year was defined as the absence of menses within the six months prior. Participants with stage IV disease or on ovarian suppression were excluded from this analysis. Univariable and multivariable modeling were used to determine demographic and treatment factors associated with TRA. **Results:** Among the 504 women included, 38% were age $\leq$ 35. Overall, 31% experienced TRA (Table 1). Univariable analysis revealed that TRA was associated with age, tamoxifen (TAM) use, and chemotherapy, but not race, BMI, smoking, co-morbidity (Charlson), or weight change since dx. Multivariable modeling revealed that relative to women age 36-40, women age 21-30 experienced significantly less TRA (OR 0.18, $p < 0.0001$). This difference was not statistically significant between women age 31-35 and women age 36-40 (OR 0.67, $p = 0.09$). TAM use (OR 1.97, $p = 0.0002$) and chemotherapy (OR 3.89, $p < 0.0001$) were also independent predictors of TRA. Effects of different modern regimens on TRA in this young cohort will be presented. **Conclusions:** This analysis represents the largest evaluation to date of very young women and confirms that older age and treatment with TAM and chemotherapy are predictors of TRA. Further research to identify differences in short and long-term risk of TRA with modern treatment, including specific chemotherapy regimens, is warranted.

	No TRA	TRA
Age (years)		
21-30 n (%)	59 (88)	8 (11)
31-35 n (%)	88 (70)	38 (30)
36-40 n (%)	200 (64)	111 (36)
Tamoxifen		
No n (%)	144 (77)	44 (23)
Yes n (%)	203 (64)	113 (36)
Chemotherapy		
No n (%)	136 (76)	26 (24)
Yes n (%)	211 (62)	131 (38)
Total n (%)	347 (69)	157 (31)

9524 Poster Session (Board #183), Sat, 1:15 PM-4:45 PM

Differences in attitudes and beliefs toward end-of-life treatments between hematologic (Heme) and solid tumor (ST) oncology specialists. *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with Heme malignancies often receive intensive care at the end-of-life. To better understand the end of life decision making process among oncology specialists, we compared the cancer treatment recommendations, and attitudes and beliefs toward palliative care between Heme and ST specialists. **Methods:** We randomly surveyed 120 Heme and 120 ST oncology specialists at our institution. Respondents completed a survey examining two aspects of end of life care: palliative systemic therapy using standardized case vignettes and palliative care proficiency. We compared the two groups using the Wilcoxon rank sum tests and Chi-square tests, and conducted multivariate logistic regression to identify predictors of treatment preferences. **Results:** 182/240 (76%) clinicians responded. Compared to ST specialists, Heme specialists were significantly more likely to favor prescribing systemic therapy with moderate toxicity and no survival benefit for patients with ECOG performance status (PS) 4 and an expected survival of 1 month (P<0.0001, Table). This decision was highly polarized. Heme specialists felt less comfortable discussing death and dying (72% vs. 88%, P=0.007) and hospice referrals (81% vs. 93%, P=0.02), and were more likely to feel a sense of failure with disease progression (46% vs. 31%, P=0.04). They were also less likely to refer patients with newly diagnosed cancer (21% vs. 43%, P=0.002) to palliative care. On multivariate analysis, Heme specialty (odds ratio 2.77, P=0.002) and comfort level with prescribing treatment to ECOG 4 patients (odds ratio 3.79, P=0.02) were associated with the decision to treat in the last month of life. **Conclusions:** We found significant differences in the attitudes and beliefs toward end-of-life care between Heme and ST specialists, and identified opportunities to standardize end-of-life care.

Treatment recommendations for case vignettes.

Patients	Heme*	ST*	P
Expected survival 1 month, PS 4	4 (2, 6)	1 (1, 3)	<0.0001
Expected survival 3 months, PS 3	4 (3, 6)	3 (2, 5)	0.0002
Expected survival 6 months, PS 2	5 (4, 6)	5 (4, 6)	0.18

*Median (IQR), where 1=strongly against treatment, 7=strongly favors treatment.

Quality of life, depression, and end-of-life outcomes in hospitalized patients with advanced cancer. *First Author: Kathryn Elizabeth Hudson, Duke University Medical Center, Durham, NC*

Background: Hospitalized cancer patients are more likely to have advanced disease and are at risk for poor outcomes, yet little is known about their quality of life (QOL) and rates of depression. We aimed to assess QOL, mood, and end-of-life outcomes in this population. **Methods:** From 2008-10 we enrolled hospitalized patients at Duke University with acute leukemia or stage III/IV solid tumor or lymphoma and whose physician stated that they "would not be surprised if they died in less than one year." 150 patients completed surveys, including demographics and validated instruments measuring QOL (FACT-G) and mood (brief CES-D). We retrospectively reviewed charts to assess end-of-life outcomes including presence of advance directives, use of palliative care, and rate of death in the hospital. Descriptive statistics, linear regression and sensitivity analyses were performed. **Results:** Mean FACT-G score was 66.9 (SD 11), 14 points worse than published cancer patient norms. QOL was significantly worse in all FACT-G subscales except for social wellbeing (24.2 vs. 22.1, $p < 0.001$). 30% of patients ($n = 45$) had a brief CES-D score of > 4, suggestive of depression. Higher scores were associated with lower performance status ($p < .05$). Patients with lower education levels had lower QOL (FACT-G 59.9 vs 68.4, $p < .05$). There were no significant differences between tumor type and performance status, QOL, or depression scores; and there was no association between time until death and QOL or depression. Markers of end-of-life care quality were poor. By this analysis, 86% (127) of patients had died. While physicians correctly estimated death within one year in 69% of cases, only 25% of patients used hospice, and only 2.7% received an in-hospital palliative care consult. 60.5% had a do-not resuscitate order, and 43% of patients died in the hospital. **Conclusions:** Hospitalized patients with advanced cancer have poor quality of life compared to established cancer patient norms and a high rate of depression. While physicians expected these patients to die within a year, end-of-life quality outcomes were poor. Hospitalized patients with advanced cancer may benefit from interventions aimed at improving mood, quality of life, and end-of-life care.

9526 Poster Session (Board #185), Sat, 1:15 PM-4:45 PM

Trends and regional variation of end-of-life cancer care in the Medicare program. *First Author: Shi-Yi Wang, Yale School of Public Health, New Haven, CT*

Background: Although there has been substantial concern of aggressiveness of cancer care near the end-of-life (EOL) in the United States, little is known about recent trends in EOL cancer care and associated regional variation in the Medicare program. **Methods:** Using the Surveillance, Epidemiology, and End Results–Medicare data, we identified 82,245 beneficiaries who had breast, prostate, lung, colorectal, pancreas, liver, kidney, melanoma, or hematological cancer diagnosed in 2004-2009 and died within 2 years as a result of cancer by December 2009. Aggressiveness of EOL care was measured by 1) chemotherapy received within 14 days of death; 2) $>$ 1 emergency department (ED) visit within 30 days of death; 3) $>$ 1 hospitalization within 30 days of death; 4) $\geq$ 1 intensive care unit (ICU) admission within 30 days of death; 5) hospital death; and 6) hospice enrollment $\leq$ 3 days before death. Using hierarchical generalized linear models, we assessed regional variation of EOL care adjusting for patient demographics, tumor characteristics and hospital referral region (HRR)-level market factors. **Results:** Proportions of receipt of at least one potentially aggressive EOL care increased from 48.3% in 2005 to 48.7% in 2009 ($P<$ .001). From 2005 to 2009, increasing proportions of patients had repeated hospitalization (14.0% vs. 14.8%; $P=$ .0113) or ICU admission (15.2% vs. 19.5%; $P<$ .001), whereas in-hospital death declined (24.1% vs. 22.0%; $P<$ .001). Proportions of receiving chemotherapy (4.4% vs. 4.0%), repeated ED visits (34.0% vs. 32.9%) and very short hospice enrollment (7.2% vs. 8.3%) did not change significantly over time. The proportions of decedents who experienced aggressive EOL care varied substantially across HRRs. After adjusting for patient and HRR-level factors, the difference in the proportion of patients receiving potentially aggressive EOL care between HRRs in the lowest and the highest quintiles was 16.9 percentage point (57.2% vs. 40.3%). **Conclusions:** Despite growing focus on providing appropriate EOL care, nearly 50% of cancer decedents in the Medicare Program received aggressive EOL care with no evidence of demonstrable improvement in reducing aggressive EOL cancer care.

9527 Poster Session (Board #186), Sat, 1:15 PM-4:45 PM

Burden of inpatient care and treatments in terminally-ill cancer patients: results from a population-based, retrospective study from administrative data in France. *First Author: Lucas Morin, Aging Research Center, Karolinska Institutet, Stockholm, Sweden*

Background: Over the past decades, dramatic changes in the treatment of advanced cancer have raised concerns regarding the quality of end-of-life care in terminally-ill patients. However, Earle et al.'s indicators of aggressive care near the end of life have never been used in population-based studies in Europe. We aimed to examine the use of inpatient care and treatments in the last months of life of cancer patients who died in hospitals in France. **Methods:** A nationwide, retrospective cohort study was conducted using administrative data. We included all cancer patients (irrespective of the tumour type) aged 20 years or older, who died in acute and rehabilitation hospital facilities between January 2010 and December 2013 in France. **Results:** Among 516,244 cancer decedents, 39% were female and 48% were 75 years or older. Main primary malignancies were gastrointestinal (30%), respiratory (20%) and haematological (10%). 17% of the patients spent their last 30 days of life in a hospital facility, 10% died in ICU, 10% in a palliative care unit, 2% within the emergency department and 64% in acute care wards. 33.8% received chemotherapy during their last 3 months of life, 28.0% over the last 2 months, 17.9% over the last month and 10.9% over the last 2 weeks before death. Between 2010 and 2013, while adjusting for sex, age and cancer type, we measured a significant increase in the likelihood of receiving chemotherapy over the last month of life (OR = 1.05, 95%CI = 1.03-1.07). Younger decedent, patients with hematological malignancies and patients with metastatic cancer were the most likely to be prescribed such treatments over the last 90 and 30 days before death ($p < 0.001$). Over the course of the last month before death, 3.3% of the decedents had more than one emergency department visit, 22.4% were admitted to an Intensive Care Unit and 21% received blood transfusion. **Conclusions:** This population-based study provides unprecedented insight into the burden of care and treatment in the last months of life of cancer patients in France. We believe these results can provide useful support for discussions regarding cancer care management near the end of life.

9528 Poster Session (Board #187), Sat, 1:15 PM-4:45 PM

Exploring the preferences for place of death among cancer patients and their caregivers. *First Author: Marieberta Vidal, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Understanding the preferred place of death (POD) for advanced cancer patients (pts) is very important when they are approaching the end of life. Meeting the preferences of pts is considered an important palliative care outcome. Prior studies reported that more than 80% of pts with terminally ill cancer prefer to die at home. In many countries such as the UK, Italy, Greece, South Korea and Japan home deaths have been falling, but in some states of the US/Canada there are indications of a reversal of trends. Dying at home may be more difficult for pts in severe physical and psychosocial distress, or when there are social or financial difficulties. The purpose of this study was to determine POD preference among palliative care pts in the outpatient center (OC) and the palliative care unit (PCU). **Methods:** A sectional anonymous questionnaire was administered to advanced cancer pts and caregivers (PCU pts and OC) between August 2012 and September 2014. PCU pts responded when there was no delirium and the primary caregiver responded when the patient (pt) was unable to respond. In the case of outpatients dyads were assessed. **Results:** Overall 141/216 (65%) preferred home death. PCU pts preferred home death less than outpatients (table). Patient and caregiver agreement regarding preferred place of death was 86% ($p < 0.001$). The preferred POD was the same as one month ago for 82/99 (83%) PCU pts and 111/116 (96%) outpatients, with significant difference between groups ($p = 0.002$). **Conclusions:** Although home is the preferred POD in advanced cancer pts, a substantial minority prefer hospital death or no difference. Pts admitted to the PCU have a higher preference for hospital death in comparison to the outpatients, likely reflecting more severe distress because they already tried home care. Pts and caregivers agree on POD in most cases. Personalized assessment of POD preference for both patient and caregiver is needed.

Preferred POD per location.

	Total		PCU*		OC**		
Preference	N=216	%	N=100	%	N= 116	%	P
Home	141	65	58	58	83	72	0.02775
Hospital	40	19	27	27	13	11	
No preference	28	13	12	12	16	14	
Others	7	3	3	3	4	3	

P-values are from Fisher's exact test comparing preference of POD between PCU & OC; *PCU = Pts (N = 24) Caregivers (N = 76); ** OC = Patients (N = 116)

9529 Poster Session (Board #188), Sat, 1:15 PM-4:45 PM

Practice pattern treating older women with early stage breast cancer at Johns Hopkins. *First Author: YaoYao Guan Pollock, Johns Hopkins School of Medicine, Baltimore, MD*

Background: The National Comprehensive Cancer Network (NCCN) Guidelines incorporated omission of radiation therapy (RT) after breast-conservation surgery in woman age ≥ 70 years with stage I, estrogen receptor positive breast cancer who plan to receive endocrine therapy (ET). This guideline change was based on The Cancer and Leukemia Group B C9343 trial. A follow up study demonstrated that there is a wide variation in implementing this change across 13 different NCCN institutions. We evaluated the practice pattern at Johns Hopkins, and sought to construct an internal guideline. **Methods:** We identified women treated at our institution from 2009-2013 age ≥ 70 years at the time of diagnosis and met the C9343 inclusion criteria. RT omission rate was calculated for each year. We explored associations between RT omission and year, age, tumor size, race, nodal status and tumor type with t tests and Fisher's exact tests. **Results:** A total of 544 women age ≥ 70 years sought treatment at our institution, and 98 (18%) were candidates for RT omission based on the NCCN guidelines. Mean age was 76.2 years (Range 70-95). Overall RT omission rate was 36/98 (37%), but varied greatly by year (Range 8-56%, $p = 0.03$). This variation in omission rate was still present after excluding women who did not tolerate ET (Range 9-67%, $p = 0.02$). Older age was associated with higher RT omission rate (mean age 78.7 vs. 74.8, $p = 0.002$). Women who did not undergo nodal evaluation had higher RT omission rate (68%) than women who had nodal evaluation (29%) even when the evaluated node(s) were negative ($p = 0.003$). The RT omission rate did not vary by race (Caucasians: 24/69, 35%; Non-Caucasians: 11/27, 40%; $p = 0.64$), tumor type (ductal: 27/72, 38%; non-ductal: 9/26, 35%; $p > 0.99$), or tumor size (< 1cm: 17/37, 46%; 1-1.4cm: 10/34,29%; 1.5-2cm: 8/25, 32%; $p = 0.35$). **Conclusions:** The implementation of the NCCN guideline, which was based on category I evidence, is not consistent at our institution. Our results suggest that other tools should be used to apply the guidelines more consistently. To achieve this, we have developed a Quality Improvement Protocol that incorporates life expectancy estimate and a brief geriatric assessment to the treatment of all woman age ≥ 70 years at our breast centers.

9530 Poster Session (Board #189), Sat, 1:15 PM-4:45 PM

Frailty and outcomes in older adults undergoing pancreaticoduodenectomy. *First Author: Tri Minh Le, University of Virginia, Charlottesville, VA*

Background: Pancreaticoduodenectomy (PD) is the only potentially curative treatment for pancreatic cancer. Studies show older adults are at higher risk for poor outcomes. The Balducci Frailty Criteria have been shown to risk-stratify older adults with cancer in non-surgical settings. The purpose of this retrospective, single-institution review is to examine the correlation between preop frailty criteria and postop outcomes in older cancer pts undergoing PD. **Methods:** Pts ≥ 65y who underwent PD for cancer of the pancreas, ampulla, duodenum, or bile ducts between January 2002 and October 2013 were eligible for the study. A pt was considered "frail" if at least 1 were true: 1. Age ≥ 85y; 2. ≥ 3 significant comorbidities; 3. Dependent for ≥ 1 ADL; 4. Geriatric syndrome present. Primary study endpoints were 30 and 90 day mortality, with secondary endpoints of postop surgical site infections, pneumonia, UTI, sepsis, ventilator dependence > 48 hours, unplanned re-intubation, 30-day readmission, discharge to home versus assisted living, and median hospital stay. P-values were calculated using a chi-square test. Length of hospital stay was analyzed using the Wilcoxon rank-sum test. **Results:** 201 consecutive pts were included, and 88 were considered "frail". A significant increase was noted in the "frail" group for rates of postop UTI (OR = 2.86, 95% CI = 1.10-7.44, $p = 0.025$), ventilator dependence > 48 hours (OR = 4.8, 95% CI = 0.97-23.69, $p = 0.035$), unplanned re-intubation (OR = 3.67, 95% CI = 0.94-14.25, $p = 0.047$), assisted living discharge (OR = 2.34, 95% CI = 1.18-4.67, $p = 0.014$) and median hospital stay (7.0 vs 9.0 days, $p = 0.008$). There were no differences between groups for 30 day mortality (OR = 1.31, 95% CI = 0.32-5.41, $p = 0.42$), 90 day mortality (OR = 2.29, 95% CI = 0.80-6.59, $p = 0.26$) or other study endpoints. Increasing age was independently associated with increases in UTI ($p = 0.017$) and assisted living discharge ($p = 0.037$), but not other endpoints. **Conclusions:** There was no difference in early mortality between groups, but "frail" pts had higher rates of several adverse outcomes. These findings suggest that preoperative evaluation of frailty may help identify older adults at risk of complications following PD for malignant disease.

9531 Poster Session (Board #190), Sat, 1:15 PM-4:45 PM

Evaluation of two different doses of weekly nab-paclitaxel (NP) in older breast cancer (BC) patients (pts). *First Author: Laura Biganzoli, Sandro Pitigliani Medical Onc Unit, Prato, Italy*

Background: NP compares favorably with conventional taxanes in terms of safety, efficacy and convenience of administration. These features make NP an interesting agent for evaluation in elderly pts. **Methods:** Pts aged ≥ 65 years (y) with HER2-negative (or HER2-positive but with contraindication to anti-HER2 therapy) advanced BC are randomized to receive as first-line chemotherapy NP at either 100 (Arm A) or 125 mg/m2 (Arm B), days 1, 8, 15 q 28 until an event (defined as progressive disease, functional decline or death) unacceptable toxicity (tox) or maximum benefit according to the Investigator. Due to the absence of prospective data on weekly NP in older BC pts, compliance and adverse events (AE) data in this population, even if preliminary, are clinically relevant and are reported in the present analysis. **Results:** 81 pts have been randomized so far. Evaluable for the present analysis are 44 pts who have received ≥ 1 cycle of NP and have a documented interruption of study treatment. Pts's median age is 75y (65-84) in Arm A and 74y (65 -82) in Arm B. ECOG Performance status is 0 in both arms. No impairments in Instrumental Activities of Daily Living is reported in 16 pts in both arms. Median number of affected domains at Cumulative Illness Rating Scale-Geriatric is 2 with range 0-3 in Arm B and 0-4 in Arm B. Treatment's compliance and safety data are reported in the Table. **Conclusions:** Both doses of weekly NB can be safely administered to older BC pts. Fatigue and neurotoxicity are the most frequently reported AE in both arms. Only 1 patient experienced G4 non hematological tox. Clinical trial information: 2012-002707-18.

9532 Poster Session (Board #191), Sat, 1:15 PM-4:45 PM

Novel method to stratify elderly patients with prostate cancer. *First Author: Ruben Carmona, UC San Diego, La Jolla, CA*

Background: Standard prognostic methods do not optimally stratify patients according to the risk of cancer death relative to competing events. In contrast, competing event (CE) models (ref: PMID 24969798) have the potential to better inform practitioners regarding when to treat elderly patients with localized prostate cancer (PC). **Methods:** Using SEER-Medicare data, we identified 68,259 patients with localized PC treated with either radical prostatectomy (RP) or radiotherapy (RT) alone, splitting each group into 60% training / 40% test sets. Using patients' demographic, tumor, and clinical characteristics, we trained risk scores based on CE models vs. standard Cox models for cancer-specific and all-cause mortality (ACM). In test sets, we compared how well models stratified subpopulations according to the ratio (ω) of the hazard for prostate cancer mortality (PCM) to the hazard for ACM. We tested the predictive ability for the cause-specific events, using the area under the curve (AUC). **Results:** For patients treated with RP, the CE risk score was associated with increased risk of PCM (HR 1.93, $P < .001$). Similar findings were observed for the cancer-specific and ACM risk scores. However, unlike standard models, increasing CE risk score was not associated with second cancer mortality (HR 0.90, $P = .19$) or non-cancer mortality (HR 0.96, $P = .56$). For patients treated with RT, the CE risk score was associated with increased risk of PCM (HR 2.13, $P < .001$), but was not associated with second cancer mortality (HR 0.90, $P = .19$), and was associated with decreased risk of non-cancer mortality (HR 0.84, $P < .001$). For patients treated with RP, the AIC was superior for CE models, relative to the cancer-specific and ACM models (AIC, 50.1 vs. 54.6 vs. 53.8, respectively). Similar findings were observed for RT patients (AIC, 43.4 vs. 45.2 vs. 54.4). The CE models also created greater separation in AUC for cancer mortality vs. non-cancer mortality, compared to the cancer-specific and ACM models ($P < .001$). **Conclusions:** Compared to standard methods, CE models more efficiently stratify elderly PC patients according to likelihood to benefit from therapy.

9533 Poster Session (Board #192), Sat, 1:15 PM-4:45 PM

Health related quality of life (HRQOL) in older adults with cancer: The potential of a single-item screen. *First Author: Mackenzi Pergolotti, UNC Chapel Hill, Chapel Hill, NC*

Background: Older adults with cancer often value maintaining or recovering their HRQOL over overall survival. This study aims to (1) describe patient reported global measures of physical and mental HRQOL in a large sample of older adults with cancer and (2) to evaluate associations with demographics and other measures of health status to better screen and identify populations at-risk of poor HRQOL. **Methods:** The Health Registry/Cancer Survivorship Cohort is an institutional database at University of North Carolina designed to aid in cancer survivorship research (http://unchealthregistry.org). Outcome measures of patient-reported HRQOL included FACT-G (range 0-108), PROMIS global Physical and Mental health (mean = 50, SD = 10 in general US population). Higher scores indicate better HRQOL. Other measures of health status: the single item Patient-Generated Subjective Global Assessment Performance Assessment (PG-SGA-PA), number of co-morbidities, FACT Cognitive Function, PROMIS Sexual Function, and global physical activity. **Results:** Of the 807 older adults (65y+) with cancer, mean age was 72y, 60% female, and 88% Caucasian. The cohort was comprised of 25% genitourinary, 24% breast, 22% gastrointestinal, and 15% gynecologic malignancies. Only 37% reported a high level of physical activity, 24% had ≥ 4 co-morbid conditions, and 25% reported that they lived alone. Mean scores for HRQOL were: FACT-G (85, range: 25-108); PROMIS-Physical (48, range: 16-67) and PROMIS-Mental (51, range: 21-67). In the multivariable models including demographics and health status measures, ≥ 4 comorbidities, poor PG-SGA-PA and lower levels of cognition were associated with poor HRQOL for each outcome measure (all $p < .0001$). **Conclusions:** Older adults with cancer with a high comorbidity burden, reduced cognition, and poorer scores on the PG-SGA-PA have poorer HRQOL. This study found that the single item PG-SGA-PA was independently associated with complex measures of global physical and mental health and with further validation could be a useful tool for oncologists to quickly identify older adults with poor HRQOL.

9534 Poster Session (Board #193), Sat, 1:15 PM-4:45 PM

Novel method to stratify elderly patients with head and neck cancer. *First Author: Ruben Carmona, UC San Diego, La Jolla, CA*

Background: Head and neck cancer (HNC) patients are at high risk of death due to competing events. We hypothesized that a competing event (CE) modeling approach (ref: PMID 24969798), which is used to optimize patients according to the risk of cancer death relative to competing events, would improve stratification of the elderly HNC population compared to standard methods. **Methods:** Using SEER-Medicare data, we identified 9,677 patients with advanced stage HNC, who were treated with radiotherapy (RT) ± surgery and chemotherapy, split into 60% training and 40% test sets. Using patients' demographic and clinical characteristics, we trained a risk score based on the CE approach versus standard Cox proportional hazards models for HNC-specific mortality and all-cause mortality (ACM). Using the test set, we compared how well the CE risk score stratified patients according to the ratio (ω) of the cause-specific hazard for HNC mortality to the hazard for ACM, using the Akaike Information Criterion (AIC). We tested the predictive ability for the cause-specific events, using the area under the curve (AUC). **Results:** Using the CE model, an increasing risk score was associated with increased HNC mortality (HR 2.16, $P < .001$) and second cancer mortality (HR 1.39, $P < .001$), but *decreased* non-cancer mortality (HR 0.62, $P < .001$). Both increasing HNC-specific and ACM risk scores were associated with increased risk of HNC mortality, second cancer mortality and non-cancer mortality. The AIC was superior for the CE model (50.1), relative to the HNC-specific (54.6) and ACM (53.8) models. The difference between the predictive ability for cause-specific events was also greater for the CE model (AUC: HNC mortality = 0.64 vs. non-cancer mortality = 0.47, $P < .001$) than the HNC-specific Cox model (AUC: HNC mortality = 0.72 vs. non-cancer mortality = 0.64, $P < .001$) and the ACM Cox model (AUC: HNC mortality = 0.72 vs. non-cancer mortality = 0.69, $P > .05$) **Conclusions:** Compared to standard methods, CE models more efficiently stratify elderly HNC patients according to likelihood to benefit from therapy. This method could improve the efficiency of clinical trials and help personalize therapeutic decisions.

9535 Poster Session (Board #194), Sat, 1:15 PM-4:45 PM

Construction of a frailty index for older adults with cancer using a geriatric assessment. *First Author: Emily Jean Guerard, UNC Chapel Hill, Chapel Hill, NC*

Background: Frailty is a state of increased vulnerability to adverse outcomes and can be defined by counting the number of health deficits an individual acquires. This study constructs a frailty index from a geriatric assessment (GA), defines the prevalence of frailty in older adults (65+) with cancer, and evaluates associations of frailty with sociodemographic and GA variables. **Methods:** The Carolina Senior Registry (CSR) is an institutional database (NCT01137825) that contains GA data on older adults with cancer. From the CSR, a 32-item frailty index (range 0-1) was developed by deficit counting as previously reported [Searle *et al.* BMC Geriatrics 2008] and categorized as robust (0-0.2), pre-frail (0.2-0.35), and frail (> 0.35) based on prior studies. Fisher's exact tests and linear regression were used to evaluate associations. **Results:** Of the 1179 total patients, the median age was 72, 87.7% Caucasian, 69.6% female, 90.7% had at least a high school education, 58.7% married, and 44.3% had a breast cancer diagnosis. Overall 59% were robust, 25.3% were pre-frail, and 15.7% were frail. Frailty and pre-frailty were more prevalent among lung cancer patients (54.6%) compared to patients with hematologic malignancies (46.5%) and breast cancer (34.1%). In a multivariable model, increasing age, African American race, lower education, increasing number of daily medications, and decreasing Karnofsky Performance Status were significantly associated with increased frailty (all $p < 0.001$). Gender, marital status, and cancer type were not associated with frailty in this model. Frailty status was also associated with measures of physical function such as falls and a Timed Up and Go of greater than 14 seconds ($p < 0.001$). **Conclusions:** We created a 32-item frailty index using GA data from a cohort of older adults with cancer. Frailty was prevalent and significantly associated with sociodemographic variables. Additional work will be focused on validating our frailty index by using outcomes data. Because frail older adults with cancer are at an increased risk for adverse outcomes, a frailty index constructed from a cancer-specific GA may provide a straightforward way to identify frail patients who should be targeted for further intervention.

9536 Poster Session (Board #195), Sat, 1:15 PM-4:45 PM

Feasibility of administering a geriatric assessment to older adults with cancer using web-based and touchscreen platforms. *First Author: Jerome G. Kim, City of Hope, Duarte, CA*

Background: A geriatric assessment (GA) can help identify factors that increase the risk for chemotherapy-related toxicity in older patients with cancer. A GA has been developed which is primarily self-completed by patients using a paper and pencil questionnaire. With the shift to electronic medical records and the prospects of Big Data, a transition to an electronic GA is imperative to allow convenient deployment of this tool. The goal of this study is to 1) evaluate the feasibility of capturing patient reported GA data using 2 separate computer-based applications: web-based (REDCap [RC]) and a touchscreen (Support Screen [SS]), and 2) compare the computer responses to those obtained via paper-pencil. **Methods:** Patients (pts) aged > 65 yrs with cancer were eligible. Pts were randomized to 1 of 4 arms (RC /Paper; RC / RC; SS/Paper; SS/SS). The feasibility of each computer methodology was determined by the % of pts who could complete the GA independently, time to complete the GA (first time), and pt satisfaction with the survey platform. Correlations between the paper version and electronic version responses were evaluated. **Results:** 100 pts were accrued: median age 72 yrs (65-92 yrs), 51% female, and 63% stage IV disease. Primary cancers included lung (22%), breast (21%), GU (20%), GI (17%), and leukemia (9%). Pts' self-reported computer skills were None + Beginner (N+B, 42%) or Intermediate + Advanced (57%). The mean (SD) time to completion using RC, SS, and Paper were 23 (8), 17 (7), and 16 (5) mins. Pts with limited computer skills (N+B) were able to complete the electronic assessment independently: RC (75%), SS (100%), and preferred the computer version over the paper survey (RC 67%, SS 76%). The correlations between the paper version and the electronic versions (SS, RC) were 0.91, 0.96 for Instrumental Activities of Daily Living and 0.82, 0.96 for Medical Outcomes Survey-Physical Health scales, respectively. **Conclusions:** The majority of patients in this cohort could complete an electronic GA using either a web-based or touchscreen platform independently. A higher proportion of patients preferred the touchscreen methodology. The electronic versions have high reproducibility compared to the paper GA.

9537 Poster Session (Board #196), Sat, 1:15 PM-4:45 PM

Is standard dose appropriate in elderly non-small cell lung carcinoma (NSCLC) patients treated with erlotinib? *First Author: Frederic Bigot, Medical Oncology, Paris Descartes University, Cochin - Port Royal Hospital, AP-HP, Paris, France*

Background: Given the median age of 70 years in patients (pts) presenting NSCLC, the impact of age on outcomes including efficacy and toxicity of erlotinib remains unclear. In the BR21 study, analysis of subgroup based on age have reported similar survival benefits of erlotinib compared with placebo; however, elderly pts (³ 70 years) had significantly more toxicity, and were more likely to discontinue treatment (*Paul Wheatley-Price et al.*, J Clin Oncol 2008*).* Thus we hypothesized that elderly were more exposed than younger pts. **Methods:** All consecutive pts with advanced or metastatic NSCLC treated with erlotinib between 2010 and 2014 were eligible in this prospective cohort. Erlotinib concentrations in plasma were determined using high-performance liquid chromatography at Day 15 after treatment initiation. We compared dose-normalized concentrations between pts < or ³ 75 years old using the Mann-Whitney U test and the occurrence of acute grade ³ 2 adverse events (AE) or treatment modifications by Fisher's test. AE reports were graded using the National Cancer Institute Common Terminology Criteria V4. Lean body mass was estimated using Janmahasatian's equation. **Results:** Out of 55 pts, erlotinib plasma concentration was analyzed in 45 pts. Median age was 65.6 (range 25-83), and 14 pts were over 75 years old. Among these 45 pts, 58% were female, 93% had an adenocarcinoma subtype; 44% were never smoker. Eighty-six percent of the pts had a performans status at baseline ≤ 2. Elderly pts had significantly lower estimated lean body mass (36.6 kg vs 47.7 kg; p = 0.00038). Within 2 weeks, grade ³ 2 AE occurred in 20% of pts, and 28 % in elderly. In the subgroup of pts over 75 years old, there was a trend for higher dose-normalized concentration at day 15 (1923.3 mg/L vs 1380.9 mg/L; p = 0.07), and the difference was significant in pts older than 80 (7 pts; 2484.6 mg/L vs 1377.4 mg/L; p = 0.0074). Four pts > 75 years old had dose reduction or discontinuation versus 0 in younger pts (p = 0.014, CI95% [1.2532; infinite]). **Conclusions:** Elderly patients are susceptible to be overexposed to erlotinib at 150mg/day, resulting in increased acute toxicity and treatment discontinuation.

Functional decline during first-line chemotherapy in elderly patients can be predicted by abnormal G8 score and performance status. *First Author: Camille Chakiba, Department of Medical Oncology, Institut Bergonié, Comprehensive Cancer Centre, Bordeaux, France*

Background: Predicting major adverse events such as functional decline during chemotherapy is an important issue in geriatric oncology. Recent studies have shown that different parts of comprehensive geriatric assessment (CGA) (Geriatric Depression Scale and Instrumental Activities of Daily Living) were predictive of functional decline. However CGA is time-consuming and has to be performed by trained geriatricians who are not in sufficient number to face the increasing demand of elderly cancer patients. Thus screening tools, such as G8-score validated on 1435 patients, have been developed to identify patients who may benefit from CGA. In addition to its value as a screening tool, the value of the G8 as a predictive tool of survival has been suggested and we here investigate whether it can be used to predict functional decline during chemotherapy. **Methods:** We tested on a cohort of 364 patients over 70 year-old treated with first-line chemotherapy the value of clinical (G8, age, sex, performance status –PS-, disease localization, extension) and biological factors (platelets, creatinine clearance, albumin, CRP, neutrophils) in predicting early functional decline, defined as a decrease of 0.5 points on the Activities of Daily Living (ADL) scale between the beginning of chemotherapy and the second cycle. We performed a multivariate analysis using logistic regression model. **Results:** Of the 364 patients, 312 were assessable for functional status and 68 experienced functional decline. On univariate analysis, PS 2 to 4, low platelets, metastatic disease and abnormal G8 (≤ 14) score were associated with functional decline. On multivariate analysis, abnormal G8 score (OR, 3.56; 95% CI 1.22; 10.34; p = 0.02) and PS 2 to 4 (OR, 2.0; 95% CI 1.1; 3.6; p = 0.04) were significantly associated with increased likelihood of early functional decline. **Conclusions:** G8 has been developed as a screening tool to predict abnormal geriatric assessment. We have shown here that it could also be used together with performance status to select elderly patients more likely to develop functional decline during chemotherapy. These data reinforce the routine use of G8 in all elderly patients treated for cancer.

9539 Poster Session (Board #198), Sat, 1:15 PM-4:45 PM

Association of baseline pro-inflammatory (IL-6, CRP) and coagulation (D-dimer) markers with relative dose intensity (RDI) in women with breast cancer (BC) undergoing (neo) adjuvant chemotherapy (chemo). *First Author: Yuan Yuan, City of Hope, Duarte, CA*

Background: Chemo decreases the risk of relapse and mortality from BC. Chemo efficacy depends on RDI, and patients (pts) who receive <85% RDI have poorer overall survival. Pro-inflammatory and coagulation factors such as IL-6, CRP and D-dimer serve as biomarkers for aging. The utility of these markers as biologic correlates of the ability to deliver chemo (i.e. RDI) in pts with BC is unknown. This study was performed to determine if prechemo IL-6, CRP and D-dimer correlate with RDI in women with stage I-III BC requiring chemo. **Methods:** This is a prospective longitudinal study that enrolled 153 women with BC who had pre-chemo peripheral blood assayed for IL-6, CRP, and D-dimer. (Neo)Adjuvant chemo regimens were prescribed at the physician's discretion. Univariate analyses evaluated the association of these 3 markers with <85% RDI and clinical factors (patient age, physician rated Karnofsky performance status (KPS) and number of co-morbidities). Multivariate analyses were performed to evaluate the association of each biomarker and clinical factor with RDI. **Results:** 153 pts (mean age of 56 y, range 30-81 y) with stage I-III BC (Stages I [23%], II [54%], III [24%]) were enrolled. Chemo regimens include: doxorubicin+cyclophosphamide /paclitaxel (AC-T: 44%), docetaxel+cyclophosphamide (TC: 35%), docetaxel/carboplatin/trastuzumab (TCH: 7%) and other regimen (14%). RDI was less than 85% for 26% of pts. There were associations between RDI <85% and higher D-dimer (p<0.01) and IL-6 (p=0.02) levels pre-chemo (Table 1). There was no association between RDI <85% and CRP or above clinical factors. **Conclusions:** Higher pre-chemo levels of IL-6 and D-dimer correlate with reduced RDI (<85%). Future studies are underway to validate these findings. Table 1. Association of pre-chemo biomarkers, clinical factors and RDI <85%. Clinical trial information: NCT01030250.

Biomarkers/ Clinical factors	OR (95%CI)	p value
D-dimer	2.47 (1.35-4.73)	0.01
CRP	1.00 (1.00-1.00)	0.82
IL6	1.10 (1.02-1.21)	0.02
Age	1.01 (0.95-1.06)	0.49
KPS	1.01 (0.98-1.04)	0.32
No. Comorbidities	0.97 (0.66-1.40)	0.33

9540 Poster Session (Board #199), Sat, 1:15 PM-4:45 PM

Combination of eribulin (E) and capecitabine (C) in elderly metastatic breast cancer (MBC): Update of a new option suitable in older elderly. *First Author: Ignazio Ugo Carreca, University of Palermo, Palermo, Italy*

Background: E mesylate, a nontaxane microtubule dynamics inhibitor is widely prescribed for MBC pts pretreated with at least 1-2 lines of chemotherapy, including anthracyclines and taxanes (A&T). Elderly Patients (EP) develop rapid and sometimes fatal toxicity during standard treatments because of their pharmacokinetic features. We designed a new combination schedule (E+C) to evaluate its suitability for elderly MBC patients. **Methods:** Treatment plan: E 0.96 mg/sqm IV on d1 every 21d - C 900 mg/sqm bid d1-14 every 28d (Dose-adjustement if necessary was according to Kintzel-Dorr's formula for EP), schedule would be continued until progression or intolerable toxicity. Eligibility criteria: histologically confirmed diagnosis of MBC, written informed consent, at least 1 measurable lesion, at least 1 site of visceral mts (not brain mts), age $>$ 70 years, previous treatment with A&T, Comprehensive Geriatric Assessment evaluation (CGA) permissive for chemotherapy, adequate renal, bone marrow and liver function. Charlson's Score Comorbidity Scale was also considered. Evaluations tools: Clinical Benefit (CB) as Stable Disease + Objective Response Rates according to WHO criteria, toxicity profile using NCI-CTC v2.0 and Quality of Life (QoL) score through EORTC QLQ-C30 questionnaires. **Results:** From 2013 jan to 2014 dec 39 metastatic EP, mean age 80.5 (range 71 - 90) were treated and 37 are still under maintenance therapy (2 pts discontinued treatment for personal reasons). A total of 599 cycles were delivered to the 37 pts without G4 toxicity. No delay in therapy delivery was needed. QoL score shows no worsening with improvement in about 55% (72-78 y/o group) after treatment in comparison with baseline. Total CB was 80%. **Conclusions:** A further period of monitoring allowed to confirm our previous report in this setting with this combination schedule. It appears more fit with comorbidity or frailty than other standard chemotherapy regimens for MBC. In this updated analysis this schedule has showed non-inferiority vs standard treatments and more suitability for older EP. This study will be extended to confirm these outcomes in order to validate a schedule devoted to EP.

9541 Poster Session (Board #200), Sat, 1:15 PM-4:45 PM

Safety of biosimilar filgrastim in elderly patients undergoing neutropenia-inducing chemotherapy: a subanalysis of the NEXT study. *First Author: Didier Kamioner, Hopital Prive de l'Ouest Parisien, Trappes, France*

Background: Febrile neutropenia (FN) is a serious and frequent complication of cytotoxic chemotherapy (CT), especially in elderly patients (pts). Biosimilar filgrastim (Nivestim, Hospira Inc.) is a granulocyte-colony stimulating factor (G-CSF) licensed for the treatment of neutropenia and FN induced by myelosuppressive CT. This subanalysis of the NEXT (Nivestim safety profile in patiEnts treated with cytotoXic in real-life clinical pracTice) study explored tolerability and efficacy of biosimilar G-CSF in elderly pts. **Methods:** NEXT was a prospective, non-interventional, longitudinal, multicentre study conducted in France to evaluate the safety of biosimilar filgrastim. Recorded data included pt demographic and clinical characteristics, biosimilar filgrastim treatment-related data on efficacy and safety, such as adverse events (AEs) and FN. Pts were monitored for 1–6 CT cycles with three visits at inclusion, during treatment, and following CT. Here we present a subanalysis of pts aged $\geq$ 70 years. **Results:** Overall, 2114 pts were enrolled in the study; this subanalysis includes 708 pts aged $\geq$ 70 years (55.9% male; mean age $\pm$ standard deviation (SD) 76.3$\pm$4.7 years; performance status rated 3 or 4:10.5%; 68.2% solid tumours; 31.8% haematological malignancies). The majority (98.3%) of pts received prophylactic biosimilar filgrastim (primary prophylaxis: 91.7%; secondary prophylaxis: 8.3%).For pts receiving prophylactic biosimilar filgrastim, the median time to treatment initiation was 2 days after the last CT dose; mean treatment duration $\pm$ SD was 6.1$\pm$4.3 days. In this subanalysis, 18.9% of pts had $\geq$ 1 AE with 11.4% of pts reporting muscle and/or bone disorders. During the study, 4.5% and 3.0% of pts had FN and infection respectively (vs 4.9% and 3.1% in the overall population). FN and/or infection led to hospitalisation of 3.5% of pts (mean duration $\pm$ SD: 11.6$\pm$15.6 days), a CT dose reduction in 3.6% of pts and a delay in administration of CT in 7.0% of pts. **Conclusions:** Biosimilar filgrastim was effective and well tolerated in in the treatment and prevention of FN in the elderly and is an alternative therapeutic option for pts with CT-induced neutropenia. Clinical trial information: NCT01574235.

9542 Poster Session (Board #201), Sat, 1:15 PM-4:45 PM

Association of geriatric assessment factors with falls in older adults initiating chemotherapy. *First Author: Tanya Marya Wildes, Washington Univ School of Medicine, St. Louis, MO*

Background: In older adults with cancer, falls are common and associated with injury, functional decline, and poorer quality of life and survival. Prior oncology studies have been inconsistent in identifying factors associated with or predictive of fall risk. Identifying individuals with cancer at greater risk for falls is essential to allow targeted intervention to prevent falls. **Methods:** In a previously reported prospective study (Hurria et al, JCO 2011), 500 older adults with cancer underwent geriatric assessment (GA) prior to initiation of a new course of chemotherapy. In this analysis, we examined cross-sectional demographic, cancer and GA factors associated with falls in the 6 months before GA using logistic regression with bidirectional stepwise selection ($p<0.15$ for factor retention). **Results:** We analyzed 401 evaluable patients. The median age was 73 (range 65-91); 58% were female; 87% were white race, and just over half (59%) had stage IV disease. The most common cancers included lung (28%), gastrointestinal (27%) and gynecologic (19%). The median MD-rated Karnofsky performance status was 90 (range 50-100). About 18% (73 patients) reported one or more falls in the previous 6 months; of these, 62%, 15%, and 23% reported 1, 2, and 3+ falls respectively. On multivariate analysis, antidepressant use, benzodiazepine use and dependence in instrumental activities of daily living (IADLs) were associated with increased odds of falls (Table). The area under the curve of our model is 0.71, with positive and negative predictive values of 0.5 and 0.84, respectively. **Conclusions:** In older adults with cancer, falls are associated with antidepressant use, benzodiazepine use and dependence in IADLs. Prospective study of incident falls will be required to confirm that the presence of these factors at baseline increases the risk of subsequent falls.

Predictor	Adjusted Odds Ratio	95% Confidence Intervals	p
Antidepressant use	2.96	(1.40, 6.16)	0.004
Hospital Anxiety and Depression Scale Anxiety score ≥8	1.72	(0.81, 3.52)	0.15
Benzodiazepine use	2.17	(1.00, 4.65)	0.05
Proton Pump Inhibitor use	1.73	(0.98, 3.04)	0.06
Age ≥75	1.70	(0.98, 2.97)	0.06
IADL dependence	1.77	(1.01, 3.11)	0.05
Timed Up & Go ≥13.5sec	1.66	(0.90, 3.01)	0.10

9543 Poster Session (Board #202), Sat, 1:15 PM-4:45 PM

Feasibility of a home-based walking program in female breast cancer patients age 60+ during chemotherapy. *First Author: Kirsten A Nyrop, UNC Chapel Hill, Chapel Hill, NC*

Background: National guidelines recommend 150 minutes a week of moderate-intensity physical activity for adults with a cancer diagnosis. Our study investigated the feasibility of a self-directed walking in women age 60 or older undergoing cytotoxic chemotherapy treatment for breast cancer. *Feasibility* was defined as at least 50% of study participants reporting an average of 150 minutes or more of walking/week for exercise or pleasure during the first 6 weeks of chemotherapy. **Methods**: *Eligibility*: Female, age 60+; Stage I-III breast cancer; scheduled for chemotherapy; physician permission to engage in physical activity; English speaking. *Intervention*: Evidence-based physical activity program for adults with arthritis – "Walk With Ease". *Measures*: Patients self-reported the average number of days and number of minutes per day of walking for exercise or pleasure during chemotherapy. Study participants also maintained a daily walking diary throughout the first 6 weeks of chemotherapy. *Data analysis*: Descriptive statistics. **Results**: Study sample (N = 22): mean age 68 (60-79), 95% Caucasian, 41% high school degree or less, mean Body Mass Index/BMI 31 (20-50), 50% two or more comorbidities. At baseline (pre-chemotherapy), 29% of participants reported walking at least 150 minutes/week. During chemotherapy, the proportion walking $>$ 150 minutes/week: 41% Week 1, 54% Week 2, 32% Week 3, 45% Week 4, 50% Week 5, 45% Week 6. During chemotherapy, the proportion walking $>$ 100 minutes/week: 68% Week 1, 73% Week 2, 77% Week 3, 64% Week 4, 68% Week 5, 65% Week 6. **Conclusions:** A home-based, self-directed walking program can encourage older female breast cancer to engage in regular exercise during chemotherapy at a level that is higher than pre-chemotherapy. Achievement of the goal of 150 minutes per week is challenging, and more feasible at a level of 100 minutes per week. This pragmatic physical activity intervention is now being tested in a 4-year efficacy trial with a large sample of female breast cancer patients age 65 or older during chemotherapy treatment, to evaluate the impact of exercise on $p16^{INK4a}$ (biomarker of aging), fatigue and other patient-reported outcomes. Clinical trial information: NCT01789983.

9544 Poster Session (Board #203), Sat, 1:15 PM-4:45 PM

Do quality of life, physical function, or the Wheatley Index at diagnosis predict 1-year survival with intensive chemotherapy in older and younger acute myeloid leukemia patients? *First Author: Narhari Timilshina, University of Toronto, Brampton, ON, Canada*

Background: Treatment decision-making is complicated in older adults with acute myeloid leukemia (AML) because of poor prognosis and significant treatment toxicities. Improved prognostication at the time of diagnosis, such as with the Wheatley Index, may aid clinical decision-making. However, the Wheatley Index has not been validated outside clinical trials. Additionally, quality of life (QOL) or objective physical performance measures (PPM) may predict outcomes such as survival in oncology. We investigated the predictive value of baseline QOL, physical function, and the Wheatley Index at diagnosis on 1-year survival during IC in younger ($<$ 60 years) and older (60+ years) AML patients. **Methods:** AML patients undergoing intensive chemotherapy (IC) at the Princess Margaret Cancer Centre were enrolled in a prospective study. At the baseline assessment (pre-IC), patients completed the EORTC QLQ-30 questionnaire in addition to 3 PPMs (grip strength, 2-minute walk test, and timed chair stands). The prognostic risk category (good, standard and poor) was categorized according to the index defined by Wheatley et al. for older adults and modified for younger adults. Predictive value for 1-year survival was analyzed with multivariable Cox proportional hazards regression. **Results:** 140 younger and 97 older patients were recruited. Overall 1-year mortality was 22.1% in younger and 37.1 % in older patients. One-year mortality was significantly higher among the poor Wheatley risk category than the other 2 risk categories in both younger and older groups (40.0% and 63.3%, $P < 0.05$, respectively). Global health and PPMs were not predictive of 1-year survival. Poor Wheatley risk category was the most significant predictor in both univariate and multivariate survival models ($p < 0.001$) in both older and younger groups. **Conclusions:** Although QOL and PPMs at diagnosis were not good predictors of 1-year survival among younger and older AML patients, the Wheatley index may help inform clinicians and patients about up-front therapy in AML.

9545 Poster Session (Board #204), Sat, 1:15 PM-4:45 PM

Differences between patient and caregiver assessments and their association with caregiver burden in caregivers of older adults with cancer. *First Author: Tina Hsu, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: Caregivers are a valuable support for patients and an important source of information about patient health, particularly in older adults who are more likely to be frail or have cognitive impairment. We sought to determine whether a) differences exist between patient and caregiver assessments and b) these differences were associated with increased caregiver burden. **Methods:** 100 cancer patients, age $\geq$ 65, and their caregivers independently assessed patient function, comorbidities, nutrition, psychological status, social activity and social support. Caregiver Strain Index (CSI) was used to assess caregiver burden. Patient-caregiver assessments were compared using the Wilcoxon signed rank test. The relationship between caregiver burden and variables in which patient-caregiver assessment differed was determined using a linear regression model and adjustment for confounders was done. **Results:** Median patient age was 70, 70% had advanced disease, 62% were on chemotherapy. Patients reported a median of 2 comorbid conditions, no falls within 6 months, and 39% reported $>$ 5% weight loss. Patients reported good function (median KPS 90 and Medical Outcomes Study (MOS)-physical function 67), independence with most instrumental activities of daily living (IADL) (median OARS-IADL 13), having good social support (median MOS-social support survey 92), and good mental health (median Mental Health Index 85). 75% of caregivers experienced some caregiver burden (mean CSI 3.1 ± 3.2; 15% had high burden). Caregivers were more likely than patients themselves to rate patients as having poorer function [needing more help with IADLs ($p = 0.008$), lower KPS ($p = 0.02$), and lower MOS-physical function ($p < 0.0001$)], poorer mental health ($p = 0.0002$), but more social supports ($p = 0.03$). Only a difference in patient-caregiver assessment of a patient's need for help with IADLs was associated with increased caregiver burden ($p = 0.002$). **Conclusions:** Patients and caregivers differ in their assessment of patient function, mental health, and social support. However, only differences in patient-caregiver reported need for help with IADLs were associated with increased caregiver burden.

9546 Poster Session (Board #205), Sat, 1:15 PM-4:45 PM

Advanced cancer patients' reported priorities regarding wishes at the end of life: A randomized controlled study. *First Author: Marvin Omar Delgado-Guay, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Conversations about wishes around the end-of-life(EOL) are challenging and difficult for all clinicians. There is limited literature about the type and stability of patient's reported EOL priorities. We compared a set of 36 cards ("Go-wish-Game":GWG) v. a paper list to assist patients in establishing priorities. **Methods:** Randomized controlled study. Patients were randomized to GWG or to a list of 36 Wishes/Statements(LOS) and were asked to categorize them as very, somewhat, or not important; Group A received LOS followed by LOS 4-24 hours later; group B: GWG-GWG; group C: GWG-LOS, and group D: LOS-GWG. The State-Trait Anxiety inventory for Adults (STAI) was done after the first set of questionnaires. **Results:** 100 patients. Median age (IQR range): 56(27-83)years. 60% female. 68% White, 17% Hispanic, and 9% African-American. Age, education and cancer diagnosis weren't significant different among groups. All patients were able to complete GWG. 43/50(88%) agreed GWG had clear instructions and easy to understand (92%). 31/50(63%) patients exposed to both tools, preferred GWG. 31/50(63%) expressed having conversations about priorities near EOL was beneficial to them. STAI median (IQR) score after GWG was 48(39-59) v. 47(27-63) for LOS, $p = 0.2952$. 39/50(80%) expressed that GWG did not increased their anxiety. The 10 most common "Very important" wishes expressed by patients the first and second time they received the test(%; Spearman, p-value) were: to be at peace with God(74% v. 71%; $r = 0.73$, $p < 0.0001$), to pray(62% v. 61%, $r = 0.53$, $p < 0.0001$), to have my family with me(57% v. 61%; $r = 0.23$, $p = 0.02$), to be free from pain(54% v. 60%, $r = 0.31$, $p = 0.001$), not being a burden to my family(48% v. 49%, $r = 0.23$, $p = 0.02$), to trust my doctor(44% v. 45%; $r = 0.49$, $p < 0.0001$), to keep my sense of humor(41% v. 45%; $r = 0.53$, $p < 0.0001$), to say goodbye to important people in my life(41% v. 37%; $r = 0.46$, $p < 0.0001$); to have my family prepared for my death(40% v. 49%; $r = 0.48$, $p < 0.0001$), and to be able to help others(36% v. 31%; $r = 0.73$, $p < 0.0001$). **Conclusions:** End-of-life wishes were similar and persistent using both GWG and LOS. All patients were able to complete and most preferred GWG. Completing both GWG and LOS did not increase anxiety.

9547 Poster Session (Board #206), Sat, 1:15 PM-4:45 PM

Evaluation of the MPM2 score versus clinical predictions of mortality in a tertiary cancer center. *First Author: Alison Wiesenthal, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prognostication is an essential yet challenging clinical skill for oncologists, even as patients approach death. Goals-of-care discussions may be improved by giving patients and families objective reference for likelihood of mortality, but tools are needed to assist clinicians in identifying which patients are at the highest risk of dying in hospital. The aim of this study was to evaluate the transferability of the ICU-derived Mortality Probability Models Version 2 (MPM2) score to the general wards at a comprehensive cancer center, and to compare it to clinical predictions of dying in hospital (CPDH). **Methods:** Prospective case series of inpatients receiving palliative medicine consultations over a 3 month period. Prior to calculating MPM2 score, the CPDH was estimated in categories: unlikely ($<$10%), less likely (25%), possible (50%), probable (75%), consistent with ($>$90%). Overall survival was determined 6 months after end of enrollment. Calibration of MPM2 in these patients was evaluated by logistic regression. For survival analysis, MPM2 scores were grouped as $<$10%, 10-50%, $>$50%. **Results:** Of 79 patients consecutively evaluated, 18 (22%) died in hospital. Another 41 (52%) died after discharge. MPM2 score and CPDH were each significantly predictive of dying in hospital ($p<0.001$). Agreement between CPDH categories and corresponding MPM2 categories was fair (weighted kappa 0.37), CPDH being more pessimistic overall and avoiding use of the middle category (see Table). Overall survival was significantly different between the three MPM2 groups (median 131.5, 36 and 6 days respectively; log rank test df 2, $\chi 2=42.6$, $p<0.001$). **Conclusions:** The MPM2 score shows promise as a clinical tool for determining in-hospital mortality outside of the ICU. It was most helpful for identifying and correctly classifying patients with intermediate likelihoods of surviving. Larger studies in this and other settings are needed.

CPDH category	n	Died in hospital n (%)	Categorized MPM2 score	n	Died in hospital n (%)
Unlikely	36	3 (8)	0-10%	49	6 (12)
Less likely	20	1 (5)	10.1-25%	13	2 (15)
Possible	0	--	25.1-74.9%	11	5 (45)
Probable	15	7 (47)	75-90%	3	3 (100)
Consistent with	8	7 (88)	>90%	3	2 (67)

9548 Poster Session (Board #207), Sat, 1:15 PM-4:45 PM

Distress in older adult cancer patients approaching end of life. *First Author: Elizabeth Ann Kvale, Birmingham VA Medical Center, Birmingham, AL*

Background: Lay health navigators are able to address various issues that cause distress in older cancer survivors by administering and responding to distress thermometers (DT). **Methods:** Lay navigators in the UAB Patient Care Connect Program assist cancer patients ≥ 65 years old with traditional Medicare insurance at 12 cancer centers in Alabama, Mississippi, Georgia, Florida, and Tennessee. Navigators documented distress levels, causes of distress, and requests for intervention.. Distress screening data from the final DT administered prior to death were used to describe care gaps for older adults with advanced cancer. **Results:** DTs were collected on a representative sample of 1060 patients who were evenly divided with respect to gender and 18% minority. Median number of days from date of last DT to date of death was 42(1-544). Distress score ≥ 4 were observed in 43% of patients;10% reported scores ≥ 8. Forty four percent of patients attributed distress to physical symptoms such as pain and fatigue. Twenty two percent indicated mobility issues contributed while 15% indicated informational needs related to their illness or treatment. Patients were more likely to ask for help from navigators with informational issues related to their illness (63%) or hospice (75%) than mobility (35%) or physical symptoms (33%). **Conclusions:** Through distress screening lay navigators are able to help older adults with advanced cancer with informational or logistical needs and advocate for proactive assistance with issues related to symptom burden. The project described was supported by Grant Number 1C1CMS331023 from the Department of Health and Human Services, Centers for Medicare & Medicaid Services. The contents of this abstract are solely the responsibility of the authors and do not necessarily represent the official views of the U.S. Department of Health and Human Services or any of its agencies.

9549 Poster Session (Board #208), Sat, 1:15 PM-4:45 PM

"Months, Not Years": Impact of Clinical Discussions of Advanced Cancer Life-Expectancy on Patient Illness Understanding. *First Author: Andrew S. Epstein, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients' understanding of their illness often guides best practice, and this is no less true at the end of life. Data showing the influence of patients' acknowledgment of prognostic discussions on the accuracy of patients' illness understanding could inform the debate regarding how to engage in these difficult discussions. **Methods:** To evaluate the effects of recent and past oncologist-patient discussions about prognosis/life-expectancy (P/LE) on changes in advanced cancer patents' illness understanding (acknowledgement of their illness as 1. terminal; 2. incurable; 3. advance staged; and 4. associated with an estimated life-expectancy in months, not years), 208 patients (with advanced lung or upper gastrointestinal cancers that progressed on 1 chemotherapy regimen, or advanced colorectal cancers that progressed on 2) from Coping with Cancer II, a prospective observational cohort study, were interviewed before and after a visit with their oncologists who discussed scan results regarding potential additional progression. **Results:** Median time between pre- and post-scan interviews was 38 days. Controlling for potential confounds (i.e., patients' race) and adjusting for patients' pre-scan illness understanding, patients who acknowledged ever having discussions of P/LE with their oncologists were more likely to recognize that their disease was incurable (Adjusted Odds Ratio [AOR] = 2.97, p = 0.009) than those who did not. Compared to patients who denied ever having a discussion of P/LE, those who reported having both recent and past discussions of P/LE were more likely to recognize that their disease was at an advanced stage (AOR = 4.88, p = 0.012), and those who reported having only recent discussions, or both recent and past discussions, of P/LE were more likely to estimate their life-expectancy in terms of months as opposed to years (AOR = 10.1, p = 0.050, and AOR = 17.5, p = 0.006, respectively). **Conclusions:** Advanced cancer patients who acknowledge having discussions of P/LE with their oncologists have a better understanding of the terminal nature of their illnesses as compared to those who do not, and thus may be better prepared to make informed end-of-life care decisions.

9550 Poster Session (Board #209), Sat, 1:15 PM-4:45 PM

Standardizing measurement of tobacco use in cancer clinical trials. *First Author: Stephanie R Land, Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD*

Background: ASCO and AACR recommend assessment of tobacco use (TU) for all cancer patients, but there is little consensus regarding approaches for reliable, valid, and clinically meaningful TU measurement. Our aim was to develop clinically efficient evidence-based assessments that can be applied across research settings, and to provide expert recommendations for the timing of assessment. **Methods:** In 2013-2014, an expert Task Force developed candidate TU measurement items via consensus dialog and systematic evaluation of existing tools. From 9/2014-1/2015, in-depth, semi-structured cognitive interviews were conducted with three rounds of cancer patients to evaluate patient comprehension, memory retrieval, and judgment of draft versions of the instrument. Interviews were abstracted into structured reports tabulating cognitive difficulties. A subcommittee convened to recommend modifications. **Results:** Two tiers of TU measurement items were developed: a core set for all cancer studies, and a longer menu of curated items for use when comprehensive assessment is feasible. Domains include TU history, status and intensity relative to cancer diagnosis and treatment; other tobacco products; cessation approaches; and second hand smoke. We interviewed 22 participants (mean age 64; 68% male; 50% college educated; with cancers of the prostate (n = 8), bladder (3), colon & rectum (1), lung (7), pancreas (1), testis (1), thymus (1)). Numerous instrument improvements addressed patients' understanding of wording, response options, and recall periods. The final version performed well. Task Force recommendations also include a protocol for assessments at baseline and follow-up. **Conclusions:** These results provide preliminary support for content validity of the TU assessment instrument. Standardized TU assessment implemented in research across a range of disease sites and treatment modalities will permit data pooling and comparisons between populations. Recommendations facilitate TU assessment in clinical trials and will enable researchers to identify novel clinical interactions, better understand the effects of TU on cancer treatment efficacy and toxicity, address cessation, and ultimately improve clinical outcomes.

Dissonance reduction as prominent coping strategy in phase I study participants. *First Author: Diane A.J. van der Biessen, Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Phase I trials are essential for progress in cancer treatment but the reasons for patients to participate in these trials remain relatively ill-explored (Van der Biessen et al, 2013). This study aims to understand how psychological factors like coping strategies, locus of control, and hope affect the motivation to participate in these trials. **Methods:** In this prospective study we asked patients to complete a survey before initial informed consent for the phase I study was obtained for the first time. We used questionnaires regarding treatment motivation (TM, Van der Helm et al, 2012), hope (Herth Hope Index), coping (assimilation and accommodation coping-scale of Brandtstädter and Renner), locus of control (Rotter locus of control scale) and Quality of Life (QoL, EORTC QLQ-C30). To investigate relations between the scales a structural equation model (SEM) was fitted to the data. **Results:** During 18 months 135 patients enrolled in the questionnaire survey. 65 (48%) of the patients were male, with a mean age of 62 (range 30-83). The SEM-analysis showed 'hope' was significantly predicting treatment motivation $X^2(5) = 5.119$. Fit indices showed a close fit: NFI = 0.996; CFI = 0.999; TLI = 0.996; RMSEA = 0.013. An unique combination of flexible ($p < 0.01$) and tenacious ($p < 0.01$) coping, together with internal locus of control ($p < 0.01$) was predicting for 'hope'. **Conclusions:** Patients entering phase I studies seem to combine seemingly contradictory coping strategies: tenacity and flexibility. Also locus of control contributes towards hope. These data suggest a specific psychological adaptation, called dissonance reduction. This process that unconsciously discounts threatening information (i.e. about fatal prognosis of the disease) predicts for the motivation to participate in oncology phase I trials. Clinical trial information: NTR3354.

9552 Poster Session (Board #211), Sat, 1:15 PM-4:45 PM

Twelve-month prevalence of mental disorders in cancer patients across major tumor entities. *First Author: Anja Mehnert, University Medical Center Leipzig, Leipzig, Germany*

Background: Many studies have shown high levels of emotional and psychosocial distress in cancer patients. However, it is not well known yet to what extent psychological problems meet the criteria of a mental disorder according to clinical diagnosis classification systems (ICD-10, DSM-IV/V). We investigated the 12-month prevalence of mental disorders in a representative sample of cancer patients treated in different care settings in order to provide epidemiological data for evidence-based psycho-oncological service care planning. **Methods:** We interviewed a representative sample of patients with different tumour entities (N = 2,141) in outpatient, inpatient and rehabilitation settings using the standardized computer-assisted Composite International Diagnostic Interview for mental disorders adapted for cancer patients (CIDI-O). **Results:** The overall 12-month prevalence for any mental disorder was 39.4% (95%CI: 37.3-41.5%). The following prevalence rates were diagnosed: 15.8% (95%CI: 14.3-17.4%) for anxiety disorders, 12.6% (95%CI: 11.2-13.9%) for mood disorders, 9.5% (95%CI: 8.3-10.8%) for somatoform disorders, 7.3% (95%CI: 6.2-8.4%) for nicotine abuse, 3.7% (95%CI: 3.0-4.5%) for disorders resulting from a general medical condition, 1.1% (95%CI: 0.6-1.5%) alcohol abuse or dependence and 0% eating disorders. Highest prevalence of mental disorders was found in patients with head and neck cancer, breast cancer, malignant melanoma and kidney/urinary tract cancers. **Conclusions:** Mental disorders are highly prevalent in cancer patients. Having shown differences regarding type and amount of mental disorders across different tumour entities, our results emphasize a different need for psycho-oncological and psychotherapeutic support leading to an appropriate allocation of direct personnel and others resources.

9553 Poster Session (Board #212), Sat, 1:15 PM-4:45 PM

Psychosocial distress and its effects on the health-related quality of life of primary brain tumor patients. *First Author: Dina M Randazzo, Duke University Medical Center, Durham, NC*

Background: Primary brain tumor patients experience a high level of psychosocial distress, not only due to their diminished functional and neurocognitive capacities, but also due to the psychosocial stigma of being a primary brain cancer patient. The purpose of this study is to evaluate the level of psychosocial distress, the different sources of this stress, and its effect on health-related quality of life (HRQoL) in primary brain tumor patients. **Methods:** Demographic and clinical information in the PRoGREss registry at Duke's Preston Robert Tisch Brain Tumor Center was queried retrospectively for December 2013 through February 2014. Data was also obtained from patient-reported outcome questionnaires including the National Comprehensive Cancer Network's Distress Thermometer (NCCN-DT), the Functional Assessment of Cancer Therapy-Brain Cancer (FACT-Br), and the Functional Assessment of Chronic Illness Therapy- Fatigue (FACIT-F). **Results:** Among the 845 subjects completing the NCCN-DT, 385 (46%) were female and 460 (54%) were male. 98% reported physical problems with the most frequent being memory/concentration (40%) and fatigue (42%), and 41% complained of an emotional problem with nervousness (22%) and worry (29%) being the most reported concerns. 12% reported insurance/financial concerns. 94% of the subjects completed the distress thermometer with a mean score of 2.68 (SD = 2.70). There was no difference in distress between tumor grades (low grade: mean = 2.73, SD = 2.89; high grade: mean = 2.67, SD = 2.62; p = 0.8297). Females (mean = 3.05, SD = 2.81) experienced significantly more distress than males (mean = 2.39, SD = 2.57; p = 0.0007), as well as a higher rate of practical (p = 0.0026), family (p = 0.0209) and emotional (p < 0.0001) problems. Patients who reported at least one practical, family, or emotional problem had significantly lower HRQoL scores (p < 0.0001). **Conclusions:** Primary brain tumor patients experience memory dysfunction, fatigue, nervousness, worry, and financial concerns which have a negative effect on the patient's HRQoL. By identifying and addressing these stressors during a clinic visit, it may be possible to improve patient HRQoL.

9554 Poster Session (Board #213), Sat, 1:15 PM-4:45 PM

Patient-reported outcomes following choice for contralateral prophylactic mastectomy. *First Author: Eun-Sil Shelley Hwang, Duke University Medical Center, Durham, NC*

Background: Retrospective data show that the rate of contralateral prophylactic mastectomies (CPMs) is increasing; meanwhile, parallel information informing impact of CPM on quality of life (QOL) is lacking. We undertook this study to ascertain whether patient-reported outcomes (PRO), and more specifically QOL, differed between women who did or did not elect CPM. **Methods:** Women recruited from the Army of Women (AOW) with a history of breast cancer surgery took electronically-administered surveys including a background survey to collect patient, disease, and procedure specific factors, as well as the BREAST-Q, a well-validated breast surgery outcomes patient reporting tool. Descriptive statistics, univariate hypothesis testing, and regression analysis were used to evaluate the association of CPM with PRO scores in 4 QOL domains incorporated in the BREAST-Q (satisfaction with breasts, and psychosocial, physical and sexual well-being). **Results:** 7628 women completed questionnaires; of these, 4152 had mastectomy and 1519 (37%) reported receipt of CPM. Women undergoing CPM were younger (median age 53.7 y vs. 59.3 y, p < 0.0001) and reported earlier breast cancer stage at presentation than those who did not choose CPM. In univariate analysis, mean breast satisfaction was significantly higher among the CPM group (60.4 vs. 58.1, p = 0.0005) and mean physical well-being was significantly higher among those who did not have a CPM (76.6.vs. 74.6, p = 0.0002). The groups did not differ with respect to psychosocial or sexual well-being. On multivariable linear regression the CPM group continued to report higher breast satisfaction (p = 0.0019) but reported no difference from the non-CPM group in the other QOL domains. Psychosocial well-being improved over time for both CPM and non-CPM groups (p < 0.0001), but did not differ significantly within time interval since surgery. **Conclusions:** Choice for CPM was only associated with improved QOL in the breast satisfaction domain and did not impact psychosocial, physical and sexual well-being after adjustment for other factors known to influence QOL. Such PRO data are important to consider when counseling women contemplating CPM as part of their breast cancer treatment.

9555 Poster Session (Board #214), Sat, 1:15 PM-4:45 PM

Relationship between physician-adjudicated adverse events (AE) and patient-reported health-related quality of life (HRQoL) in a phase II clinical trial of patients (pts) with metastatic uveal melanoma (UM). *First Author: Thomas Michael Atkinson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clinical trials typically use physician-adjudicated AE assessment with the Common Terminology Criteria for Adverse Events (CTCAE) for decision-making. Since the capture of patient-reported HRQoL data is becoming more frequent, we compared CTCAE and HRQoL ratings for pts treated on one clinical trial to explore how this information may inform clinical trial conduct. **Methods:** Data from a phase II trial of pts with metastatic UM (Carvajal et al. JAMA. 2014) were analyzed. Pts were randomized to receive Selumetinib (sel), an oral MEK inhibitor (n = 50), or chemotherapy (n = 51); 19 pts received sel without randomization. Those randomized to chemotherapy could receive sel at disease progression. Pts reported HRQoL via the Functional Assessment of Cancer Therapy – Melanoma (FACT-M) at baseline, after 1 month and end of treatment (EOT; n = 118). Independent samples *t*-tests were used to compare mean FACT-M scores between sel, chemotherapy and crossover pts. Pearson correlations were calculated to determine the association between mean FACT-M scores and whether a patient had their dose reduced due to AEs. **Results:** 94% (median age = 62; 44% female) had a physician-adjudicated CTCAE grade > 0 for at least one treatment-associated AE of diarrhea, edema, nausea, rash, or vomiting. 20% of these pts had dosage reductions. 38 pts from the chemotherapy group progressed and received sel. Mean FACT-M scores did not significantly differ ($p > 0.05$) across sel, chemotherapy or crossover groups at each of the three time points. There were no significant correlations between dose reduction status and FACT-M scores (r = 0.07, -0.01 and 0.03 for baseline, 1 month and EOT). **Conclusions:** Despite the high rate of physician-adjudicated AEs, patient-reported HRQoL was not impacted by treatment. HRQoL did not differ in the subgroup of pts who received dosage reductions due to AEs, indicating that the patient may be willing to tolerate that level of AEs and continue the current dosage (if medically appropriate). More research is needed to determine how to best integrate HRQoL data into clinical trial conduct. Clinical trial information: NCT01143402.

9556 Poster Session (Board #215), Sat, 1:15 PM-4:45 PM

Change in second-hand smoke exposure after a lung and head and neck cancer diagnosis and subsequent patient smoking cessation. *First Author: Lawson Eng, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Exposure to second-hand smoke (SHS) after a cancer diagnosis is associated with continued smoking in lung and head and neck (HN) cancer patients (PMID: 24419133, 23765604). We evaluated whether complete reduction/cessation of SHS exposure around and after a diagnosis of lung or HN cancer is associated with smoking cessation in the cancer patient. **Methods:** Lung and HN cancer patients from Princess Margaret Cancer Centre (2006-12) completed questionnaires at diagnosis and follow-up (median 2 years apart) that assessed smoking history and SHS exposures (cohort design). These cancers were chosen because these patients had the highest rates of smoking at the time of diagnosis. Multivariate logistic regression analysis evaluated the association of cessation of SHS exposure after a diagnosis of cancer with subsequent smoking cessation, adjusted for significant covariates. A cross-sectional study (2014) of 90 lung and HNC smoking patients assessed consistency in associations. **Results:** For the cohort, 261/731 lung and 145/450 HN cancer patients smoked at diagnosis; subsequent overall quit rates were 69% and 50% respectively. 91% of lung and 94% of HN cancer patients were exposed to SHS at diagnosis while only 40% (lung) and 62% (HN) were exposed at follow-up. Cessation of SHS exposure was associated with smoking cessation in lung (aOR = 4.76, 95% CI [2.56-9.09], $P< 0.001$), HN (aOR = 5.00 [1.61-14.29], $P< 0.001$), and in both cancers combined (aOR = 5.00 [3.03-8.33], $P< 0.001$). The cross-sectional study had a similar trend for cessation of SHS with smoking cessation, but a lower magnitude of association (OR = 2.73, $P= 0.09$). However, when asked directly, only 13% of patients quit smoking with another individual. **Conclusions:** Cessation of SHS exposure was a frequent occurrence around cancer patients. This cessation of SHS exposure is significantly associated with smoking cessation in lung and HN cancer patients. However, few patients quit smoking at the same time as their friends, family or household. Changing the environment around cancer survivors to reduce SHS exposure and encouraging households/friends to quit smoking may both improve cessation rates in cancer patients.

9557 Poster Session (Board #216), Sat, 1:15 PM-4:45 PM

Psychological distress during hospitalization for hematopoietic stem cell transplantation to predict lower quality of life and high post-traumatic stress disorder symptoms at 6 months post-transplant. *First Author: Harry VanDusen, Massachusetts General Hospital, Boston, MA*

Background: Patients undergoinghematopoietic stem cell transplantation (HCT) experience a steep deterioration in quality of life (QOL) and mood during hospitalization for HCT. The impact of this deterioration on patients' long-term QOL and post-traumatic stress disorder (PTSD) symptoms is unknown. **Methods:** We conducted a prospective longitudinal study of patients hospitalized for HCT. At baseline (day-6), day+1, day+8, and 6 months post-HCT, we assessed QOL (Functional Assessment of Cancer Therapy-Bone Marrow Transplantation [FACT-BMT]) and mood (Hospital Anxiety and Depression Scale [HADS]). We used the PTSD Checklist to assess for PTSD symptoms at 6 months. We used multivariable linear regression models to identify predictors of QOL and PTSD symptoms at 6 months post-HCT. **Results:** We enrolled 97% (90/93) of consecutively eligible patients undergoing autologous (n = 30), myeloablative allogeneic (n = 30), or reduced intensity allogeneic (n = 30) HCT. Overall, patients' QOL at 6 months (mean FACT-BMT: 110, 95%CI [104-116]) recovered to baseline pre-transplant values (mean FACT-BMT: 110, 95% CI [107-115]). At 6 months, 28.4% of participants met provisional diagnostic criteria for PTSD. In multivariable regression analyses, depression and anxiety symptoms during hospitalization for HCT predicted impaired QOL (HADS-depression β = -1.8, P = 0.04; HADS-anxiety β = -1.7, P = 0.05) and PTSD symptoms (HADS-depression β = 1.0, p = 0.05; HADS-anxiety 1.2, P = 0.01) at 6 months post-HCT. **Conclusions:** While patients' overall QOL at 6 months post-HCT returned to baseline values, a significant proportion met provisional diagnostic criteria for PTSD. Psychological distress during hospitalization for HCT was the most important predictor of long-term QOL impairment and PTSD symptoms. Future studies should evaluate whether interventions to reduce psychological distress during HCT may improve long-term QOL and reduce the risk of PTSD symptoms.

9558 Poster Session (Board #217), Sat, 1:15 PM-4:45 PM

Treatment-adherence beliefs and behaviors in patients with chronic myeloid leukemia (CML). *First Author: Joanne S. Buzaglo, Cancer Support Community, Research and Training Institute, Philadelphia, PA*

Background: Tyrosine kinase inhibitors (TKIs) are effective yet chronic indefinite therapy for CML. Strong links exist between TKI adherence and optimal outcomes. Suboptimal adherence is common, affecting clinical outcomes and healthcare costs. Nonadherent patients underrecognize missed-dose impact on response. This study explored the link between belief and behavior vis-à-vis adherence. **Methods:** With outreach to online, national and community networks from 10/13 to 7/14, 484 CML patients enrolled in the Cancer Experience Registry: CML, an online project to advance CML knowledge and patient engagement. 393 (81%) completed a web-based survey including questions assessing accord with 2 statements (1) It is okay to miss a dose of my CML medicine every now and then, and (2) I need to take every dose of my CML medicine or it might not work; as well, participants reported missed TKI-dose frequency. Logistic regression was used to study the beliefs-behavior link among US patients taking TKIs (n = 318). Regression models were adjusted for age, gender, time since diagnosis, and TKI cost/month. **Results:** Responders averaged 56 y of age and 5.2 y from diagnosis; the majority was female (68%) and white (90%). 23% reported TKI spending of ≥ $100/month; 19% spent $50-100; 58% spent < $50. Regarding statement 1 and missed TKI dose, 5% strongly agreed, 28% agreed, 24% disagreed, 43% strongly disagreed. For statement 2, 6% strongly disagreed they needed to take every dose, 17% disagreed, 32% agreed, 45% strongly agreed. 19% reported missing a dose at least monthly. Compared to those who disagreed/strongly disagreed, those who agreed/strongly with statement 1 were significantly more likely to have reported missing doses monthly (OR = 7.04; 95% CI = 3.65, 13.57). Also, those who disagreed/strongly disagreed with statement 2 vs. those who agreed/strongly agreed were significantly more likely to have reported missing doses at least once monthly (OR = 5.36; 95% CI = 2.81, 10.2). **Conclusions:** CML patients' medication beliefs were strongly associated with suboptimal adherence. The results suggest multifaceted patient education would impact adherence, outcome and survival. The relationship between beliefs and drug adherence merits further study.

9559 Poster Session (Board #218), Sat, 1:15 PM-4:45 PM

Association between oncologists' dispositional affect and depressive symptoms in their patients with metastatic cancer. *First Author: William F. Pirl, Massachusetts General Hospital, Brookline, MA*

Background: While caring for patients with metastatic cancer can be emotional, relationships between the emotions of oncologists and their patients have not been examined. As patients and oncologists read emotional cues in encounters, emotions of one or both may impact the other. We explored associations between dispositional affect, tendencies to emotionally respond to situations in certain ways, in oncologists and depressive symptoms in their patients with newly diagnosed metastatic lung and gastrointestinal (GI) cancers. **Methods:** As part of an ongoing trial of early palliative care, participants were assessed at baseline for depressive symptoms (Patient Health Questionnaire-9, PHQ9) within 8 weeks of diagnosis with metastatic lung and GI cancers. Oncologists providing care for these patients completed the Positive and Negative Affect Scale (PANAS), a validated measure of dispositional affect with positive and negative dimensions. Associations between patient depressive symptoms and positive and negative dispositional affect were tested with rank sum tests and multivariate linear regressions. **Results:** Sixteen of the 18 oncologists with patients in the trial completed the PANAS. Among 323 participants with baseline assessments, 277 (86%) had oncologists who completed the PANAS. Mean age = 64.6, 129 (46%) were female, 159 (57%) had GI and 118 (43%) lung cancer, and mean PHQ9 score = 6.5. Positive and negative dispositional affect were not associated with oncologists' sex, years from training, hours in clinic, and cancer specialization. Patient depressive symptoms were significantly higher if their oncologists reported greater negative dispositional affect (p = .04). The relationship remained significant adjusting for patient age, sex, cancer type, ECOG PS, smoking, and number of oncology visits (β = .13, t= 2.1, p = .04). PHQ9 scores were not associated with oncologists' positive dispositional affect. **Conclusions:** Depressive symptoms in patients with metastatic lung and GI cancers appear to be associated with their oncologists' negative dispositional affect. Determining the direction of the association may lead to new ways of improving patients and/or oncologists moods.

9560 Poster Session (Board #219), Sat, 1:15 PM-4:45 PM

Mild cognitive impairment (MCI) in chemotherapy-treated breast cancer survivors. *First Author: Abigail Gifford, Wake Forest University, School of Medicine, Winston-Salem, NC*

Background: This abstract uses the National Institute on Aging/Alzheimer's (NIA/AA) criteria to report the prevalence of MCI in a cohort of breast cancer survivors who received adjuvant chemotherapy. **Methods:** Wake Forest NCORP Research Base prospective clinical trial 97211 enrolled 62 breast cancer survivors 1-5 year post adjuvant chemotherapy between 7/12-1/13 to test the efficacy of donepezil on cognitive function. Subjective cognitive complaints were evaluated with the Functional Assessment of Cancer Therapy-Cognition. Objective cognitive performance was assessed using standardized/validated neurocognitive measures. Functional status was evaluated with the FACIT-Fatigue. The NIA/AA MCI criteria as applied to this study were: 1) self-reported cognitive complaints (FACT-Cog score $<$ 63), 2) significant cognitive impairment ($\geq$ 1.5 SD below the normative mean) in $\geq$ 1 cognitive domains, 3) preservation of functional independence, and 4) not demented. MCI was further classified as amnestic/non-amnestic and single-/multi-domain. **Results:** Sixty women between the ages of 39 and 79 completed the objective cognitive battery. At baseline, 80% demonstrated significant cognitive impairment. 58% met the NIA/AA criteria for MCI (of those, 26% were amnestic/multi-domain, 9% amnestic/single-domain, 17% non-amnestic/multi domain, 49% non-amnestic single domain MCI). 22% had significant cognitive impairment with loss of functional independence. **Conclusions:** In this cohort, 58% met the accepted NIA/AA criteria for MCI. The American Heart and Stroke Associations have adopted these criteria to define Vascular Cognitive Impairment (VCI), vascular MCI (vMCI), and Vascular Dementia (VaD). Similarly, standard criteria to characterize cognitive dysfunction should be applied in the cancer setting. We propose implementing the terms Cancer Cognitive Impairment (CCI), cancer MCI (cMCI), and Cancer Dementia (CaD) to describe the spectrum of cancer- and cancer-treatment associated cognitive impairment.

9561 Poster Session (Board #220), Sat, 1:15 PM-4:45 PM

The price of survival: Breast cancer patient preferences about fertility. *First Author: Amirrtha Srikanthan, Princess Margaret Hospital, Toronto, Ontario, Canada*

Background: Fertility is a concern for young women diagnosed with breast cancer. Concerns have been raised that women may avoid effective anti-cancer treatments to have an opportunity to preserve fertility. Here, we explore patient preferences for chemotherapy and whether women are willing to trade-off survival benefit to maintain fertility. **Methods:** During a standardized interview, outcomes associated with adjuvant chemotherapy and 5 years of tamoxifen (CT) or 5 years of tamoxifen alone (ET) were described to breast cancer survivors diagnosed within the past 2 years. A threshold task was performed in which each participant participated in two scenarios: (1) 10% absolute survival benefit from treatment and (2) 25% absolute survival benefit from treatment. Each participant was asked which treatment option they preferred when baseline fertility post treatment was reduced initially to 50% for both scenarios (i.e. 50% chance of conceiving naturally). If the participant indicated CT, post-treatment fertility was systematically reduced further until the participant's preference changed from CT to ET. This threshold point represented the reduction in fertility the participant would accept before they would trade-off CT benefit. Descriptive statistics were used to characterize participants. Demographic factors (age, marital status, number of children at diagnosis and education) associated with willingness to trade-off survival benefit were evaluated with logistic regression. **Results:** Analysis comprised 50 women with a median age of 34.5 years (range 25-39 years). 39 (78%) women had completed university education. 34 (68%) and 45 (90%) women in scenario 1 and 2, respectively, were willing to trade-off all fertility (i.e. reduce fertility to 0% chance of conceiving naturally) in order to undertake CT and maintain survival benefits. 8 (16%) and 3 (6%) women in scenario 1 and 2, respectively, chose to not pursue CT at all in order to maintain fertility. Regression analysis did not identify any variables that were predictive of the participants' preferences. **Conclusions:** Most young women with breast cancer are not willing to trade-off survival benefits of adjuvant therapy to maintain fertility.

9562 Poster Session (Board #221), Sat, 1:15 PM-4:45 PM

Young adult cancer survivors' expectations of physicians for reproductive and sexual health care. *First Author: Ying Wang, University of British Columbia, Vancouver, BC, Canada*

Background: Infertility and sexual dysfunction resulting from cancer therapies are often inadequately addressed by physicians, even though these issues cause significant distress for young adult cancer patients. In this study, we examined survivors' expectations of their physicians regarding reproductive and sexual healthcare, and identified factors associated with these expectations. **Methods**: We surveyed patients aged 20 to 39 years who were diagnosed with solid tumors, evaluated at any 1 of 5 regional cancer centers in British Columbia, and alive at 2 or more years after their original diagnosis. Using multivariate regression models, we explored the relationships between patient expectations of their care and the factors associated with these expectations, while controlling for potential confounders. **Results:** With a survey response rate of 56%, a total of 447 patients were analyzed: median age was 35 years (IQR 31-38), 30% were men, 89% had ECOG 0, and 75% reported being in a relationship. Tumor sites included breast (222; 50%), testicular (126; 28%), gynecological (76; 17%), and colorectal (23; 5%). A significant proportion of patients received chemotherapy (65%) and radiation (47%) that posed the potential for infertility or sexual dysfunction. While the majority of patients expected their primary care providers (PCPs) and cancer specialists (CS) to share responsibility in addressing fertility and sexual health concerns (85% and 74%, respectively), a fair number of patients preferred that reproductive health be fully managed by CS (16% vs. 10%, $p = 0.005$) and that sexual health be mainly addressed by PCPs (31% vs. 21%, $p < 0.0001$). In regression analyses, prior discussions about infertility or sexual dysfunction conducted by oncologists increased the patient's expectations of their ongoing involvement in these areas ($p = 0.047$ and $p = 0.006$, respectively). **Conclusions:** Young adult cancer survivors have specific expectations about physician roles in addressing reproductive and sexual health. As discussions can modify patient expectations, early and appropriate engagement of both CS and PCPs in such conversations can facilitate the development of effective shared-care models of follow-up.

9563 Poster Session (Board #222), Sat, 1:15 PM-4:45 PM

Second primary malignancies in hepatocellular carcinoma: A population-based study. *First Author: Binay Kumar Shah, St. Joseph Regional Medical Center, Lewiston, ID*

Background: A second primary malignancy is a serious long term complication in cancer survivors. The aim of this study was to evaluate the risk of second primary malignancies in patients with hepatocellular carcinoma. **Methods:** We selected all adult patients ($\geq$ 18 years) diagnosed with hepatocellular carcinoma (HCC) from National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) 13 database. We calculated risk of second primary malignancies in the hepatocellular cancer patients using multiple primary standardized incidence ratio (MP-SIR) session of SEER* stat software. Second primary malignancy (SPM) was defined as a metachronous malignancy diagnosed six months or more after an index HCC. **Results:** A total of 15,296 patients with a diagnosis of primary hepatocellular carcinoma were reported in the SEER* 13 registry during January 1992 to December 2011. A total of 446(2.83%) developed 466 SPMs with an observed/expected (O/E) ratio of 1.07 (95% confidence interval = 0.97-1.17, $p < 0.164$) and absolute risk of 7.17 per 10,000 populations persons. The median age at diagnosis of HCC was 66.16 years (range: 42.33 - 95.5 years), and median follow up duration of patients was 28 months (range: 6 months – 18.5 years). Significant excess risk was observed for oral and pharyngeal cancers (N = 29, O/E = 1.73, confidence interval = 1.73-3.7, $P < 0.01$), stomach cancer (N = 20, O/E = 1.78, confidence interval = 1.09-2.75, $P < 0.02$), hepatobiliary cancer (N = 43, O/E = 2.71, confidence interval = 1.96-3.66, $P < 0.002$), lung and bronchial cancer (N = 82,O/E = 1.33,confidence interval = 1.05-1.65,$P < 0.01$),and hematological malignancies (N = 54,O/E = 1.52,confidence interval = 1.14-1.98, $P < 0.005$). Risk of head and neck cancer, thyroid, Kaposi sarcoma and hematologic malignancies was increased within the first two years of after diagnosis of HCC. Risk of lung and hepatobiliary cancers was increased after two years of latency. **Conclusions:** There is significant increased risk of second primary malignancies in adult patients with HCC compared to general population. Risk of specific SPM depends on latency.

9564 Poster Session (Board #223), Sat, 1:15 PM-4:45 PM

A comparison of the natural history of oxaliplatin- and paclitaxel-induced neuropathy (NCCTG N08C1, N08CB/Alliance). *First Author: Kathryn Jean Ruddy, Mayo Clinic, Rochester, MN*

Background: We examined the similarities and differences of paclitaxel and oxaliplatin neuropathy symptoms. **Methods:** Acute and chronic neuropathy data were pooled from pts receiving 1) adjuvant oxaliplatin (FOLFOX) in protocol N08CB (346 pts) and 2) weekly paclitaxel or every 3 week paclitaxel/carboplatin in protocol N08C1 (179 pts). In both trials, pts completed daily questionnaires for several days after each chemotherapy dose (to evaluate acute neuropathy) and the EORTC CIPN20 tool before each chemotherapy dose and at 1, 3, 6, and 12 months post treatment (to assess chronic neuropathy). **Results:** The acute neuropathy symptoms from both drugs peaked on day 3, with acute symptoms experienced in cycle 1 predicting occurrence in the subsequent cycles. Paclitaxel-induced acute symptoms were similar in intensity in each cycle and largely resolved between cycles. Oxaliplatin-induced acute symptoms were about half as severe in the first cycle, as in later cycles, and did not resolve completely between cycles. For chronic neuropathy, both drugs caused a predominantly sensory neuropathy (numbness and tingling much more common than pain). Oxaliplatin-induced chronic neuropathy worsened after the completion of treatment (coasting phenomenon) and began to improve 3 months post-treatment. In contrast, paclitaxel-induced chronic neuropathy typically began improving immediately after chemotherapy cessation. During treatment, paclitaxel numbness/tingling symptoms were similar in hands and feet; with oxaliplatin, hands were affected more than feet. After treatment completion, hand symptoms improved faster than foot symptoms, for both drugs, so that foot symptoms were more problematic one year later. Both paclitaxel- and oxaliplatin-induced acute neurotoxicity appeared to predict the severity of chronic neuropathy (more prominently with oxaliplatin). **Conclusions:** Patients receiving paclitaxel or oxaliplatin should be counseled regarding these patterns of neuropathy symptoms and recovery. Understanding the similarities and differences between these neuropathy syndromes should provide insight into the underlying pathophysiology and help find preventative treatment approaches. Clinical trial information: N08C1/N08CB.

9565 Poster Session (Board #224), Sat, 1:15 PM-4:45 PM

Effects of strength training intervention in breast cancer survivors. *First Author: Joanne Monterroso, University of Vermont Medical Center, Burlington, VT*

Background: Oncology rehabilitation programs provide a potential avenue for improving fitness, function and quality of life. Few studies evaluate how cancer survivors respond to such interventions. Objectives: 1. Compare upper and lower body strength of breast cancer survivors (BCS) to normative data. 2. Evaluate changes in strength after 12 weeks of resistance training. **Methods:** Participants received a 12 week, 2x per week aerobic and resistance training intervention as part of the University of Vermont Medical Center oncology rehabilitation program. One repetition maximum strength testing of upper and lower body strength was completed before and after the intervention. Strength was compared to American College of Sports Medicine normative values. Pre/post comparisons were completed for participants attending $\geq$ 25% of sessions. Breast cancer survivors were included in the analysis. **Results:** Baseline assessments were obtained on 130 participants, 91 completed at least 25% of exercise sessions. 90% completed $\geq$ 66% of training sessions. Over 90% of BCS had upper extremity strength at $< 25^{th}$ percentile and over 74% had lower extremity strength at $< 20^{th}$ percentile. Upper and lower extremity strength remained $< 25^{th}$percentile for the majority of participants after the intervention but percentiles improved 8 and 16 points respectively. For participants completing the intervention, upper extremity strength increased from 57 $\pm$ 31lbs to 70 $\pm$ 31lbs ($p < 0.001$). Lower extremity strength increased from 125 $\pm$ 45 to 154 42lbs ($p < 0.001$). There were no significant differences in strength improvement between BCS who did and did not receive chemotherapy. The upper extremity strength of women age $\leq$ 55 improved to a greater degree than women over age 55 ($p = 0.01$). **Conclusions:** Breast cancer survivors entering an oncology rehabilitation program have markedly lower upper and lower body strength compared to normative data. Strength training intervention results in improved strength in this population but strength remains below expected. The benefit of resistance training was seen regardless of age or previous exposure to chemotherapy. Opportunities for breast cancer survivors to participate in resistance training interventions should be encouraged.

9566 Poster Session (Board #225), Sat, 1:15 PM-4:45 PM

A randomized controlled trial (RCT) of a supportive care package (SurvivorCare, SC) for survivors of colorectal cancer (CRC). *First Author: Michael Jefford, Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia*

Background: Colorectal cancer (CRC) and its treatments can cause distressing short and long-term side effects as well as significant functional consequences. Current models of follow-up do not adequately address these issues. We conducted a multi-center RCT of an innovative program (SurvivorCare (SC)); designed to have a beneficial effect on psychological distress, supportive care needs (SCN) and quality of life (QOL). **Methods:** At the end of active treatment for stage I-III CRC, eligible patients ($\geq$ 18 years, adequate English) were randomized 1:1 to usual care (UC) or to UC+SC. SC comprised educational materials, needs assessment, an individualized survivorship care plan, nurse-led end-of-treatment session and three follow up (FU) phone calls. Distress (BSI-18), SCN (CaSUN) and QOL (EORTC QLQ-C30, CR29) were assessed at baseline, 2 (FU1) and 6 (FU2) months. Primary hypothesis: SC would have a beneficial effect on distress at FU1. Secondary hypotheses: SC would have a beneficial effect on (1) SCN and QOL at FU1; and (2) distress, SCN and QOL at FU2. 15 items assessed satisfaction with survivorship care. Sample size of 180 (90/arm) was based on 80% power, 2-sided alpha of 0.05, to detect a between groups difference of 3.6 on BSI-18 at FU1. Outcome analysis was ITT. **Results:** Of 221 patients randomized (111 UC, 110 SC), 4 were ineligible and 1 lost to FU, leaving 110 UC, 106 SC. Groups appeared well balanced. Median age was 64, 52% male, 56% colon, 35% rectal cancer, 10% overlap. Stage I 7%, II 22%, III 71%. Intervention fidelity was acceptable. Baseline distress and QOL were similar to population norms. Between groups differences in distress at FU1 (primary outcome), distress at FU2 and SCN and QOL at FU1 and FU2 were small and non-significant. SC patients were more satisfied with survivorship care than UC patients (significant differences on 10 of 15 items). **Conclusions:** The addition of SC to UC did not have a beneficial effect on distress, SCN or QOL outcomes but SC patients were more satisfied with survivorship care. Clinical trial information: ACTRN12610000207011.

9567 Poster Session (Board #226), Sat, 1:15 PM-4:45 PM

Results of the ASCO survey of cancer survivorship research: Summary and implications. *First Author: Paul B. Jacobsen, Moffitt Cancer Center, Tampa, FL*

Background: The ASCO Survivorship Committee identified the need to better understand the current scope of cancer survivorship research in order to identify future research priorities. A committee workgroup recently completed a survey addressing this issue. **Methods:** A survey was conducted previously to assess engagement of ASCO members in survivorship care and research. Of 14,098 members contacted, 2,899 (20.6%) responded. Of this group, 679 self-identified as (co-)principal investigator of a survivorship-related study. A follow-up survey was subsequently sent to these members and to 838 individuals at NCI-designated Cancer Centers identified through other means as being engaged in cancer survivorship research. The survey asked respondents to describe study characteristics (e.g., design, participants, outcomes) for each IRB-approved cancer survivorship-related study for which they served as (co-)principal investigator. **Results:** 609 of 1517 recipients (46%) responded and reported on 714 studies. 65% of studies were observational (OBS) and 35% were interventional (INT). OBS studies mostly focused on lymphoid/hematopoietic (26%), breast (19%), and more than one (13%) cancer, while INT studies mostly focused on breast (34%), more than one (15%) and lymphoid/hematopoietic cancers (10%). Age at time of diagnosis/treatment was most commonly 40-64 years for OBS (26%) and INT (32%) studies and least commonly $>$ 65 years for OBS studies (24%) and $<$ 21 years for INT studies (11%). Time since diagnosis was most commonly $<$ 2 and least commonly $>$ 5 years for OBS (39%, 29%) and INT (48%, 15%) studies. The most common primary/secondary objectives were physical (32%), quality of life (27%) and health behavior (22%) outcomes for OBS studies and quality of life (34%), physical (31%) and health behavior (25%) outcomes for INT studies; the least common objective was patterns and quality of care for OBS (2%) and INT ($<$ 1%) studies. **Conclusions:** Findings identify key gaps in current research that should be prioritized for future study. These include the relative lack of research on several common cancers (e.g., colorectal, prostate, and lung), on long-term and older ($>$ 65) and younger ($<$ 21) survivors, and on survivorship care delivery and quality.

9568 Poster Session (Board #227), Sat, 1:15 PM-4:45 PM

Household secondhand smoke exposure among community-dwelling cancer survivors in the United States. *First Author: Oladimeji Akinboro, Montefiore New Rochelle Hospital, New Rochelle, NY*

Background: There is little extant data regarding the prevalence of secondhand smoke exposure among cancer survivors. We sought to estimate the prevalence of household secondhand smoke exposure, as well as its association with active smoking, among community-dwelling cancer survivors in the United States (US). **Methods:** We abstracted data from the US National Health and Nutrition Examination Survey for 1,742 community dwelling adults, aged 20 years and older sampled nationwide from 2005-2012, who had survived at least 2 years since their first cancer diagnosis. We calculated the age-adjusted population-based prevalence of household secondhand smoke exposure. Multivariable logistic regression was utilized in examining the association between household secondhand smoke exposure and survivors' smoking status while controlling for age, gender, race, marital status, education, income, having a regular source of routine care, and cancer site. Survey weights were applied in estimating the population-based prevalence rates, odds ratios (OR), and 95% confidence intervals (CI). **Results:** The age-adjusted prevalence of household smoke exposure among adult cancer survivors was 22.4% (CI 17.5-27.3%). Among those exposed, 76% were females (CI 69.8-81.8%), 82% were active smokers (CI 75.5-87.1%), and 55% had survived a smoking-related cancer (CI 45.3-64.5%). Higher odds of household secondhand smoke exposure were seen with: i) active smoking (OR = 92.56, CI 46.31-185.01); ii) former smoking (OR = 2.07, CI 1.27-3.39); iii) living below federal poverty level (OR = 2.66, CI 1.29-5.48); and iv) cancers caused by active smoking (OR = 2.62, CI 1.70-4.04). **Conclusions:** The risk of household secondhand smoke exposure was highest among actively smoking adult cancer survivors but the direction of causality between active smoking and household secondhand smoking among cancer survivors cannot be inferred from this cross-sectional analysis. Nonetheless, these findings suggest that smoking cessation programs for smoking cancer patients may also need to target the households of such patients. Prospective studies are needed to parse out the effects of secondhand smoking on long-term outcomes among adult cancer survivors.

9569 Poster Session (Board #228), Sat, 1:15 PM-4:45 PM

Racial differences in upper extremity function for breast cancer survivors. *First Author: Lorraine Tiera Dean, University of Pennsylvania, Philadelphia, PA*

Background: Over 35% of breast cancer survivors face upper extremity disability due to breast cancer surgery, radiation, or chemotherapy to the upper body region. Race may be a key patient characteristic in disability, given that race is associated with factors related to poor functioning, including weight gain after breast cancer, disease stage, and treatment type. Studies of breast cancer survivors have not explicitly evaluated the associations between race and upper extremity disability using validated tools. **Methods:** The Quick-DASH (Disabilities of the Arm, Shoulder and Hand) is an 11-item self-administered questionnaire that has been validated for breast cancer survivors to assess global arm function over the past 7 days. The cross-sectional analysis assessed whether or not Black or White women had greater upper extremity disability, evidenced by higher Quick-DASH scores, in a population of 697 breast cancer survivors in the Wellness After Breast Cancer-II study. Linear regression estimated the relationship between race and Quick-DASH score, adjusting for demographics, body mass index (BMI), treatment type (lumpectomy, mastectomy, radiation, chemotherapy, and reconstruction), and other physical factors. **Results:** Black women had significantly higher BMI and age, were less likely to have had mastectomy, and had 7.7 points higher average Quick-DASH score than White ($p < 0.001$) women. After adjustment for demographics, BMI, treatment type, and other physical factors, Black women had an average 4.1-point (95% CI: 0.96-7.92) higher Quick-DASH score ($p = 0.01$) compared with White women. Mediation analysis suggested that BMI reduced the association between race and disability by 29.7%. **Conclusions:** Black women's Quick-DASH scores indicated clinically significant worse functioning, which were partially mediated by higher BMIs. Black patients may present in clinic with both worse functioning and higher BMI. Findings suggest that more research is needed to elucidate the relationship between race, BMI, and upper extremity disability, including determining additional factors beyond BMI that account for the relationship between race and disability.

9570 Poster Session (Board #229), Sat, 1:15 PM-4:45 PM

Comprehensive characterization of cisplatin-related hearing loss in U.S. and Canadian Testicular Cancer Survivors (TCS). *First Author: Heather E. Wheeler, Section of Hematology/Oncology, Department of Medicine, University of Chicago, Chicago, IL*

Background: Cisplatin is one of the most ototoxic drugs in use, causing permanent, bilateral sensorineural hearing loss in substantial numbers of patients, with many developing permanent tinnitus. Few studies, however, have systematically quantified the entire range of hearing loss (0.25-12 kHz) in patients given homogenous cisplatin-based chemotherapy using comprehensive audiometric methods and patient-reported outcomes. **Methods:** We performed detailed audiometry for 359 patients enrolled in an ongoing multi-center clinical study of TCS given cisplatin-based chemotherapy at centers in North America (NCI R01CA157823). Air conduction thresholds were measured at frequencies ranging from 0.25-12 kHz and bone conduction thresholds from 0.25-4 kHz in each ear. **Results:** Median age at evaluation was 39 years (range 20-63 years) with approximately 43% previously having seminomas and 57% nonseminomas. Over 90% of patients were white, while most (66%) had Stage II or III disease. Chemotherapy consisted largely of standardized regimens and doses, i.e., BEP X 3 (51%), EP X 4 (19%), slight modifications (27%) of either regimen, or VIP (3%). We identified 85.2% patients with hearing loss ($>$ 20 dB) at any frequency for either ear. Of these, 48.7% had conductive hearing loss and 39.2% showed evidence for noise-induced hearing loss for either ear. For each patient, we compared the area under the air conduction audiogram curve (AUC) (mean of both ears) to the expected AUC for this age group. Patients with AUCs greater than respective normal-aging AUCs were considered to have cisplatin-induced hearing loss (32.6%). Measured on a Likert scale from 0-3, 39.2% and 29.8% reported tinnitus and hearing loss (score 1+), respectively. The audiogram AUC correlated strongly with both self-reported tinnitus ($R = 0.31$, $P = 1.1e-08$) and self-reported hearing loss ($R = 0.36$, $P = 7.0e-11$). **Conclusions:** Cisplatin-induced ototoxic phenotypes affect 29-40% of TCS in this North American study. Future analytic investigations will focus on genetic and mechanistic investigations to facilitate the development of predictive, management and preventive efforts for ototoxicity in high-risk patients.

9571 Poster Session (Board #230), Sat, 1:15 PM-4:45 PM

TOPS: A randomised controlled trial of a multidisciplinary intervention for post-cancer fatigue. *First Author: Carolina Sandler, University of New South Wales, NSW Cancer Survivors Centre, Sydney, Australia*

Background: Cancer related fatigue is prevalent and disabling. When persistent and unexplained, it is termed post-cancer fatigue (PCF). Cognitive behavioural therapy (CBT) and graded exercise therapy (GET) may improve symptoms and functional outcomes. **Methods:** A randomised control trial - Treatment of Post-cancer fatigue Study (TOPS) assigned patients to an education intervention, or a 12 week integrated CBT and GET intervention supervised by an exercise physiologist and clinical psychologist. Three months post treatment for breast or colon cancer, eligible patients had: clinically-significant fatigue; no co-morbid medical or psychiatric conditions which explained the fatigue; and no clinical or laboratory evidence of cancer recurrence. The education arm included a single visit with clinicians describing the principles of CBT/GET and an education booklet. The CBT/GET arm included fortnightly individually tailored consultations. The primary outcome measures were self-reported fatigue (SOMA subscale - SPHERE questionnaire; (0 – 12)) and functional status (Role limitation due to physical health problems – SF36 questionnaire (0 – 100)) comparing baseline, end treatment (12 weeks), and follow-up (24 weeks). Outcomes were analysed by 'clinically-significant' improvement designated *a priori* as $\geq$ one standard deviation improvement in fatigue scores. **Results:** 160 patients were screened, and 34% ($n = 55$) were eligible. The primary reason for ineligibility was sub-threshold fatigue ($n = 61$, 58%). 46 patients were enrolled, including 43 women (94%), with a mean age of 51 years. Intention-to-treat analysis showed that fatigue severity improved in all enrolled subjects improved from a mean of 5.2 ± 3.1 to 3.9 ± 2.8 at week 12, suggesting a natural history of improvement. Clinically significant improvement was observed in 7 of 22 subjects in the intervention group compared to 2 of 24 in the education group ($p < 0.05$, $\chi 2$). These subjects had a mean improvement in functional status (SF-36) of 25.4 ± 33.3 compared to non-responders (6.0 ± 15.3, $p < 0.01$, t test). **Conclusions:** Combined CBT/GET improves fatigue and functional outcomes for a subset of patients with PCF. Further studies to improve the response rate are warranted. Clinical trial information: ACTRN12611000338965.

9572 Poster Session (Board #231), Sat, 1:15 PM-4:45 PM

Phase II feasibility study of a physical activity and dietary change weight loss intervention in a subset analysis of breast cancer survivors (SWOG S1008). *First Author: Heather Greenlee, Columbia University Medical Center, New York, NY*

Background: Weight loss among overweight and obese breast and colorectal cancer survivors is hypothesized to be associated with improved disease-free survival. Phase III trials are needed to test effective and implementable weight loss interventions in breast and colorectal cancer survivors. **Methods:** We conducted a feasibility study of a 12-month community-situated physical activity and telephone-based dietary change weight loss intervention in female breast and colorectal cancer survivors. We report the primary outcomes for the breast cancer (BC) cohort. Sedentary postmenopausal women with prior Stage I-III BC and BMI $\geq$ 25 kg/m^2 were eligible. Primary objectives were to assess feasibility and weight loss at 12 months. Target accrual was 25 BC participants (ppts). Ppts were assigned a telephone counselor and given a 12-month membership to a local Curves fitness center, which offers a 30-minute circuit-based exercise program. Ppts were counseled 14 times over 12 months and were instructed to exercise 150 minutes/week, walk 10,000 steps/day, and decrease caloric intake by 500 kcal/day. The intervention would be considered feasible if full accrual was met within 10 months, $\geq$ 68% of ppts met minimum goals for exercise (attend $\geq$ 2 exercise sessions/week for $\geq$ 36 weeks) and diet (reduce caloric intake by $\geq$ 100 kcal/day and/or increase fruit/vegetable intake by $\geq$ 1 serving/day) (adherence), and $\geq$ 68% of ppts provided anthropometric measures at 12 months (retention). **Results:** Among 25 evaluable ppts, median age was 57.3 years with median BMI 37.5 kg/m^2 (range 27.7-54.6), 64% Stage I, and median 2.1 years from diagnosis. Accrual occurred in 10 months, 80% of ppts provided anthropometric measures at 12 months, 96% of ppts met the diet goal, and 28% of ppts met the exercise goal. Thus feasibility goals were met, with the exception of exercise adherence as defined a priori. At 12 months, average weight loss was 7.6% (95% CI -3.9%, 19.2%) with median weight loss of 7.1%. **Conclusions:** It is feasible to recruit and retain BC survivors in a multicenter weight loss trial using dietary change plus physical activity to achieve clinically meaningful weight loss over 12 months. Clinical trial information: NCT01453452.

9573 Poster Session (Board #232), Sat, 1:15 PM-4:45 PM

Survival outcome of cancer patients with pericardial effusions. *First Author: Danielle El Haddad, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pericardial effusion is a common finding in cancer patients and can be related to the tumor infiltration of the pericardial space or can be secondary to cancer therapy (chemotherapy or chest radiation). Impact of mechanism of effusions (malignant versus non-malignant effusions) on cancer patient's outcome is not well defined. Our aim was to evaluate survival outcome of these patients based on the presence or absence of malignant cells in their effusions. **Methods:** A total of 212 cancer patients who underwent pericardiocentesis for pericardial effusion between November 2009 and October 2014 at UT/MDACC were included in the study. **Results:** Overall median survival of the cohort was 143 days (95% CI, 95 to 221) and 130 (61%) patients died within 2 years from the procedure. The two most common solid tumors associated with pericardial effusions were lung [61(29%)] and breast [22 (10%)] cancer. In a multivariable analysis model, age $>$ 65y, lung cancer, platelet counts $<$ 20.000, and the presence of malignant cells in the pericardial fluid were independently associated with poor prognosis. Malignant pericardial effusion was pathologically confirmed in 37 (61%) patients with lung cancer and 16 (73%) patients with breast cancer. Lung cancer patients with proven malignant effusions had a significantly shorter overall median survival compared to those with non-malignant effusions (24 patients or 39% of lung cancer patients) (1-year survival estimate of 16.2% (95% CI, 5.6%-31.6%) versus 49.0% (95% CI, 26.7%-68.0%) respectively. Log-rank test p-value = 0.0101). Such finding was not observed in the subgroups of breast cancer patients (1-year survival estimate of 40.2% (95% CI, 16.0%-63.6%) versus 40.0% (95% CI, 5.2%-75.3%) respectively. Log-rank test p-value = 0.4170). **Conclusions:** The presence of proven malignant cells in pericardial effusion appears to significantly impact survival outcome of patients with lung cancer, but not those with breast cancer.

9574 Poster Session (Board #233), Sat, 1:15 PM-4:45 PM

Cancer survivors' experiences with insurance, employment and personal finances: Results from a multi-site study. *First Author: Larissa Nekhlyudov, Harvard Medical School and Harvard Vanguard Medical Associates, Boston, MA*

Background: Prior studies have shown that cancer has significant implications for survivors' insurance coverage, employment and financial status. We aimed to examine whether these implications may differ for survivors depending on the type of cancer experienced. **Methods:** Using the Cancer Survivorship Supplement of the Medical Expenditures Panel Survey, we surveyed a cohort of cancer survivors enrolled in one of three health plans in Massachusetts, Colorado and Washington State in 2013. We stratified our sample to include those diagnosed with breast, colorectal, lung, and prostate cancers and melanoma between 2003 and 2008. **Results:** Of the 615 eligible respondents, 590 reported having had insurance at some point during/since their diagnosis, and few of those reported coverage barriers in seeing doctors or facilities of their choice. About half (n = 334) of the respondents reported having been employed at some time during/since their cancer; of those, approximately 25% reported they or their spouses remained at their jobs due to concerns about losing insurance, with no significant differences observed by cancer type. Further, of those employed, the majority (63%) reported making changes in their jobs (e.g., taking extended time off, working part time) or career choices due to cancer. These changes were more common among those with lung (80%), colorectal (74%) and breast cancer (68%) compared to prostate cancer (53%) and melanoma (38%) ($p < 0.001$). Additionally, 42% reported that cancer interfered with their physical and/or mental tasks at work or reduced their productivity. These limitations were again more common among lung, colorectal, and breast cancer survivors ($p = 0.001$). Of all survivors, approximately 15% reported financial hardships due to their cancer; most often among those with lung (23%) and breast cancer (22%) ($p < 0.001$). **Conclusions:** In this insured population, few experienced restrictions with their cancer care coverage, though maintaining coverage often drove employment decision making. Having cancer was associated with significant impact on survivors' work schedules, job productivity and personal finances, particularly among those with lung, breast and colorectal cancer.

9575 Poster Session (Board #234), Sat, 1:15 PM-4:45 PM

Distress in cancer survivors attending a multidisciplinary survivorship clinic. *First Author: Tara Beth Sanft, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Distress is defined as an unpleasant emotional experience that may interfere with the ability to cope with cancer or its treatment. Distress screening is recommended during transitions including survivorship. We describe distress in cancer survivors before and after participation in a multidisciplinary survivorship clinic. **Methods:** All patients participating in the Yale Adult Survivorship Clinic were asked to complete the National Comprehensive Cancer Network Distress Thermometer (DT) immediately before and after a visit. Survivors ranked distress from 0 (none) to 10 (extreme) and indicated associated problems from a 39-item list. A score $\geq$ 4 was considered clinically significant. Survivors were seen by an MD/APRN, social worker, registered dietitian and physical therapist. Survivors received individual counseling on topics including survivorship care, diet and exercise, and coping. All were offered a follow-up visit approximately 8 weeks later. Distress screening was repeated at the follow-up visit. Distress scores before and after each visit were compared using paired t-tests. **Results:** 377 survivors completed DTs before and after a survivorship clinic visit in 18 months. Survivors were mostly female (91%), white (77.2%), with a history of breast cancer (73%). The mean distress score prior to the initial visit was 4.82 (+/-2.82), and 2.45 (+/-2.15) after the visit (mean change -2.34, +/- 2.06, $p < 0.0001$). The top problems identified were worry (53%), fatigue (43%), and fears (30%). 191 survivors (51%) had clinically significant distress ($\geq$ 4) before the initial visit; however, only 74 (20%) reported significant distress after the visit ($p < 0.001$) Of survivors who returned for a follow-up visit (N = 107), avg distress score was 4.20+/-2.97 before and 1.86+/-2.01 after (mean change -2.42, +/- 2.50 $p < 0.0001$). At the follow-up, 49 (46%) had clinically significant distress before and 17 (16%) after ($p < 0.0001$). **Conclusions:** More than half of all survivors participating in a multidisciplinary survivorship clinic reported clinically significant distress. Distress scores were significantly lower after the visit. These results suggest participation in a survivorship clinic is an intervention for distress.

9576 Poster Session (Board #235), Sat, 1:15 PM-4:45 PM

Prevalence of hypogonadism in patients with previously treated germ cell tumors. *First Author: Trent James Miller, Indiana Univ, Indianapolis, IN*

Background: The vast majority of men with germ cell tumors (GCT) will be cured of their disease and may face long-term risks associated with survivorship. This may include hypogonadism (HG), which can be associated with depression, fatigue, and a lower quality of life (QOL). It is thus important to identify the prevalence of HG and correlation with symptoms in survivors of GCT, both in patients treated with platinum combination chemotherapy (PCC) as well as chemo-naïve patients. **Methods:** Patients treated with chemotherapy (Group 1) or with orchiectomy and/or other surgery or radiotherapy for GCT (Group 2), were 18-50 yrs of age, and not receiving supplemental testosterone at baseline were eligible. Total testosterone was measured at baseline and at 3, 6, and 12 mos. Either A.M. and P.M. lab draws were done depending upon time of patient follow-up. HG was defined as a serum total testosterone $<$ 300 ng/dl. Cancer diagnosis and treatment variables were obtained from medical records. Patients completed a validated QOL questionnaire at baseline, 3, and 6 mos. **Results:** We evaluated 172 patients treated for GCT. The overall prevalence of HG at baseline was 49.4% (95% CI 41.9-57.0). In Group 1 (N = 103), prevalence was 51.5% (95% CI 41.7-61.2). In Group 2 (N = 69), prevalence was 46.4 (95% CI 34.5-58.3). Overall prevalence of HG was not statistically different between the two groups (p = 0.5371). Within Group 1, there was no difference in prevalence of HG when patients were divided into those who received $<$ 3 cycles of PCC, 3 cycles of PCC, $>$ 3 cycles of PCC, or salvage chemo (p = 0.8131). Overall, compared to patients with testosterone $\geq$ 300, patients with baseline testosterone $<$ 300 reported worse perceived general health (p = 0.0003) and worse sleep quality (p = 0.0344), but no statistically significant difference in depression (p = 0.3131) or fatigue (p = 0.0622). **Conclusions:** The overall prevalence of HG is higher than would be expected in the general population. Testosterone levels are lower in the P.M., so the prevalence may have been artificially high due to P.M. as well as A.M. lab draws. There was no difference between the prevalence of HG between the two groups. HG can be a potential cause of medical and psychological distress if not recognized and treated.

9577 Poster Session (Board #236), Sat, 1:15 PM-4:45 PM

Self-efficacy through survivorship: Results from the LIVESTRONG Cancer Navigation Study. *First Author: Bree Hemingway, LIVESTRONG Foundation, Austin, TX*

Background: With more than 13.7 million cancer survivors in the U.S., two-thirds of whom will live beyond five years post-treatment, creating programs to support survivors can be challenging as their needs evolve through each stage of survivorship. LIVE**STRONG** Cancer Navigation (LCN) offers services designed to address survivors' needs at all stages of the cancer experience. Survivors experience new challenges and concerns when they transition from treatment to post-treatment care. We present the results of a LCN research study to describe how clients' self-efficacy (SE) and needs vary depending on their stage of survivorship. **Methods:** In 2012, researchers studied LCN to determine how well the program enables cancer survivors to manage their health and practical concerns. Participants (n = 1388) completed surveys at intake, two, and six weeks post-intake to measure quality of life outcomes including cancer-related concerns, SE and distress. The SE score is based on three items that assess the individual's confidence related to: emotional support; communication with their doctor; and making themselves feel better. Participants' needs were documented at intake and those who completed two or more surveys (63%) were included in the analytical sample (n = 874) and were categorized into three groups: in treatment (60.9%), $<$ 5 years post-treatment (24%) and 5+ years post-treatment (4.5%). **Results:** At all three time points, SE was lowest among individuals who finished treatment 5+ years ago. Significant differences in the mean number of needs were also found between participants at different stages of survivorship ($p<$ .003). Participants in treatment reported the most needs (6.6), followed by participants 5+ years post-treatment (6.3). Participants 5+ years post-treatment reported significantly higher cancer concern score than participants who had completed treatment $<$ 5 years ago. Additional outcomes will be shared. **Conclusions:** Findings suggest that SE decreases post-treatment. Understanding the various challenges and type of support survivors need at all stages of survivorship can inform service design in clinical and community-based settings that can continue to support clients into survivorship.

9578 Poster Session (Board #237), Sat, 1:15 PM-4:45 PM

Cardiac care after myocardial infarction in cancer survivors: A population-based study. *First Author: Kelvin K. Chan, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Cancer survivors (CS) may receive suboptimal non-cancer related care, such as lower rates of bypass surgery after myocardial infarction (MI) in the US. Secondary prevention (SP) after MI is an important aspect of survivorship care. We aim to examine the use of medications and interventions for SP after MI in CS vs. non-cancer patients (NCP). **Methods:** All acute MI patients (pts) hospitalized in Ontario between 1995 and 2012 were identified from the Canadian Institute of Health Information databases, and linked to the Ontario Cancer Registry to determine whether they were CS or NCP. Those who were diagnosed with cancer $<$ 1 year before their MI were excluded. The cohort was linked to other administrative databases to determine demographics, comorbidities, cardiac risk factors, hospital-based interventions and, for those over age 65, outpatient-based medication use. Propensity scores derived from baseline characteristics were used to create a 1:4 (CS:NCP) matched cohort. The use of medications and interventions within the first 90 days of MI, and medication adherence (measured by proportion of days covered (PDC) within the first year of MI) were compared between CS and NCP using matched analyses. **Results:** We identified 102,415 MI pts (CS = 20,483; NCP = 81,932) with 57% male and 86% $>$ age 65. Slightly fewer CS vs. NCP received angiograms (37.4% vs. 38.6%; p = 0.003) and percutaneous coronary interventions (17.0% vs. 17.8%; p = 0.01), but similar CS and NCP received bypass surgery (2.5% vs. 2.5%). For pts who were $>$ age 65 and active users of the public drug programs with MI $<$ 5 years after cancer diagnosis, fewer CS vs. NCP received ACEi/ARB (67.0% vs. 70.6%; p $<$ 0.001), statins (54.9% vs. 60.0%; p $<$ 0.001), and clopidogrel (27.8% vs. 33.8%; p $<$ 0.001), but the differences for those with MI $>$ 5 years after cancer diagnosis were much less (all interaction p $<$ 0.01). Similar CS and NCP received beta-blockers and nitrates. Both groups had similar degree of medication adherence, except for ACEi/ARB (PDC: 76.0% (CS) vs. 76.9% (NCP), p = 0.03). **Conclusions:** Slightly fewer CS than NCP received SP after MI, especially for those occurred within 5 years after cancer diagnosis. Further studies are needed to examine the outcome implications of this finding.

9579 Poster Session (Board #238), Sat, 1:15 PM-4:45 PM

Healthcare plan and provider ratings among cancer survivors. *First Author: Michael T. Halpern, University of Arizona Coll of Public Health, Tucson, AZ*

Background: Providing optimal healthcare for cancer survivors is important to address symptoms from cancer and cancer treatment, reduce risks of subsequent cancers, and improve quality of life. However, little is known about patient-level factors influencing ratings of healthcare plans or providers by survivors. **Methods:** This study used ratings provided by cancer survivors in the Consumer Assessment of Healthcare Providers and Systems (CAHPS) Medicare Survey linked to data from NCI's Surveillance, Epidemiology, and End Results (SEER) Program (SEER-CAHPS). CAHPS data on self-reported general and mental health status and three rating categories (overall care [OC], physician [MD], and healthcare plan [HP]) were linked to SEER data on patient sociodemographics and cancer characteristics. Medicare beneficiaries diagnosed with cancer in SEER regions 1997-2011 who participated in the CAHPS Medicare Survey at least one year after cancer diagnosis were included. The study included only individuals alive at least one year following CAHPS survey completion, age $>$66, and diagnosed with non-metastatic breast, colorectal, lung, or prostate cancer. **Results:** We identified 23,969 cancer survivors with linked SEER-CAHPS data. Higher self-rated general health was largely associated with higher ratings for OC, MD, and HP for all four included cancer types. However, other factors significantly associated with ratings tended to differ by both rating category and cancer type (see table). Time since diagnosis and type of Medicare plan (FFS vs. HMO) were not significantly associated with any ratings. **Conclusions:** Beyond self-rated general health, survivor characteristics predicting higher ratings varied substantially by cancer and rating type. These results suggest that the experience of care among cancer survivors is diverse and is significantly influenced by their cancer type. Efforts to improve care for cancer survivors will need to be tailored for each survivor group.

Significant (p<0.01) predictors of higher (+) or lower (-) CAHPS ratings.

Using survivorship care plans (SCP) to improve cancer communication and care coordination. *First Author: Deborah Mayer, UNC Chapel Hill Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: There is a need for closer collaboration between oncologists and primary care providers (PCP) to improve survivorship care. However, PCPs often feel unprepared to manage survivor needs. We conducted a pilot study to evaluate SCP +/- a coordinated PCP visit effect on confidence in survivorship care for patients (pt) and PCP. **Methods:** Pts completed baseline measures and then received a SCP after completing curative treatment during a scheduled post-treatment visit; half were randomized to attend a PCP visit within 30 days to review the SCP. Pre-Post measures for pts and PCPs included Confidence in Survivorship Information (CSI), Assessment of Survivor Concerns (general and cancer worries), Expectations for Care, and Patient Activation Measure. Wilcoxon signed-rank and rank sum tests were used for comparisons. **Results:** Pts (n = 34) were male (65%), age 57 (29-73), Caucasian (82%), and married (79%). PCPs (N = 30) were male (50%), age 48 (26-67), Caucasian (83%) with 19.5 years in practice (range 2-39); 52% were in family medicine. Patient: After receipt of the SCP, all pts had improved knowledge about next steps ($p = 0.06$) and less contradictory information about care ($p < .0001$). CSI and concerns improved after SCP receipt ($p < 0.0001$). While no significant differences at baseline, SCP benefits were greater in highly activated patients (n = 26) who had more CSI ($p = 0.008$) and less concerns ($p = 0.007$) than lower activated patients (n = 8). The general worry score rose for the controls and decreased for the intervention group ($p = 0.05$). At follow-up, most patients (82%) discussed with their oncologist being followed by them for cancer but only 32% discussed this with their PCP. Provider: PCPs reported improved CSI ($p = 0.001$) after receiving the SCP. They agreed it was their role to provide non-cancer related health care but were less clear about cancer surveillance and screening. Only 30% had discussions with pts' other providers over who would follow cancer issues. **Conclusions:** SCP led to greater benefits for highly activated patients in CSI and concerns about cancer care; survivors who had a PCP visit after receiving the SCP had fewer worries than controls. PCP also had improved confidence in survivorship care after SCP receipt. Clinical trial information: UNC HENC LCCC 1325.

9581 Poster Session (Board #240), Sat, 1:15 PM-4:45 PM

Cancer patients' attitudes, knowledge, and preferences for smoking cessation (SC). *First Author: Lawson Eng, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Smoking tobacco by cancer patients can lead to poorer treatment outcomes, prognosis and quality of life. We evaluated ambulatory cancer patients' understanding of SC. **Methods:** 295 lung and head and neck cancer (HNC) patients (85% curative) at any point in their disease course were surveyed cross-sectionally about their knowledge on the effect of smoking on cancer treatment/prognosis and their interest/preferences towards SC. Multivariate logistic regression analyses identified predictors of knowledge gaps and interest in SC. **Results:** 52% of patients had HNC; 31% smoked at diagnosis, 35% were ex-smokers. Half of patients reported being unaware that continued smoking negatively impacts cancer surgery (48%), radiation (57%), chemotherapy (49%) and treatment efficacy (55%); some patients were unaware it impacted prognosis (38%) and second-primary risk (36%). This lack of knowledge was not associated with stage, specific treatments, or SC. Compared to HNC, lung cancer patients more likely believed that continued smoking negatively impacted surgery (aOR = 1.82, 95% CI[1.06-3.10]), efficacy (aOR = 2.10[1.26-3.50]), prognosis (aOR = 2.29[1.20-4.40]) and second-primaries (aOR = 2.02[1.05-3.89]). Receiving any recent (< 3 months) treatment was associated with believing that smoking negatively impacts treatment ($aOR_{radiation}$= 2.34[1.36-4.04], aOR_{chemo}= 1.73[1.05-3.44]). Although 75% felt a SC program would be beneficial and 67% felt it should be part of routine cancer care, only 43% of smokers at diagnosis wished to take part; mainly lung cancer patients (aOR = 5.14[1.79-14.80]) and early-stage cancer patients (aOR = 3.42[1.11-10.50]). 51% preferred discussing SC at their first visit, 52% through a smoking counsellor, and 93% preferred same-day programs with their clinic visits. 50% of patients uninterested in a SC program described wishing to quit on their own. **Conclusions:** Cancer patients undergoing treatment were more likely to feel that smoking can impact treatment; interventions during this time may improve SC rates. Compared to lung cancer, HNC patients were less aware of the impact of smoking on outcomes, and less interested in SC programs.

9582 Poster Session (Board #241), Sat, 1:15 PM-4:45 PM

Degradation of extracellular matrix measured in serum for predicting mortality risk in women diagnosed with cancer: The Prospective Epidemiologic Risk Factor (PERF I) study. *First Author: Nicholas Willumsen, University of Southern Denmark, Odense, Denmark*

Background: Extracellular matrix (ECM) turnover mediated by matrix metalloproteinase (MMP) has been speculated to be associated with cancer diagnosis and mortality. No tools have so far been able to quantify this. Degradation of ECM is part of the malignant changes that drives cancer. The most abundant ECM protein is type I collagen. MMP mediated degradation of type I collagen in serum can be quantified by the novel C1M ELISA assay. The aim of the current study was to investigate whether MMP mediated ECM degradation (C1M) was predictive of cancer mortality in a large prospective study. **Methods:** In the period 1999-2001, 5,856 women aged 60-85 participated in the Prospective Epidemiologic Risk Factor (PERF I) study. Demographics and serum samples were collected at time of enrollment. Cancer diagnoses, cause and time of death were obtained from Danish registries ultimo 2014. Serum C1M levels were assessed by ELISA and divided into quartiles (Q1-Q4). Hazard ratios (HR) for all-cause and cancer-specific mortality were determined by Cox-regression analysis and adjusted for common risk factors: age, smoking, alcohol intake, exercise and BMI. Women deceased >3 years after enrollment was excluded from analysis. **Results:** Within 3 years from PERF I enrollment subjects with high serum C1M levels at baseline showed significant increased mortality (see Table). The 3-year HR for all-cause mortality and cancer-specific mortality was >2 when comparing Q1 to Q4 for all women. Women diagnosed with cancer (n=1280) had an HR for all-cause mortality of >2.5 compared to cancer survivors. Adjusting for common confounders did not change significance. **Conclusions:** MMP-mediated degradation of the ECM was predictive of cancer mortality by 2.3 fold, and predicted for mortality for cancer patients with >2.5-fold within 3 years of follow-up.

Cohort	All		With cancer diagnosis
Mortality	All cause	Cancer specific	All cause
n, total	4408	4333	1280
n, death within 3 years from enrollment	187	112	112
HR (95% CI), C1M Q4 relative to Q1, p-value	2.08 (1.30-3.33), p=0.0024	2.31 (1.27-4.19), p=0.0064	2.59 (1.45-4.63), p=0.0014

9583 Poster Session (Board #242), Sat, 1:15 PM-4:45 PM

Outcomes and predictors of hospital mortality in metastatic cancer patients receiving life sustaining treatments (LSTs). *First Author: Kah Poh Loh, Baystate Medcl Ctr, Springfield, MA*

Background: Hospital mortality for patients with metastatic cancer is high, especially for those who receive LSTs. Information on predicting the probability of surviving the hospitalization will help patients and clinicians make an informed decision. **Methods:** We used the 2010 California Healthcare Cost and Utilization Project - State Inpatient Database to identify metastatic cancer patients (≥18 years). Using ICD-9-CM diagnosis codes, we limited the dataset to patients receiving LSTs (mechanical ventilation, tracheostomy, PEG tube, TPN and acute use of dialysis). We described characteristics and outcomes in patients who survived hospitalization and who did not. We used multivariate logistic regression models to identify predictors for hospital mortality. **Results:** We identified 9,438 admissions among metastatic cancer patients who received LSTs. Mean age (65 years) and gender distribution were similar in both groups. Hospital mortality was 33%. Of those who survived, 31% were discharged to acute or post-acute facilities. Other outcomes are listed below. Predictors of hospital mortality included non-white race, unscheduled admissions, infectious, cardiovascular and circulatory or pulmonary diagnosis (vs. cancer-related) and greater burden of comorbidities. Comorbidities including ESRD (OR 2.03, 95% CI 1.12-2.94) and liver disease (OR 1.94 95% CI 1.55-2.33) were significantly associated with hospital mortality. Compared to lung cancer, colorectal (OR 0.32, 95% CI 0.26-0.38) and GU (OR 0.58, 95% CI 0.46-0.70) cancers were less likely to die in the hospital. Admissions with DNR status were strongly associated with hospital mortality (OR 2.32, 95% CI 2.01-2.63). **Conclusions:** Patients with metastatic cancer who survived in the hospital had longer LOS and one-third of them were discharged to facilities. Predictors of hospital mortality include lung cancer, ESRD, liver disease, DNR status, higher co-morbidity score and an unscheduled admission.

Outcomes	Died (n=3055)	Alive (n=6273)	P-value
Comorbidity score[a]	3.1 (2.3)	2.5 (2.2)	<0.0001
Total charge per patient[b] ($100,000)	1.5 (2.1)	1.5 (1.9)	<0.01
Length of stay[a] (days)	13.4 (17.0)	15.5 (14.8)	<0.0001

a Mean (SD). b Median (IQR).

9584 Poster Session (Board #243), Sat, 1:15 PM-4:45 PM

Treatment-specific risks of second malignancy and cardiovascular disease in Hodgkin lymphoma survivors. *First Author: Simone de Vries, Department of Psychosocial Oncology and Epidemiology, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Hodgkin lymphoma (HL) survivors are at increased risk to develop late treatment-related complications, including second malignant neoplasms (SMNs) and cardiovascular disease (CVD). Research to date has focused on separate risk estimates and therefore, we aimed to assess the combined risk of developing SMN and/or CVD. **Methods:** Our multicenter cohort comprised 2,480 5-year HL survivors, treated before age 51 between 1965 and 1995. CVD endpoints (coronary heart disease [CHD], cardiomyopathy and congestive heart failure [HF], and valvular heart disease) were assessed through general practitioners. Data on SMN were derived from linkage with the Netherlands Cancer Registry. Standardized incidence ratios (SIRs) were estimated to compare SMN and CVD risk with the general population. Cumulative incidences of SMN and/or CVD were calculated with death from other causes as competing risk. Treatment-specific risks of developing SMN and/or CVD were quantified using Cox regression analysis. **Results:** After a median follow-up of 22 years, we identified 874 SMNs and 1368 CVDs. 1246 patients developed ≥ 1 major event, of whom 276 developed both SMN and CVD. HL survivors had a 5.2-fold increased SIR of any SMN (95%CI: 4.8-5.6), compared to the general population, corresponding to 141 excess cases/10,000 person-years. The SIRs of CHD and HF were 3.5 and 7.8, respectively (95%CI: 3.2-3.9 and 6.8-8.8), resulting in 83 and 60 excess cases/10,000 person-years. After 40 years, at a median attained age of 60 years, the cumulative incidence of SMN or CVD was 73.3% (95%CI: 70.6-75.7), whereas 22.5% (95%CI: 19.8-25.3) of patients had developed both events. Both supradiaphragmatic RT (Hazard Ratio [HR]: 2.6, 95%CI: 2.1-3.1) and anthracycline-containing CT (HR: 1.5, 95%CI: 1.3-1.7) independently increased the risk of SMN and/or CVD. Supradiaphragmatic RT was associated with a strongly increased (HR: 4.4, 95%CI: 2.6-7.7) risk of developing both SMN and CVD. **Conclusions:** HL survivors experience a high disease burden during follow-up, with the cumulative incidence of SMN and/or CVD rising to 73% after 40 years from initial treatment. Supradiaphragmatic RT most strongly increased this risk.

9585 Poster Session (Board #244), Sat, 1:15 PM-4:45 PM

Sexual morbidity and unmet needs among members of a metastatic breast cancer registry. *First Author: Joanne S. Buzaglo, Cancer Support Community, Research and Training Institute, Philadelphia, PA*

Background: An estimated 155,000 people are living with metastatic breast cancer (MBC) in the US. As the duration of survival increases, quality of life needs become more salient. Women treated for MBC often report adverse sexual effects, yet many surveys suggest that oncology providers rarely discuss sexual issues. Our objective was to study the impact of MBC on sexual morbidity. **Methods:** Since March 2013, we registered 909 people living with MBC to the Cancer Experience Registry: MBC, an online initiative designed to study the psychosocial impact of MBC. 599 registrants completed questions about sexual morbidity and a cancer-related distress screening tool, including a depression subscale. The sample was predominantly Caucasian (91%), well educated (69% had college degree), with a median age of 56 years. Median time since MBC diagnosis was 3 years. **Results:** Overall, 71% reported MBC negatively impacted their sexual life, and 50% reported sexual activity was a source of distress. Specifically, 80% reported they had no interest in sex, 76% reported vaginal dryness, 68% had pain during or after sex, 64% had difficulty having an orgasm, 71% felt anxious about having sex, and 64% did not enjoy sex. Having no interest in sex ($p = 0.014$), difficulty having an orgasm ($p = 0.020$), and feeling anxious about sex ($p = 0.002$) were significantly more common among those at risk for depression. Difficulty having an orgasm was more common among women concerned about body image ($p = 0.001$). More than half (59%) felt they could talk to a member of their health care team about sexual concerns, yet only 20% reported that a member of their health care team ever asked about sexuality. Only 17% sought treatment for sexual dysfunction, and 39% said they would never go to a mental health expert for sexual counseling even if it was free. **Conclusions:** MBC has a significant impact on sexual health. Patients report substantial sexual morbidity which is associated with symptoms of mood disorder. The direction of the association is unclear, and should be studied in prospective surveys. More efforts are needed in oncology settings to screen for sexual problems in people with MBC and make appropriate referrals for care. Research on effective treatment programs is also lacking.

9586 Poster Session (Board #245), Sat, 1:15 PM-4:45 PM

QOL at 3 years after diagnosis in aggressive lymphoma survivors. *First Author: Carrie A. Thompson, Mayo Clinic Rochester, Rochester, MN*

Background: Patients with aggressive lymphoma are potentially curable, but longer-term effects of treatment may adversely impact quality of life (QOL). We examined QOL scores at baseline enrollment and 3 year follow-up in survivors of aggressive lymphoma. **Methods:** Newly diagnosed lymphoma patients were prospectively enrolled within 9 months of diagnosis in the University of Iowa/Mayo Clinic SPORE Molecular Epidemiology Resource (MER) and systematically followed. We measured baseline QOL at time of enrollment and at 3 years after diagnosis with the Functional Assessment of Cancer Therapy-General (FACT-G) scale. This scale measures well-being (WB) in 4 QOL domains—physical (PWB), social/family (SWB), emotional (EWB), functional (FWB)—along with a total FACT-G score (TOT). For this study, we defined "survivor" as alive at 3 year follow-up with no active disease or treatment within the previous year. **Results:** From 2002-2009, 1902 patients with aggressive lymphoma were prospectively enrolled. Of these, 477 completed QOL questionnaires at both baseline and 3 years and met the study definition of survivor. Median age at diagnosis was 62 years (range 18-87) and 58% were male. Distribution of NHL subtypes were 61% DLBCL, 12% mantle cell, 10% FL grade III, 9% T cell, and 8% other. Each FACT-G subscale was significantly higher than assessment at diagnosis with the exception of SWB, which was significantly lower (all $p < 0.0001$), with mean changes ranging from -1.8 (SWB) to 7.0 (TOT) points. After adjusting for baseline QOL, there was a modest association between older age and smaller change from baseline QOL for TOT ($p = 0.021$), PWB ($p = 0.012$), and FWB ($p = 0.001$); otherwise there were no other clinical associations between change in TOT from diagnosis to 3 years (all $p > 0.11$). Compared to the US general population, 3-year survivors have significantly higher QOL (EWB $p = 0.039$, all other $p < 0.0001$), while their QOL at baseline was similar to the general population for FWB ($p = 0.59$), higher for SWB ($p < 0.0001$) and TOT ($p = 0.0033$), and lower for PWB ($p = 0.0003$) and EWB ($p < 0.0001$). **Conclusions:** In survivors of aggressive lymphoma, QOL improves over time and is higher than the QOL for the US general population at 3 years post-diagnosis.

9587 Poster Session (Board #246), Sat, 1:15 PM-4:45 PM

Employment and quality of life (QOL) in human papillomavirus-related (HPV+) oropharynx cancer treated with definitive chemoradiation (CTRT). *First Author: Shrujal S. Baxi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HPV+ oropharynx cancer affects younger patients and is often treated with CTRT. We aimed to assess the impact of CTRT on employment and QOL in these patients. **Methods:** We completed a cross-sectional survey of clinically cancer-free patients with advanced, M0, HPV+ oropharynx cancer ≥ 1 year from primary CTRT. We assessed employment status using study-specific items. QOL was measured using the EQ5D and EORTC QLQ-H&N35. We examined the association between sociodemographic and clinical factors on employment outcomes and QOL at time of survey. **Results:** 129 patients (mean 23 months. post-CTRT) completed the survey. Median age was 57 years (range 25-76); 91% were male; 56% had an ECOG functional status score of 0 (vs1/2); 83% had stage IVA disease. High-dose cisplatin was the most common chemotherapy (63%). 53% reported at least one problem on the EQ5D, most commonly pain (29%) and anxiety (24%). Despite high rates of dry mouth (88%), thick saliva (69%), coughing (54%) patients reported high overall QOL, as measured by EQ5D. At diagnosis, 107 (83%) patients were employed including 23/23, 58/65 and 26/41 of patients ages < 50, 50-59, and > 60 years, respectively ($p < 0.001$); 80% were professionals or managers. Employment at diagnosis did not vary by pretreatment functional status. During CTRT, 10 (9%) stopped working and did not return, 74 (69%) took time off but returned to work, 20 (19%) reduced responsibilities but kept working, and 3 (3%) continued working. Of the 74 patients who took time off, median time to return to work was 14 weeks (interquartile range 8-24 weeks). There was no significant difference in time off by chemotherapy type, ECOG status, or age. At time of survey, 75% were employed. Current employment status did not vary by overall QOL at the time of survey. **Conclusions:** Despite persistent effects of CTRT, survivors of HPV+ oropharynx cancer reported good QOL. CTRT interrupted employment in the majority of these patients, but most returned to work. More efforts are needed to evaluate the determinants of employment, return to work and the socioeconomic burden of CTRT in this working-age population.

9588 Poster Session (Board #247), Sat, 1:15 PM-4:45 PM

Young and strong: A randomized study to improve care for young women with breast cancer. *First Author: Ann H. Partridge, Dana-Farber Cancer Institute, Boston, MA*

Background: Research has revealed that needs of young women with breast cancer are not being met, particularly fertility concerns. A QOPI audit found rates of attention to fertility of < 30% in practices. We conducted a cluster-randomized study to determine the effect of an exportable education and support intervention for young women with breast cancer (YWI) and their oncologists. **Methods:** Sites were randomized 1:1 to YWI or a physical activity intervention (PAI) stratified by academic or community; up to 15 women age < 45 with newly diagnosed breast cancer were enrolled at each academic site, 10 at community sites. The primary endpoint was attention to fertility prior to systemic treatment by medical record review. Pts were surveyed at 3, 6, and 12 mos; physicians surveyed after enrolling their first patient. The study was designed to have 80% power to detect an improvement in attention from 10% with PAI to 38% with YWI using General Estimating Equations, two-sided alpha = 0.05. **Results:** 467 patients across 54 sites (14 academic, 40 community) enrolled between 7/2012 -12/2013. Median age at dx was 40yrs (range 22-45); patient characteristics did not vary by arm. Attention to fertility by 3 mos after enrollment was observed in 55% YWI pts and 58% on PAI (p = 0.88). Rates were strongly correlated with age (p < 0.0001), highest in pts < 30 (100% YWI, 94% PAI) vs. 30-40 (68% YWI, 59% PAI) vs. 40-45 (42% YWI, 52% PAI) although interaction testing age x intervention was not significant (p = 0.12). At 3 mos, pts rated YWI/PAI as valuable in educating them (64% YWI, 63% PAI). Of responding providers (145/171, 85%), most reported YWI/PAI educated providers (55% YWI/51% PAI) and pts (79% YWI, 77% PAI), and improved care (79% YWI, 60% PAI). **Conclusions:** This study failed to show improvement in attention to fertility with YWI vs. PAI. Rates were high in both arms, especially in women < 40 and the study had limited power to detect an age-dependent effect. Pts and providers valued both interventions. This work serves as a novel model to educate and support patients and providers to improve care. Clinical trial information: NCT01647607.

9589 Poster Session (Board #248), Sat, 1:15 PM-4:45 PM

A feasibility study of an electronic interface between Internet-based survivorship care plans and electronic medical records (EMR)/tumor registries. *First Author: Christine Hill-Kayser, University of Pennsylvania, Philadelphia, PA*

Background: SCP are recommended for all cancer survivors by the Institute of Medicine and Commission on Cancer (CoC). Barriers to implementation include time/ resource limitations, survivor access, and concerns about accurate treatment summary information. This study was performed to evaluate the feasibility of interface development between an SCP and an EMR and cancer registry. **Methods:** An information technology (IT) application was developed to extract data from the EMR in use at Penn Medicine (EPIC), as well as from the registry at Baptist Memorial Hospital in Memphis, a community hospital utilizing the CoC Rapid Quality Reporting System (RQRS). Data were transferred via XML tunnel to auto-populate an Internet-based tool for creation of SCP (LIVESTRONG Care Plan) that had been previously used for creation of more than 35,000 plans and available at www.oncolink.org / www.livestrongcareplan.org. **Results:** Design phase involved IT staff at Penn Medicine, RQRS, and OncoLink. Data (demographics, surgeries, chemotherapy drugs, radiation site) were extracted from EMR/RQRS, de-identified, and tunneled to the OncoLink platform, without transfer of PHI. Care plans were created and linked to EMR/registry via global unique identifiers; after auto-population and creation, SCP were tunneled back to the EMR to become part of the medical record, with the entire process occupying less than one minute. During clinical testing at the EMR site, SCP were created by nurse practitioners during scheduled clinic visits. Overall, 147 survivors were screened, 146 eligible, and 89 received SCP. Of these, 60 received breast cancer SCP, 27 colorectal SCP, and 2 both. Survivors were 85% women, 58% Caucasian, median age 56y (24-81y). **Conclusions:** This is a feasible and rapid solution for the auto-population of SCP with EMR and/or registries, taking less than 1 minute to complete. It represents a future methodology through which widespread implementation of SCP may be undertaken. Future directions include further clinical testing, as well as assessment of provider perceived usefulness, ease of use, and integration into routine clinical care.

9590 Poster Session (Board #249), Sat, 1:15 PM-4:45 PM

Failure to follow directions for prescription medications to save money among cancer survivors. *First Author: Ahmedin Jemal, American Cancer Society, Atlanta, GA*

Background: To examine the patterns of not following prescription medication due to financial reasons among nonelderly and elderly cancer survivors in the US. **Methods:** The 2011 to 2013 National Health Interview Survey data was used to identity recently diagnosed (≤ 1 year; n = 639) and previously diagnosed (1 year; n = 8,292) cancer survivors, and individuals without a cancer history (n = 93,058). Survey questions about not following prescription medication asked whether a participant took the following measures to save money: 1) skipped medication doses; 2) took less medicine; 3) delayed filing a prescription; 4) asked doctor for lower cost medication; 5) bought prescription drugs from another country; and 6) used alternative therapies. All analyses were stratified by age (nonelderly: 18-64; elderly: 65+). Multivariable logistic regressions were fitted to estimate the adjusted percentage of individuals reporting not following prescription medication controlling for age, sex, race/ethnicity, marital status, education, number of comorbidities, health insurance, and geographic region. **Results:** Previously diagnosed cancer survivors were more likely to report not following prescription medication in order to save money compared to individuals without a cancer history, primarily among nonelderly cancer survivors (28.4% vs 22.8%), i.e. skipping medication doses (8.6% vs 6.7%), took less medicine (9.3% vs 7.0%), delayed filing a prescription (11.7% vs. 8.8%), asked for lower cost medicine (22.5% vs 17.2%), bought prescription drugs from another country (2.5% vs 1.9%), and used alternative therapies (6.3% vs 5.0%) to save money (all p < .05). In contrast, all recently diagnosed cancer survivors were not statistically different from individuals without a cancer history in terms of not following prescription medication due to financial reasons. **Conclusions:** Compared to nonelderly individuals with no history of cancer, nonelderly long time cancer survivors were less likely to follow their prescription medication as needed in order to save money.

Prediction models of smoking cessation in lung and head and neck cancer patients: Role of second-hand smoke (SHS) exposure. *First Author: Geoffrey Liu, Ontario Cancer Institute, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Some cancer survivorship programs incorporate components of healthy lifestyle behavior modification. We evaluated the role that various clinical variables and smoking habits play in predicting which cancer survivors are more likely to quit smoking. Such knowledge may help with resource allocation within these programs. **Methods:** We focused on lung cancer (LC) and head and neck cancer (HNC) patients as these have the highest active smoking rates among all cancer sites at Princess Margaret Cancer Centre. Patients from 2006-12 completed questionnaires at diagnosis (baseline) and follow-up (median 2 years apart) that assessed smoking status. Baseline clinical and demographic information was obtained. Multivariate logistic regression analysis evaluated the association of smoking and clinical variables at diagnosis to subsequent smoking cessation. Predictive models were assessed for their discriminatory capabilities (concordance-index or area under the curve, AUC). **Results:** In this cohort, 261/731 LC and 145/450 HNC patients smoked at diagnosis; subsequent overall quit rates were 69% and 50% respectively. Univariate factors associated with smoking cessation included having LC (p = 0.001), being married (p = 0.02), having at least completed secondary school (p = 0.049), having less cumulative smoking (pack-years; p = 0.004), and having adequate social support (p = 0.009). In multivariate modeling, fewer pack-years, having LC and being married remained significant and this predictive model was associated with moderate predictive ability (AUC 0.68 [95% CI: 0.62-0.73]. However, the addition of either SHS household exposure (AUC 0.76 [0.71-0.81]) or spousal smoking (AUC 0.77 [0.71-0.82]) further improved the predictive model. The addition of SHS variables in other exploratory predictive models of smoking cessation improved those models in a similar manner. Similar improvements in prediction were seen in subgroup analysis of LC and HNC. **Conclusions:** SHS exposure significantly improves the predictive abilities to determine which patients who smoked at their cancer diagnosis would subsequently quit. Cessation programs may benefit from allocating resources accordingly.

9592 Poster Session (Board #251), Sat, 1:15 PM-4:45 PM

Sexual and marital dysfunction in women with gynecologic cancer: A multi-institutional, cross-sectional trial. *First Author: Saketh Guntupalli, University of Colorado Anschutz, Aurora, CO*

Background: Sexual dysfunction is a serious issue for women with gynecologic cancer. This study examines sexual function following cancer treatment and its impact on marital relationships. **Methods:** A multi-institutional study of women with gynecologic cancer was conducted with a 181item survey of instruments to assess sexual/marital dysfunction. Sexual dysfunction was measured by change in the Female Sexual Function Index (FSFI). A significant decline in sexual function was determined to be 7.6 point decrease using a Reliable Change Index Statistic (RCIS). Marital relationships were assessed using Intimate Bond Measure (IBM). Standard statistical analyses were used. **Results:** A total of 290 women were enrolled. Cancer diagnoses included uterine/endometrial (41%), ovarian (37%) cervical/other (22%). Treatments included surgery (92%), chemotherapy (62%), and radiation (30%). Among all women, sexual function declined from a score of 23.2±11.2 prior to diagnosis to 15.2±10.2 after treatment ($P<$ 0.001) and sexual activity decreased from 6.1±6.8 to 2.6±4.9 times/month following treatment ($P<$ 0.001). Sexual dysfunction after treatment was associated with younger age (51.8±12.2 to 57.3±12.1, $P=$ 0.004), being premenopausal (27% vs 13.5%, OR 2.38, 95%CI 1.23-4.71), chemotherapy (69.8% v 51.9%, OR 2.05, 95%CI 1.10-3.84), and being in a committed relationship (97.3% vs 82.7%, OR 7.43, 95%CI 1.67-33.11). IBM scores, relationship length, surgery and radiation therapies, cancer site diagnosis/stage and race were not associated with sexual dysfunction. Women with sexual dysfunction reported decreased sexual activity (Δ5.3±4.8 vs Δ2.1±3.8, $P<$ 0.001) and increased relationship counseling, 13.7% vs 4.9%, (OR 3.11, 95%CI 1.02-9.53) compared to those with no impairment. **Conclusions:** Women with gynecologic cancer are at significant risk for sexual dysfunction. Young, premenopausal women, chemotherapy, and women in committed relationships are at particularly risk for these issues. Patients with sexual dysfunction reported greater decline in sexual activity and sought counseling following treatment. Practitioners should address these issues and engage patients during treatment.

9593 Poster Session (Board #252), Sat, 1:15 PM-4:45 PM

National data on sorafenib therapy adherence for veterans with hepatocellular carcinoma. *First Author: Sheetal Malhotra, North Central Bronx Hospital, Bronx, NY*

Background: Medication adherence can help improve disease progression and survival. One way to improve adherence is to facilitate ease of administration, i.e., oral vs. intravenous. Our study of veterans with hepatocellular cancer (HCC) on Sorafenib therapy aimed to assess the factors that affect adherence and overall survival. **Methods:** A retrospective analysis of national level data from 2007 to 2013 collected by 120 VA medical centers across the country on diagnosing and treating patients with cancer was used for the study. Data on age at diagnosis, gender, race, marital status, comorbidities concurrent medication use, days from diagnosis to treatment, days medication was supplied for, and medication refills were obtained. Chemotherapy adherence was calculated from the medication supply and refill information. Survival till time of death or endpoint was also calculated. Data were analyzed through descriptive analysis, Chi Square tests, t-tests, Pearson correlations and Regression analysis to assess factors related to adherence and survival as well as differences in adherence and survival. **Results:** In our study, about 2,778 were prescribed Sorafenib. Most veterans were males (99%) with a mean age of 62 years. Of these, 2006 (72%) were adherent to the treatment in some way. Adherence was associated significantly with ethnicity ($P < 0.001$). Those adherent to their therapy were older at time of diagnosis compared to those who were not adherent (62.4 years vs. 61.4 years, $t = 3.041$, $P < 0.01$). There were no significant associations with marital status, gender, or presence of comorbidities. Increased adherence percentage was negatively related to cost of treatment ($r = -0.14$, $P < 0.001$) and positively related to overall survival ($r = 0.353$, $P < 0.001$). The number of concurrent medications (OR 0.969, 95% CI = 0.95- 0.99, $P < 0.01$) and total number of treatment days were (OR 0.997, 95% CI = 0.997- 0.998, $P < 0.001$) significantly related to chemotherapy adherence. In regression analysis, overall survival was also related to total treatment days ($r^2 = 0.503$, $P < 0.001$). **Conclusions:** Understanding and targeting factors that affect chemotherapy adherence can affect disease outcomes, including survival.

9594 Poster Session (Board #253), Sat, 1:15 PM-4:45 PM

A phase II randomized, double-blind, placebo-controlled study to evaluate naldemedine for the treatment of opioid-induced constipation (OIC) in patients with cancer pain. *First Author: Narikazu Boku, St Marianna University School of Medicine, Kawasaki, Japan*

Background: While opioid analgesics play a central role in managing cancer pain, opioid-induced constipation (OIC) is one of the most common side effects. Naldemedine is a novel peripherally-acting μ-opioid receptor antagonist (PAMORA) being developed to treat OIC. **Methods:** This study assessed naldemedine doses of 0.1, 0.2, or 0.4 mg once-daily (QD) for 2 weeks in cancer patients with OIC. Eligibility criteria included: regular opioid use for $\geq$ 2 weeks, $\leq$ 5 spontaneous bowel movements (SBMs) during a 14-day screening period despite laxative use. The primary endpoint was the change from baseline in frequency of SBM/week during the 2-week treatment period. The SBM responder rate, defined as $\geq$ 3 SBMs/week and an increase from baseline of $\geq$ 1 SBM/week, was a secondary endpoint. Safety assessments included adverse events (AEs), Clinical Opiate Withdrawal Scale (COWS) questionnaire and 11-point Numerical Rating Scale (NRS) pain questionnaire. Patients scored bowel movement (BM) consistency using the Bristol Stool Scale; BMs with a score of 7 were to be reported as AEs of diarrhea. The primary analysis was conducted using ANCOVA with frequency of SBM/week at baseline as a covariate. The planned total sample size was 212 (53 per group) to ensure at least 80% power in the two-sample t-test with a level of significance of 0.05 (two-sided). **Results:** A total of 227 patients were randomized to one of three naldemedine doses or placebo (PBO). The least-squares mean of change from baseline in frequency of SBM/week was 1.50 for PBO, 3.43 for 0.1 mg ($P = 0.0465$), 4.75 for 0.2 mg ($P = 0.0007$), and 7.29 for 0.4 mg ($P < 0.0001$). All three groups demonstrated a significantly higher SBM responder rate vs. PBO. The most common AE was diarrhea (25.0%, 26.8%, 39.7% and 51.8% in PBO, 0.1, 0.2, 0.4 mg groups, respectively). Most AEs of diarrhea were mild. No clinically meaningful changes in NRS scores or COWS scores were observed. **Conclusions:** In this study naldemedine was effective and generally well tolerated in patients with cancer pain with OIC. Based on its efficacy and safety profile, 0.2 mg QD was selected as the dose for phase 3 studies. (Clinical trial information: JapicCTI-111510) Clinical trial information: JapicCTI-111510.

9595 Poster Session (Board #254), Sat, 1:15 PM-4:45 PM

Can pregabalin prevent paclitaxel-associated neuropathy?: A pilot trial. *First Author: Shivani S. Shinde, Mayo Clinic, Rochester, MN*

Background: Paclitaxel, a commonly used chemotherapeutic drug, can cause an acute pain syndrome (P-APS), considered to be an acute form of neuropathy, and chronic chemotherapy-induced peripheral neuropathy (CIPN). There are no good means to prevent and/or treat these prominent clinical problems. The purpose of this randomized, placebo-controlled, double-blinded pilot study was to obtain pilot data to support or refute the utility of pregabalin for the prevention of P-APS and CIPN, based on anecdotal reports suggesting that gabapentinoids were helpful in this setting. **Methods:** Patients scheduled to receive adjuvant weekly paclitaxel (80 mg/m2/dose) were randomized to receive pregabalin 75mg or a placebo, twice daily, starting on the first night of chemotherapy and continuing during the 12 weeks of chemotherapy. Patients completed the EORTC QLQ-CIPN20 questionnaire at baseline, prior to each dose of paclitaxel, and monthly for 6 months post treatment. Patients completed an acute pain syndrome questionnaire daily, for 6 days after each dose of paclitaxel. The primary endpoint was to determine the effect of pregabalin on the maximum of the worst acute pain scores for the week following paclitaxel administration for cycle 1. Secondary endpoints included the effect of pregabalin on paclitaxel-induced peripheral neuropathy and pregabalin-associated toxicities. **Results:** 46 patients were randomized; data regarding the acute pain syndrome and CIPN are presented in the Table. There were no differences in pain score or evidence of toxicity differences between the two study arms. **Conclusions:** The results of this pilot trial do not support that pregabalin is helpful for preventing P-APS or paclitaxel CIPN. Clinical trial information: NCT01637077.

P-APS (Pain score over 6 days following initiation of paclitaxel; higher scores are worse)

	Placebo (N = 22)	Pregabalin (N = 19)	p-value
Worse pain: Mean (SD)	3.2 (3)	2.6 (2.5)	0.56
Average pain: Mean (SD)	2.2 (2.6)	2.6 (2.2)	0.48
EORTC CIPN20 Sensory Neuropathy (higher scores represent fewer symptoms)			
	Placebo (N = 22)	**Pregabalin (N = 19)**	**p-value**
Mean (SD)	84.5 (16.7)	88.4 (12.5)	0.46
Median (Range)	90.7 (36.5-100)	91.9 (56.5-100)

Predictors of hand-foot syndrome (HFS) in randomised double-blind, placebo-controlled trial of pyridoxine for prevention of capecitabine induced HFS. *First Author: Yoon Sim Yap, National Cancer Centre Singapore, Division of Medical Oncology, Singapore, Singapore*

Background: Hand-foot syndrome (HFS)is a common side effect of capecitabine, although East Asian patients appear to have better tolerability. **Methods:** This study aimed to evaluate the incidence of grade ≥ 2 HFS in patients receiving pyridoxine versus placebo (primary objective), compare the time to onset of grade ≥ 2 HFS, and identify biomarkers predictive of HFS, including baseline folate and vitamin B12 levels, plus genetic polymorphisms (secondary objectives). Patients starting capecitabine single-agent chemotherapy for breast, colorectal and other cancers in National Cancer Centre Singapore were randomized to receive concurrent pyridoxine (200mg) or placebo daily for a maximum of 8 cycles of capecitabine, with stratification by gender and use in adjuvant/neoadjuvant versus palliative setting. Patients were withdrawn from the study upon development of grade ≥ 2 HFS or cessation of capecitabine. **Results:** The trial was terminated before reaching the original target of 296 patients due to slow accrual. Grade ≥ 2 HFS occurred in 33 of 105 patients (31.4%, 95% CI: 22.6% - 40.3%) receiving pyridoxine compared to 39 of 103 patients (37.9%, 95% CI: 28.5% - 47.2%) receiving placebo (p = 0.329). The median starting dose of capecitabine was 1000mg/m^2 (range 793-1250 mg/m^2) bid in the pyridoxine arm, and 1011mg/m^2 (range 845-1250 mg/m^2) bid in the placebo arm (p = 0.667). The median time to onset of grade ≥ 2 HFS was not reached in patients on pyridoxine, compared to 174 days in patients on placebo (p = 0.677). On multivariate analysis, baseline serum folate (odds ratio 1.27 for every increase of 5nmol/l; 95% CI: 1.10-1.47; p = .001) was associated with increased risk of grade ≥ 2 HFS. Pyridoxine did not significantly decrease the risk compared to placebo (odds ratio 0.50; 95% CI: 0.24-1.03; p = 0.061). Initial dose intensity and baseline red cell folate were associated with increased risk of grade ≥ 2 HFS on univariate, not multivariate analysis. Genotyping with Zhonghua SNP arrays is in progress. **Conclusions:** Pyridoxine did not significantly prevent or delay the onset of grade ≥ 2 HFS. Serum folate was a significant predictor of HFS. Clinical trial information: NCT00486213.

9597 Poster Session (Board #256), Sat, 1:15 PM-4:45 PM

Should all antiemetic guidelines recommend adding a NK_1 receptor antagonist (NK_1RA) in patients (pts) receiving carboplatin (carbo)? Efficacy evaluation of NEPA, a fixed combination of the NK_1RA, netupitant, and palonosetron. *First Author: Karin Jordan, University of Halle, Halle, Germany*

Background: Controversy continues whether a NK1RA should be added to a 5HT3RA + dexamethasone (DEX) in pts receiving carbo, with inconsistent guideline recommendations by NCCN, ASCO, and MASCC/ESMO. It is routine to use a NK1RA for pts receiving cisplatin where a 12%-20% benefit is seen. A subset analysis in 192 pts receiving carbo in a 2009 randomized trial (Rapoport, Supp Care Cancer) indicated a 14% benefit in pts receiving a NK1RA as part of triple antiemetic therapy (no emesis rate: 84%, 95% CI 77-91% versus 70%, 95% CI 59-79% with 2 drugs, p < 0.02). Similar results were seen in other trials. We undertook this post-hoc subset analysis of pts receiving carbo as part of a NEPA Phase 3 trial to determine if NEPA would show a consistent complete response (CR: no emesis/rescue) rate and to examine nausea control. **Methods:** 196 chemotherapy-naïve pts randomized to NEPA + DEX (n = 145) or aprepitant (APR) + PALO + DEX (n = 51) received carbo in cycle 1. CR and no significant nausea (NSN: score ≤25 on 100mm visual analog scale) rates were calculated for all pts and by gender / age for NEPA pts over multiple cycles. **Results:** The overall (0-120h) CR rates for cycles 1-4 were similar for NEPA (80%, 91%, 92%, and 93%) and APR (82%, 88%, 88%, and 90%). Cycle 1-4 NSN rates were also similar (NEPA 84-96%; APR 82-90%). In the NEPA pts, 54% had lung cancer and 21% ovarian; cycle 1 overall CR rates were 77% / 77%, respectively. NEPA results by risk groups are in the Table. **Conclusions:** This subset analysis of pts receiving carbo shows consistent 5-day CR rates with an added NK1RA in this and historical studies; additionally, it documents high control rates of nausea with NEPA even in women and younger pts. Given the consistency of the control rates for added NK1RAs, as seen for NEPA and APR, guideline groups and practitioners should consider giving a NK1RA antiemetic triplet in pts receiving carbo. Clinical trial information: NCT01376297.

Cycle 1	NEPA + DEX	
Overall 0-120h	CR [95% CI]	NSN
All Pts (N = 145)	80% [73, 86]	84% [77, 89]
Females (N = 66)	73% [61, 82]	88% [78, 94]
Males (N = 79)	86% [76, 92]	81% [71, 88]
< 55 years (N = 53)	85% [73, 92]	87% [75, 94]
≥ 55 years (N = 92)	77% [68, 85]	83% [74, 89]

9598 Poster Session (Board #257), Sat, 1:15 PM-4:45 PM

Palonosetron or granisetron for prevention of CINV in patients with breast cancer receiving dexamethasone and fosaprepitant following anthracycline plus cyclophosphamide (AC) regimen. *First Author: Koji Matsumoto, Hyogo Cancer Center, Akashi-shi, Japan*

Background: Superiority of palonosetron to granisetron is uncertain, for patients with breast cancer receiving both steroid and NK1 inhibitor against CINV caused by AC regimen. **Methods:** We conducted a randomized double-blind active-controlled study. 341 chemo-naïve patients treated with AC regimen were randomized 1:1 to either (1) palonosetron 0.75 mg + dexamethasone + fosaprepitant or (2) granisetron 1mg + dexamethasone + fosaprepitant. Stratification factor was age (< / > 55 yrs) and type of anthracycline (epirubicin / doxorubicin). Patients recorded episodes of emesis, nausea and rescue medication using a formed diary during 0 -120 hrs post-chemotherapy. Primary endpoint was complete response (CR = no emesis and no rescue medication) in delayed phase (> 24 -120 hrs). Secondary endpoints include CR in acute (0-24 hrs) and overall (0 - 120hrs) phase. Nausea and emesis in acute, delayed, or overall phase was also evaluated. Treatment comparisons were performed using chi-square test with Yates' continuity correction. **Results:** From Dec. 2012 to Oct. 2014, 326 evaluable patients were enrolled with comparable characteristics across groups; median age 54, 87 % of patients received epirubicin, 71 % of patients were light or no drinkers, 71 % of patients had no motion sickness, and 52 % of patients had morning sickness. CR rates were similar for patients treated with palonosetron and granisetron in delayed (62.3 vs 60.4 %; p = 0.8), acute (75.9 vs 73.2 %), and overall (54.9 vs 54.9 %) phase, respectively. Palonosetron reduced nausea (59.9 vs 72 %; p = 0.029) and emesis (10.5 vs 17.7 %; p = 0.088) in delayed phase. Adverse events occurred at similar rates across both groups. **Conclusions:** Although nausea and emesis in delayed phase was reduced, palonosetron at highest effective dose did not prove superiority to granisetron for prevention of CINV in patients with breast cancer receiving dexamethasone and fosaprepitant following AC regimen. Three drugs combination with steroid, 5-HT3 receptor antagonist, and NK1 receptor antagonist did not achieve CR in almost half of patients in this population. A new class of agents is needed. Clinical trial information: UMIN000008897.

9599 Poster Session (Board #258), Sat, 1:15 PM-4:45 PM

Use of mobile device technology to collect patient-reported symptoms during radiotherapy for head and neck cancer: A prospective feasibility study. *First Author: Aaron David Falchook, NC Cancer Hospital, Chapel Hill, NC*

Background: Accurate assessment of toxicity allows for timely delivery of necessary supportive measures during radiotherapy (RT) treatment for head and neck cancer. The purpose of this prospective trial is to evaluate the feasibility of using mobile device technology to collect daily patient reported symptoms. **Methods:** A HIPAA-secure mobile application was developed to allow patients receiving RT for head and neck cancer to report symptom severity in five domains (fatigue, pain, nausea/vomiting, decreased appetite, anxiety) using the Patient Reported Symptom Monitoring System questionnaire. Patients were asked to report symptoms using a smartphone and/or tablet at least once daily during treatment or more often as needed. Patient surveys regarding use of mobile devices were obtained after completion of RT. Descriptive statistics, linear regression, and Fisher's exact test were used to examine factors associated with symptom reporting. **Results:** 22 patients enrolled and 1 withdrew consent. A total of 921 symptom reports were collected during treatment. Median treatment duration was 45.5 days (interquartile range [IQR] 42-49). The median number of reports submitted per patient was 33.5 (IQR 21-54). Median reporting compliance (defined as number of days with report / duration between enrollment and end of RT) was 71% (IQR 44-81). There were no significant associations between reporting compliance and patient characteristics or symptom severity. Timing of symptom reporting is summarized (Table). Patients reported high levels of satisfaction with use of mobile devices to report symptoms. **Conclusions:** It is feasible and convenient for patients to use mobile devices to continuously report symptoms throughout an entire course of RT for head and neck cancer, including nights and weekends. Future studies will evaluate the impact of mobile device symptom reporting on improving patient outcomes.

Association of severe pain with poor response to opioids, psychological distress, and aberrant drug taking behaviors in a large cohort of cancer patients. *First Author: Vinnidhy Dave, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pain is one of the most feared consequences of cancer. Systematic reviews indicate opioids are effective for cancer pain, but are often under-utilized. At the same time, there is increased societal concern about opioid abuse. Identifying patients with a history of cancer who are at risk for poor pain outcomes is important when considering opioid therapy. The aim of this study was to evaluate associations between pain intensity, analgesic effectiveness, disability, distress and aberrant drug taking in the subpopulation from Memorial Sloan Kettering Cancer Center of a pain clinic registry. **Methods:** At each outpatient encounter, patients completed the Brief Pain Inventory, Condensed Memorial Symptom Assessment Scale (CMSAS) and Current Opioid Misuse Measure (COMM). Though not yet validated in patients with cancer, in other chronic pain populations a COMM score greater than 9 has a positive likelihood ratio for diagnosing opioid misuse/abuse of 3.5. Data analysis performed by International Severity Information Systems, Salt Lake City, UT. **Results:** From 6/18/2011 to 12/10/2014, 1593 of 2085 (76.4%) patients completing 5599 surveys reported continuing pain despite taking opioids. Average pain score was mild (1-4) in 25%, moderate (5-6) in 41%, severe (7-10) in 34%. Those with severe pain reported less relief from their pain medicine, were more disabled (higher pain interference), and had more physical and psychological distress and higher COMM scores (see Table, all p values < 0.001). **Conclusions:** Ambulatory patients with a cancer history who report severe pain despite taking opioids are a challenging management problem. These data suggest they have concomitant disability, physical and psychological distress, and behaviors suggestive of opioid misuse/abuse. To improve their outcomes, more research is needed to understand the causal links between these associations.

Score	Mild	Moderate	Severe
Average pain intensity	3.2	5.5	7.8
Pain relief	62%	54%	45%
Pain interference	4.0	5.6	7.0
Physical symptom distress score, CMSAS	1.5	1.7	1.9
Psychological distress score, CMSAS	1.3	1.6	2.0
COMM score	8.1	8.5	10.7

9601 Poster Session (Board #260), Sat, 1:15 PM-4:45 PM

Minimal clinically important differences in the Edmonton Symptom Assessment Scale in cancer patients: A prospective study. *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ESAS is widely used for symptom assessment in the clinical and research settings. We determined the MCID for improvement and deterioration for each of the 10 ESAS symptoms using the anchor based sensitivity-specificity approach. **Methods:** This multicenter, prospective, longitudinal study enrolled patients with advanced cancer. ESAS was measured at a first palliative care clinic visit and a second visit 3 weeks later. For each symptom, we assessed the Patient's Global Impression (PGI) ("better", "about the same", or "worse") at the second visit as the external criterion. We determined the MCID based on the optimal cutoff for sensitivity/specificity in receiver-operating characteristic (ROC) curve using the Youden's J method. We conducted sensitivity analyses by estimating MCIDs using other anchor-based and distribution-based approaches. The planned sample size was powered to estimate sensitivity/specificity with 80% power at 0.5% significance (accounting for 10 symptoms). **Results:** Among the 796 cancer patients from 6 centers, the average age was 57 (range 19-85), 380 (48%) were female, and the median duration between the 2 study visits was 21 days (interquartile range 18-28 days). The area under the ROC curve varied between 0.70-0.87, suggesting good responsiveness. For all 10 ESAS symptoms, the optimal cutoff based on the ROC curve was ≥ 1 point for improvement and ≤ -1 point for deterioration, with sensitivities of 59%-85% and specificities of 69%-85%. Sensitivity analyses showed similar findings: in within-patient analysis, the MCIDs varied between 0.8 and 2.2 for improvement and between -0.8 and -2.3 for deterioration; in ½ standard deviation distribution approach, MCID varied between 1.2 and 1.6; in standard error of measurement approach, MCID varied between 1.3 and 1.7. Using ≥ 1 as the MCID cutoff, between 27% and 48% of patients experienced a clinical response. **Conclusions:** ESAS was responsive to change. The optimal cutoffs were ≥ 1 point for improvement and ≤ -1 point for deterioration for all 10 ESAS symptoms. Our findings have implications for sample size calculations and response determination.

9602 Poster Session (Board #261), Sat, 1:15 PM-4:45 PM

Safety and efficacy of eltrombopag (EPAG) vs placebo (PBO) for treatment of chemotherapy (CTx)-induced thrombocytopenia (TCP) in patients (Pts) with solid tumors receiving gemcitabine (GEM)-based CTx: A phase 2 study. *First Author: Eric S. Winer, Rhode Island Hospital, Providence, RI*

Background: A phase 1 EPAG study showed favorable results for the treatment of CTx-induced TCP in pts receiving GEM-based CTx. **Methods:** This was a phase 2, blinded, PBO-controlled, multicenter study in adults with solid tumors and TCP receiving ≤6 cycles of CTx. Pts received GEM on days 1 and 8 (every 21 days) and cisplatin on day 1 (or divided dose on days 1 and 8) or carboplatin on day 1, or received GEM alone on days 1, 8, and 15 (every 28 days). Pts were randomized (2:1) to EPAG 100 mg or PBO daily for 5 days before and after day 1 of CTx. **Results:** We report early results of 44 pts randomized to EPAG (n = 31) or PBO (n = 13). Data review with an external, independent physician after ≥ 2 cycles showed no safety concerns. Myelosuppression was the most common adverse event (AE), with lower rates of anemia, neutropenia, and TCP seen with EPAG versus PBO (Table). In the EPAG arm, 23% of patients developed TCP (all grade 3/4) vs 46% (31% grade 3/4) of PBO patients. Proportionately fewer serious AEs (SAEs)/deaths occurred with EPAG than with PBO. CTx dose delays/reductions for any reason, specifically for TCP, were lower for EPAG pts than PBO pts, with a greater difference shown in later treatment cycles. **Conclusions:** These early safety and efficacy results are encouraging, with a potential trilineage benefit as seen in other EPAG studies. Enrollment was completed in 2014, with a total of 75 pts. Study NCT01147809 was funded by GlaxoSmithKline. Clinical trial information: NCT01147809.

	EPAG (n = 31)	PBO (n = 13)

9603 Poster Session (Board #262), Sat, 1:15 PM-4:45 PM

Febrile neutropenia risk factors: A subanalysis of the NEXT study. *First Author: Nicolas Jovenin, Institut Jean Godinot, Reims, France*

Background: Biosimilar filgrastim is a Granulocyte-Colony Stimulating Factor (G-CSF) licensed for the treatment of neutropenia and febrile neutropenia (FN) induced by myelosuppressive chemotherapy (CT). This subanalysis of the NEXT study attempts to assess the impact of each of the FN risk factors defined in the EORTC guidelines for the use of G-CSF. **Methods:** NEXT was a prospective, post-marketing, non-interventional, longitudinal, national multicenter study aimed to assess the safety of biosimilar filgrastim in patients (pts) undergoing CT for malignancies (excluding chronic myeloproliferative and myelodysplastic syndrome). FN risk factors defined in the EORTC guidelines were tested by univariate analyzes and were also included in a logistic regression model. A search of the age at which pts in the NEXT study were significantly more likely to have a FN was also conducted. **Results:** Overall, the NEXT study analyzed 2102 pts but only 1838 pts who received primary prophylaxis (PP) with biosimilar filgrastim were included in this subanalysis. Apart from CT-related FN risk, other factors that may increase the FN risk are in order of importance: age > 65 years, advanced disease, history of prior FN, no antibiotic prophylaxis, no G-CSF use, poor performance and/or nutritional status, female gender, Hemoglobin < 12 g/dL, liver, renal or cardiovascular disease. The analysis of age distribution of pts with FN, who received PP in NEXT study, shows a threshold at 62 years. The only factor statistically significantly associated with FN occurrence among those included in the logistic regression is age > 62 years, confirming the age-related high risk of FN. Indeed, patients older than 62 years are more likely to have a FN than younger patients (OR [95% CI]: 2.1 [1.1 - 4.0]). The limit to 65 years stated in the EORTC guidelines is not significant in our analysis. **Conclusions:** According with the EORTC guidelines, this analysis confirms the age-related high risk of FN. Caution is required even before the 65 years stated in these guidelines. Indeed, we might wonder about the need for G-CSF prophylactic use in > 62-years patients with a CT-related FN risk 10-20%. Clinical trial information: NCT01574235.

9604 Poster Session (Board #263), Sat, 1:15 PM-4:45 PM

Pilot trial assessing the efficacy and safety of a supplemental B vitamin complex to reduce the onset and severity of chemotherapy-induced peripheral neuropathy. *First Author: Janet Margaret Schloss, The University of Queensland, Woolloongabba, Australia*

Background: Chemotherapy induced peripheral neuropathy [CIPN] is a debilitating side effect resulting from the administration of neurotoxic chemotherapy agents. It is estimated that a third of all patients undergoing chemotherapy experience CIPN, with a third of those progressing to a permanent neuropathy. Patients experiencing moderate to severe CIPN report reduced quality of life, chronic discomfort and disruption of physical abilities for general life activities which can be temporary or permanent. Moreover, CIPN can lead to a dose reduction or possible cessation of treatment, which may adversely impact disease outcomes. **Methods:** In a randomised placebo-controlled trial, newly diagnosed patients undergoing chemotherapy treatment with paclitaxel, oxaliplatin or vincristine were assessed for the safety and efficacy of an oral B group vitamin to reduce the incidence of CIPN. The primary outcome was the TNS and secondary outcomes included B vitamin pathology, EORTC QoL, Brief Pain Inventory and PNQ. **Results:** A total of 71 subjects were randomised from 121 evaluable patients (B vitamin n = 38; placebo n = 33). Participants between groups were matched for gender, chemotherapy agents, age and BMI. No statistical significance was found for the prevention of CIPN from vitamin B supplementation through total TNS score (p = 0.73). Statistical significance was recorded for sensory peripheral neuropathy in the PNQ (12 weeks p = 0.03; 24 weeks p = 0.005; 36 weeks p = 0.021). The risk estimate for the PNQ was also statistically significant with an OR = 5.78, 95% CI = [1.63-20.5]. **Conclusions:** B vitamin supplementation throughout chemotherapy administration was not superior to placebo ($p > 0.05$) for the prevention of CIPN. Patient perception of reduced sensory peripheral neuropathy with B vitamin supplementation over placebo was statistically significant. Although not significant a trend was observed for the prevention of the onset and severity of CIPN throughout chemotherapy with B vitamins supplementation over placebo. Furthermore, patients with moderate to severe CIPN may have a vitamin B12 deficiency that may lead to a worse symptomatic presentation. Clinical trial information: 12611000078954.

9605 Poster Session (Board #264), Sat, 1:15 PM-4:45 PM

Prospective multicenter study evaluating adrenal suppression after dexamethasone therapy as an antiemetic in cancer patients: a KSWOG (Korean South West Oncology Group) study. *First Author: Hye Sook Han, Chungbuk National University Hospital, Cheongju, South Korea*

Background: Dexamethasone has a high therapeutic index for the prevention of chemotherapy-induced nausea and vomiting; however, the chronic use of high-dose glucocorticoids is associated with adrenal insufficiency. The objective of the present study was to assess the prevalence and associated factors of adrenal suppression after antiemetic dexamethasone therapy in cancer patients receiving chemotherapy. **Methods:** Patients who were scheduled to receive at least three cycles of highly or moderately emetogenic chemotherapy with dexamethasone as one of antiemetics were enrolled. Patients with a suppressed baseline adrenal response before chemotherapy and those administrated corticosteroids within 6 months of study commencement were excluded. **Results:** Between October 2010 and August 2014, 481 patients receiving chemotherapy underwent the rapid ACTH stimulation test to assess eligibility; 350 of these patients were included in the final analysis. Fifty-six patients (16.0%) showed a suppressed adrenal response in the rapid ACTH stimulation test at 3 or 6 months after the first chemotherapy with dexamethasone as an antiemetic. Multivariate analysis revealed that the incidence of adrenal suppression was significantly associated with the duration of megestrol acetate use ($P < 0.001$). Adrenal suppression did not correlate with age, sex, performance status, primary tumor site, tumor stage, intent of first chemotherapy, emetic risk of first chemotherapy, chemotherapeutic agents used, or the dose and duration of dexamethasone. **Conclusions:** This large prospective study indicates that approximately 15% of cancer patients with a normal adrenal response showed suppressed adrenal responses after antiemetic dexamethasone therapy; this was particularly significant for patients co-treated with megestrol acetate.

9606 Poster Session (Board #265), Sat, 1:15 PM-4:45 PM

Patient self-evaluation of side-effects related to adjuvant chemotherapy in breast cancer: A prospective study. *First Author: Filippo Montemurro, Fondazione del Piemonte per l'Oncologia, Candiolo Cancer Institute, Candiolo, Italy*

Background: There is a growing interest in patient-reported outcomes (PRO) in cancer treatment. We evaluated a Common-toxicity criteria (CTC) v4.02-based, self-administered questionnaire to collect 10 common chemotherapy-related side effects (CSE) in patients (pts) undergoing standard adjuvant chemotherapy (ACT) for operable breast cancer. **Methods:** In this prospective study, 610 pts at 11 sites were administered the questionnaire after the first and the third cycle of ACT. For each item (nausea, vomiting, constipation, anorexia, taste alterations, diarrhea, fatigue, pain, neuropathy and dyspnea) the CTC v4.02 definitions of grade of severity were translated into Italian and rephrased. Pts were asked to choose the definition that best represented the worst CSE experienced after ACT. At each time/point, information on CSE was extracted from the medical charts to compare pts- vs doctors (drs)-reported CSE. **Results:** 596 and 581 questionnaires were collected after cycle 1 and cycle 3 of ACT. A median of 82% of the fields was completely filled-in. 594 and 573 pts-questionnaires had a corresponding drs-questionnaire. The frequency of $G \geq 1$ CSE was systematically higher in pts than in drs questionnaires, as was the grade of severity. For example, Constipation (any grade), Anorexia (any grade) and Dysgeusia (any grade) were reported by pts almost twice as frequently as by drs. Notably, Paresthesia and Dyspnea (any grade) were rarely reported by drs (4% for both), but were reported by 24% and 27% of the pts, respectively, reaching grade 2 or higher in 6% and 11% of the pts respectively. Finally, we found a significant positive correlation between the magnitude of the discrepancy in the frequency of CSE reporting and the number of patients enrolled at each site, suggesting an influence of workload on discrepancy. **Conclusions:** Self-evaluation of adjuvant chemotherapy-related toxic effects according to the CTC system is feasible in the clinical practice and potentially time saving. Whether the observed discrepancy is due to pts overestimating or drs underreporting CSE needs to be clarified, but our results suggest a potential effect of the patient workload on this phenomenon.

9607 Poster Session (Board #266), Sat, 1:15 PM-4:45 PM

Identifying predictors of taxane-induced peripheral neuropathy using shotgun proteomics technology. *First Author: Meghna S. Trivedi, Columbia University Medical Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common side effect of taxanes. Advances in proteomic technologies incorporating mass spectrometry (MS) for biomarker discovery show great promise in providing molecular profiles from complex biological samples. We evaluated the association between protein cargos in serum exosomes and severity of CIPN. **Methods:** We conducted a nested case-control study within a prospective cohort of women with early stage breast cancer receiving adjuvant taxane chemotherapy. Neuropathy was assessed at baseline, completion of taxane, and 6 and 12 months after taxane completion using the Functional Assessment of Cancer Therapy-GOG-Neurotoxicity (FACT-Ntx) score (range 0-44). Blood samples were collected at baseline, completion of taxane, and 12 months. The changes in FACT-Ntx score from baseline to follow-up time points were used to identify 2 groups of subjects: those with no change in FACT-Ntx score (N = 8) and those with a $\geq$ 20% worsening in FACT-Ntx score (N = 8). MS-based proteomics technology was used to identify proteins present in serum exosomes and potential biomarkers for CIPN. One-way ANOVA analysis with $p < 0.05$ as the threshold cutoff for statistical significance was applied using the Qlucore Omics Explorer to identify biomarkers predictive of developing CIPN. **Results:** From the serum exosomes derived from this cohort, MS-based proteomics technology identified over 700 proteins known to be in different subcellular locations (*e.g.,* 32% cytoplasm and 19% nucleus) and have different functions (*e.g.,*15% enzymes, 6.8% transcription regulators, and 5% kinases). We found a 12-protein signature from the baseline serum samples that can be used to distinguish between patients with or without CIPN after taxane treatment ($p < 0.05$) suggesting that the baseline samples can predict subsequent neurotoxicity. **Conclusions:** We were able to identify a serum exosomal profile that is associated with taxane-induced peripheral neuropathy. We believe that this new panel of biomarkers could be used to identify patients at high risk of developing severe CIPN. We plan to validate the 12-protein profile in a larger cohort of patients who have received taxane therapy.

9608 Poster Session (Board #267), Sat, 1:15 PM-4:45 PM

A randomized trial of vitamin D_3 in aromatase inhibitor-associated musculoskeletal symptoms. *First Author: Alice C. Shapiro, Frauenshuh Cancer Center and Park Nicollet Institute, Minneapolis, MN*

Background: Vitamin D_3 supplementation (D_3) has been suggested as a treatment for aromatase inhibitor (AI)-associated musculoskeletal symptoms (AIMSS), but efficacy and safety are unclear. **Methods:** We randomly assigned 113 post-menopausal women ($\geq$ 18 years; stage I-IIIA breast cancer; taking an AI and experiencing AIMSS), to either 600 IU D_3 (control: n = 56) or 4,000 IU D_3 (experimental: n = 57), daily for 6 months (6 mos). The primary study endpoint was change in musculoskeletal symptoms (MS) from baseline to 6 mos, measured by: The Breast Cancer Prevention Trial Symptom Scales-MS subscale (BCPT-MS), the Australian/Canadian Osteoarthritis Hand Index (AUSCAN), the Western Ontario and McMaster Osteoarthritis Index (WOMAC) and hand grip strength (Dynamometer). Plasma AI pharmacokinetics (AI-PK) were estimated using non-linear mixed-effects modeling. Effects of D_3 on AI-PK were tested by likelihood ratio test. Serum 25(OH)D was quantified by chemiluminescent immunoassay (DiaSorin, Stillwater, MN). Sample size was calculated on a change of 0.62 in BCPT-MS score. Assuming a two-tailed test with $\alpha = 0.05$ and power = 80%, adequate sample size was 116 (58 per group). Primary endpoint analyses were based on intent-to-treat and determined using a General Linear Model controlling for possible effect modifiers. **Results**: The groups did not differ on demographic or clinical characteristics nor on AIMSS measures. After 6 mos, serum 25(OH)D was 33$\pm$8 ng/mL vs. 46$\pm$11 (mean$\pm$sd; control vs experimental; $p < 0.001$). There were no statistically significant differences between groups (control vs exp) in mean change in AIMSS scales from baseline to 6 mos: BCPT-MS: -0.45 vs. -0.24; WOMAC function: -1.23 vs -3.96; WOMAC pain: -0.56 vs. -1.18; WOMAC stiffness: -0.47 vs -0.54; AUSCAN function: -0.75 vs -1.12; AUSCAN pain: -0.24 vs. -0.90; AUSCAN stiffness: -0.11 vs. -0.08; hand grip: 1.06 vs 1.78 (all $p > 0.1$). AI clearance did not differ significantly between groups (baseline vs 6 mos; $p > 0.5$). **Conclusions**: Women randomly assigned to higher dose D_3 (4,000 IU) showed no improvement in AIMSS over usual dose D_3 (600 IU). While D_3 does not appear to adversely affect AI drug metabolism, it may have other health effects in this population. Clinical trial information: NCT01509079.

9609 Poster Session (Board #268), Sat, 1:15 PM-4:45 PM

Usefulness of denosumab to nonsquamous non-small cell lung cancer patients with bone metastases. *First Author: Hibiki Udagawa, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Denosumab reduces the incidence of the skeletal-related events (SRE) in patients with bone metastases (BM) from solid tumors. However, there have been no detailed reports about the efficacy of Denosumab to the untreated non-squamous non-small cell lung cancer (NSCLC) patients with BM. **Methods:** The medical records of patients less than 75 years of age, with BM from non-squamous NSCLC and treated with platinum-doublet or EGFR-TKI as 1st-line systemic chemotherapy at our institution from May 2010 to April 2014 were retrospectively reviewed. The overall survival (OS), progression-free survival (PFS) of platinum-based chemotherapy and/or EGFR-TKI and time to SRE (radiation or surgery to bone, spinal cord compression or pathologic fracture) were analyzed according to the treatment for the BM (Denosumab, Zoledronic Acid or no treatment). **Results:** A total of 149 patients were eligible. Fifty-two patients received Denosumab (Dmab-group), 51 received Zoledronic Acid (ZA-group) and 46 did not receive the treatment for the BM (Non-group). The frequency of the prior SRE in the Non-group was lower than the Dmab-Group and ZA-group (21.7%, 44.2% and 43.1%, respectively), but there was no difference of other clinicopathological characteristics among 3 groups. The OS in the Dmab-group was significantly longer than that in the ZA-group or Non-group (25.4 months vs 13.9 months, 11.2 months, respectively; $p = 0.01$). In the multivariate analysis, Dmab-group was significantly associated with a favorable survival [vs ZA-group; $p < 0.01$, HR 0.365 (95 %CI, 0.209-0.621). vs Non-group; $p < 0.01$, HR 0.388 (95%CI, 0.213-0.691)]. The Dmab-group showed significantly longer PFS for patients treated with platinum-based chemotherapy than the ZA-group or Non-group (5.1 months vs 3.3 months, 4.3 months, respectively; $p = 0.046$). No significant difference in the PFS for patients treated with EGFR-TKI or time to SRE was observed among 3 groups. **Conclusions:** Our results suggest that Denosumab may improve overall survival compared with Zoledronic Acid or no treatment for BM in patients with non-squamous NSCLC and BM.

9610 Poster Session (Board #269), Sat, 1:15 PM-4:45 PM

Phase II study of preventive effect of topical menthol for chemotherapy-induced peripheral neurotoxicity. *First Author: Kumi Nakamura, Aizawa Hospital, Matsumoto, Japan*

Background: Chemotherapy-Induced Peripheral Neurotoxicity (CIPN) is a major dose-limiting toxicity of many commonly used chemotherapeutic agents that not only negatively affects quality of life, but also can limit successful disease control in cancer care. Menthol is a compound derived from mint leaves that functions as an agonist of Transient Receptor Potential Melastatin-8 (TRPM-8). TRPM-8 is distributed in peripheral nerves and has been shown to be associated with cold hypersensitivity, noxious cold and sensory disturbance. It is also related to the occurrence of CIPN. We previously reported that applying topical menthol reduced existing CIPN in 75% of patients in a phase II study. As the next step, we conducted a phase II study about the preventive effect of menthol for CIPN. **Methods:** Patients who were to start regimens containing oxaliplatin (l-OHP) were included in this study. l-OHP is widely used for colorectal cancer (CRC), and is reported to cause grade 2+ CIPN (45-54% at the cumulative dose of 500mg/m2). Participants applied 1% topical menthol twice daily to their hands and feet from the start of l-OHP treatment. CIPN symptoms were assessed using the FACT&GOG-Ntx and Visual Analog Scale (VAS). The primary endpoint was the frequency of Grade 2{CIPN at the cumulative l-OHP dose of 500 mg/m^2. **Results:** Thirty-two CRC patients who were to start regimens containing l-OHP were enrolled in this study. Twenty-two patients were in adjuvant setting and 10 were in metastatic setting.Treatment regimens were capecitabine and l-OHP (CapeOx) (n = 22), CapeOx plus bevacizumab (n = 9) and FOLFOX plus cetuximab (n = 1). Of the 32 registered patients, 8 terminated or changed their chemotherapy regimens before reaching a cumulative l-OHP dose of 500 mg/m^2 and were excluded from analysis. The frequency of Grade 2{CIPN was 12.5% (95% CI: 2.7-32.4%) at the cumulative l-OHP dose of 500 mg/m^2. This was significantly lower than the expectation value (25%). The means of the FACT/GOG-Ntx score and the VAS scale were 3.6 (0-14) and 2.5 (0-8.8), respectively. There were no adverse events reported from menthol application. **Conclusions:** This phase II study showed preventive menthol application significantly reduced l-OHP-induced CIPN. Clinical trial information: UMIN000009655.

9611 Poster Session (Board #270), Sat, 1:15 PM-4:45 PM

Longitudinal study of pneumonitis and esophagitis-related symptoms in patients receiving concurrent chemoradiation for NSCLC. *First Author: Xin Shelley Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clinical practice and research often solely rely on clinician ratings of treatment toxicities, where a simple "symptomatic/not symptomatic" question to the patient is typically used in addition to clinical signs as evidence of toxicity. Prospective, patient-reported outcome (PRO)-based studies that quantify symptom development and major toxicity levels related to concurrent chemoradiation therapy (CXRT) are lacking. We longitudinally examined the relationship between PROs and clinician-rated toxicities in patients with locally advanced non-small cell lung cancer (NSCLC) treated with CXRT. **Methods:** 155 patients repeatedly reported symptoms on a 0-10 scale via the MD Anderson Symptom Inventory (MDASI-Lung Cancer), from pre-CXRT for up to 6 months. Clinicians rated toxicity using the CTCAE 4.0. Patient factors (age, sex, comorbidities), worst CTCAE score of each toxicity during the study, radiation dose/volume variables, and days from start of CXRT were included in the longitudinal mixed modeling. **Results:** We observed a significant linear increase in coughing and shortness of breath over time during the study (both $P < .0001$), whereas the most-severe symptoms overall (fatigue, lack of appetite, disturbed sleep) exhibited a decrease by the end of treatment. Post-CXRT, patients with grade 2+ radiation pneumonitis (RP) had significantly more-severe cough and shortness of breath, compared with those with grade $\leq$ 1 RP ($P < .0001$). Mean lung dose was predictive of grade 2+ RP (OR, 1.27 (1.09-1.49), P = .0023). Gross tumor volume was significantly related to increased cough severity ($P < .01$). Pain, sore throat, and difficulty swallowing peaked by the end of CXRT, and all were significantly worse for patients with grade 2+ esophagitis vs. grade 0-1 (all $P < .0001$). There was no difference in symptom severity pre-CXRT by toxicity group. **Conclusions:** Longitudinal analysis identified temporal associations between clinician-rated toxicity and emerging patient-reported symptom burden from CXRT for NSCLC. Further investigation of the benefits of routine symptom assessment for clinical management and early prevention of RP and esophagitis is warranted.

9612 Poster Session (Board #271), Sat, 1:15 PM-4:45 PM

The conversion ratio (CR) for opioid rotation (OR) from strong opioids to transdermal fentanyl (TDF) in cancer patients. *First Author: Akhila Sunkepally Reddy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cancer patients frequently undergo OR for uncontrolled pain or opioid induced neurotoxicity (OIN). TDF is one of the most common opioids prescribed to cancer patients. However, the accurate CR for OR from other opioids to TDF is unknown and various currently used methods result in a wide variation of CRs. Our aim was to determine the CR of morphine equivalent daily dose (MEDD) to TDF when correcting for MEDD of breakthrough opioids (net MEDD) in cancer outpatients. **Methods:** We reviewed records of 22,532 consecutive patient visits at our Supportive Care Center in 2010-13 for OR from other opioids to TDF. Data regarding Edmonton Symptom Assessment Scale (ESAS) and MEDD were collected in patients who returned for follow up within 5 weeks. Linear regression analysis was used to estimate the CR between TDF dose and net MEDD (MEDD prior to OR minus MEDD of breakthrough opioid used along with TDF after OR). Successful OR was defined as 2-point or 30% reduction in pain score and continuation of the new opioid at follow up. **Results:** 129 patients underwent OR from other opioids to TDF. The mean age was 56 years, 59% male, and 88% had advanced cancer. The median time between OR and follow up was 14 days. Uncontrolled pain (80%) was the most frequent reason for OR and 59% had a successful OR with significant improvement in ESAS pain, constipation, and symptom distress scores. In 101 patients with OR and no worsening of pain at follow up, the median CR (range) from net MEDD to TDF mg/day was .01 (-0.02-0.04) and correlation of TDF dose to net MEDD was .77 ($P < .0001$). The CR was not significantly impacted by variables such as mucositis, serum albumin, and body mass index (BMI). The CR of .01 suggests that MEDD of 100mg is equivalent to 1mg TDF/day or 40mcg/hour TDF patch (1000mcg/24hours). **Conclusions:** The median CR from MEDD to TDF mg/day is .01 and the CR from MEDD to TDF mcg/hour patch is 0.4. Further validation studies are needed.

Association of high symptom burden with oral oncolytic agents. *First Author: Jane Alcyne Severson, University of Michigain Health System, Ann Arbor, MI*

Background: Increasing numbers of cancer patients are being treated with oral oncolytics. This change represents a shift from frequent direct observation during intravenous therapy to periodic observation and self-management. Despite this shift, patients are still at risk for many of the same chemotherapy-associated symptoms and toxicities. We sought to characterize the symptom burden experienced by patients prescribed oral oncolytics. **Methods:** Michigan Oncology Quality Consortium (MOQC) sponsored a collaborative focused on improving oral oncolytic care. Eight oncology practices participated. Patient symptoms were assessed with a modified Edmonton Symptom Assessment System (ESAS) prior to each outpatient visit. 13 symptoms were categorized as mild (0 to 3), moderate (4 to 6), and severe (7 to 10). A total of 1196 surveys were analyzed. **Results:** Overall, the average ESAS symptom score was mild in 83% of patients, moderate in 12% of patients, and severe in 5% of patients. These composite scores, however, obscure the significant symptom burden in select ESAS domains. For example, 34% of patients categorized their overall well-being as being moderate/severely affected; 35% of patients felt they were moderate/severely fatigued, and 20% indicated moderate/severe pain symptoms. Notably, 271/1196 (23%) of the assessments had 4 or more symptoms reported moderate to severe. (See table). **Conclusions:** Whether due to underlying disease or medication side effects, patients taking oral oncolytics experience significant symptom burden that impacts quality of life. Intolerance of oral oncolytics may lead to adherence issues, potentially affecting expected outcomes. Given the prevalence of symptoms and potential for toxicity, self-management strategies to improve early recognition and treatment of symptoms by patients taking oral oncolytics are necessary.

Oral oncolytic symptom burden profile.

	Mild (0-3)	Moderate (4-6)	Severe (7-10)
Pain	80%	15%	5%
Tiredness	65%	21%	14%
Drowsiness	76%	16%	8%
Nausea	92%	6%	2%
Appetite	79%	13%	8%
Shortness of Breath	88%	9%	3%
Depression	87%	11%	2%
Anxiety	87%	10%	3%
Well Being	66%	21%	13%
Constipation	88%	9%	3%
Diarrhea	92%	5%	3%
Tingling/ Numbness	82%	12%	6%
Mouth Sores	96%	3%	1%
Overall Symptom Burden (n = 1196)	83%	12%	5%

9614 Poster Session (Board #273), Sat, 1:15 PM-4:45 PM

Randomized pilot study comparing high-dose (HD) influenza vaccine to standard-dose (SD) influenza vaccine in adult oncology patients younger than 65 receiving chemotherapy. *First Author: Saad Jamshed, Rochester General Hospital, Rochester, NY*

Background: Pts on chemotherapy often fail to develop a robust response to influenza vaccine. Compared to SD influenza vaccine, HD vaccine has shown improved immunogenicity & protection against influenza illness in adults ≥65 yrs. This study compared the immunogenicity & tolerability of HD to SD vaccine in pts <65 yrs receiving chemotherapy. **Methods:** 105 pts were randomized to receive either SD or HD (51 vs 54) vaccine on day1 of chemotherapy during 2012-2013 & 2013-2014 seasons. HAI titers were measured prior to & 4-wks after vaccination. HAI were summarized as GMT, seroconversion & seroprotection rates. Sample size calculation was based on 30-50% effect size on GMTs. Equal numbers were expected in each group & assumed 80% power. GMTs for each strain were transformed to log 2, t-test was performed on log-transformed HAI titer. χ^2 was used for seroconversion rate. A p-value > 0.05 was considered significant. **Results:** 5 pts were excluded, 1 received the vaccine twice. 4 pts who enrolled both yrs, were included only once (yr 1). Mean age (52.9 vs 53.9 yrs) and baseline HAI titers were equivalent; 90% in both arms had solid tumors & 58 vs 50% were receiving curative therapy in SD vs HD arms, respectively. Both vaccines were well tolerated with no SAEs. Seroprotection was excellent for all antigens in both arms. Seroconversion rate for all 3 influenza antigens & post vaccination GMTs for H3N2 & B strains were significantly improved with HD vaccine (Table). **Conclusions:** Trivalent HD influenza vaccine can be safely administered to chemotherapy pts with improved immunogenicity over SD vaccine. A larger study is needed to show clinical benefits with HD vaccine. Clinical trial information: NCT01666782.

Vaccine Antigen	SD (n = 50) Post HAI GMT (95% CI)	HD (n = 50) Post HAI GMT (95% CI)	(*t*-test)
H1N1	979.1 (609.1-1349.0)	1350.1 (819.8-1880.4)	$p = 0.106$
H3N2	811.2 (401.2-1221.3)	1143.4 (739.6-1547.3)	$p = 0.005$
B	228.0 (129.9-326.2)	351.6 (215.6-487.7)	$p = 0.02$
Seroconversion Rate (%) (≥ 4 fold change)			(χ^2)
H1N1	46.0	72.0	$p = 0.014$
H3N2	58.0	80.0	$p = 0.029$
B	44.0	80.0	$p = 0.0004$

9615 Poster Session (Board #274), Sat, 1:15 PM-4:45 PM

Impact of rolapitant on quality of life (QoL) in patients (pts) receiving highly emetogenic chemotherapy (HEC) and moderately emetogenic chemotherapy (MEC). *First Author: Martin Chasen, Palliative Care, at The Ottawa Hospital Cancer Centre and the Medical Director of the Palliative Rehabilitation Program at the Élisabeth Bruyère Hospital, Ottawa, Ottawa, ON, Canada*

Background: Rolapitant is a novel NK-1 receptor antagonist with a half-life of 180h, and does not inhibit CYP3A4 as other drugs do in the class, and therefore requires no dose modifications of concomitant steroids. Rolapitant demonstrated efficacy for prevention of CINV in phase 3 trials (HEC1, HEC2, and MEC). This pooled analysis examined the effect of rolapitant on QoL. **Methods**: In 3 double-blind, active-controlled studies, pts were randomized to oral rolapitant 200 mg or placebo 1–2 h before chemotherapy. All pts received active control: granisetron 2 mg oral or 10 mcg/kg IV and oral dexamethasone 20 mg. In the MEC study, granisetron was continued on Days 2 and 3. QoLwas assessed on Day 6 using the Functional Living Index-Emesis (FLIE) Questionnaire, and reported as a total score and by nausea and vomiting domains. Pts with a valid questionnaire from the MITT population (all randomized pts who received at least 1 dose of study drug) in the 2 pooled HEC studies and one MEC study were analyzed. **Results**: Baseline characteristics were comparable across treatment groups. Most common cancers were breast for MEC and lung for HEC studies. At Day 6, significant improvements ($P < 0.05$) were observed with rolapitant vs. active control for FLIE total, nausea, and vomiting domain scores (Table). **Conclusions**: Rolapitant improved QoLin pts receiving both HEC and MEC compared with active control, in addition to providing significant protection from CINV. Clinical trial information: NCT01500213; NCT01499849; NCT01500226.

Evaluation of brain-derived neurotrophic factor (BDNF) genetic polymorphism (rs6265) on chemotherapy-associated cognitive impairment in early-stage breast cancer (ESBC) patients. *First Author: Terence NG, National University of Singapore, Singapore, Singapore*

Background: BDNF is a neurotrophin that regulates neuronal function and development, which is implicated in several neurodegenerative conditions. There is preliminary data to suggest that the reduction of BDNF concentrations may lead to post-chemotherapy cognitive impairment. We hypothesized that a single nucleotide polymorphism (rs6265) of the *BDNF* gene may down-regulate BDNF levels, predisposing certain patients with cognitive impairment. This study was designed to evaluate the impact of *BDNF* gene polymorphism on chemotherapy-associated cognitive impairment. **Methods:** Overall, 145 chemotherapy receiving ESBC patients (mean age: 50.8 ± 8.8 years; 82.1% Chinese) were recruited between 2011 and 2014. Patients' self-perceived cognitive function were assessed longitudinally over three time points, using the validated FACT-Cog (v.3) to examine six cognitive domains: concentration, functional interference, memory, mental acuity, multitasking ability and verbal fluency. Genotyping was performed using Sanger sequencing. Logistic regression was used to evaluate the association between *BDNF* Val66Met polymorphism and cognition, adjusting for ethnicity and clinically important covariates. **Results:** 54 (37%) patients reported cognitive impairment post-chemotherapy. 38 (26.2%) patients were homozygous for Val/Val, 74 (51.0%) were heterozygous for Val/Met, and 33 (22.8%) were homozygous for Met/Met without deviation from the *Hardy-Weinberg equilibrium ($p > 0.05$)*. The *BDNF* Met/Met genotype was associated with statistically significantly lower odds of developing cognitive impairment (OR = 0.26, 95% CI: 0.08-0.92, $p = 0.036$). Furthermore, the Met-carriers were less likely to experience impairment in the verbal fluency (OR = 0.34, 95% CI: 0.12-0.90, $p = 0.031$) and multitasking ability (OR = 0.37, 95% CI: 0.15-0.91, $p = 0.030$) domains, comparing to the Val/Val homozygote. **Conclusions:** This is the first study to provide evidence that carriers of the *BDNF* Met allele are protective against chemotherapy-associated cognitive impairment. Further validation studies are required to confirm the findings.

9617 Poster Session (Board #276), Sat, 1:15 PM-4:45 PM

Development and validation of a Clinical Index of Severe Febrile Neutropenia: A prospective multicenter study. *First Author: Juan Virizuela Echaburu, Hospital Universitario Virgen Macarena, Seville, Spain*

Background: To develop and validate a prognostic score for serious neutropenic events based on characteristics available prior to starting chemotherapy **Methods:** FINITE is a prospective, multicenter study to assess prognostic factors and patterns of care in adult cancer patients with seemingly stable febrile neutropenia. For this analysis, we used only those clinical variables that are routinely available on Day 1 of chemotherapy in all solid tumor patients. The main outcome measure was occurrence of serious complications. A logistic regression with Penalized Maximum Likelihood Estimations (PMLE) was applied; to build an additive score, estimates were rounded as integers. To validate the model, the bootstrap bias-corrected c-index was calculated as a measure of prediction performance. A separate dataset with 216 patients was used for external validation. **Results:** We enrolled 1238 patients from 25 centers. The primary end point (serious complications) ensued in 161 patients (13%; 95% CI, 11.1%-14.9%) and 21 patients died (1.7%; 95% CI, 1.1%-2.6%). We developed a *Clinical Index of Severe Febrile Neutropenia*-(CISFN) with six baseline explanatory covariates associated with serious complications: Eastern Cooperative Oncology Group Performance Status ≥ 2 (2 points), chronic obstructive pulmonary disease (1 point), chronic cardiovascular disease (1 point), protein-energy malnutrition (1 point), chronic corticoids (1 point), and inoperable locally advanced or metastatic cancer (1 point). We integrated these predictors into a score from 0 to 7, which classifies patients into three risk groups: low (0 points), intermediate (1-2 points), and high risk (≥ 3 points). Complications rates were 4.1% in low, 8.7% in intermediate, and 38% in high risk groups ($p < 0.001$). Mortality within each class was 0.2%, 1.4%, and 4.9%, respectively ($p < 0.001$). This model was well calibrated (Hosmer-Lemeshow test, $p > 0.1$) and resulted in an optimism-corrected c-index of 0.762 (95% CI, 0.759-0.763). The validation in a separate dataset yielded a c-index of 0.745 (95% CI, 0.665-0.825). **Conclusions:** This study identified predictive factors for serious neutropenic events with potential implications for G-CSF prophylaxis.

Efficacy and safety of rolapitant for prevention of chemotherapy-induced nausea and vomiting (CINV) in patients (pts) receiving anthracycline-cyclophosphamide (AC)-based chemotherapy. *First Author: Ian D. Schnadig, Compass Onc, Tualatin, OR*

Background: Rolapitant, a novel NK-1 receptor antagonist, demonstrated efficacy in the prevention of CINV in pts receiving moderately- or highly emetogenic chemotherapy (MEC; HEC). In this post-hoc analysis, we evaluated safety and efficacy outcomes in pts receiving AC-based therapy, now considered HEC. **Methods**: This double-blind, active-controlled study randomized pts to oral rolapitant 200 mg plus granisetron 2 mg and dexamethasone 20 mg or granisetron and dexamethasone alone (active control). Complete response (CR=no emesis and no use of rescue medication), no emesis, no significant nausea, and time to emesis or rescue medication during overall, acute, and delayed phases and treatment-emergent adverse events (AEs) are presented. **Results**: 703 pts received AC-based therapy, of which 97% had breast cancer. CR was significantly higher for rolapitant vs. active control for delayed and overall phases in pts receiving AC-based therapy (Table). Time to first emesis or use of rescue medication was significantly longer with rolapitant vs. active control (between-group comparison, p = 0.032); median was not reached in either treatment arm. A significantly greater proportion of pts on rolapitant (73.0%) vs. active control (60.2%) had no emesis during the overall phase ($p < 0.001$). Rates of no significant nausea were similar for rolapitant (63.7%) and active control (62.4%) in the overall phase (p = 0.728). Treatment-related AEs (TRAEs) during Cycle 1 occurred in 8.7% and 8.8% of pts on rolapitant vs. active control,. Most frequent TRAEs were constipation (2.9% vs. 2.7%), fatigue (2.3% vs. 2.2%), and headache (2.3% vs. 3.3%). **Conclusions**: Rolapitant was superior to active control in preventing CINV during delayed and overall phases after AC-based chemotherapy. There were no differences in the safety profile of rolapitant in the pt groups. These results are consistent with the overall pt population in this study. Clinical trial information: NCT01500213; NCT01499849; NCT01500226.

	Rolapitant	Active Control	
Phase	N=344	N=359	p-value*
Overall (0–120 h)	216 (62.8%)	197 (54.9%)	0.033
Delayed (>24–120 h)	230 (66.9%)	214 (59.6%)	0.047
Acute (0–24 h)	264 (76.7%)	276 (76.9%)	0.966

9619 Poster Session (Board #278), Sat, 1:15 PM-4:45 PM

Evaluating the effect of neutropenic diet on infection and mortality rate in cancer patients: A meta-analysis. *First Author: Mohamad Bassam Sonbol, Georgia Regents University, Augusta, GA*

Background: Dietary manipulation for patients undergoing chemotherapy has been proposed as a method to reduce the risk of infection. These diets, referred to as "neutropenic diets (ND)" usually restrict fresh raw fruits, raw vegetables, raw meat or soft cheeses. Regular diets (RD) generally include foods restricted in ND and are prepared within standardized FDA food safety guidelines. ND are used in transplant centers and hospital wards where cancer patients are being treated. The goal of this meta-analysis was to determine the effectiveness of ND over RD at preventing infection **Methods:** We searched the medical literature to identify studies comparing ND with RD in patients with cancer. Primary outcomes were mortality of any cause, major infections (pneumonia, bacteremia, or fungemia, or pneumonia accompanied with bacteremia or fungemia), and the composite outcome of neutropenic fever or infection (major infections as defined above, minor infections, or fever). The overall effect was calculated by use of a random effects model. A sensitivity analysis was conducted to evaluate influence of the included observational trials on outcomes. **Results:** Four studies were identified, 3 randomized trials and 1 observational study, encompassing 918 patients with cancer or stem cell transplant. Patients randomized to ND had no difference in major infection rate compared to the RD group (RR = 1.08, CI 0.72 to 1.61). ND patients also had a comparable mortality rate to the RD group (RR = 1.08, CI 0.78 to 1. 50). These results persisted after omitting the observational study from analysis. When analyzing for the overall composite outcome of any infection or fever, the hazard was significantly higher in ND arm compared to RD arm (RR 1.18, CI 1.05 to 1.34). **Conclusions:** This study shows no superiority or advantage with respect to mortality or infection of using neutropenic diet over a regular diet in neutropenic cancer patients. Larger randomized controlled studies are needed to further study this important dietary issue for patients. In the meantime, it may be time to relax the restrictions of ND in order to attain better nutrition.

9620 Poster Session (Board #279), Sat, 1:15 PM-4:45 PM

Risk assessment of anticancer treatments beyond performance status: A prospective study in 277 cancer patients. *First Author: Anne Jouinot, Medical Oncology, Paris Descartes University, Cochin - Port Royal Hospital, AP-HP, Paris, France*

Background: Alterations of performance status (PS) and of nutritional status are predictors of acute toxicity following anticancer treatment. Resting energy expenditure (REE) is often increased in cancer patients and may be a major determinant for the alteration of nutritional status and the development of precachexia and cachexia. We investigated whether abnormal metabolism could predict early acute toxicity (EAT). **Methods:** In this prospective observational monocentric study, REE was measured by indirect calorimetry before anticancer treatment initiation. C-Reactive Protein (CRP), albumin, transthyretin and PS were collected. Measured REE was compared with predicted REE as defined by the Harris-Benedict formula. Patients were classified as hypometabolic (REE $<$ 90%), normometabolic (90-110%) or hypermetabolic ($>$ 110%). Toxicity was assessed after the first cycle of treatment. An EAT was defined as any event leading to unplanned hospital admission, dose reduction, treatment delay ($>$ 7 days) or discontinuation. **Results:** A total of 277 patients (pts) with solid tumors (gastro-intestinal 25%, genitourinary 23%, thoracic 22%) were included. Sex ratio: 1.25; median age: 63 years (20-91). Most of the pts (211; 76%) had locally advanced or metastatic disease and were treated with chemotherapy (246; 89%) or tyrosine-kinase inhibitor (30; 11%). Calorimetry revealed pts with either normo- (29%), hyper- (51%) or hypometabolism (20%). A subset of 59 pts (21%) experienced an EAT. The occurrence of EAT was associated with poor PS (2-3 vs 0-1: OR = 2.04 [1.12-3.73], p = 0.029), low albumin ($<$ 35 vs $\geq$ 35g/l: OR = 2.39 [1.03-5.54], p = 0.048), inflammation (CRP $\geq$ 10 vs $<$ 10mg/l: OR = 2.43 [1.35-4.37], p = 0.004) and abnormal metabolism (abnormal vs normal: OR = 2.36 [1.13-4.95], p = 0.023). In multivariate analysis, elevated CRP was an independent predictor of EAT (p = 0.047). The REE was associated with higher sensitivity (83%) than CRP (55%), PS (41%) and albumin (17%) to predict EAT. **Conclusions:** Pts with abnormal metabolism experience more early acute toxicity. The measurement of resting energy expenditure might improve the detection of patients at risk for toxicity and missed with the standard clinical evaluation.

9621 Poster Session (Board #280), Sat, 1:15 PM-4:45 PM

Clinical predictors of recurrent venous thromboembolism (VTE) in cancer patients from a randomized trial of long-term tinzaparin versus warfarin for treatment: The CATCH study. *First Author: Alok A. Khorana, Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH*

Background: Cancer patients with VTE continue to remain at high risk for recurrent VTE even with adequate anticoagulation. We determined baseline clinical predictors of recurrent VTE, including the previously developed Ottawa Score, in a pre-specified analysis of the CATCH study. **Methods:** The CATCH study was a randomized, open-label, multicenter, Phase III trial (NCT01130025) comparing tinzaparin 175 IU/kg once daily for 6 months with initial tinzaparin transitioning to dose-adjusted warfarin (target INR 2–3) for 6 months in patients with active cancer and acute, symptomatic proximal deep vein thrombosis and/or pulmonary embolism. Clinical predictors of recurrent events were identified using Fisher's exact test; competing risk regression analysis was then conducted accounting for multiple variables. **Results:** We evaluated multiple clinical variables present at or prior to randomization. Of 900 randomized patients, 492 (54.7%) had metastatic disease, 288 (32.0%) were on chemotherapy, 286 (31.8%) had recent hospitalization, 209 (23.2%) had ECOG performance status 2, 129 (14.3%) had venous compression from mass or adenopathy and 92 (10.2%) had recent radiation therapy; VTE occurred in 6.9% of the tinzaparin arm versus 10.0% of the warfarin arm (HR 0.65; 95% CI 0.41–1.03), as reported. In multivariate analysis, risk factors associated with recurrent VTE included venous compression (HR 2.96; 95% CI 1.8–4.86; $P<$ 0.001) and diagnosis of hepatobiliary cancer (HR 2.91; 95% CI 1.2–7.02; $P=$ 0.018). Ottawa score did not predict for recurrence risk, with recurrent VTE rates of 3.4, 9.7 and 8.2% in low-, intermediate- and high-risk groups, respectively. **Conclusions:** Cancer patients with acute VTE are at significant risk for recurrent events, despite anticoagulation. Major clinical predictors of recurrence include tumor venous compression and a diagnosis of hepatobiliary cancer. More intense treatment strategies for higher-risk patients should be considered. Clinical trial information: NCT01130025.

9622 Poster Session (Board #281), Sat, 1:15 PM-4:45 PM

Efficacy and safety of rolapitant for prevention of chemotherapy-induced nausea and vomiting (CINV) in moderately emetogenic therapy (MEC). *First Author: Paul Joseph Hesketh, Lahey Hosp and Med Ctr, Burlington, MA*

Background: Rolapitant, a novel NK-1 receptor antagonist, showed efficacy for prevention of CINV in patients (pts) receiving MEC (anthracycline/cyclophosphamide (A/C) and other regimens) in a global phase 3 trial. Recent anti-emetic guidelines consider A/C based regimens to be highly emetogenic. In this post hoc analysis, the efficacy and safety of rolapitant was assessed during Cycle 1 in pts receiving non-AC MEC. **Methods**: In a double-blind, active-controlled study, pts were randomized to oral rolapitant 200 mg or placebo 1–2 hours before MEC. All pts received granisetron 2 mg oral on days 1-3 and oral dexamethasone 20 mg on day 1. Pt subgroups were carboplatin-based MEC and Other MEC (OM; non-AC, non-carboplatin). Complete response (CR=no emesis and no use of rescue medication), no emesis, and no nausea were assessed during overall (0-120 h), acute (0-24 h), and delayed (>24-120 h) phases. **Results**: CR was significantly (P<0.05) higher with rolapitant than active control for overall and delayed phases in the carboplatin subset and for acute and overall phases in the OM subset (Table). No emesis rates were significantly (p<0.05) higher with rolapitant in carboplatin and OM subsets in the overall phase. No nausea rates were significantly higher with rolapitant during the overall (p= 0.023) and delayed (p=0.034) phases in carboplatin-based MEC. Incidences of treatment-related AEs in Cycle 1 with rolapitant vs. active control were 11.3% vs. 6.7% in carboplatin-based and 9.2% vs. 6.0% in OM-based therapy. Most common AEs with rolapitant and active control were constipation, fatigue, and headache. **Conclusions**: Rolapitant was superior to active control in preventing CINV in pt subgroups receiving either carboplatin or other non-AC MEC regimens. Rolapitant was well tolerated with low incidence of AEs. Clinical trial information: NCT01500226.

	Carboplatin (N = 401)		Other MEC (OM) (N = 228)

9623 Poster Session (Board #282), Sat, 1:15 PM-4:45 PM

Establishing a new quality of life (QL) / patient reported outcome (PRO) / symptom scale in advanced cancer: Content validity for the "CSS" based on input from 3860 patients. *First Author: Julia Chia-Ying Shih, Albert Einstein College of Medicine - Jacobi Medical Center, Bronx, NY*

Background: Preserving or improving QL while managing symptoms are major goals in cancer care. To achieve these ends, the input of patients (pts) is mandatory as these are true PROs. The CSS (Cancer Symptom Scale) is a measure for pts with advanced cancer based on issues common to most malignancies; additionally, the CSS is designed to enhance patient input in late in life care settings such as hospice. While other measures exist, few if any are used in these settings routinely. The CSS is based on the model of the well-validated LCSS, and is planned to be a feasible and acceptable measure appropriate for use on an ePRO platform to minimize patient and caregiver burden. **Methods:** 50 cancer health care providers (HCPs) developed an initial list of issues to be evaluated by pts. This anonymous web-based survey used the resources of Nexcura.com and was then sent to pts to rate 18 to 21 issues on a 5 point scale ranging from "not important at all" to "very important (VI)." **Results:** Responses were given by 3,860 pts with: lung (660), breast (1072) and prostate (2128) cancer. 299 pts with advanced cancer had low performance status (KPS ≤60%) / stage IV extent. Results based on the top 2 categories (VI + important) of the leading 15 issues are listed below in the Table. **Conclusions:** 1) Responses from all 3860 pts are similar to those of the 299 with advanced disease, except for greater concern for pain and appetite in those with advanced cancer, and less importance for body image; 2) HCPs often rated items similarly to pts, but underestimated pt concern with concentration; and 3) the 5 items of greatest importance to patients are not symptoms but are items of global concern, and must be included in validated PRO measures. We believe this content validity survey for the CSS is the largest obtaining PROs from pts with cancer.

9624 Poster Session (Board #283), Sat, 1:15 PM-4:45 PM

Sleep quality and its association with fatigue, symptom burden, and mood in patients with advanced cancer in a phase 1 clinic. *First Author: Goldy George, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Limited data exist about sleep quality (SQ) in patients (pts) on phase 1 clinical trials. Poor SQ is often not captured as an adverse event (AE) and its association with fatigue, one of the most frequently reported AEs, is not documented routinely. Here, we describe SQ and the relation between SQ and fatigue, symptoms, and mood in pts in the MD Anderson phase 1 clinical trials clinic. **Methods:** Sleep, fatigue, symptom severity/interference and mood were assessed using the validated Pittsburgh Sleep Quality Index (PSQI), Brief Fatigue Inventory, MD Anderson Symptom Inventory, and Profile of Mood States, respectively; ECOG was from medical records. Statistics included multivariable regression models. **Results:** The sample (N = 262) was 52% female, 80% ECOG 0-1, mean age 58.4 ± 0.7y. The % of "poor" sleepers (global PSQI score > 5) was 64%. In contrast, pts' subjective self-assessment of SQ was: 27% as "bad" or "fairly bad", 59% as "fairly good" and 14% as "very good". Among pts, 28% took medicines for sleep; 15% slept < 6 hours at night; 20% had sleep latency > 30 minutes for ≥ 3 nights per week; and 42% reported poor sleep efficiency (< 85% time in bed spent sleeping). The % of pts reporting fatigue were 35% as "severe", 14% as "moderate", 39% as "mild", and 12% "none". In an adjusted multivariable regression model, poor overall SQ was associated with greater fatigue ($P < 0.001$). Interestingly, SQ (PSQI) sub-components associated with greater fatigue were sleep disturbance (OR = 2.6, 95% CI = 1.3, 5.1, $P < 0.007$) and daytime dysfunction (OR = 4.1, 95% CI = 2.3, 7.6, $P < 0.001$), but sleep latency, and sleep efficiency were not related to fatigue. Poor overall SQ also was associated with higher symptom severity (Pearson's r = 0.6, $P < 0.001$), mood disturbance (Pearson's r = 0.5, $P < 0.001$), and greater fatigue-(Pearson's r = 0.4, P < 0.001) and symptom-related interference (Pearson's r = 0.5, P < 0.001) with activity, walking ability, relationships with others, and enjoyment of life. **Conclusions:** Poor SQ is a significant problem (64% pts) and associated with greater fatigue, symptom severity, symptom interference, and greater mood disturbance. Deciphering SQ should be routine practice in phase 1 clinical assessments.

9625 Poster Session (Board #284), Sat, 1:15 PM-4:45 PM

Patient-reported experience combining complementary and alternative medicine (CAM) with conventional oncology treatment (COT). *First Author: Alvaro G. Menendez, Roger Williams Medical Center/ Boston University School of Medicine, Providence, RI*

Background: CAM encompasses a diverse group of interventions not generally considered to be part of COT. The objective of this study is to describe the characteristics, factors and patient reported experiences associated with the use of CAM by patients (pts) receiving COT. **Methods:** An IRB approved, 14 item questionnaire was offered to all pts receiving COT at a single institution cancer center over a defined 2 mo interval. Demographics, prevalence and type of CAM used; as well as specific questions to define oncologist endorsement of CAM in combination with COT were collected. **Results:** 198/215 (92%) questionnaires were completed and analyzed. Utilization of CAM before the diagnosis (dx) of cancer was seen in 21/198(11%) pts. Following a cancer dx, 114/198(58%) reported the use of CAM. Dietary supplements were the most commonly used 57/108(52%); 41/108(38%) used massage and other mind-body techniques; while 10/108(9%) used multiple types of CAM. The source of CAM information was the oncologist in 42/138(30%), TV in 26/138(19%) and friends/family in 23/138(17%). Analysis demonstrated no significant difference in the use of CAM by gender, age, level of education or family income; however Hispanic ethnicity was a statistically significant variable (p = 0.027) in reported quality of life improvement with CAM. 141/198(71%) of pts reported a desire to discuss CAM integration into their COT, however only 95/198(48%) did so. After discussion with their oncologist, 30/45(66%) of pts reported receiving additional information about CAM, 11/45(24%) reported that CAM use was acceptable but did not receive additional information and 4/45(9%) were discouraged from CAM use. **Conclusions:** This study reveals that routine CAM use is not uncommon, but is four times more frequent after a dx of cancer. The majority of pts do not address CAM with their oncologist, despite a reported interest in doing so. About 1/3 of oncologists were reported not to provide additional information and actually discouraged CAM. This study identifies that the majority of pts with cancer use CAM, however potential barriers between patients and oncologists exist for the effective integration of CAM with COT.

9626 Poster Session (Board #285), Sat, 1:15 PM-4:45 PM

Interpreting the febrile neutropenia rates from randomized controlled trials for consideration of primary prophylaxis in the real world: A systematic review and meta-analysis. *First Author: Judy Truong, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Guidelines recommend primary prophylaxis (PP) with granulocyte colony stimulating factors (G-CSF) for patients above a febrile neutropenia (FN) risk threshold of 20%. When considering the role of PP with G-CSF, practitioners often use FN rates of regimens based on data from randomized controlled trials (RCTs), which are often comprised of highly selected patients. Patients who received these regimens in the real world may be at higher risk of FN. **Methods:** A systematic literature search was conducted using MEDLINE, EMBASE, and CENTRAL databases for full-length articles reporting FN rates for breast cancer-related chemotherapies between Jan/96 and Feb/14. A regimen was included if there was at least 1 RCT and 1 observational study (ObS). Any pilot, dose-finding, feasibility, phase I, or phase II studies were excluded. Meta-regression using logistic regression with fixed-effects and random-effects was used to model the odds ratio (OR) of FN with 95% confidence intervals (CI). **Results:** 128 studies involving 29 regimens and 50,069 patients were identified. 65 ObS (n = 7,812) and 110 RCT (n = 42,257) cohorts were included. The unadjusted FN rate was 11.7% in ObS and 7.9% in RCT cohorts. The univariable fixed effects OR for FN in the ObS compared to RCT cohorts was 1.58 (CI: 1.09-2.28; p= 0.017). The FN rates remained significantly higher in the ObS compared to RCT cohorts (OR = 1.74; CI: 1.15-2.62; p =0.012) in the multivariable mixed effects model adjusted for age, chemotherapy intent, chemotherapy regimen and accounted for random effects of study and chemotherapy regimen. This meant that a 13% FN rate in RCT would translate into 20% FN rate in ObS study. The unadjusted FN rates were higher in taxane regimens than non-taxane regimens in both the ObS (16.5% vs. 6.4%) and RCT (10.0% vs. 4.7%) cohorts. **Conclusions:** FN rates in ObS are significantly higher than suggested by RCTs in many breast cancer-related chemotherapy regimens. A 13% FN rate in RCT appeared to correspond to the 20% FN rates in the real world. Large population-based studies are needed to confirm FN rates of different regimens in the real world to ensure optimal utilization of G-CSF.

9627 Poster Session (Board #286), Sat, 1:15 PM-4:45 PM

Can a homeopathic medicine complex reduce hot flashes induced by adjuvant endocrine therapy in localized breast cancer patients? Results of a randomized placebo-controlled phase III trial. *First Author: Pierre-Etienne Heudel, CENTRE LEON BERARD, Lyon, France*

Background: Homeopathy is already used for the management of menopausal hot flashes (HF) and could reduce this frequent endocrine therapy's (ET) side effect. **Methods:** Localized breast cancer patients (pts), treated for at least one month with adjuvant ET and complaining of HF were included in a multicentric randomized double-blind phase III study. Primary endpoint, analyzed in an intent-to-treat basis, was the variation of HF score (HFS) between pre and 4 weeks (w) post randomization. HFS was calculated (over 1 w) as the mean of HF frequency, weighted by a 4-level intensity scale. After a run-in period of placebo (2-4 w to exclude pts with strong placebo effect), only pts maintaining a HFS ≥ 10 were randomized to receive Actheane (a homeopathic medicine complex BRN-01) (A) vs Placebo (P) during 2 months. The trial was powered (90% power, two-sided alpha of 5%) to detect a 5-point (± 8.6) difference of HFS variation between arms; 138 randomized pts were needed. Secondary endpoints were HFS variation after 8 w of treatment, compliance, tolerance, quality of life (QoL) and satisfaction of pts. **Results:** From February 2010 to April 2014, 299 pts were included and 138 (46.2%) randomized (65 to A and 73 to P). Patients' characteristics were well balanced between groups. Median age was 51 years [range 36-72], 82 pts were postmenopausal, 79 were treated by tamoxifen and 59 by aromatase inhibitor. No statistical difference was observed in HFS variation after 4 w (median of -2.9 points for A vs -2.5 for P; p = 0.76, corresponding to a median decrease of 17.2% vs 15.4% of HFS). However, HFS decreased for 75.4% of pts in A arm vs 67.6% in P. QoL score after 4 w was stable or improved for respectively 71.7% vs 73.9% of pts. Compliance to study treatment was similar between the 2 arms (82% for A vs 85% for P, p = 0.61). None of the 3 grade 3 adverse events declared (1 cholecystitis and 2 joint pains) were related to treatment. **Conclusions:** Although efficacy hypothesis was not reached, the management of HF globally decreased HFS, with positive impact on QoL. Because HF are a disabling symptom without validated treatment, Actheane could be a well-tolerated therapeutic option. Clinical trial information: NCT01246427.

9628 Poster Session (Board #287), Sat, 1:15 PM-4:45 PM

A randomised, open-label trial of a Multimodal Intervention (Exercise, Nutrition and Anti-inflammatory Medication) plus standard care versus standard care alone to prevent / attenuate cachexia in advanced cancer patients undergoing chemotherapy. *First Author: Stein Kaasa, Trondheim University Hospital, Trondheim, Norway*

Background: The pathophysiology of cancer cachexia is multi-factorial consisting of muscle wasting, negative protein and energy balance, and systemic inflammation. There is no established treatment for cachexia, paradoxical to the importance of this condition in limiting oncology treatment. New approaches are needed to address the complexity of the syndrome and to challenge the accepted therapeutic nihilism. To treat cachexia optimally it has been argued that a multimodal intervention is necessary to enable the multi factorial pathophysiology to be targeted. Integral to this is targeting inflammation as the main driver of cachexia. **Methods:** An international, multicentre randomised phase II study was conducted. Eligible patients had advanced lung cancer or pancreatic cancer and were due to start palliative chemotherapy. Patients were randomised (1:1 ratio) to receive either a multimodal intervention (exercise, anti-inflammatories, energy dense nutritional supplements combined with dietary advice) or standard cancer care. Primary outcome measures were feasibility of the intervention assessed by compliance and enrolment. Secondary outcomes examined weight, physical activity (using ActivPAL) and CT based muscle mass. Means and standard deviations (SD) are reported. **Results:** Forty-six patients were recruited from three regional cancer center's (Glascow (UK), Trondheim and Oslo (Norway). Overall compliance was $>$ 54% in all components of the intervention. Patients' in the treatment arm weight increased (0.91% (SD 2.46)), whilst those in the control arm lost weight (-2.12% (SD 2.50)), $p < 0.001$ ($N = 41$). Patients in the control arm lost 2.2% more muscle than the treatment arm, $p =$ 0,69. There were no statistical significant differences in physical activity in the patients that had repeated measurements of physical activity with ActivPal ($n = 22$). **Conclusions:** A multimodal cachexia intervention is feasible and improves weight in patients with incurable lung or pancreatic cancer. Based on these exciting findings, a definitive phase III study is now underway. Clinical trial information: NCT01419145.

9629 Poster Session (Board #288), Sat, 1:15 PM-4:45 PM

A phase III, randomized, double-blind study of single-dose intravenous fosaprepitant in preventing chemotherapy-induced nausea and vomiting associated with moderately emetogenic chemotherapy. *First Author: Bernardo Leon Rapoport, The Medical Oncology Center of Rosebank, Johannesburg, South Africa*

Background: This is the first study performed to directly evaluate the efficacy and safety of a single dose of intravenous (IV) fosaprepitant (FA), an NK1 receptor antagonist, used with a 5-HT3 antagonist and corticosteroid in subjects receiving moderately emetogenic chemotherapy (MEC). **Methods:** This was a global, phase 3, randomized, double-blind, parallel-group study in adult subjects naive to MEC and highly emetogenic chemotherapy (HEC) scheduled to receive an IV dose of ≥ 1 MEC agents on treatment day 1. Subjects were randomly assigned 1:1 to a control or FA regimen. Those in the control regimen received 8 mg oral ondansetron, 20 mg dexamethasone, and IV saline as placebo before the first dose of MEC on day 1, and 8 mg oral ondansetron 8 hours after the first dose, followed by 8 mg oral ondansetron every 12 hours on days 2 and 3. Those in the FA regimen received the same dose of oral ondansetron on day 1, along with 12 mg dexamethasone and a single dose of 150 mg IV FA before the first dose of MEC on day 1, with no additional prophylactic antiemetic beyond day 1. Primary outcomes were the proportion of subjects with a complete response (CR: no vomiting and no rescue medication use) during the delayed phase (25 to 120 hours after MEC) and FA safety/tolerability. **Results:** Baseline characteristics were generally balanced among the 1000 subjects in the primary efficacy population (502 FA, 498 control). The majority were white, $\geq$ 50 years of age, and female. CR was achieved in 396 (78.9%) subjects in the FA regimen and 341 (68.5%) in the control regimen during the delayed phase (treatment difference of 10.4%, $P <$ 0.001). Safety profiles were comparable between the treatment groups; drug-related adverse events occurred in 8.5% (FA) vs 9.1% (control). There were no cases of severe infusion-site pain, erythema, or induration reported; 3 cases of infusion-site thrombophlebitis were observed in the FA regimen compared with 0 in the control regimen. **Conclusions:** Single-dose 150-mg IV FA regimen is generally safe and well tolerated and provides superior control of CINV associated with MEC as measured by the proportion of subjects with CR in the delayed phase. Clinical trial information: NCT01594749.

9630 Poster Session (Board #289), Sat, 1:15 PM-4:45 PM

Effective complementary ASCO policy and day to day decision support strategies optimize anti-emetic choices. *First Author: Anmol Baranwal, Oncology Analytics, Inc., Plantation, FL*

Background: Emetogenicity is a common reason for patients forgoing effective chemotherapy. ASCO, in its 2013 Top Five list, recommends against overuse of antiemetics and for the use of cost-effective agents. Oncology Analytics (OA) is a cancer care decision-support entity comprised of oncologists, PharmDs and oncology RNs, interacting with some 5000 oncologists and promoting high quality cost-effective cancer treatment based on level I data and national guidelines. We hypothesize that on-patent antiemetics are overused in comparison to equally effective generics; that this misuse/overuse induces financial toxicity; and that these ill effects can be offset by ASCO policy initiatives and OA decision support activities. **Methods:** We analyzed antiemetic requests in 2013 & 2014 in Georgia and Florida. Linear regression and chi-squared were utilized to determine time trends for the ratio of palonosetron vs. generic antiemetic regimens (ondansetron and granisetron) across these 7 quarters. We contrasted prescribing behavior concurrent with ongoing OA interaction, before and after the release of ASCO recommendations against unnecessary expensive anti-emetics. **Results:** 12,116 antiemetic requests were assessed in a pre-approval setting. After the 2013 ASCO policy recommendation, there was an immediate increase in the likelihood of requests for cost-effective regimens compared to more expensive "on -patent" choices (chi-squared $p = 0.004$). Over a thousand (1164/5341, 22%) of the requests for branded medications were inappropriate according to ASCO and/or NCCN guidelines, and discouraged by OA. Over this time span, there is a clear trend toward cost-effective generic choices, decreasing extrapolated costs by about $300,000 annually. **Conclusions:** The ASCO-defined overuse of expensive antiemetics in Florida and Georgia is substantial. ASCO national Policy, supported by daily OA interventions, diminishes the unnecessary use of expensive anti-emetics, increases the use of cost-effective antiemetic alternatives, and diminishes financial toxicity while enhancing cancer care quality. ASCO guidelines, when supported by a decision support program, result in significant cost savings.

9631 Poster Session (Board #290), Sat, 1:15 PM-4:45 PM

Do cancer patients present with subclinical peripheral neuropathy prior to initiating neurotoxic chemotherapy? *First Author: Sabrina Ramnarine, Edinburgh Cancer Research UK Centre, University of Edinburgh, Edinburgh, United Kingdom*

Background: Chemotherapy-induced peripheral neuropathy (CIPN), is a common dose-limiting toxicity which may compromise patient survival, leaving many with chronic pain, disability and a negative impact on quality of life. The natural history and underlying pathophysiological mechanisms are unclear. Clinical management is challenging, therefore, early identification and prediction of patients who will develop CIPN is critical. Using a translational approach, this study aims to investigate and characterise the presence of subclinical peripheral neuropathy in gynaecological, colorectal and lung cancer patients. **Methods:** Quantitative Sensory Testing (QST) was conducted on 21 patients with the above cancers prior to starting neurotoxic chemotherapy and compared with 21 age and gender matched healthy controls, to characterise somatosensory profile. Skin temperature, thresholds for thermal, mechanical and sharpness detection along with sensorimotor function (grooved pegboard test) were assessed. Resting heart rate was measured as a marker of autonomic function. **Results:** Heart rate differed significantly between the two groups (healthy, mean 72.3 vs 87.9 in patients; $p < 0.0001$). Detection of painful thermal thresholds (lower limb) were also significantly different in the healthy group compared to patients (hot: 47.4°C vs 45.4°C; $p = 0.005$: cold: 9.7°C vs 16.2°C; $p =$ 0.04) with evidence of variance in the upper limb for hot (42.0°C vs 39.4°C; $p = 0.03$). Although not statistically significant, large differences existed between the groups in the pegboard test: dominant hand 75.6secs vs 83.2secs ($p = 0.15$), non-dominant hand, 79.0secs vs 88.4secs ($p =$ 0.06). **Conclusions:** This cohort of patients exhibited signs suggestive of subclinical autonomic and sensory nerve dysfunction prior to initiating chemotherapy manifested as: increased resting heart rate, hot and cold hyperalgesia and evidence of some sensorimotor impairment. This indicates a cancer-mediated process potentially contributing to CIPN and may provide insight into the complexities of the underlying pathophysiological mechanisms.

9632 Poster Session (Board #291), Sat, 1:15 PM-4:45 PM

Cost communication preferences, financial burden, and health-related quality-of-life (HRQoL). *First Author: Jonas A. De Souza, University of Chicago Medicine, Chicago, IL*

Background: Care team- patient communication regarding costs has been suggested as a means of minimizing patients' financial burden (FB) in oncology. However, it is unknown how cost communication preferences are related to FB or HRQoL. **Methods:** Patients with advanced cancers who had completed at least 3 months of chemotherapy were asked whether they agreed or disagreed with the following communication preference items: (1) willingness to discuss costs; (2) willingness to know the costs before treatment; (3) willingness to allow costs to be incorporated into shared-decision making (SDM); (4) wishing costs had been discussed in the past; (5) and whether costs were actually discussed. FB was assessed by the COST (COmprehensive Score for financial Toxicity), as well as by the EORTC financial impact (FI). Demographics, resource utilization, and HRQoL, measured by the FACT-G and EORTC QLQ-C30, were collected. Linear regression and chi-square tests were performed. **Results:** 233 patients were assessed. Most of the patients (n = 190, 82%) had never discussed costs with their care team. There was no association between preferences and HRQoL. Patients with FB by either instrument were more likely to report item (4) (COST, $p < .01$; FI, $p < .001$). Out of the 43 (18%) patients who agreed with this item, 34 (79%) had FB by COST, and 37 (86%) by the FI. There was no significant association between items (1), (2), (3), (5) and FB. Factors associated with communication preferences included age (item 4), race (2 and 4), employment (4), income (4) and education (1), as listed in the table below. **Conclusions:** HRQoL is not significantly associated with cost communication preferences. An opportunity for intervention was identified, as most of the patients who wished to have discussed costs in the past were now experiencing FB. The knowledge of these preferences may indicate the best timing and population with whom costs should be discussed.

Willingness to:	A%	D%	U%	Age	Race	Employment	Income	Education
(1) to discuss	45	29	26	NS	NS	NS	NS	*
(2) to know	68	15	17	NS	*	NS	NS	NS

9633 Poster Session (Board #292), Sat, 1:15 PM-4:45 PM

Randomized trial of a home-based exercise intervention for patients with advanced colorectal cancer: Effects on physical functioning and activity levels. *First Author: Karen Basen-Engquist, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Considerable evidence demonstrates the benefits of exercise for cancer survivors, but few studies focus on those living with advanced disease. We conducted a randomized trial of a home-based exercise intervention for patients with advanced colorectal cancer (CRC), and investigated the effects on physical functioning (primary) and physical activity. **Methods:** 152 patients with advanced CRC were recruited through the Community Clinical Oncology Program, and were randomized to: 1) a 4 month home-based exercise intervention (EX), or 2) a relaxation control group (R). Both groups received telephone coaching/prompts, instructional materials, and brief coaching and letters from their provider. The EX arm received pedometers and resistance bands. Participants completed self-reports of physical functioning and activity, and performance tasks (2-min step test, 8-ft up and go, arm curl test, 30-sec sit–to-stand test) at baseline and end of study (EOS). Linear mixed model analysis tested intervention arm effects on EOS outcomes, adjusting for baseline and accounting for random effects of study site and physician. **Results:** Of the 152 randomized patients, 55 (72%) in EX and 57 (75%) in R completed the study. No serious adverse events were attributable to the interventions. At EOS, the EX arm reported more light and moderate activity at EOS than the R arm ($p = 0.003$ and 0.002, respectively), and performed better on the 30-sec sit-to-stand than R group participants ($p = 0.05$), with a trend toward better performance on the 8-ft up-and-go ($p = .12$). There were no significant group differences in SF-36 physical functioning, step test, or arm curl test. **Conclusions:** In one of the first trials to test home-based exercise for patients with advanced CRC, EX effectively increased activity levels and improved select aspects of physical functioning, suggesting it may be a safe and useful intervention in this population. Clinical trial information: NCT00985400.

Estimated effects of EX on physical functioning.

Outcome	Effect estimate (SE)	p
30-sec sit-to-stand	1.1 (0.6)	0.05
8-ft Up-and-Go	-0.9 (0.6)	0.12
2-min step	4.5 (4.7)	0.33
Arm curl	0.5 (0.7)	0.53
SF-36 Physical Functioning	3.2 (4.6)	0.49

TPS9634 Poster Session (Board #293a), Sat, 1:15 PM-4:45 PM

A feasibility trial of geriatric assessment and integrated care plan for older cancer patients. *First Author: Martine Puts, University of Toronto, Toronto, ON, Canada*

Background: The majority of persons diagnosed with cancer are older adults. A comprehensive geriatric assessment (CGA) can identify current health care issues, start interventions to prevent/postpone adverse outcomes and maintain/improve the functional status and well-being of older adults. However, there is limited and conflicting evidence to support the effectiveness of CGA in oncology settings. Here, we explore the impact of a CGA and integrated care plan in optimizing outcomes in older patients with advanced breast (BC), gastrointestinal (GI) or genitourinary (GU) cancer **Methods:** A two-group parallel single-blind phase II RCT is enrolling 60 patients aged 70 years and over, diagnosed with GI, GU or BC, referred for first line chemotherapy or having received < 2cycles (< 6weeks) of chemotherapy at Princess Margaret Cancer Centre. Patients need to be fluent in English, have a life expectancy > 6 months, ECOG PS 0-2 and able to provide informed consent. Randomization to intervention and control group is 1:1 and stratified by treatment intent (adjuvant vs. palliative). The intervention includes a full CGA by a multidisciplinary geriatric team followed by an integrated care plan to address the issues identified. Based on the CGA and discussion with the patient, tailored evidence-based interventions will be carried out by the team using a standardized intervention protocol. Participants in the intervention group are seen by the intervention team at baseline for the CGA and development of the integrated care plan; and at 3 and 6 months to assess intervention fidelity and measure outcomes. The co-primary outcomes are: 1) Maintaining/improving quality of life (EORTC QLQ-C30); 2) Modification of the cancer treatment plan. The secondary outcomes are: 1) Functional status (OARS Instrumental Activities of Daily Living); and 2) Feasibility of the study by tumor site. 15 of 60 planned patients have been enrolled to date. This will be one of the first RCTs of CGA in geriatric oncology to show feasibility and provide estimates of impact on relevant outcomes to inform the design of a phase 3 trial. Clinical trial information: NCT02222259.

TPS9635 Poster Session (Board #293b), Sat, 1:15 PM-4:45 PM

VOTRAGE study pazopanib in vulnerable elderly patients after geriatric assessment—A phase I study with geriatric criteria. *First Author: Loic Mourey, Institut Universitaire du Cancer - Oncopole, Toulouse, France*

Background: Efficacy and toxicity of targeted therapies don't seem to vary considerably with age, but the impact of side effects in elderly patients is a major concern for clinicians. Our study aims to find the maximum tolerated dose (MTD) of Pazopanib (P) in a population of elderly patients, classified as "vulnerable" after comprehensive geriatric assessment (CGA), with a phase I methodology, integrating a geriatric criterion (2 points drop in ADL). Pharmacokinetic and pharmacogenomic studies are also planned. **Methods:** Open-label, multicenter (4), non-randomized, phase 1 dose escalation study to determine MTD and DLT (dose-limiting toxicity) of P in a population of vulnerable elderly patients, selected after CGA.Eligible patients will be enrolled into a standard 3+3 design with a dose of P of 400, 600 and 800 mg daily. DLT will be assessed during the first month. Patients will receive P until progression or untolerable toxicities (30 pts max). **Main inclusion criteria:** Age ≥ 75; metastatic cancer (kidney, lung, neuroendocrine pancreatic, sarcoma, ovary, thyroid, bladder, breast); No geriatric syndrome, no ADL impairment; Geriatric disorders (and/or); CIRSG: ≤2 gr 3 comorbidities; IADL: <8; SPPB: 6-9; MNA: 17-23; MMSE: < 24; GDS 15: >5 **Geriatric assessment:** G8 ADL: Activities Daily Living, IADL: Instrumental ADL MMSE: Mini-Mental State Examination SPPB: Short Physical Performance Battery MNA: Mini-Nutritional Assessment CAM: Confusion Assessment Method GDS-15: Geriatric Depression Scale CIRS-G: Cumulative Illness Rating Scale for Geriatrics **DLT definition:** The MTD is defined as the highest dose level for which 6 patients were treated with a maximum of one patient (~20%) presenting a DLT during the first month of treatment. DLT is defined as follow: -geriatric criteria: drop ≥2 points in ADL -classical hematologic and non hematologic criteria. **Status of the study**: 11 patients included (2^{nd} cohort of 2^{nd}level - 600 mg daily) **Conclusions:** This study is an attempt to adapt a phase I methodology to vulnerable elderly patients. The results will help clinicians to prescribe Pazopanib in this particular but numerous population, relying on geriatric assessment. Study funded by GSK Clinical trial information: NCT01642017.

TPS9636 Poster Session (Board #294a), Sat, 1:15 PM-4:45 PM

Cancer-related cognitive dysfunction (CRCD) and psychosocial development in young adult cancer survivors. *First Author: Kim Edelstein, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Chemotherapy is associated with long-lasting neurocognitive sequelae and structural and functional brain imaging changes in about 25% of older adults who do not receive central nervous system (CNS) directed treatment. This suggests that cancer or its treatment affects the brain regardless of primary tumor site. Because the brain continues to develop into the 3rd decade of life, younger adults (YA; age 18-39 yrs) may be vulnerable to CRCD. Cancer also disrupts acquisition of developmental milestones in YA. CRCD may exacerbate those disruptions, but this has never been studied. Study aims are to characterize CRCD in YA, explore its relation to psychosocial development, and identify subgroups at risk of adverse outcomes. **Methods:** In this prospective, inception-cohort study, we are recruiting YA who do not require CNS-directed therapy from ambulatory clinics at the Princess Margaret Cancer Centre (leukemia, lymphoma, breast, gynecology, gastrointestinal, genitourinary, sarcoma) and the YA Oncology clinic at the Jewish General Hospital: 200 YA with cancer who require chemotherapy, 100 YA with cancer who do not require it, and 100 healthy YA with no cancer history. As of Jan 30 2015, 113 participants were enrolled. Chemotherapy patients are assessed prior to treatment, and then 6 and 12 months later. The other groups are assessed at similar time intervals. The 2-hr test battery consists of standardized neurocognitive tests sensitive to CRCD and validated self-report psychosocial measures. Repeated measures mixed effects models will be used to examine longitudinal changes in each of the neurocognitive domains and each of the psychosocial development scores, using the predicted residual sum of squares method to avoid interpretation problems associated with repeated testing. Relationships between CRCD, psychosocial development, treatment, cancer type, and individual characteristics will be examined using regression. Exploratory analyses will investigate whether demographic, disease, or treatment factors contribute to longitudinal changes. Results will provide the basis for interventions that alleviate the psychosocial and cognitive sequelae in this underserved population.

TPS9637 Poster Session (Board #294b), Sat, 1:15 PM-4:45 PM

Rehabilitation of cognitive dysfunction in brain tumor patients. *First Author: Nadine M. Richard, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Quality of life is increasingly recognized as important to comprehensive cancer care. Individuals with brain tumors face the particular challenge of cognitive impairment from their disease and/or treatment effects. Prevalent deficits in processing speed, memory, attention and executive functions interfere with patients' interpersonal relationships, occupational activities and functional independence. Standard medical care typically provides minimal education or intervention for cognitive symptoms. Cognitive rehabilitation is a relatively new field, with very few well-controlled studies in cancer patients. As a result, oncology and supportive care teams lack accessible, reliable tools to address cognitive dysfunction. **Methods:** Building on research in other cognitively-impaired populations, we designed two behavioural interventions for brain tumor patients. Each offers a structured yet client-centered program through 8 weekly individual treatment sessions and between-session exercises. Goal Management Training (GMT) is a neuroscience-based intervention combining mindfulness practice and strategy training. The Brain Health Workshop (BHW) is a supportive psycho-educational program about the brain, cognition, and living with effects of a brain tumor. Using a prospective randomized controlled design, 54 brain tumor patients (with chronic cognitive dysfunction, $\geq$ 3 months post-radiation or surgery) are being enrolled in one of three study arms: GMT, BHW, or standard care (wait-list control). Patients complete a battery of tests assessing cognitive functioning, daily functioning, and quality of life (1) prior to intervention, (2) after the 8-week behavioural intervention (or wait-list) period, and (3) after an additional 4 months to evaluate longer-term outcomes. Analyses of variance will examine treatment effects, with regression analyses to explore moderating effects of participant demographics, severity of baseline cognitive impairment, and tumor and treatment factors (e.g., tumor location, radiation dose and distribution). Results of this trial will lay the groundwork for implementation of evidence-based cognitive interventions for brain tumor and cancer patients across other disease sites.

TPS9638 Poster Session (Board #295a), Sat, 1:15 PM-4:45 PM

A phase III randomized double-blind study of prophylactic topical dapsone 5% versus moisturizer for cetuximab-induced papulopustular (acneiform) rash. *First Author: Mario E. Lacouture, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Epidermal growth factor receptor inhibitors (EGFRI) such as cetuximab, are associated with an acneiform rash that can affect up to 90% of treated patients, and can lead to interruptions and discontinuation of treatment by 76% and 32% of oncologists, respectively. Affected patients experience significant impairment in their quality of life (QoL) and psychosocial well-being. Prophylactic therapies include topical corticosteroids in combination with oral antibiotics, or the latter as single agents. No nonsteroidal topical agent has hitherto been investigated for the prevention of rash. Dapsone, a sulfone anti-microbial agent with known anti-inflammatory properties, is approved for the topical treatment of acne vulgaris. It suppresses neutrophil recruitment (interferes with migration and β-2 integrin-mediated adherence), inhibits release of prostaglandins and leukotrienes, IL-8 (from keratinocytes), and generation of toxic, oxygen-derived free radicals. While the exact pathogenesis of the acneiform rash to EGFRIs is not known, neutrophil recruitment and activation appear to play a key role. Therefore, we hypothesized that topical dapsone may be a safe and effective preventative strategy. **Methods**: We designed a prospective, randomized double-blind controlled trial to measure the ability of twice daily split-face and chest application of topical dapsone 5% gel versus moisturizer, to reduce the total lesion count (of the acneiform rash) by 20% at day 28, in conjunction with oral antibiotics. Up to 40 subjects (80 sides) with metastatic colorectal cancer or head and neck squamous cell carcinoma will be randomized and monitored for 6 weeks. Secondary objectives include evaluation of the difference in dermatologic QoL between the side of the face/ chest treated with dapsone versus the contralateral side treated with moisturizer, using the Skindex-16/FACT-EGFRI-18 questionnaires. The difference in global severity of rash between the two application sides will also be evaluated by measuring the agreement of blinded independent dermatologists' review of day-28 standardized photography of both sides. ClinicalTrials.gov: NCT01931150. Clinical trial information: NCT01931150.

TPS9639 Poster Session (Board #295b), Sat, 1:15 PM-4:45 PM

Efficacy and safety of olanzapine combined with aprepitant, palonosetron, and dexamethasone for the prevention of cisplatin-based chemotherapy-induced nausea and vomiting for gynecological cancer: KCOG G-1301 phase II trial. *First Author: Masakazu Abe, Department of Gynecologic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Olanzapine is proved to be effective for chemotherapy-induced nausea and vomiting (CINV). But its preventive efficacy in combination with standard antiemetic therapy (palonosetron, aprepitant, and dexamethasone) is unknown. The purpose of this study is to prove the preventive effect of olanzapine for the prevention of CINV caused by highly emetogenic chemotherapy (HEC) when used with standard antiemetic therapy. We started a prospective multicenter phase II study at six facilities related to Kansai Clinical Oncology Group (KCOG) since September 2013. **Methods:** Chemo-naïve patients aged 20-79 years old is enrolled. They are gynecologic cancer patients who are treated with HEC regimen containing cisplatin (more than 50 mg/m2). Target sample size is 40. Since olanzapine is contraindicated in patients with diabetes mellitus, their blood sugar level and HbA1c are checked to confirm that they do not have glucose intolerance before treatment. All patients are informed of drug information and the consent of using olanzapine are obtained. Aprepitant is administered at a dose of 125 mg before chemotherapy on day 1 and at 80 mg on days 2 and 3. Palonosetron (0.75 mg) is given before chemotherapy on day 1. Dexamethasone is administered at a dose of 9.9 mg before chemotherapy on day 1 and at 6.6 mg on days 2–4. 5mg oral olanzapine is administered for 6 days from the day before chemotherapy. All of patients record the self-evaluation diary about their emesis every 24 h throughout the overall phase (0–120 h after cisplatin). The primary endpoint is the proportion of patients with a complete response (no vomiting and no rescue therapy) throughout the overall phase. The secondary endpoints are the proportion of patients with complete response in the acute phase (0–24 h after cisplatin) and in the delayed phase (24–120 h after cisplatin) of the study, as well as the proportion of patients with complete control (no vomiting, no rescue therapy, no significant nausea (numeric rating scale 0-2)) and total control (no vomiting, no rescue, no nausea) throughout the study and in the acute and delayed phases. Clinical trial information: UMIN000011857.

TPS9640 Poster Session (Board #296a), Sat, 1:15 PM-4:45 PM

TabPRO trial: Tablet-based real-time detection of patient-reported outcomes during adjuvant outpatient chemotherapy for breast cancer. *First Author: Michael R. Mallmann, Department of Obstetrics & Gynecology, University Hospital of Bonn, Bonn, Germany*

Background: Current symptom inquiry during adjuvant chemotherapy is based on symptom reporting at regular intervals, usually at the start of the subsequent cycle of chemotherapy or by telephone interviews during chemotherapy cycles. Consequently there exists a time lag between occurrence of symptoms, reporting by the patient and initiation of side-effect directed therapy. In contrast, a real-time reporting of symptoms might fasten reaction towards side effects and thus improve patient care. **Methods:** This prospective multicenter trial determines the feasibility of an App-based query system to collect patient-reported outcomes (PRO) during outpatient adjuvant chemotherapy for breast cancer and to treat side effects during chemotherapy in real-time. The system includes an App-based symptoms assessment software for patients and an either Tablet- or computer-based symptoms-control software for physicians and health-care professionals offering a daily checkup of symptoms using a visual and intuitive App-based symptom assessment. Thus far, all 57 anticipated patients that are treated with adjuvant therapy for breast cancer in the participating trial centers have been enrolled. We evaluate all chemotherapy-related symptoms in terms of frequency, severity, both association with chemotherapy cycles or patient characteristics and course during chemotherapy on at least a daily basis. Moreover, we evaluate time of reaction between reporting of PRO by the patient and both assessment and contacting by the physician. We evaluate the frequency of intervention as well as satisfaction with such a system by both patients and physicians. Electronic tablet-based PRO might increase efficiency of data collection and transmission, the patient-physician communication and consecutively patient compliance. Due to early intervention this type of outcome-monitoring might help to minimize chemotherapy-induced side effects by a rapid reaction to the reported symptoms. Consequently the TabPRO trial with its daily reporting of PRO has the potential to change the current assessment of chemotherapy-related side effects and to optimize patient care during outpatient chemotherapy. Clinical trial information: NCT01991691.

TPS9641 Poster Session (Board #296b), Sat, 1:15 PM-4:45 PM

Three-arm randomized trial of sodium alginate, orally administered mucoprotective agent, for preventing radiation esophagitis in pts with locally advanced non-small-cell lung cancer (LA-NSCLC) receiving concurrent chemoradiotherapy (CRT): Okayama Lung Cancer Study Group 1401. *First Author: Katsuyuki Hotta, Department of Respiratory Medicine, Okayama University Hospital, Okayama, Japan*

Background: Concurrent CRT is the standard treatment in LA-NSCLC. Our phase 3 trial also showed a favorable efficacy of cisplatin-docetaxel and concurrent thoracic radiotherapy (JCO 2010). However, this intensive therapy can cause G3 or worse severe esophagitis of around 14%~27%, which would deteriorate pt's QOL and then lead to poor treatment compliance. Unfortunately, various types of supportive therapy including amifostine have failed to demonstrate the prevention of this toxicity. Sodium Alginate, already approved in Japan for gastritis, is highly viscous enough to stay long on the esophageal mucosa, leading to a mucosal protective effect in esophagus. To investigate if the agent indeed has a preventive effect for severe esophagitis in pts receiving concurrent CRT, we started three-arm randomized trial of sodium alginate with two different schedules vs. water. **Methods:** Pts have to meet the followings: untreated LA-NSCLC; suitable for receiving CRT; PS of 0 or 1; age $>$ 20 yrs. The primary endpoint is set as proportion of $\geq$ G3 esophagitis by CTCAE ver.4.0. With the stratification by institute, PS and esophagus V35 (Technol Cancer Res Treat. 2013), pts will be randomly assigned centrally to one of the followings; sodium alginate initiated concomitantly with CRT (A), sodium alginate initiated soon after developing extremely mild esophagitis during CRT (B), or water administered through CRT (C). Sodium alginate is administered at a dose of 60 ml per day. Assuming the proportion of $\geq$ G3 esophagitis would be 8% each in arms A and B and 27% in arm C, the required sample size is 200 pts (1-β: .7, α: .05). The secondary endpoint includes QOL, the frequency of additional prescription of analgesics, response and survival. Enrollment began in 2014, and will complete by 2017. UMIN registration number of 000013113 Clinical trial information: 000013113.

TPS9642 Poster Session (Board #297a), Sat, 1:15 PM-4:45 PM

Anticoagulation therapy in selected cancer patients at risk of recurrence of venous thromboembolism. *First Author: Annie Young, University of Warwick, Coventry, United Kingdom*

Background: Venous thromboembolism (VTE) in cancer patients is an important and increasingly frequent clinical problem. The impact of VTE on cancer patients can be considerable. Targeted patient selection by identifying patients with clinically relevant recurrent VTE may have wider health economic benefits whilst reducing patient risk through over-treatment. In the UK, dalteparin is the licensed anticoagulant for the extended treatment and prevention of recurrence of VTE in cancer patients and thus, the gold standard. Rivaroxaban is a highly selective direct Factor Xa inhibitor with oral bioavailability. **Methods:** Select-d is a prospective, randomised, open label, multicentre pilot trial comparing dalteparin (200 IU/kg daily subcutaneously for 1 month and 150 IU/kg months 2-6); and rivaroxaban (15 mg orally twice daily for 3 weeks and 20mg once daily for 6 months in total) for cancer patients with VTE, with a second placebo-controlled randomisation (rivaroxaban vs placebo) comparing the duration of therapy (6 vs 12 months) in residual vein thrombosis (RVT) positive patients. 70% of patients are estimated to be RVT positive after initial treatment. 530 patients are being recruited toprovide reliable estimates of the primary outcome (VTE recurrence rates) to within the 95% confidence interval of 8% assuming VTE rates are 10% at six months. The secondary objectives include safety, acceptability, biomarker identification and health economics. The select-d trial is amongst the first randomised trials of the new oral anticoagulants in patients with cancer, following recommendations from the UK National Institute of Health and Care Excellence. The select-d trial will recruit for two years with a minimum of one year follow up. The results will support optimal treatment for this key patient group. The independent TSC and DSMC fully support this important trial. Clinical trial information: ISRCTN86712308.

TPS9643 Poster Session (Board #297b), Sat, 1:15 PM-4:45 PM

Phase 3 randomized double blind placebo controlled trial evaluating Omega-3 in the prevention of Taxane or Platinum Induced Peripheral Sensory Neuropathy. *First Author: Ralph Maroun, Department of Oncology, McGill University Health Center, Montreal, QC, Canada*

Background: Chemotherapy induced peripheral neurotoxicity (CIPN) is a common and feared side effect of taxanes and platinum based chemotherapy. CIPN often leads to a decrease in dose intensity and or premature discontinuation of chemotherapy. Omega-3 fatty acids (OFA) have beneficial effects on neurological disorders including diabetic neuropathy, primarily by inhibition of the formation of proinflammatory cytokines involved in peripheral neuropathy (PN). A small study by Ghoreishi et al. has shown benefit of OFA in the prevention of taxane induced neuropathy. We hypothesize that the supplementation of OFA should diminish and or delay platinum or taxane induced PN. **Methods:** Randomized double blind placebo controlled trial to investigate the efficacy of OFA in reducing incidence and severity of taxane or platinum-induced PN. Eligible patients with breast cancer randomly assigned to take mammalian OFA with Vit D3 (provided by Auum Inc) 5cc sublingual tid vs placebo tid for 6 months. Clinical and electrophysiological studies were performed before the onset of chemotherapy and one month after cessation of therapy to evaluate CIPN based on "reduced Total Neuropathy Score"(rTNS). Eligibility criteria: Age 18-75, ECOG $<$ 2, receiving taxane or platinum based chemotherapy Endpoints:The primary endpoint was the incidence of grade 2+ CIPN (CTCAE v 3.0) in each treatment arm, analyzed by chi-square testing. Planned sample size was 100 patients per arm to provide 80% power to detect a difference in incidence of grade 2+ CIPN from 25% in the placebo group to 10% in the OFA group. Secondary endpoints: 1. rTNS to evaluate the existence and severity of CIPN (rTNS consists of subjective sensory symptoms and objective measured by nerve conduction studies). The patients receive an rTNS score ranging from 0 to 28. The severity of CIPN then is graded as follows:1.mild (total score 1–10), moderate (total score 11-19); and severe (total score 20–28).) 2.Brief pain inventory and 3.The 11-item FACT/GOG-Ntx, version 4 (questionnaires validated to assess neuropathy due to chemotherapy). Conduct to Date: Study activation: Dec 2014. Enrollment: 15 subjects. Clinical trial information: NCT02294149.

10000 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Morbidity and mortality associated with subsequent meningiomas among childhood cancer survivors exposed to cranial radiotherapy: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Daniel C. Bowers, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Survivors of childhood cancer who were exposed to cranial radiotherapy (CRT) are at increased risk of subsequent meningiomas. However, incidence rates, neurological sequelae and impact on mortality are not well defined. **Methods:** Among 4,221 survivors exposed to CRT, subsequent meningiomas were self-reported and confirmed by pathology, medical records or death certificate. Age of onset of specific neurologic conditions was self-reported and proxy-reported. Standardized incidence ratios (SIRs) and absolute excess risk (AER) were estimated using expected age-, gender-, and calendar-year specific rates from SEER. Hazard ratios (HRs) for neurological sequelae and mortality were estimated using Cox proportional regression. **Results:** 199 meningiomas were identified among 169 survivors. The median age at meningioma diagnosis was 28 years (range, 7 – 50 years); median age at last follow-up was 32 years of age (range, 9 – 56 years). Median interval from primary cancer to first meningioma diagnosis was 22 years (range, 5 – 37 years). The cumulative incidence of a subsequent meningioma by age 40 years was 5.6% (95% CI: 4.7% – 6.7%). The SIR for a subsequent meningioma was 619.4 (95% CI: 532.7 – 720.2) and the AER was 21.8 per 10,000 person-years (95% CI: 18.5 – 25.1). Within 12 months of diagnosis of a subsequent meningioma, 13.6% of participants reported new-onset seizures, 10.7% auditory-vestibular-visual deficits, 11.8% focal neurological dysfunction and 6.5% severe headaches. With a median follow-up of 72 months following subsequent meningioma diagnosis, 22 (13%) participants died (6 deaths attributed to meningioma). Adjusting for cranial radiotherapy dose, a diagnosis of subsequent meningioma was independently associated with increased all-cause mortality (HR = 2.3; 95% CI: 1.5 – 3.5; $p < 0.01$). **Conclusions:** CRT-exposed childhood cancer survivors with subsequent meningiomas experience considerable new-onset neurological morbidity and increased all-cause mortality. Effective screening methods for subsequent meningiomas may reduce neurological morbidity.

10001 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Chemotherapy and brain function in long-term survivors of childhood acute lymphoblastic leukemia (ALL). *First Author: Yin Ting Cheung, St. Jude Children's Research Hospital, Memphis, TN*

Background: Limited data are available on associations among chemotherapy treatment and brain function in long-term survivors of childhood ALL. This study evaluated associations between treatment exposure, neurocognitive testing, and functional magnetic resonance imaging (fMRI) in children treated on an institutional protocol, which featured chemotherapy without cranial irradiation. **Methods:** Long-term survivors of ALL (n = 213; 51.2% male; mean[SD] age 14.8[4.8]; 7.7[1.7] years post-diagnosis), completed neurocognitive testing and brain fMRI during an executive function/attention task. During chemotherapy, serum concentrations of high-dose intravenous methotrexate (HD-MTX), plasma homocysteine (HYC) following HD-MTX, and dexamethasone (DEX) were quantified as area under the curve (AUC). Serum cortisol level was also measured following oral DEX. These variables, along with number of triple intrathecal therapy doses, were analyzed with general linear modeling as predictors of neurocognitive and fMRI outcomes. fMRI analysis was performed using SPM8. **Results:** Survivors performed below normative data on two standard measures of executive function: cognitive flexibility (mean[SD] Z-score = -0.55[1.2]) and fluency (-0.38[0.9]), both *p's* < 0.0001. After adjustment for demographic factors, poorer cognitive flexibility was associated with higher MTX AUC (Est. -0.024; $p = 0.015$) and higher HYC AUC (Est. -0.011; $p = 0.049$). Poorer fluency was also associated with higher MTX AUC (Est. -0.023; $p = 0.007$). Survivors diagnosed at younger ages performed poorly on fluency at any level of MTX AUC, while those diagnosed at older ages performed poorly only if exposed to high MTX AUC ($p = 0.063$). Brain activation was positively correlated with MTX AUC in bilateral frontal and caudate nuclei, and left putamen and anterior cingulate cortex. Of note, these brain regions are associated with cognitive flexibility and fluency, as well as other executive functions. **Conclusions:** Higher serum concentrations of MTX and plasma HYC following HD-MTX for childhood ALL may predict those at greatest risk for neurocognitive problems, particularly executive dysfunction, and altered brain activity during long-term survivorship.

10002 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Neurocognitive function of children treated for high-risk B-acute lymphoblastic leukemia (HR-ALL) randomized to Capizzi (CMTX) versus high-dose methotrexate (HDMTX): A report from the Children's Oncology Group (COG). *First Author: Naomi J. Winick, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Survivors of childhood HR-ALL are at risk for neurocognitive deficits. The causes are multifactorial including treatment, host and environmental factors. This study evaluated the relative impact of two different approaches to methotrexate delivery while simultaneously examining associations with demographic and treatment factors, in the absence of cranial radiation, on neurocognitive functioning after completion of therapy. **Methods:** Patients with HR-ALL, treated on COG AALL0232, were randomized to receive HD-MTX with leucovorin rescue versus lower dose, escalating CMTX with asparaginase. Intellectual functioning (IQ), working memory, and processing speed (PS) of participants was evaluated 8 - 24 months following completion of therapy. **Results:** Two-hundred thirty-seven participants were eligible and enrolled on study, with 195 (54% female) submitting valid data. Mean age at diagnosis was 8.9 years (SD = 5), with 46% (n = 90) under age 10 at diagnosis. Method of methotrexate delivery was unrelated to differences in neuropsychological outcomes. Survivors younger than 10 at diagnosis, however, had an 11.8 point decrement (SE = 2.1) in estimated IQ ($p < .01$), and a 5.3 (SE = 2.2) point estimated decrease in PS scores ($p < .05$), compared to older participants, after controlling for ethnicity, race, gender, insurance status and time off treatment [(raw IQ: 94.9 + 15 vs. 107.2 + 15), (PS: 94.9 + 15 vs. 98.7 + 16)]. Additionally, participants covered by US public insurers had adjusted IQs that were 12.0 points lower (SE = 2.8, $p < .01$), than participants with private insurance (raw IQ: 93.1 + 15 vs. 106.1 + 15). **Conclusions:** Even in the absence of cranial radiation, young survivors of HR-ALL are at risk for deficits in global intellectual functioning and processing speed. Critically, insurance status was also strongly associated with neurocognitive outcomes. These data may serve as a basis for developing screening protocols and potential interventions to both identify children with deficits and to ameliorate the impact of therapy on their neurocognitive outcomes. Clinical trial information: NCT00437060.

10003 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Langerhans cell histiocytosis in children: Correlation of *BRAF* status with clinical characteristic. *First Author: Sébastien Héritier, Versaille University & APHP, Trousseau hospital, Paris, France*

Background: In 2010, *BRAF* mutations were reported in patients with Langerhans cell histiocytosis (LCH). We have shown that $BRAF^{V600E}$ mutations are also present in more than half of Erdheim Chester disease (EDC), and that lesions of both ECD and LCH are responsive to treatment with vemurafenib. This study aims to define the clinical features of LCH children with or without *BRAF* mutations. **Methods:** 319 children (age < 18 years) were included in the French nationwide GeneHistio study. This study was approved by an ethical comity, and signed informed consent was obtained for all patients. LCH diagnosis was validated by pathological central review, and detection of $BRAF^{V600E}$mutation was performed by pyrosequencing. **Results:** 240 (80%) patients were informative for *BRAF* mutation. This cohort was similar to the 1423 patients of the French LCH cohort who were not analyzed for *BRAF*, except for the frequency of hematologic involvement (15% versus 10%, $P = 0.044$). Median age at diagnosis was 5.0 years [range, 0-17 yr], mean follow-up was 4.7 years, and sex ratio was 1.2. LCH was a single-system disease (SS) in 55%, and multisystemic disease without (MSRO-) or with (MSRO+) risk organ in 20% and 25% of cases respectively. Affected organs were bone (82%), skin (33%), pituitary (17%), hematological involvement (15%), liver (14%), spleen (13%), lung (13%) and central nervous system (CNS) (7%). The 5 years relapse free survival was 58%, and 7 death occurred. $BRAF^{V600E}$ mutation was detected in 125 cases (52%). Univariate analysis showed that $BRAF^{V600E}$ was associated with skin or liver or spleen involvement, or with hematological dysfunction ($P < 0.05$). Furthermore the frequency of $BRAF^{V600E}$ was different in children with SS, MSRO- and MSRO+ disease ($P < 0.005$). Multivariate analysis showed that skin and hematologic involvement had a higher frequency of $BRAF^{V600E}$ with Odds ratio of 3.6 (95%CI [1.6-8.5] and 8.3 (95%CI [1.7-39.9] respectively. Sequelae of LCH were detected in 24% and 12% of patients with or without $BRAF^{V600E}$ ($P = 0.02$). **Conclusions:** In children with LCH, $BRAF^{V600E}$ mutation is associated with features commonly found in more aggressive forms of the disease.

10004 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Phase 1 study of dabrafenib in pediatric patients (pts) with relapsed or refractory *BRAF* V600E high- and low-grade gliomas (HGG, LGG), Langerhans cell histiocytosis (LCH), and other solid tumors (OST). *First Author: Mark W. Kieran, Dana-Farber Cancer Inst-PND, Boston, MA*

Background: Dabrafenib is an orally available, selective ATP-competitive inhibitor of BRAF V600E kinase, approved in unresectable or metastatic melanoma pts with the V600E mutation. This international study was designed to determine the recommended phase 2 dose (RP2D) in pts < 18yrs based on maximum tolerated dose, or systemic exposure similar to that seen in adult pts (AUC, 4000–5500 ng*h/mL), whichever came first. **Methods:** Dabrafenib was given orally twice daily, beginning at 3.0mg/kg/day. Toxicity, pharmacokinetics, and response were assessed by disease-appropriate criteria at each dose for pts > 12yrs and ≤ 12yrs. Doses of 3.0, 3.75, 4.5, and 5.25mg/kg/day were assessed by a rolling six design. When a dose level was filled and under assessment, additional pts could join the previous dose level deemed tolerable. **Results:** Enrollment for phase 1 completed at 27 pts, 15 male, median age 9yrs (range 1–17), with HGG n = 8, LGG n = 15, LCH n = 2, and OST n = 2. One pt had a dose-limiting toxicity (DLT) of grade 3 maculopapular rash (MR) at 4.5mg/kg/day, but is on study ≈9mths after restarting dabrafenib at 3.75mg/kg/day. Serious adverse events judged related to dabrafenib included MR (1 pt); hypotension, disseminated intravascular coagulation, fever (1 pt, outside DLT period); and arthralgia (1 pt). Duration on study ranged from 9wks to 19mo (ongoing); 20 pts remain on treatment. The RP2D for pts > 12yrs is 4.5mg/kg/day (median AUC 5285) and 5.25mg/kg/day (median AUC 4384) for ≤ 12yrs. Investigator-assessed best radiographic responses included 3 complete response (CR), 3 partial response (PR) and 2 progressive disease (PD) in HGG; 8 PR, 6 stable disease (SD) and 1 PD in LGG; 2 CR in LCH; 1 SD and 1 PD in OST (source data verification ongoing). **Conclusions:** The RP2D of dabrafenib for children > 12yrs and for those ≤ 12 was determined based on the target AUC when taken twice daily. The drug was well-tolerated with manageable toxicity. A high proportion of pts demonstrated radiographic responses in this phase 1 trial in different *BRAF* V600E-positive tumors. The disease stratified phase 2 component of the study is underway (NCT01677741). Clinical trial information: NCT01677741.

10005 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Phase I study of ceritinib in pediatric patients (Pts) with malignancies harboring a genetic alteration in ALK (ALK+): Safety, pharmacokinetic (PK), and efficacy results. *First Author: Birgit Geoerger, Institut Gustave Roussy, Paris, France*

Background: Ceritinib is a potent ALK inhibitor with durable efficacy in adult pts with *ALK*-translocated non-small cell lung cancer. This report describes the results of a phase I study (NCT01742286) in pediatric pts with ALK-aberrant malignancies: anaplastic large cell lymphoma (ALCL); myofibroblastic tumor (MT)/inflammatory (IMT) rhabdomyosarcoma (RMS) and neuroblastoma (NB). In these tumors *ALK* aberrations differ: ALCL and IMT carry gene translocations, NB amplifications or mutations, and RMS copy number gain or no change. **Methods:** This trial enrolled pediatric pts ≥ 1 to <18 yrs. ALK gene aberration was required, except in ALCL and RMS, where ALK+ by immunohistochemistry was sufficient. In a fasted, dose-escalation phase, pts received ceritinib at 300–560 mg/m^2/day to determine the recommended dose for expansion (RDE). Pts were assessed for safety, PK and efficacy. **Results:** Twenty-two pts were enrolled (22 centers in 10 countries) over 13 months including: 2 ALCL, 6 IMT, 1 MT, 7 NB, 6 RMS. Median age was 10 years (range 2-17), 14 were male and 3 were crizotinib-pretreated (1 NB, 2 IMT). Completion of the fasted escalation phase established a RDE of 510 mg/m^2. Common adverse events (% Any Grade [G]; G3/4) were diarrhea (86.4; 9.1), vomiting (81.8; 0), nausea (54.4; 0), elevated ALT (45.5; 18.2), abdominal pain (40.9; 9.1), decreased appetite (40.9; 0), elevated AST (36.4; 18.2), pyrexia (36.4; 0), and fatigue (31.8; 0). Two pts had dose limiting toxicity at 560 mg/m^2: G3 elevated ALT and persistent G2 abdominal pain. PK at the RDE (AUC and CL/F) was comparable to that reported for adults at this dose. Early data show responses in 2 of 2 pts with ALCL and 4 of 7 pts with MT/IMT (2 CR: 1 in a crizotinib-pretreated pt). To date, one pt with ALK F1174L mutated NB had shrinkage of a retroperitoneal mass; disease progressed in the brain, where lower ceritinib exposure is expected. Dose escalation with food is ongoing. **Conclusions:** The RDE in children is 510 mg/m^2/day without food. The toxicity profile is similar to that in adults. Food may reduce gastrointestinal symptoms and allow further dose escalation. Ceritinib showed efficacy in pediatric pts with ALCL and MT/IMT. Clinical trial information: NCT01742286.

10006 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Outcomes of dasatinib plus intensive chemotherapy or stem cell transplant (SCT) for Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph$^+$ ALL) on Children's Oncology Group AALL0622. *First Author: William Birdsall Slayton, Shands At the Univ of Florida, Gainesville, FL*

Background: Children, adolescents and young adults with Ph$^+$ALL treated on COG AALL0031 had an outstanding 70% 5-year disease-free survival (DFS) rate with intensive chemotherapy plus imatinib given continuously. We hypothesized that dasatinib would improve outcomes compared to imatinib due to increased potency, better CNS penetration, and activity against imatinib-resistant clones. **Methods:** AALL0622 tested the safety and feasibility of adding dasatinib 60 mg/m^2 daily to AALL0031 chemotherapy in newly diagnosed Ph$^+$ALL subjects (1-30 yrs). Cohort 1 subjects received dasatinib 2 wks out of each 3-4 wk block, whereas Cohort 2 subjects received dasatinib continuously. SCT was recommended for subjects with a sibling donor and those with high risk (HR) disease based on rate of response measured by flow cytometry at end induction and consolidation. The remaining standard risk (SR) subjects were treated with chemotherapy plus dasatinib. While all AALL0031 subjects received cranial XRT, only CNS3 cases on AALL0622 received the same. **Results:** Sixty eligible subjects were enrolled from 7/2008 to 2/2012 (39 Cohort 1 and 21 Cohort 2); 33 completed protocol therapy; 18 came off therapy to have SCT, 2 were inevaluable for cohort based analysis, and 7 were dropouts. Dasatinib plus chemo was well tolerated with no toxic deaths. For the 51 evaluable subjects, 3 yr event-free (EFS) and overall (OS) survival were 79±6% and 93±3%, respectively. SR subjects (n = 48, 19% underwent SCT) had a 3-yr EFS/OS of 83±6%/96±3% and HR subjects (n = 9, 78% underwent SCT) had an EFS/OS of 63±19%/88±13%. Ten percent (6/60) had an isolated or combined CNS relapse on AALL0622 vs 6% (3/54; p = 0.50) on AALL0031. No difference in DFS was seen between AALL0031 subjects receiving imatinib continuously and AALL0622 whole cohort (3-yr DFS of 79 ±6% for both studies, p = 0.39). **Conclusions:** Dasatinib with intensive chemotherapy was well tolerated. Subjects with rapid response had excellent outcomes without SCT. Further follow-up and additional trials are necessary to define the relative role of dasatinib and imatinib in promoting long-term survival in pediatric Ph$^+$ ALL. Clinical trial information: NCT00720109.

10007 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Feasibility of intensive post-Induction therapy incorporating clofarabine (CLOF) in the very high risk (VHR) stratum of patients with newly diagnosed high risk B-lymphoblastic leukemia (HR B-ALL): Children's Oncology Group AALL1131. *First Author: Michael Burke, Medical College of Wisconsin, Milwaukee, WI*

Background: Four-year disease free survival (DFS) for patients with B-ALL classified as VHR is approximately 70%. Strategies to improve DFS with intensive post-Induction therapy using fractionated cyclophosphamide (CPM), etoposide (ETOP) and CLOF were evaluated on AALL1131. **Methods:** AALL1131 enrolled patients 1-30 years old with newly diagnosed HR B-ALL. The VHR subset was randomly assigned post-Induction to the Control Arm (CA) with modified BFM CPM + fractionated cytarabine + mercaptopurine, Experimental Arm 1 (Exp1) with CPM + ETOP, or Experimental Arm 2 (Exp2) with CLOF (30 mg/m^{2}x 5 days) + CPM + ETOP during Part 2 of Consolidation (CON) and Delayed Intensification. All arms included identical doses of vincristine and pegaspargase. **Results:** The rates of Grade 4/5 infection and Grade 3/4 pancreatitis were significantly increased in Exp2 compared to CA and Exp1 (Table). The dose of CLOF was subsequently reduced from 30 to 20 mg/m^{2}x 5 days and myeloid growth factor was required following CLOF administration. Despite these changes, 3/39 patients developed Grade 4 infections and one of these patients later developed a Grade 5 toxicity [acute kidney injury (AKI)] attributed to CLOF versus no Grade 4/5 infections on CA (n = 20) or Exp1 (n = 47). Four patients on Exp2 had prolonged cytopenias > 60 days during the 28 day CON Part 2 versus none on CA or Exp1. Two of the Exp2 patients failed to recover counts, one had Grade 5 AKI on day 92 and one was removed from protocol therapy on day 92. **Conclusions:** CLOF as administered with CPM/ETOP on Exp2 showed greater toxicity and was not considered feasible due to infectious toxicities and prolonged cytopenias. Exp2 was permanently closed to accrual in September 2014. Clinical trial information: NCT01406756.

Toxicities: CON part 2

CLOF (30 mg/m^2 x 5 days)

Toxicity	CA (N = 26)	Exp 1 (N = 49)	Exp 2 (N = 50)	p
Gr4/5 Infection	1 Gr 4	1 Gr 4	12 Gr 4 (11) Gr 5 (1)	0.0017
Gr3/4 Pancreatitis	0	0	5	0.0238
Gr3/4 AKI	0	0	2	0.3517

CLOF (20 mg/m^2 x 5 days)

Toxicity	CA (N = 20)	Exp 1 (N = 47)	Exp 2 (N = 39)	p
Gr4/5 Infection	0	0	3 (7.7%)	0.14
Gr3/4 Pancreatitis	0 (0%)	1 (2.1%)	1 (2.6%)	1.00
Gr3/4/5 AKI	0 (0%)	0 (0%)	1 (2.6%)*	0.56

*Also listed as a Gr 4 infection.

10008 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Gemtuzumab ozogamycin (GO) and toxic mortality (TM) in children and adolescents with acute myeloid leukemia (AML) enrolled on Children's Oncology Group (COG) trial AAML0531. *First Author: Jaszianne A. Tolbert, Childrens Mercy Hosp, Kansas City, MO*

Background: Survival benefit in children with AML using GO was seen in COG AAML0531, though with greater TM. This retrospective analysis examines the overall causes of mortality focusing on the impact of GO and other potential risk factors of TM. **Methods:** Patients with *de novo*AML were randomized to chemotherapy with (GO) or without GO (noGO). Low risk and intermediate risk patients without a matched sib donor received 5 chemotherapy courses while all others received 3 chemotherapy courses and stem cell transplant (SCT). GO included a 3mg/m2/dose on day 6 of Induction I and, if not receiving SCT, on day 7 of Intensification II. Induction death (ID) was defined as any death during the two induction courses. Treatment-related mortality (TRM) was defined as death in the intensification cycles while in complete remission. ID and TRM risk factoring in patient, disease and treatment factors were analyzed. SCT recipients were censored after Intensification I. **Results:** 1,022 patients (511 per arm) age 0-29 yrs enrolled; 49 experienced first event death during therapy. 22 (2%) died in induction and 29(3%) died while in remission. ID was identical between arms (n = 11), with most deaths in Induction I. TRM occurred more frequently among GO recipients (NoGO 9[2%] v GO 18[4%]; p = 0.096). The majority of TRM occurred in Intensification II and III (NoGO 9[100%] v GO 16[89%]). Infection-related complications were the main cause of all TM (NoGO 13[65%] v GO 19[65%]). ID was proportionately greater in infants < 1yo (p = .01) yet no infant experienced TRM. Multivariate analysis excluding infants showed that WBC > / = 100,000 (OR 3.67, p = 0.013) and non-white race (OR 3.45, p = 0.018) were risk factors for ID. The only significant negative impact upon TRM was obesity (OR 3.33, p = 0.01). **Conclusions:** GO did not increase ID, but did non-significantly increase TRM during intensification in those not going to SCT. Excluding infants, high WBC and non-white race were significant risk factors for ID whereas obesity was the primary risk factor for TRM. As infection was the primary cause of all TM, continued focus on preventing and treating infection in these identified risk groups is imperative. Clinical trial information: NCT00372593.

10009 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Augmentation of therapy for favorable-histology Wilms Tumor with combined loss of heterozygosity of chromosomes 1p and 16q: A report from the Children's Oncology Group studies AREN0532 and AREN0533. *First Author: David B. Dix, British Columbia Childrens Hosp, Vancouver, BC, Canada*

Background: In National Wilms Tumor Study-5, tumor-specific combined loss of heterozygosity (LOH) of chromosomes 1p and 16q was associated with adverse outcome in patients with favorable histology Wilms Tumor (FHWT): stage I/II patients treated with Regimen EE4A (vincristine (VCR)/ dactinomycin (DACT)) had 4-year EFS of 91.2% without LOH and 74.9% with LOH; stage III/IV patients treated with Regimen DD4A (VCR/ DACT/ doxorubicin(DOX)) and radiotherapy (RT) had 4-year EFS of 83% without LOH and 65.9% with LOH. The AREN0533/AREN0532 studies assessed whether augmenting therapy would improve EFS for FHWT with combined 1p/16q LOH. Stage I/II patients were treated with the addition of DOX (Regimen DD4A) but no RT. Stage III/IV patients were treated with Regimen M (VCR/DACT/DOX alternating with cyclophosphamide/etoposide) and RT. **Methods:** Patients were enrolled through the AREN03B2 Biology and Classification study between10/2006 and 7/2013. All patients underwent central review of pathology, surgical reports and diagnostic imaging. Tumor tissue was evaluated for LOH 1p and 16q by microsatellite testing. Descriptive statistics were used to compare the EFS/OS between NWTS-5 and the current studies. **Results:** Median follow up for 1,134 patients enrolled on AREN0532/0533 was 3.6 years (0.1 to 8.1 years). Combined LOH 1p and 16q was detected in 35 evaluable stage I/II patients and 52 stage III/IV patients. At analysis in December 2014 the number of events was 6 observed versus 9 expected for stage I/II, and 4 observed versus 18 expected for stage III/IV. The 4 year EFS for the stage I/II LOH patients and stage III/IV LOH patients was 83.9% (95%CI: 64.9%, 93.1%) and 91.5% (95%CI: 78.5%, 96.8%) respectively. Grade 3 or higher hematological toxicity was the most common toxicity observed with Regimen M, affecting 60% of patients. There were no unexpected toxicities. **Conclusions:** Regimen M therapy improved EFS for patients with stage III/IV FHWT with LOH at 1p/16q as compared to the historical comparison group treated with Regimen DD4A. The benefit of using Regimen DD4A instead of Regimen EE4A for stage I/II FHWT with LOH is less clear. Clinical trial information: NCT00379340; NCT00352534.

10010 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Outcome and prognostic factors in stage III favorable histology Wilms tumor (FHWT): A report from the Children's Oncology Group (COG) study AREN0532. *First Author: Conrad Vincent Fernandez, IWK Health Centre, Halifax, NS, Canada*

Background: National Wilms Tumor Study 5 showed an inferior outcome for stage III FHWT patients with combined Loss of Heterozygosity (LOH) at chromosomes 1p and 16q when treated with Regimen DD4A (vincristine/dactinomycin/ doxorubicin/radiation therapy (RT)). Patients with combined LOH were thus treated with increased therapy on COG study AREN0533. We evaluated the outcomes and prognostic utility of clinical and biological variables for the remaining stage III FHWT patients. **Methods:** From October 2006 to August 2013, 583 eligible patients met COG stage III criteria on central review of pathology, diagnostic imaging and surgical reports. Forty patients found to have combined LOH 1p and 16q were excluded from the survival analysis. All patients received DD4A; those with anaplasia at delayed nephrectomy were removed from protocol therapy. Tumor 1p and 16q LOH status was determined by microsatellite analysis. **Results:** Median follow up was 42 months (1.5-90). Median age at diagnosis was 45 months (range 1.4-220); 381 (70%) were white. Median tumor weight was 550 grams (22-3140). The 4-year event-free survival (EFS) and OS estimates were 88% (95%CI: 85-91%) and 96% (95%CI 93-98%), respectively. Fifty-eight out of 62 events occurred in the first 2 years. Site of relapse: lung +/- other (n = 35), abdomen or pelvis (n = 5), liver (n = 5), other (n = 15). Causes of death: relapse (n = 12), toxicity (n = 2), second malignancy (n = 1), non-cancer death (n = 1), other (n = 1). 123/543 (23%) had delayed nephrectomy. Submitted delayed nephrectomy histology showed: Anaplasia (n = 8); Low Risk/completely necrotic (n = 5; 0 relapses), Intermediate risk (n = 54; 6 relapses), High-Risk/Blastemal Type (n = 4; 4 relapses) and Indeterminate (n = 2; 2 relapses). Other prognostic variables examined in the table below. **Conclusions**: Most stage III FHWT patients had very good EFS and OS with DD4A and RT. Lymph node status, post-chemotherapy histology, and LOH were predictive of EFS. Future trials should consider modifying therapy based on identified prognostic markers. Clinical trial information: NCT00352534.

		n	EFS	P value	OS	P value
Lymph Nodes	Negative	237	95%	< 0.01	98%	0.18
	Positive	152	83%		95%	
Gross residual disease	Negative	394	89%	0.14	97%	0.39
	Positive	134	85%		93%	
LOH	Neither	382	92%	< 0.01	97%	0.55
	16q only	99	83%		97%	
	1p only	56	74%		93%	

10011 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Omission of lung radiation in patients with stage IV favorable histology Wilms Tumor (FHWT) showing complete lung nodule response after chemotherapy: A report from Children's Oncology Group study AREN0533. *First Author: David B. Dix, British Columbia Childrens Hosp, Vancouver, BC, Canada*

Background: In National Wilms Tumor Study-5, patients with stage IV FHWT with metastases limited to the lung had 5-year EFS of 74% in the setting of incomplete lung nodule response by Day 70 versus 85% with complete lung nodule response (CR). All patients were treated with Regimen DD4A (vincristine/dactinomycin/doxorubicin) and whole lung irradiation (RT). To decrease the risk of long-term toxicities associated with RT, the AREN0533 study sought to determine whether patients with lung nodule CR after 6 weeks of chemotherapy would maintain excellent EFS without the use of lung RT. **Methods:** Patients were enrolled between February 2007 and February 2013 after undergoing central review of surgical reports, pathology slides and chest CT scans on the AREN03B2 Biology and Classification Study. Lung nodule response after 6 weeks of chemotherapy was determined by central radiology review. The null hypothesis was that 4-year EFS for CR when treated with DD4A therapy and pulmonary RT is 85%. The study was designed to have 90% power (testing at 10% 1-sided) to detect an increase in the risk of failure corresponding to 4-year EFS of 75%. **Results:** Among 391 patients enrolled, 296 had lung-only metastases, of which 105 (39%) had CR. At interim analysis in June 2014, 20 events were observed, compared to 14.5 expected under the null hypothesis (p = 0.15). 19 of the 20 events were recurrences and 1 was a second malignancy. Among the 19 recurrences, there were 2 deaths with a median follow-up of 2.3 years from recurrence. Recurrences were in the lung only (17), lung and liver (1) and abdomen (1). The 4-year EFS and OS estimates for the CR patients were 78% (95% CI: 68%, 86%) and 95% (95% CI: 83%, 98%). **Conclusions:** Patients with FHWT with week 6 lung nodule CR treated without lung RT had EFS somewhat less than the historical standard treated with lung RT, though this difference was not statistically significant. The excellent OS suggests that omission of lung RT may provide an acceptable treatment approach for this patient subgroup. Clinicians should balance the benefit of avoidance of lung RT against the possibility of a modest increase in relapse risk. Clinical trial information: NCT00379340.

10012 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Risk-based treatment for synovial sarcoma in patients under 30 years of age: Children's Oncology Group study ARST0332. *First Author: Rajkumar Venkatramani, Baylor College of Medicine, Houston, TX*

Background: Synovial sarcoma (SS) is the second most common soft tissue sarcoma in children. ARST0332 evaluated a risk-based treatment strategy for young soft tissue sarcoma patients designed to limit therapy for low-risk disease and to test neoadjuvant chemoradiotherapy for unresected high-risk disease. **Methods:** Newly diagnosed SS patients < 30 years old were assigned to 4 treatment arms based on disease features including POG grade: A (surgery only): grossly excised intermediate-grade and ≤ 5 cm widely excised high-grade tumor; B (55.8 Gy radiotherapy [RT]): ≤ 5 cm marginally resected high-grade tumor; C (ifosfamide/doxorubicin chemotherapy + 55.8 Gy RT): > 5 cm grossly resected high-grade tumor ± metastases; D (neoadjuvant ifosfamide/doxorubicin chemotherapy and 45 Gy RT, then surgery and RT boost based on margins): > 5cm unresected tumor ± metastases. Patients treated in Arm A and B were considered *low-risk* (LR), Arm C and D without metastases as *intermediate-risk* (IR) and those with metastases as *high-risk* (HR). **Results:** Of the 149 SS patients enrolled, 129 were eligible for analysis: LR (43), IR (66) and HR (20). Most (74%) were 10-19 years of age and 52% were female. Tumors were 79% extremity, 71% > 5 cm, 30% intermediate-grade, 70% high-grade, 63% invasive, 96% deep, and 16% metastatic. Thirty-nine patients (30%) did not receive RT. There were no toxic deaths and only 5 unexpected grade 4 adverse events. By risk group, at a median follow-up of 2.6 years, estimated 3-year event-free survival was: LR 83%, IR 79%, HR 16% and overall survival was: LR 97%, IR 93%, HR 29%. After accounting for risk category, none of the other patient or disease characteristics (age, gender, tumor site, neurovascular invasiveness, depth) were statistically significantly associated with outcome. **Conclusions:** The novel risk-based treatment strategy used in ARST0332 produced favorable outcomes in non-metastatic SS patients relative to historical controls using RT less frequently and at lower doses. The outcome for metastatic SS remains unsatisfactory and new therapies are urgently needed. Besides risk group, no other factors predictive of outcome were identified. Clinical trial information: NCT00346164.

10013 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Long-term risks for chronic medical conditions and premature mortality in survivors of pediatric soft tissue sarcoma: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Emily L Mueller, Indiana University, Indianapolis, IN*

Background: Approximately 67% of children with soft tissue sarcoma (STS) survive 5+ years. Late mortality, subsequent malignant neoplasms (SMN), and frequency or severity of chronic medical conditions (CMC) have not been extensively assessed. **Methods:** The CCSS, a multi-institutional retrospective cohort study of 5+ year survivors of childhood cancer, assessed outcomes for 1,246 STS survivors and 4,023 siblings with up to five questionnaires over 14 years. Self-reported CMCs were graded using CTCAE v4.03. Cox proportional hazards models provided hazard ratios (HR) and associated 95% confidence intervals (CI) for CMC. SMNs ≥ 5 years from primary cancer diagnosis were confirmed by pathology report, medical record, or death certificate. Standardized incidence ratios (SIR) and standardized mortality ratios (SMR) were generated using SEER and US mortality rates, respectively. **Results:** Median age at diagnosis was 8 years (range 0-20); median follow-up was 20 years (1.5-33.9). 243 survivors died, with SMR 5.3 (95% CI 4.7-6.0) and cumulative incidence 17.1% at 35 years from diagnosis. Compared with siblings, 42% of survivors reported ≥ 1 severe, disabling or life-threatening (grade 3-4) CMC (HR 3.5; 95% CI 2.9-4.2). Hearing, vision, and/or speech were the most prevalent severe chronic morbidities at 35 years post diagnosis (cumulative incidence at 35 years 17.0%, CI 14.7-19.3%), with survivors 2.6 times more likely to have experienced this CMC as compared to siblings (CI 1.8-3.8). Survivors who received radiation to the brain, head or neck (HR = 3.3, CI 1.8-6.4), pelvis (HR = 4.2, CI 2.2-7.8), or extremities (HR = 4.2, CI 2.2-8.1) were at particular risk for multiple (≥ 2) severe to life-threatening CMCs. The SIR of SMN was 5.6 (CI 4.6-7.0). The most frequent SMN was new (non-recurrent) soft tissue sarcoma (n = 22, SIR 22.6, CI 14.9-34.3), but risk was highest for the development of a secondary osteosarcoma (n = 12, SIR = 55.0, CI. 31.3-96.9). **Conclusions:** Survivors of pediatric STS, especially those exposed to radiation, experience significant long-term sequelae. This observation should guide long-term surveillance and inform the evolution of new therapies.

10014 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Association of recurrent or progressive p of form types II and III pleuropulmonary blastoma (PPB) with poor outcome: A report from the international PPB registry. *First Author: Kris Ann Pinekenstein Schultz, Childrens Hosps and Clinics - Minnesota, Minneapolis, MN*

Background: Pleuropulmonary blastoma (PPB) is a rare malignancy of the lung presenting in young children. PPB is the sentinel disease of the PPB-*DICER1*familial syndrome. The International PPB Registry (IPBBR) has pathologically confirmed 425 cases of PPB. Three pathologic subtypes correlate with outcome: Type I/Ir, purely cystic; Type II, combined cystic solid; Type III, purely solid. Five-year survival rates for Types I/Ir, II and III PPB are 91%, 71% and 53%, respectively. The outcome of Type II and III PPB after a relapse (recurrence or progression) is unknown. **Methods:** Yearly follow-up is requested for all patients by the IPPBR. All PPB was confirmed by central pathology review. Reports of relapse and second malignancies were obtained by the IPPBR from the local institution. In most cases, the pathology of relapse or second malignancy was available for additional central review. **Results:** A total of 107 PPB patients relapsed, of them 35 (33%) were alive at a median of 15 months (range 0-61) and 72 (67%) had died at a median of 10 months (range 0-60). Twenty-nine (27%) relapsed with isolated CNS metastasis, 51 (48%) with isolated chest relapse, and 27 (25%) with other relapse; of them 66%, 53% and 96% respectively have died. Of the survivors, 34/35 (97%) had isolated disease either in the chest or CNS. In addition to the patients with recurrence, 6 patients had secondary malignancies believed to be related to prior therapy and 5 had a metachronous *DICER1*-related tumor; of these 83% and 100% respectively, were alive. **Conclusions:** In this cohort of centrally-reviewed relapsed PPB only one-third were alive at last follow-up. Patients with isolated CNS or chest maybe sometimes survive, but patients with bone metastasis rarely survive. Novel treatment regimens for relapsed PPB are urgently needed.

	Alive	Dead	Total
Relapse			
-Isolated CNS	10 (34%)	19 (66%)	29
-Isolated chest	24 (47%)	27 (53%)	51
-Other (combined chest + CNS or systemic)	1 (4%)	26 (96%)	27
Total Relapse	35 (33%)	72 (67%)	107
Secondary malignancy	5 (83%)	1 (17%)	6
DICER1*-related metachronous malignancies	5 (100%)	0 (0%)	5

*Thyroid carcinoma, Sertoli-Leydig cell tumor, cervical embryonal rhabdomyosarcoma.

10015 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Early results from Children's Oncology Group (COG) ARST08P1: Pilot studies of cixutumumab or temozolomide with intensive multiagent chemotherapy for patients with metastatic rhabdomyosarcoma (RMS). *First Author: Suman Malempati, Oregon Health and Science University, Portland, OR*

Background: Data from a previous COG study (ARST0431) showed an early FFS improvement but no long-term survival benefit with intensive interval-compressed chemotherapy in metastatic RMS. ARST08P1 aimed to determine the feasibility of adding cixutumumab (insulin-like growth factor-1 receptor (IGF-1R) monoclonal antibody) or temozolomide to an intensive chemotherapy backbone. **Methods**: A series of non-randomized single-arm pilot studies were conducted. After determining feasibility, pilots were expanded to assess efficacy. Eligible patients were < 50yrs with metastatic RMS. Backbone therapy consisted of blocks of vincristine/irinotecan (weeks 1-6, 20-25, 47-51), interval-compressed vincristine/doxorubicin/cyclophosphamide alternating with ifosfamide/etoposide (weeks 7-9 and 26-34), and vincristine/actinomycin-D/cyclophosphamide (weeks 38-46). In Pilot 1, patients received cixutumumab (3, 6, or 9 mg/kg) IV once weekly throughout therapy. In Pilot 2, patients received oral temozolomide (100mg/m2) daily x 5 days with irinotecan. Patients received radiation therapy (RT) at weeks 20-25. RT was also permitted at weeks 1-6 or 47-51. **Results**: 168 eligible patients were enrolled (1/2010 - 7/2013). 71 patients received temozolomide and 97 patients received cixutumumab (19 at 3 mg/kg, 18 at 6 mg/kg, and 60 at 9 mg/kg). Most patients were ≥ 10 yrs old (73%) with alveolar histology (70%) and with bone and/or bone marrow metastases (59%). Two cases of Grade 4 and one grade 5 sinusoidal obstructive syndrome (SOS) occurred with cixutumumab at 9 mg/kg in combination with the chemotherapy backbone. Otherwise, toxicities were similar to ARST0431. With a median follow-up of 1.6 yrs, 18-month EFS was 68% with cixutumumab and 39% with temozolomide (log rank p-value < 0.001). **Conclusions**: Addition of cixutumumab or temozolomide to intensive multi-agent chemotherapy for metastatic RMS was safe and feasible. SOS may be a concern with higher doses of cixutumumab combined with intensive chemotherapy. Early FFS was better with cixutumumab than temozolomide. Overall outcome for metastatic RMS remained poor. Clinical trial information: NCT01055314.

10016 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Banked EBV-specific T-cells from HLA-partially matched normal donors to induce durable remissions of rituximab refractory EBV$^+$ B-cell lymphomas post hematopoietic and organ allografts. *First Author: Susan Prockop, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: EBV-LPD complicating allogeneic hematopoietic cell transplant (alloHCT) most frequently present as malignant, high grade, diffuse large B cell lymphomas (DLBCL) that do not respond to reduction in immune suppression. Rituximab induces remissions in about 55% of those with radiographic evidence of disease. Survival of rituximab-refractory EBV-LPD patients (pts) is 16 – 56 days. There are few other treatment options. We evaluated the efficacy and safety of EBV-CTLs in 2 clinical trials in alloHCT recipients with EBV+ disease. **Methods:** As part of 2 ongoing clinical trials (95-024 and 11-130) 57 pts received EBV-CTLs derived from unrelated third-party donors (13 on 95-024 and 18 on 11-130) or primary stem cell donors (26 on 95-024). Fifty-one pts were treated for monomorphic DLBCL, 3 polymorphic, 1 NK/T cell lymphoma and 2 for viremia alone. Subjects on 11-130 had all failed prior rituximab. On 95-024 28 of 39 pts had failed prior rituximab. Subjects in both studies received up to 5 cycles of EBV-CTL infusions; each cycle 1 or 2×10^6 cells/kg weekly for 3 weeks. **Results:** Of the 18 recipients of 3rd party EBV-CTLs on 11-130, 9 had complete response (CR), 3 partial response (PR) and 1 stable disease (SD) for a response rate of 67% and non-progression rate of 72%. The median duration of CR+PR was 318d. Kaplan-Meier (KM) overall survival (OS) was 71.8% at 1 and 2y. KM progression-free survival was 66.7% at 1y. Of 39 pts on 95-024, 23 had CR, 1 PR, and 3 SD, for a response rate of 62%. Strikingly, the 1y OS for rituximab-refractory pts in both studies was 50% and 49% for pts treated with 3rd party and transplant donor-derived EBV-CTLs respectively. Four patients on 11-130 and 6 patients on 95-024 died soon after the first EBV-CTL infusion; no death was considered related to treatment. EBV-CTLs had low toxicity: no pts developed cytokine release syndrome or required therapy for EBV-CTL-related GvHD. **Conclusions:** EBV-CTLs produce high response rates that are durable; pts who achieved CR had no relapses of EBV LPD. The OS in both studies far exceeded the survival reported for this patient population. EBV-CTLs had a favorable safety profile and were well tolerated. Clinical trial information: NCT01498484.

10017 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A feasibility and phase II study of the hu14.18-IL2 immunocytokine in combination with GM-CSF and isotretinoin in patients with recurrent or refractory neuroblastoma: A Children's Oncology Group study. *First Author: Suzanne Shusterman, Dana Farber Cancer Inst, Boston, MA*

Background: Combining anti-GD2 (disialoganglioside) monoclonal antibody with GM-CSF, IL2 and isotretinoin is now standard of care for high-risk neuroblastoma (NB) minimal residual disease (MRD) therapy. The humanized anti-GD2 antibody conjugated to IL2 (hu14.18-IL2) has clinical activity in NB and is more effective in NB-bearing mice than antibody and cytokine given separately. We therefore evaluated the safety, tolerability and anti-tumor activity of hu14.18-IL2 given with GM-CSF and isotretinoin in a schedule similar to current MRD therapy. **Methods:** Hu14.18-IL2 was given at the phase II dose (12 mg/m^2) on days 4-6 of a 28 day cycle with GM-CSF (250 μg/m^2/dose, days 1-2, 8-14) and isotretinoin (160 mg/m^2/day, days 11-25). Tolerability was determined based on the number of patients who developed an unacceptable toxicity (required pressor support or intubation). Response was evaluated every 2 cycles for patients with disease measurable by standard radiologic criteria (stratum 1), and for patients with disease evaluable only by MIBG and/or bone marrow histology (stratum 2). Disease burden was described in stratum 2 patients based on Curie scoring. **Results:** Fifty-two patients were enrolled on study; 51 were evaluable for toxicity and 44 were evaluable for response. Four patients had unacceptable toxicities, well below the protocol-defined rule for safety. Other grade 3 and 4 non-hematologic toxicities were reversible and expected based on prior trials. No responses were seen in stratum 1 (n = 14). In stratum 2 (n = 30), 7 responses were confirmed by central review (5 CRs and 2 PRs). The median baseline Curie score of the responders was 2 compared to 10 for non-responders (Wilcoxon rank-sum two-sided p-value = 0.0345). **Conclusions:** Hu14.18-IL2 given with GM-CSF and isotretinoin is safe and tolerable. Patients with only MIBG and/or bone marrow disease had a 23% response rate, confirming activity of the combination. Responders had a significantly lower disease burden than non-responders at study entry. These data support further study of hu14.18-IL2 in high-risk NB patients with MRD or a relatively low disease burden. Clinical trial information: NCT01334515.

Pulmonary function in adult survivors of childhood cancer: A report from the St. Jude Lifetime Cohort Study (SJLIFE). *First Author: Daniel M. Green, St. Jude Children's Research Hospital, Memphis, TN*

Background: The relationship between treatment exposures and long-term pulmonary function of childhood cancer survivors (CCS) treated with pulmonary toxic therapies has not been well studied. **Methods:** 606 of 989 SJLIFE CCS treated with pulmonary toxic therapy underwent assessment of forced vital capacity (FVC), forced expiratory volume in 1 second (FEV_1), single breath diffusion capacity for carbon monoxide corrected for hemoglobin ($DLCO_{corr}$) and total lung capacity (TLC) according to American Thoracic Society standards. Results were expressed as percent of race-, age-, and sex predicted values. Lung radiation dose was estimated using the patients' actual treatment ports and a CT dosimetry phantom. Associations were assessed using logistic regression. Variables significant at $p < 0.1$ on univariate analysis were entered into the multivariable models. **Results:** Median age at evaluation was 34.2 years [interquartile range (IQR), 28.7 to 40.1] and median time from diagnosis 21.9 years (IQR 16.6 to 27.8). Among survivors, 50.7% had $FEV_1 < 80\%$ of predicted, 47.2% FVC < 80%, 31.2% TLC < 75%, and 44.6% $DLCO_{corr} <$ 75%. Only 0.8% of survivors had obstructive ($FEV_1/FVC < 0.7$), but 31.2% had restrictive (TLC < 75%) lung defects. Risk factors are shown in the Table. **Conclusions:** These risk factors identified CCS who may benefit from interventions to improve pulmonary function.

	Odds Ratio (95% Confidence Interval)		
Risk factor	$DLCO_{corr}$ < 75% predicted	FEV1 < 80% predicted	TLC < 75% predicted
Age at diagnosis (years)			
5 – 9	0.81 (0.44, 1.50)	0.41 (0.21, 0.81)	0.71 (0.38, 1.35)

Second malignancies in neuroblastoma patients: A report from the International Neuroblastoma Risk Group. *First Author: Mark A. Applebaum, University of Chicago, Chicago, IL*

Background: Exposures to radiation and chemotherapy are associated with increased risk of second malignant neoplasms (SMN) in neuroblastoma survivors. However, it remains unclear if modifications in risk-based treatment strategies during the past 25 years have changed SMN rates. **Methods:** The International Neuroblastoma Risk Group (INRG) Task Force created a database of neuroblastoma patients diagnosed from 1974-2013. SMN risk was measured by cumulative incidence, standardized incidence ratios (SIR) and absolute excess risk (AER) per 10,000 person-years relative to a matched United States population. Poisson regression compared rates of SMN between different groups. **Results:** Of the 16,520 patients in the INRG database, 9,261 enrolled on Children's Oncology Group protocols had SMN data available. 79 (0.85%) patients developed SMN, including hematologic malignancies (n = 38), sarcomas (n = 19), carcinomas (n = 10), CNS tumors (n = 10), hepatoblastoma (n = 1), and nephroblastoma (n = 1). The incidence of SMN of the entire cohort was almost 9-fold higher than expected (SIR 8.9 (95% CI: 7.1-11.1), AER 13.3). High-risk patients had more than a 20-fold higher incidence of SMN than expected (SIR 20.1 (95% CI: 14.7-26.9), AER 32.5). Intermediate-risk patients showed a 6-fold rise in SMN (SIR 6.2 (95% CI: 3.3-10), AER 8.3), and low-risk patients trended toward higher than expected SMN rates (SIR = 2.6 (95% CI: 0.95-5.7), AER 2.8). High-risk patients had a significantly higher cumulative incidence of SMN compared to intermediate- or low-risk patients (1.6% vs. 0.98% vs. 0.37%; p = 0.01). The cumulative incidence of SMN for two treatment eras (1: 1990-1996; 2: 1997-2009), corresponding to intensification of treatment regimens for high-risk disease, showed a higher frequency of SMN for those treated in Era 2 compared to Era 1 (1.4% vs. 0.39% at 10-years, p = 0.012). **Conclusions:** The incidence of SMN is higher than expected in high and intermediate-risk neuroblastoma survivors. The exposure to more intensive treatment likely contributes to the higher incidence of SMN observed in high-risk patients diagnosed after 1996. Genome-wide association studies (n = 5,188) to identify modifiers of SMN susceptibility are ongoing.

Temporal trends in health status among adults in the Childhood Cancer Survivor Study (CCSS). *First Author: Kirsten K. Ness, St. Jude Children's Research Hospital, Memphis, TN*

Background: The impact of temporal changes in childhood cancer therapy on long-term health status has not been evaluated. With expansion of CCSS, information about health status is available for 5+ year survivors diagnosed from 1970-1999. **Methods:** We estimated prevalence of poor general and mental health, functional impairment, activity limitation and cancer-related anxiety and pain at baseline evaluation among 15,830 survivors of childhood cancer. Outcomes were compared among treatment decades using log-binomial regression to calculate relative risk (RR) and 95% confidence interval (CI), adjusted for age, sex, race and diagnosis. **Results:** Proportions of survivors treated with radiation and amputation decreased; proportions treated with anthracyclines or alkylating agents increased over time. Survivors diagnosed more recently were more likely to report poor general health, pain and anxiety, and less likely to report functional impairment. Diagnoses with large increases ($p < 0.001$) in prevalence of adverse outcomes from 1970-79 to 1990-99 were leukemia (9.8 to 12.6% poor general health), bone tumor (23.2 to 30.7% pain) and Hodgkin lymphoma (15.7 to 19.2% anxiety). CNS tumor survivors had the largest decrease in functional impairment prevalence (37.7 to 19.7%). **Conclusions:** While the proportion of childhood cancer survivors reporting functional impairment in the most recent era decreased, particularly among CNS tumor survivors, proportions reporting poor general health, pain and anxiety increased slightly from 1970 to 1999.

Survival and late effects in the risk-stratified hepatoblastoma patients treated by JPLT-2 protocol. *First Author: Eiso Hiyama, Hiroshima University, Hiroshima-Shi, Japan*

Background: The Japanese Study Group for Pediatric Liver Tumor (JPLT) has conducted cooperative treatment studies on hepatoblastoma (HB) since 1991. The main aim in JPLT-2 study launched in 1999 and closed in 2012 to evaluate the efficacy of cisplatin/pirarubicin in risk-stratified HB. This protocol was launched in 1999 and closed in 2012 to evaluate the cure rate of risk-stratified HB: standard risk HB (a tumor involving three or fewer sectors of the liver), intermediate risk HB (a tumor involving all sectors of the liver or invasion into portal or hepatic vein) and high risk HB (a tumor involving all sectors of the liver or with metastasis). **Methods:** Until 2012, 385 HB children who were younger than 15 years of age were eligible for inclusion in the JPLT2 study in which the cisplatin/pirarubicin regimen (CITA) is kept as the first line. In this study, we examined the outcome and late effects of the HB patients by the risk-stratified three groups (standard, intermediate and high risk groups). **Results:** Among 385 cases, PRETEXT I was 31, II was 120, III was 145, and IV was 89 including 86 cases (18%) with metastatic tumors. The 3-year EFS/OS of the cases with standard risk HB were 94/82%, while those of the cases with Intermediate and high risk HB was 64/49% and 34/28%, respectively. Except for 40 cases who underwent primary resection, complete resection of primary after CITA was performed 86% of standard risk, 66% of intermediate risk and 56% of high risk patients. And the late phase complications were 5 cases with maldevelopment, 17 with cardiac complications, 26 with ototoxicity and 5 with second malignancies. **Conclusions:** As compared with other multicenter cooperative protocols, CITA regimens achieved similar rates of survival and resectability in standard risk patients. More promising strategies including adequate liver transplantation and new targeting drugs should be developed for intermediate and high risk HBs. Clinical trial information: UMIN000001116.

The *DICER1* syndrome: Genotype-phenotype correlation in PPB patients. *First Author: Leslie Ann Doros, Childrens Natl Med Ctr, Arlington, VA*

Background: Mutations in *DICER1* were first described in 2009 from individuals diagnosed with pleuropulmonary blastoma (PPB). Since then, *DICER1* mutations have been found in individuals with other tumor types. Collectively, mutations in this gene and associated tumors make up the *DICER1* Syndrome. About 40% of PPB patients or first/second-degree relatives exhibit ≥ 1 feature of the syndrome. Through a multi-institutional study, we aim to better understand the *DICER1*syndrome disease spectrum and genotype-phenotype correlations. **Methods:** Informed consent was obtained from participants or legal guardians. Use of Sanger and Next-Gen sequencing, and targeted aCGH on blood, saliva and tumor tissue was performed. Phenotypes were abstracted from the International PPB Registry (IPPBR) records. **Results:** To date, 409 PPB patients have enrolled in the IPPBR. More than 150 individuals with PPB have undergone genetic testing; 111 have a deleterious mutation. About 43% of PPB mutation positive individuals were found to have additional related conditions: benign lung cysts (22%), cystic nephroma(CN)/renal cysts (16%), thyroid hyperplasia/cancer (20%), embryonal rhabdomyosarcoma (5%), nasal chondromesenchymal hamartoma (6%), ovarian Sertoli-Leydig cell tumor (4%), ciliary body medulloepithelioma (2%), and rarely Wilms tumor, Hodgkin's lymphoma, neuroblastoma, and brain tumors. Twelve (30%) mutation negative PPB patients were found to have additional related conditions with the most common being CN and thyroid disease. Patients with mosaic RNase IIIb mutations had the greatest number of disease foci. **Conclusions:** The germline mutation detection rate among this cohort is ~67% via Sanger sequencing. Use of Next-Gen sequencing and targeted aCGH increased detection to 75%. Deletions and mosaicism have been identified through these means. *DICER1* mutation positive PPB patients are at significant risk for other conditions. Sanger and Next-Gen sequencing mutation negative patients with multiple conditions require further molecular analysis. Understanding the *DICER1* syndrome spectrum of conditions and specific genotype-phenotype correlations will improve surveillance recommendations.

Clinical outcome and biological predictors of relapse following nephrectomy only for very low risk Wilms tumor (VLR WT): A report from Children's Oncology Group AREN0532. *First Author: Conrad Vincent Fernandez, IWK Health Centre, Halifax, NS, Canada*

Background: An earlier study of observation only following nephrectomy for VLR WT defined as stage I, age < 2 years, favorable histology with a weight<550 grams was suspended for excess relapse. Follow up revealed a higher salvage rate than originally predicted and suggested novel prognostic biomarkers. In this study, we sought to determine if 1) an observation alone strategy in centrally reviewed VLR WT demonstrates an Event Free Survival (EFS) of > 85% and Overall Survival (OS) of > 95%, and 2) to validate prognostic biomarkers. **Methods:** From 10/30/2006-8/12/2013, 116 eligible patients were enrolled with VLR WT; negative lymph node sampling was required and predisposition syndromes were excluded. All cases had central review of pathology, diagnostic imaging and surgical reports on the AREN03B2 biology and classification study. Evaluable tumors were analyzed for mutation of *WT1,* 1p and 16q loss of heterozygosity (LOH) using microsatellite analysis, 1q gain, 1p and 16q loss by MLPA, and 11p15 loss or retention of imprinting (LOI, ROI) using methylation restriction sites analysis. **Results:** Median follow up was 80 months (5-97). Median age was 11.5 months (0.1-23). 12 patients relapsed with no deaths. Estimated 4-year EFS was 89.7% (95% CI 84.1-95.2%) and OS was 100%. 1 patient is alive with disease after 4 relapses. First site of relapse was lung (n=5), tumor bed (n=4), abdomen (n=2), contralateral kidney (n=1). Median time to first relapse was 4.2 months (2.2-43). The presence of intralobar (p=0.46) or perilobar rests (p=1.0) was not associated with relapse, nor was histological subtype (p=0.16). 1q gain, 1p loss and/or 16q loss did not predict relapse, nor did *WT1* mutation (but 13/14 with *WT1* mutations also had 11p15 LOH). 11p15 methylation status predicted relapse. **Conclusions:** Most patients meeting VLR criteria can be safely managed by nephrectomy alone. 11p15 LOH/LOI predicts relapse. Future trials considering expansion of an observation alone strategy for low risk WT should incorporate these biomarkers. Clinical trial information: NCT00352534.

	Relapse No	Relapse Yes	Total	P value
11p15 LOH	32 (80%)	8 (20%)	40	0.0106
11p15 ROI	58 (97%)	2 (3%)	60	
11p15 LOI	6 (75%)	2 (25%)	8	
Total	96 (89%)	12 (11%)	108

Loss of STAG2 expression and prognosis in Ewing sarcoma family of tumors. *First Author: Armita Bahrami, St. Jude Children's Research Hospital, Memphis, TN*

Background: The Ewing sarcoma family of tumors (ESFTs) is an aggressive primitive sarcoma of bone and soft tissue. Although several clinical factors are associated with patient outcomes, few biomarkers have prognostic relevance. Recurrent inactivating mutations or deletions in the cohesin complex subunit *STAG2* have been recently described in 15-20% of ESFTs, but their prognostic significance is uncertain. We previously reported that concurrent *STAG2* and *TP53* mutations in ESFTs predict clinical aggressiveness. In this study of an independent cohort, we evaluated the prognostic significance of STAG2 deficiency on clinical outcomes in correlation with established clinical risk markers. **Methods:** Immunohistochemical (IHC) analysis for STAG2 was performed on 143 ESFT samples from 111 patients (90 osseous; 21 extraosseous). The Cox regression model was used to study the association between overall survival (OS) and potential risk factors [age at diagnosis (< 15 vs. ≥ 15 years), gender, primary tumor site (axial vs. extremities), metastatic disease at diagnosis, and STAG2 status]. p53 IHC was performed on STAG2-deficient ESFTs to determine the frequency of coexisting *TP53* missense mutations (*TP53mut*). **Results:** ESFTs occurred in 68 (66%) male and 43 (34%) female patients with a median age of 12.9 years (range, 5 months to 22 years). Tumors involved extremities in 47 (42%) patients and axial/pelvis in 64 (58%) patients. Metastatic disease at diagnosis was seen in 27 (24%) patients. Of the 111 patients, 38 were alive (median follow-up, 16.1 years), 64 died of disease, and 9 died of other causes (median time to death, 2.8 years). STAG2 was expressed in 95 (86%) tumors and not in 16 (14%) tumors. Of the 16 STAG2-negative tumors, 4(25%) harbored concurrent *TP53mut*. Cox regression analysis identified metastatic disease at diagnosis as the most significant adverse prognostic indicator for OS ($P = 0.0005$). Axial location and STAG2 deficiency were associated with a lower OS, but neither reached statistical significance ($P = 0.053$ and $P = 0.059$, respectively). **Conclusions:** Our findings do not support using STAG2 loss as single predictor of outcome. The effects of STAG2 deficiency in ESFTs may be mediated by coexisting genetic modifiers such as *TP53* alterations.

Activity of Hsp90-inhibitor drug conjugate (HDC) STA-12-8666 in preclinical models of pediatric sarcoma. *First Author: Christine Heske, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: Long-term survival in patients with metastatic relapsed or recurrent Ewing sarcoma (ES) and rhabdomyosarcoma (RMS) is poor. Early phase studies have shown encouraging responses in these patients using irinotecan. However, limitations of irinotecan, including a low conversion rate to its active metabolite (SN38) and a high excretion rate of the inactive form, diminish delivery of this drug to tumors and hinder efficacy. In addition, systemic toxicity limits dose escalation in the clinical setting, especially in drug combinations. Hsp90 is widely expressed in cancer cells, and Hsp90 inhibitors display favorable pharmacokinetics for anticancer use as they remain in tumors for a prolonged period of time and at higher levels, compared to normal tissue. This property makes them ideal intracellular delivery vehicles for chemotherapeutic drugs, allowing for high tumor exposure and low systemic toxicity. STA-12-8666 (Synta Pharmaceuticals) is an HDC conjugated to SN38. The purpose of this study was to test this HDC in xenograft models of pediatric sarcoma. **Methods:** To test therapeutic efficacy of this HDC, female SCID mice underwent orthotopic injection of ES or RMS cells. When tumors reached between 100 and 500 mm3 (ES) or 50 and 90 mm3 (RMS), mice were randomized and then treated weekly with STA-12-8666, vehicle, irinotecan or ganetespib (an Hsp90 inhibitor). Tumors were measured twice per week with calipers, and mice were weighed weekly to determine drug tolerability. Tumors were harvested at midpoints and at study endpoint for biology studies. **Results:** In xenograft models of both ES and RMS, treatment with STA-12-8666 produced superior antitumor efficacy compared to controls. All tumors underwent complete regression with tumor eradication persisting for greater than 11 weeks. Additional early data has shown regression of larger tumors up to 1000 mm3. Studies are ongoing and will be reported. Tolerability was excellent with no toxicity-related deaths or significant weight loss in treated mice. Dose titration arms and pharmacodynamic studies of tumors are ongoing. **Conclusions:** Preclinical data suggest that STA-12-8666 may be a promising anticancer agent for ES and RMS patients.

RNA helicase DDX3 is a novel therapeutic target for Ewing sarcoma. *First Author: David Mark Loeb, Johns Hopkins Univ, Baltimore, MD*

Background: There is growing interest in RNA and DNA helicases as therapeutic targets in a variety of sarcomas. We investigated the expression and function of RNA helicase DDX3 in Ewing sarcoma and have begun to explore the effect of a novel DDX3 inhibitor, RK-33. **Methods:** We determined DDX3 expression in Ewing sarcoma cell lines, xenografts, and tissue microarrays by quantitative RT-PCR, western blotting, immunohistochemistry and quantitative proteomics using isobaric mass tags (tandem mass tags, TMTs). Stable DDX3-knockdown cell lines were created and evaluated. Proliferation, clonogenic activity in soft agar, sphere formation, and growth in immunodeficient mice were assayed. The effect of RK-33 on Ewing sarcoma was evaluated in cell lines and xenografts. **Results:** RNA helicase mRNA and protein are expressed at high level in Ewing sarcoma cell lines and patient-derived xenografts, and immunohistochemical staining is seen in 22 of 25 biopsy samples. Knockdown of DDX3 impairs proliferation, soft agar clonogenic activity, and sarcosphere formation and increases radiation sensitivity by slowing DNA damage repair in Ewing sarcoma cell lines, and impairs tumor growth in xenografts. Proteomic analysis implicates DDX3 in the translation of proteins important for numerous cellular pathways, including DNA damage repair and resistance to apoptosis. The DDX3 inhibitor, RK-33, is cytotoxic to Ewing sarcoma cell lines in vitro, including to chemotherapy-resistant Ewing sarcoma stem cells, and increases radiation sensitivity, and knockdown of DDX3 inhibits cytotoxicity. RK-33 also impairs the growth of a DDX3-positive Ewing sarcoma xenograft. **Conclusions:** Our data implicate DDX3 in Ewing sarcoma tumorigenesis. In light of data implicating other helicases in the pathogenesis of Ewing sarcoma and osteosarcoma, this work supports the idea that this enzymatic family plays a key role in the development of sarcomas in general, and that helicase inhibitors might be an important new class of therapeutics. In fact, we found that a novel DDX3 inhibitor, RK-33, shows strong therapeutic promise, either as a direct cytotoxic agent or as a radiation sensitizing agent.

The methylome of pediatric acute myeloid leukemia. *First Author: Stanley Pounds, St. Jude Children's Research Hosiptal, Memphis, TN*

Background: DNA methylation can alter gene expression by either creating binding sites for methylation-dependent repressor proteins, or by disrupting the binding of transcription factors to their target sequences. DNA methylation has been studied extensively and associated with survival in adults with AML. However, a detailed genome-wide study of epigenetic regulation of gene expression and its pharmacological and clinical impact in pediatric AML patients has not been performed. **Methods:** In this study, we obtained Illumina 450K methylation array profiles for 175 pediatric patients and Affymetrix U133A gene expression arrays for 166 pediatric patients treated in the multicenter AML02 clinical trial (NCT00136084). **Results:** We found a very significant canonical correlation of methylation with expression (FDR ≤ 0.01) in 1,978 genes with several of the top ranked genes having established roles in the biology and treatment of AML. An analysis adjusting for risk group found that the canonical correlation methylation and expression variables of 24 genes showed statistically significant evidence of a biologically meaningful pattern of associations with in vitro sensitivity to cytarabine, minimal residual disease assessed by flow cytometry after the first course of chemotherapy, and event-free survival ($p \leq 0.001$; FDR ≤ 0.32). Finally, we observed differential methylation according to clinical risk group at 36,667 markers scattered throughout the genome (FDR ≤ 0.01) with low-risk patients showing hypomethylation at 32,920 of those 36,667 (89.8%) markers. **Conclusions:** Given the methylation differences in clinical risk groups incorporation of demethylating agents might be a useful strategy to improve the outcome of high-risk AMLs by modifying the methylome to more closely resemble that of low-risk AMLs, which are most sensitive to cytarabine. Our results illustrate the power of combined profiling of methylation and expression to improve our understanding of the disease and the molecular level and identify potentially useful therapeutic targets.

Accuracy of adverse event reporting on a phase III clinical trial for pediatric acute myeloid leukemia: A report from the Children's Oncology Group. *First Author: Tamara P. Miller, Children's Hosp of Philadelphia, Philadelphia, PA*

Background: Adverse events (AE) on Children's Oncology Group (COG) trials are reported by clinical research associates (CRA) on case report forms using the Common Terminology Criteria (CTC). CTC has increased in complexity from initially 49 AEs to 789 currently. This complexity challenges CRAs to accurately identify AEs. This study sought to evaluate the accuracy of AE reporting on a COG clinical trial and to determine if Pediatric Health Information System (PHIS) billing or microbiology data can improve AE reporting. **Methods:** Two pediatric oncologists performed chart review to identify 12 Grade III-V AEs (Table) for patients enrolled on AAML0531 at 11 hospitals across the United States and establish a gold standard. The sensitivity and PPV for COG AEs and AEs based on PHIS billing or microbiology data were calculated comparing to the gold standard. **Results:** Chart abstraction was performed on 179 patients (661 courses). PHIS billing data were available on all patients and PHIS microbiology data were available on 53 patients (202 courses) at 3 hospitals. The sensitivity of COG AE reports was lower than PHIS billing data, but COG reports had a higher PPV (Table). Sensitivity and PPV for viridians group streptococci (VGS) bacteremia using PHIS microbiology data were 92.3% (95% CI 79.1-98.4) and 97.3% (95% CI 85.8-99.9), respectively. **Conclusions:** The sensitivity of COG AE reports is modest with a relatively good PPV. PHIS billing data are generally more sensitive but have a lower PPV. While nearly 25% of VGS episodes were missed by COG AE report, the sensitivity and PPV of PHIS microbiology data for VGS was greater than 92%. These data suggest that current COG AE reporting is not sensitive and that accuracy may be improved by using external laboratory data.

Sensitivity and PPV of 12 AEs.

	COG AE Report		PHIS Billing Data	
AE	**Sensitivity %**	**PPV %**	**Sensitivity %**	**PPV %**
Hypertension	23.1	66.7	65.4	39.5

Temsirolimus and intensive re-induction chemotherapy for 2nd or greater relapse of acute lymphoblastic leukemia (ALL): A Children's Oncology Group study. *First Author: Susan R. Rheingold, Children's Hosp of Philadelphia, Philadelphia, PA*

Background: PI3K/mTOR signaling, a critical pathway in cell proliferation, metabolism, and apoptosis, is commonly dysregulated in ALL. A phase 1 trial of the mTOR inhibitor temsirolimus in combination with re-induction chemotherapy was performed in children with second or greater relapse of ALL. **Methods:** Temsirolimus was administered with 4-drug chemotherapy (UK R3 ALL re-induction; Parker, Lancet 2010). The starting dose level (DL1) of intravenous temsirolimus was 10mg/m^2 weekly x3 ; subsequent cohorts received temsirolimus 7.5mg/m^2 weekly x3 (DL0); or 7.5mg/m^{2}weekly x2 (DL-1). PI3K pathway inhibition was measured by phosphoflow analysis (PFA) of peripheral blood. **Results:** Sixteen patients, age 1-21, [15 pre B-ALL (3 MLL infants, 2 Ph+); 1 T-ALL] were enrolled, 15 were evaluable. Dose-limiting toxicity (DLT) occurred in 2/5 patients at DL1; 3/6 at DL0 and 3/5 at DL-1. DLTs were hypertriglyceridemia, mucositis, gastric ulcer, hypertension with reversible posterior leukoencephalopathy, elevated GGT and alk phos, and severe infections including 1 death due to sepsis. Seven patients had a complete response, 3/7 had MRD $<$ 0.01% at end therapy. Responses occurred at all dose levels of temsirolimus. Phospho(p)S6 and/or p4EBP1 were inhibited in a subset of patients with compensatory upregulation of pPI3K, pmTOR, and pAkt. High basal PI3K pathway signaling was observed in patients with poorer response to therapy. **Conclusions:** Temsirolimus in combination with UK R3 chemotherapy can induce responses in children with ALL; however, this intensive regimen is associated with unacceptable toxicity. A trial evaluating temsirolimus in combination with etoposide/cyclophosphamide in children with relapsed ALL is ongoing. Clinical trial information: NCT01403415.

Dose Level	ID	Response	DLT
10mg/m^2 x 3	1 MLL	PD

10030 Poster Session (Board #100), Sun, 8:00 AM-11:30 AM

Association of higher lung dose received during total body irradiation for allogeneic hematopoetic stem cell transplantation in children with acute lymphoblastic leukemia with inferior progression-free and overall survival: A report from the Children's Oncology Group. *First Author: Natia Esiashvili, Emory Univ, Atlanta, GA*

Background: Lung shielding is not standardized during total body irradiation (TBI) preparative regimens for hematopoietic stem cell transplantation (HSCT), leading to differences in pulmonary radiation dose received by patients. We examined the relationship between lung radiation dose and transplant-related mortality (TRM), relapse-free (RFS) and overall survival (OS) in children and adolescents undergoing TBI-based HSCT for acute lymphoblastic leukemia (ALL) on Children's Oncology Group trial ASCT0431. **Methods:** The lung radiation dose received during TBI (1200 or1320 cGy given bid in 6 or 8 fractions) was analyzed in relation to the following variables: total TBI dose, TBI dose per fraction, TBI dose rate, TBI fields, patient position during TBI, pulmonary toxicity, acute graft versus host disease (GVHD), veno-occlusive disease (VOD), TRM, donor type, minimal residual disease (MRD) levels, RFS and OS. **Results:** From a total of 143 enrolled, 109 patients had lung doses available for analysis. Patients treated with lateral fields were significantly more likely to receive lung doses $\geq$ 800cGy ($p < 0.001$). Patients receiving lung dose $\geq$ 800cGy had higher rates of relapse or TRM ($p = 0.034$), a trend for higher rates of death ($p = 0.078$). There was no significant association between lung dose and rates of reported pulmonary toxicity ($p = 1.000$). In univariate analysis, lung dose $\geq$ 800cGy, grade IV vs. grade I-III GVHD, VOD, pulmonary toxicity, MRD, higher disease risk group and unmatched donor types were associated with significantly inferior RFS and OS. Multivariate analysis identified lung dose $\geq$ 800cGy to be significantly associated with inferior RFS (HR 1.9; $p = 0.031$) and OS (HR 2.1; $p = 0.023$) while controlling for risk group and donor type. **Conclusions: A**nalysis of ASCT0431 data showed that lung irradiation dose $\geq$ 800 cGy as part of TBI was associated with inferior RFS and OS. While understanding the mechanisms underlying these results requires more research, reducing the lung dose to 800cGy for TBI regimens administering $>$ 1200cGy is recommended. Clinical trial information: NCT00382109.

10031 Poster Session (Board #101), Sun, 8:00 AM-11:30 AM

Intramuscular (IM) or intravenous (IV): Impact of *Erwinia* asparaginase route of administration on asparaginase activity. *First Author: Olanrewaju O Okusanya, U.S. Food and Drug Administration, Silver Spring, MD*

Background: *Erwinia* asparaginase (*Erwinia)* 25000 IU/m^2 IM was approved in 2011 as a component of treatment for patients with acute lymphoblastic leukemia (ALL) with hypersensitivity to E. coli-derived asparaginase. In 2014, FDA approved the IV route of administration for *Erwinia*based on the PK and safety findings described herein. **Methods:** Data from a single arm PK study in children (1 – 17 yrs) with ALL given *Erwinia* 25000 IU/m^2 IV every Monday/Wednesday/Friday (M/W/F) were evaluated. The proportion of patients with 2-day and 3-day nadir serum asparaginase activity (NSAA) levels $\geq$ 0.1 IU/mL during the first 2 wks of IV *Erwinia* was compared to that of IM *Erwinia*. Population PK (PPK)-based simulations were used to determine IV *Erwinia* doses that would result in the same proportion of patients with 2-day and 3-day NSAA levels as that achieved with 25000 IU/m^2 IM. The safety of IV and IM *Erwinia* administration was also compared. **Results:** IV dosing resulted in a mean (%CV) t½ of 7.5 h (24%) compared to 16 h (21%) for IM (PMID: 8355045). A smaller proportion of patients achieved 2-day or 3-day NSAA levels $\geq$ 0.1IU/mL while experiencing more adverse events with IV compared to IM administration (Table). PPK-based simulations showed that IV Erwinia doses of 35000 IU/m^2 every M/W/F would be needed to attain NSAA levels of $\geq$ 0.1 IU/mL in 90% of the patients on Wednesday or Friday (2-day NSAA) and doses $>$ 95000 IU/m^{2}every M/W/F would be needed to achieve the same target on Monday (3-day NSAA). **Conclusions:** IV administration of Erwinia 25,000 IU/m^2 every M/W/F, while clinically acceptable, led to a lower rate of target attainment (NSAA $\geq$ 0.1 IU/mL) and a higher rate of serious adverse events and discontinuations. Improving target attainment with higher IV doses would require clinical investigation.

Efficacy and safety of Erwinia.

Endpoint	IM Study	IV Study
Proportion (n/N) and 95% CI		
Efficacy		
2-day NSAA $\geq$ 0.1 IU/mL	100% (35/35) [90, 100]	83% (20/24) [63, 95]
3-day NSAA$\geq$ 0.1 IU/mL	100% (13/13) [77, 100]	43% (9/21) [22, 66]
Safety		
Serious Adverse Events	32.8% (19/58)	50% (15/30)
All Grade Hypersensitivity	9% (5/58)	37% (11/30)
Grade 3/4 Hypersensitivity	5% (3/58)	3% (1/30)
Discontinuation rates	24% (14/58)	40% (12/30)

10032 Poster Session (Board #102), Sun, 8:00 AM-11:30 AM

Long-term outcome of six months maintenance chemotherapy for ALL in children: TCCSG L92-13E study. *First Author: Motohiro Kato, University of Tokyo, Tokyo, Japan*

Background: Standard duration of maintenance therapy for childhood acute lymphoblastic leukemia (ALL) is generally considered as one year or longer. In our previous clinical trial, the TCCSG L92-13 (1992 – 1995, n = 347), maintenance therapy was shortened to 6 months and it resulted in decreased EFS of 59.5% at 5.5 years (Toyoda Y, et al. J Clin Oncol 2000), indicating that excess shortening of maintenance therapy could lead to high relapse rate. Conversely, it should be noted that about 60% of ALL achieved continuous complete remission with this short maintenance therapy. Thus, to confirm long-term outcome of ALL with short maintenance therapy, and to identify subgroups which do or do not require the standard duration of maintenance therapy, we conducted L92-13E study, an extended follow up of patients enrolled on the L92-13 study. **Methods:** In the L92-13 trial, children (15 years or younger) with ALL were enrolled, and were assigned to three risk groups, standard-risk (SR), high-risk (HR) and extremely high-risk (HEX). In this extended follow-up study, 45 patients who relapsed/died before 1 year from diagnosis were excluded in order to assess the long-term effect of the shortened therapy. **Results:** As of December 2014, a median of follow up period (n = 302) was 16.1 years. EFS at 15 years for all patients was 65.4 +- 2.8%. Incidences of relapse and non-relapse mortality were 3.2 +- 2.7% and 1.1 +- 0.7%, respectively. Of interest, patients in HEX group (n = 78) showed good EFS (75.4%), compared to SR (60.4%, n = 117) and HR (63.9%, n = 107). Male gender and high-hyperdiploid (HHD) was strongly associated with poor outcome, EFS was 57.1 +- 4.1% for boys, while 73.9 +- 3.7% for girls (p = 0.003). EFS of HHD was significantly poor (55.6 +- 11.7%), although it was recognized as good prognostic factor. On the contrary, EFS of TCF3-PBX1 positive patients was 80.0% +- 17.9%. **Conclusions:** The L92-13E study showed that a certain portion of ALL, including male, HHD required the standard duration of maintenance, whereas HEX group, female could be cured even with very short maintenance therapy. This result provides precise information of leukemia biology and highlights the role of maintenance therapy.

10033 Poster Session (Board #103), Sun, 8:00 AM-11:30 AM

Identification of patients with post-induction CNS 2 status and outcomes in acute lymphoblastic leukemia. *First Author: Arun Gurunathan, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: In the past decade there has been increased scrutiny of the prognostic implications of low level blasts (CNS 2) in the cerebrospinal fluid (CSF) of pediatric patients with acute lymphoblastic leukemia (ALL). The significance of CSF blasts is complicated by the increased cell recovery by newer cytocentrifuge machines (Huppman, et al. *Am J Clin Pathol.* 2012). **Methods:** A retrospective cohort study was conducted at the Children's Hospital of Philadelphia (CHOP) to compare the proportion of CNS 2 CSF results using Shandon (2005–2008) and Wescor (2010-2014) cytocentrifuge machines. Logistic regression was used to compare CNS 2 results from the two time periods. Outcomes of patients with at least one post-Induction CNS 2 CSF result were tracked, focusing on proportion of patients who ultimately relapsed using Fisher's exact test. Infant ALL was analyzed separately. **Results:** Of the 306 de novo ALL patients (excluding 10 infants) identified, 273 had pre-B ALL and 33 had T-ALL. Of the 4477 lumbar punctures analyzed in this cohort, there was a 6.7-fold increase in proportion of CNS 2 results on the new (Wescor) machine (2% vs. 0.3%, p < 0.0001). This remained significant after adjusting for gender, immunophenotype, and end of induction risk stratification. In both time periods, the majority of CNS 2 results were CNS 2a. Of the 42 patients who were CNS 2 at least once post-Induction in either period, 9 relapsed (8 pre-B ALL; 1 T-ALL). Having a post-Induction CNS 2 CSF did confer an increased risk of relapse (21.4% vs. 8.8%, p = 0.025), primarily due to increased non-CNS relapse. Two of 3 patients with CNS 2 CSF on the Shandon relapsed; 7 of 39 patients who had a CNS 2 CSF on the Wescor relapsed. Despite the small sample size in Infant ALL, there was also an increase in CNS 2 results on the Wescor (4.5-fold increase, p = 0.042). **Conclusions:** The enhanced efficiency of cell recovery afforded by the Wescor cytocentrifuge machine resulted in increased proportion of CNS 2 results. Having a CNS 2 CSF on the Shandon was more predictive of relapse than on the Wescor. The finding that post-induction CNS 2 status is associated with an increased risk of relapse (non-CNS > CNS) warrants further investigation and may influence management decisions.

10034 Poster Session (Board #104), Sun, 8:00 AM-11:30 AM

Kidney Injury Molecule-1 and its association with delayed clearance and drug exposure in pediatric oncology patients treated with high dose methotrexate. *First Author: Andrew J. Bukowinski, Cincinnati Childen's Medical Center, Cincinnati, OH*

Background: High-dose methotrexate (HD-MTX) is a critical component of therapy for pediatric malignancies. The ability to identify patients at risk for delayed MTX clearance and acute kidney injury (AKI) is limited. Kidney Injury molecule-1 (KIM-1) is a urinary biomarker which is an early indicator of tubular injury. The current study evaluates associations between urinary KIM-1, delayed MTX clearance, and MTX exposure. **Methods:** 47 patients (31 M, 16 F; median age 9.5 yrs, range 3-31) received 1-12 g/m^{2}HD-MTX over 4 or 24 hours for a total of 96 courses of MTX. Diagnoses included: leukemia/lymphoma (42 pts), osteosarcoma (5 pts). Data was collected on up to 4 courses of HD-MTX. Serum creatinine (SCr) and MTX were measured per standard clinical practice. Urine samples were obtained prior to the infusion and at 12, 24, and 36-48 hours after start. KIM-1 was measured by enzyme linked immunosorbent assay and normalized to urine creatinine. Delayed methotrexate clearance (DC) was defined by plasma MTX levels exceeding "high risk" concentrations per Crom & Evans (1992) as incorporated into standard oncology treatment regimens, failure to clear MTX within 72 hours, or a 50% rise in SCr. Toxicity data was collected by chart review. Univariate analyses were conducted using Wilcoxon Rank sum testing. MTX area under the curve (AUC) was calculated with MW/Pharm software using Bayesian estimation. Linear regression was used to analyze KIM-1 and AUC for correlations. **Results:** Patients with DC had higher AUC levels ($p < 0.05$). Kim-1 at 12 hours correlated with AUC ($p < 0.04$) in leukemia patients receiving 1st course of HD-MTX. KIM-1 is associated with DC at 12 and 24 hours for 1st and 2nd courses of HD-MTX ($p < 0.05$). Prior to infusion KIM-1 is associated with previous DC ($p < 0.05$). **Conclusions:** Increased KIM-1 is associated with both MTX AUC and DC and is indicative of renal tubular injury. This association is most pronounced in course 1 and may be due to attrition of patients with severe toxicity, dose reduction, and enhanced supportive care. KIM-1 provides an early indication of kidney injury from HD-MTX and with additional evaluation may be a target for enhanced supportive care strategies.

10035 Poster Session (Board #105), Sun, 8:00 AM-11:30 AM

Association of intravenous (IV) and intramuscular (IM) pegaspargase (PEG) administration with rate of adverse events (AE) in standard risk (SR) Acute Lymphoblastic Leukemia (ALL) Children's Oncology Group (COG) trials. *First Author: Kelly W. Maloney, Children's Hosp Colorado, Aurora, CO*

Background: COG AALL0331 administered PEG IM in induction (IND) and Delayed intensification (DI) whereas AALL0932 administers the same dose IV. We compared grade 3/4 toxicities resulting from the single doses of PEG given in the IND and DI phases on the standard arms of AALL0331 and AALL0932 that gave only 2 doses of PEG (excluded arms with additional PEG). **Methods:** AALL0331 and AALL0932 shared a common 3 drug IND: dexamethasone (DEX) 6 mg/m^2/day X 28 days, vincristine (VCR) 1.5 mg/m^2/dose on days 1, 8, 15, 22, IT methotrexate (age adjusted dosing) on days 8, 29, and PEG 2500 units/m^2/dose IM on day 4, 5, or 6 (AALL0331) or IV on day 4 (AALL0932). DI (Days 1-28) for both protocols consisted of: DEX 10 mg/m^2/day (days1-7, 15-22), VCR 1.5 mg/m^2/dose and Doxorubicin 25 mg/m^2/dose IV (days 1, 8, 15), PEG 2500 units/m^{2}on day 4 (AALL03131 IM; AALL0932 IV). Toxicity was graded using CTCAE v4.0, however, AALL0331 collected data using CTCAE v3.0, which was subsequently mapped to v4.0. **Results:** During IND, the rates of anaphylaxis/allergic reaction were similar between IM and IV PEG (0.2% vs. 0.3%, p = 0.842). The rate of anaphylaxis/allergic reaction in DI was 0.5% (IM) vs 1.8% (IV) (p = 0.007). The rates of pancreatitis, elevated lipase and amylase, and hyperglycemia were similar between IM and IV PEG in both IND and DI. **Conclusions:** The rates of AEs with PEG administration (IV or IM) are low but more grade 3/4 anaphylaxis/allergic reactions were reported with IV PEG compared to IM PEG during DI. This may be due to more stringent reporting on 0932 or the challenges of determining infusion reactions vs. allergic reactions when PEG is administered IV. Clinical trial information: NCT00103285.

Toxicities (%)		Grades	AALL0331	AALL0932	p-value
Allergic reaction/ Anaphylaxis	IND	3-4	0.2	0.3	0.84
	DI		0.5	0.8	0.0007
Pancreatitis	IND	3-4	0.5	0.8	0.07
	DI		0.4	0.3	0.79

10036 Poster Session (Board #106), Sun, 8:00 AM-11:30 AM

Phase I trial of ontuxizumab (MORAb-004) in children with relapsed or refractory solid tumors: A Children's Oncology Group Study. *First Author: Robin Elizabeth Norris, Rainbow Babies and Children's Hosp, Moreland Hills, OH*

Background: Ontuxizumab is a humanized IgG mAb that targets the cell-surface glycoprotein endosialin (TEM-1/CD248). Endosialin is found in tumor stroma and vasculature across various tumors, with high expression in sarcoma and neuroblastoma but generally limited expression in normal tissue. Ontuxizumab binding to endosialin may interfere with platelet-derived growth factor (PDGF) signaling and prevention of protein interactions involved in tumor-stroma organization and new vessel formation. **Methods:** Ontuxizumab was administered intravenously on days (d) 1, 8, 15, and 22 of a 28 d cycle. Three dose levels (4, 8, and 12mg/kg) were evaluated using a rolling 6 design. Further dose escalation to 16mg/kg would proceed only if the ontuxizumab systemic clearance (CL) was $\geq$ 30% higher in children compared to adults and the maximum tolerated dose (MTD) was not reached. Primary endpoints were to describe toxicities, define MTD or recommended phase 2 dose (RP2D) and to characterize the pharmacokinetics (PK) of ontuxizumab in children. Following determination of MTD/RP2D an additional cohort of 6 pts $<$ 12y was enrolled. PK was evaluated using non-compartmental and population PK modeling. **Results:** Twenty-seven eligible pts (17 male, median age 15y, range 3 – 21y) were enrolled. Twenty-two pts [neuroblastoma (5), Ewing sarcoma (4), rhabdomyosarcoma (4), other (9) tumors] were fully evaluable for toxicity. Five pts did not complete cycle 1 due to tumor progression. Grade $\geq$ 3 regimen-related non-hematologic toxicities included hypophosphatemia (1) and hyponatremia (1). One pt had grade 3 lymphopenia and 1 pt had grade 3 anemia in cycle 1. Grade $\leq$ 2 fever or infusion related reactions occurred in 9 pts. Dose-limiting bacteremia was observed during cycle 1 in 1 pt at dose level 3 (12mg/kg). Clearance was dose-dependent and within 30% of adult value (0.193 mL/h/kg) at 12mg/kg. Therefore there was no further dose escalation. **Conclusions:** The recommended dose of ontuxizumab in children is 12mg/kg administered weekly. This dose appears to be well tolerated in children with relapsed or refractory solid tumors. PK does not appear to be significantly different in children compared to adults. Clinical trial information: NCT01748721.

10037 Poster Session (Board #107), Sun, 8:00 AM-11:30 AM

Exploring Tenascin-C as a novel therapeutic target in pediatric brainstem glioma. *First Author: Amanda Muhs Saratsis, Ann & Robert H. Lurie Children's Hospital of Chicago (Northwestern University Feinberg School of Medicine), Chicago, IL*

Background: Diffuse intrinsic pontine glioma (DIPG) is the most deadly solid tumor of childhood. Histone 3 mutation occurs in up to 80% of DIPGs, causing global epigenetic aberration. Tenascin-C (TNC) is an extracellular matrix protein expressed during brain development by oligodendroglial progenitor cells (OPCs), the purported DIPG cell of origin. TNC is highly expressed in adult glioma, contributing to local invasion and poor survival. We report increased TNC in tumor tissue and cerebrospinal fluid (CSF) from children with high-grade glioma, including DIPG, and characterize TNC expression in relation to histone 3 mutation and DNA methylation. **Methods:** Tissue collected intraoperatively or post-mortem from children with brainstem (DIPG, n = 14), supratentorial (n = 7), and cerebellar astrocytoma (n = 2), and CSF from DIPG (n = 9) and supratentorial astrocytoma (n = 17), were subjected to MS/MS proteomic analysis. Tissue gene expression, DNA methylation, and H3F3A or HIST1H3B sequencing was performed. TNC expression was validated and correlated with tumor grade and H3K27M status via Western blot and immunohistochemistry. Data integration was performed via Partek Genomics Suite and Ingenuity Pathway Analysis. **Results:** TNC protein expression was significantly increased in 75% of glioma tissue specimens compared to normal tissue, including all DIPG specimens tested (fold change $>$ 2, $p < 0.05$). Secreted TNC was detected in 7/9 DIPG CSF specimens (77.8%). Tumor-specific TNC expression was confirmed with Western blot and tissue immunohistochemistry. Greater relative TNC expression correlated with tumor grade and was associated with Notch pathway activation, H3K27M mutation, and TNC promoter hypomethylation. **Conclusions:** We report increased TNC expression in tissue and CSF of pediatric high-grade astrocytomas, including DIPGs, associated with promoter hypomethylation and H3K27M mutation. Given the effect of TNC on OPC proliferation, migration and differentiation, TNC could serve as a clinical biomarker of disease and rational therapeutic target for a substantial subgroup of DIPG patients. Further studies exploring the mechanism of TNC overexpression and effects of targeting TNC expression in DIPG are currently underway.

10038 Poster Session (Board #108), Sun, 8:00 AM-11:30 AM

Diagnostic and prognostic role of circulating *miR-206* in rhabdomyosarcoma patients. *First Author: Mitsuru Miyachi, Department of Pediatrics, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan*

Background: *miR-206* is a muscle-specific microRNA and is much more strongly expressed in rhabdomyosarcoma (RMS) tumors than in non-RMS tumors. Here, we analyzed the diagnostic and prognostic significance of circulating *miR-206* values in serum specimens of RMS patients. **Methods:** Total RNA was extracted from serum samples (200 μL) from 60 patients (28 RMS, 32 non-RMS) and quantified by real-time quantitative RT-PCR. Receiver-operating characteristics (ROC) curves were established to evaluate the diagnostic value. Survival curves for RMS patients were calculated by the Kaplan-Meier method and were compared using the log-rank test. The median follow-up time was 30 months. Serum *miR-206* expression level and prognostic factors were evaluated with a univariate analysis. The factors included age, primary tumor size, regional lymph node involvement, distant metastasis, fusion gene status, histologic subtype and primary tumor site. A multivariate analysis was conducted using the Cox proportional hazards regression method. The variables correlated with progression-free survival (PFS) in the univariate analysis were included in the model. **Results:** Serum *miR-206* expression levels were higher in RMS patients than in non-RMS patients ($p < 0.001$) with an area under the ROC curve of 0.8705 (95% confidence interval [CI], 0.7791-0.962), sensitivity of 0.714 and specificity of 0.938. The cut-off value was 164.1 copies/μl serum. PFS was negatively influenced by a high serum *miR-206* expression level (2.5-year PFS; 10.7 % (n = 14) vs 77.9 % (n = 14), p = 0.0019) and the presence of both distant metastasis and locoregional lymph node involvement (2.5-year PFS; 30.9 % (n = 18) vs 80.0 % (n = 10), p = 0.017) in univariate analysis. In the multivariate analysis, a high serum *miR-206* expression level had an independent prognostic significance (hazard ratio: 3.50 [95% CI: 1.12-11.0], p = 0.031). **Conclusions:** *miR-206* can be a novel biomarker for both diagnosis and treatment stratification of RMS. The limitations of our study include a retrospective design, small sample size and non-uniform treatment. The Japan Rhabdomyosarcoma Study Group will prospectively validate its prognostic significance in a large cohort of uniformly-treated patients.

10039 Poster Session (Board #109), Sun, 8:00 AM-11:30 AM

Anti-tumor efficacy in SIOPEL 6: A multi-centre open label randomised phase III trial of the efficacy of sodium thiosulphate (STS) in reducing ototoxicity in patients receiving cisplatin (Cis) monotherapy for standard risk hepatoblastoma (SR-HB). *First Author: Penelope Rachel Brock, Great Ormond Street Hospital, London, United Kingdom*

Background: SR-HB is defined as tumor extension limited to PRETEXT I, II or III, no portal, hepatic veins, or intra-abdominal extra-hepatic disease, AFP $>$ 100ng/ml and no metastases. Cis can cause permanent bilateral high-frequency hearing loss. STS may reduce this risk, but could also reduce Cis anti-tumor efficacy. **Methods:** Newly diagnosed patients with SR-HB were treated with 2-weekly cycles of Cis, 4 before primary tumor resection and 2 after. Patients were randomized to Cis alone or Cis and STS. Cis 80mg/m^2 was administered i.v. over 6 hrs. STS was administered i.v. exactly 6 hrs after stop of Cis over 15 minutes at 20g/m^2. Response was assessed after 2 and 4 cycles pre-operative with serum AFP and liver imaging. In case of progression after 2 cycles, STS was stopped and doxorubicin 60mg/m^2 continuous infusion over 48 hrs added. The primary endpoint is centrally reviewed absolute hearing threshold, at the age of $\geq$ 3.5 years, by pure tone audiometry. With a sample size of 102, the trial has 80% power to detect a reduction in hearing loss defined as Brock grade $\geq$ 1 from 60% of patients with Cis to 35% with Cis+STS. Short term anti-tumor efficacy endpoint is disease status at end of treatment which was evaluated after every 20 patients and submitted to the IDMC. Throughout the trial, the IDMC recommended continuation after interim review of efficacy results. **Results:** From 2007 to end 2014, 45 sites from 12 countries randomized 53 patients to Cis and 60 to Cis+STS, median age at diagnosis was 12.8 months. Treatment was well tolerated and acute toxicity similar between arms. Efficacy results after 4 pre-op chemo cycles for the first 94 patients (47 Cis, 47 Cis+STS) were PR/SD/PD for Cis: 86%/8%/6% and for Cis+STS: 90%/5%/5%. Complete remission after resection and post-op chemo was 92% and 98%. In January 2015, 2 pts had died (Cis arm), and 2 (Cis) and 1 (Cis+STS) had progressed. **Conclusions:** End of treatment anti-tumor efficacy in SR-HB treated on the above protocol shows no adverse outcome related to STS. Final evaluation of hearing loss at $\geq$ 3.5 yrs of age, the primary endpoint, is expected in 2017. Clinical trial information: NCT00652132.

10040 Poster Session (Board #110), Sun, 8:00 AM-11:30 AM

Proton versus conventional radiotherapy for pediatric salivary gland tumors: Acute toxicity and dosimetric characteristics. *First Author: Stephen Richard Grant, Baylor College of Medicine, Houston, TX*

Background: Adjuvant radiotherapy (RT) is often a component of treatment for high-risk salivary gland tumors. Minimizing irradiation of surrounding normal tissues is particularly important for pediatric patients. We compared acute toxicity profiles, clinical outcomes, and dosimetric data for children with parotid or submandibular tumors treated with adjuvant photon/electron-based RT (X/E RT) or proton RT (PRT). **Methods:** We retrospectively identified 24 pediatric patients who had received adjuvant RT at a single institution for salivary gland tumors (20 parotid, 4 submandibular). Demographic, disease control and survival data were extracted from the medical records and dosimetric data from the treatment planning systems. Toxicity was scored according to the Common Terminology Criteria for Adverse Effects 4.0. **Results:** Eleven patients received X/E RT and 13 PRT. The median prescribed dose was 60 Gy for each group. PRT was associated with significantly lower mean doses to the thyroid (1.5 vs. 22.5 Gy, $P< 0.05$), oral cavity (4.6 vs. 20.7 Gy, $P< 0.05$), and larynx (11.3 vs. 44.3 Gy, $P< 0.05$); and the contralateral parotid (0.0 vs. 4.6, $P< 0.05$), hemi-mandible (0.0 vs. 11.9 Gy, $P< 0.05$), and submandibular gland (0.0 vs. 13.5 Gy, $P< 0.05$). In the X/E RT group, 27% had acute grade 3 dermatitis, 18% grade 3 mucositis, and 9% grade 3 dysphagia, and the median weight loss was 5.3%. No patient in the PRT group experienced acute grade 3 toxicity, and a median weight gain of 1.2% was noted. At a median follow-up time of 35 months, no disease recurrence or deaths were observed in either group. **Conclusions:** Compared with X/E RT, PRT significantly reduced the radiation dose to many surrounding normal tissues, which translated to reductions in clinical acute toxicity. Continued follow-up is needed to identify any differences in long-term toxicity and disease control.

10041 Poster Session (Board #111), Sun, 8:00 AM-11:30 AM

Molecular mechanisms for telomere maintenance in neuroblastoma. *First Author: Armita Bahrami, St. Jude Children's Research Hospital, Memphis, TN*

Background: Despite a well-developed risk classification schema utilizing both clinical and biologic factors, the clinical outcome of neuroblastoma (NB) is remarkably heterogeneous. Replicative immortality in cancers is mediated by 2 known telomere maintenance mechanisms (TMMs): telomerase reactivation and alternative lengthening of telomere (ALT). We hypothesized that TMMs are essential for cancer development in high-risk NBs (HR-NBs) but not low-risk or stage 4S NBs that frequently undergo spontaneous regression. We investigated the prevalence of known molecular events involved in TMMs in NB risk categories. **Methods:** The analysis included 47 NBs from 27 patients with high-risk disease and poor outcomes and 19 patients with low- or intermediate-risk disease and good outcomes (LR-NBs). Presence of the ALT phenotype was determined by telomeric fluorescence in situ hybridization (FISH), and its association with *ATRX* alterations was evaluated by immunohistochemistry. Direct sequencing of the *TERT* promoter (*TERT*-p) to screen for hotspot mutations and *TERT* copy number FISH to assess gene amplification were conducted. For methylation analysis, 500 ng of bisulfite-converted DNA was processed and hybridized on the Illumina HumanMethylation450 BeadChip. RNA in situ hybridization (ISH) for TERT was performed on 4 HR-NBs to observe TERT expression. **Results**: Methylation analysis showed that *TERT*-p CpGs at positions ch5:1295737 and 1295799 were the most differentially methylated regions between HR-NBs and LR-NBs ($P< 0.0005$). Of the 27 HR-NBs, 11 (41%) were hypermethylated in one or both CpG regions; 7 (26%) exhibited an ALT phenotype, of which 5 were associated with heterogeneous or loss of ATRX expression; 3 had *TERT* amplification; 2 carried a *TERT*-p mutation; and 5 (19%) showed no alterations. In contrast, the assays were negative in all 19 LR-NBs. RNA ISH for TERT showed high-resolution signals in *TERT*-p methylated but no signals in ALT-phenotype HR-NBs. **Conclusions**: Molecular mechanisms for telomere maintenance in HR-NB are diverse and commonly associated with hypermethylation of the *TERT*-p region. Future studies to assess the prognostic relevance of these biomarkers on clinical outcomes in patients with NB are warranted.

10042 Poster Session (Board #112), Sun, 8:00 AM-11:30 AM

Outcome of recurrent osteosarcoma patients enrolled in seven phase II trials through CCG, POG, and COG: Learning from the past to move forward. *First Author: Joanne P. Lagmay, University of Florida Shands Hospital for Children, Gainesville, FL*

Background: The use of radiographic response as the primary endpoint in phase II osteosarcoma (OS) trials may limit optimal detection of treatment response due to the calcified tumor matrix. We assessed outcome data for children with recurrent/refractory OS enrolled on single agent Children's Oncology Group phase II trial to establish this cohort's baseline expected survival outcome. **Methods:** We performed a retrospective analysis of outcome for children with recurrent/refractory OS enrolled on one of seven phase II trials with an OS stratum conducted by COG and predecessor groups from 1997-2007. Trials included A09713 (topotecan), ADVL0122 (imatinib), ADVL0421 (oxaliplatin), ADVL0524 (ixabepilone), CCG-0962 (docetaxel), P9761 (irinotecan) and P9963 (rebeccamycin analogue). All trials used RECIST or WHO with primary endpoint as response rate. Event Free Survival (EFS) was correlated with the following potential prognostic factors: age, trial, number of prior chemotherapy regimens, gender and race. To determine the historical disease control rate for patients with fully resected disease, we used the EFS in a Phase II study (AOST0221) of osteosarcoma patients given inhaled GMCSF with first pulmonary recurrence, which had a biological endpoint. **Results:** In each included trial the OS stratum failed to meet the primary endpoint. Radiographic responses were observed in only 3 trials. The highest response rate was 11% seen in A09713. EFS for 96 subjects with OS and measurable disease was 12% at 4 months (95% CI: 6-19%). There was no impact of age, gender or race on EFSnor was there a significant difference in EFS across trials or by number of prior treatment regimens**.** The 12-month EFS for the 42 subjects enrolled in AOST0221 was 20% (95% CI: 10-34%). **Conclusions:** The aggregate outcome for children with recurrent/refractory OS in these previously conducted single arm phase II trials was disappointing. Given the poor EFS for children with recurrent/refractory OS it is unlikely that active agents were missed using traditional RECIST response. Nevertheless, we have now defined baseline EFS outcomes that can be incorporated into future phase II trial design for recurrent osteosarcoma.

10043 Poster Session (Board #113), Sun, 8:00 AM-11:30 AM

Vesicular monoamine transporter protein expression in neuroblastoma: A report from the Children's Oncology Group. *First Author: Steven G. DuBois, University of California, San Francisco, San Francisco, CA*

Background: Vesicular monoamine transporters 1 and 2 (VMAT1 and VMAT2) are thought to mediate MIBG uptake in adult neuroendocrine tumors. VMAT expression has not been comprehensively investigated in neuroblastoma. **Methods:** We evaluated VMAT1 and VMAT2 expression by immunohistochemistry (IHC) in neuroblastoma tumors from 76 patients with high-risk disease treated on COG protocol A3973. All patients had baseline MIBG diagnostic scans centrally reviewed. IHC results were scored as the product of intensity grading (0-3+) and percent of tumor cells expressing the protein of interest. Association of VMAT1 and VMAT2 scores with clinical and biological features was tested using Wilcoxon rank sum tests. **Results:** Patient characteristics were typical of high-risk neuroblastoma, though the cohort was intentionally enriched for patients with MIBG non-avid tumors ($n = 20$). VMAT1 and VMAT2 were expressed in 62% and 75% of neuroblastoma tumors, respectively. VMAT1 and VMAT2 scores were both significantly lower in *MYCN* amplified tumors, non-adrenal primary tumors, and in tumors with high mitotic karyorrhectic index. MIBG avid tumors had significantly higher VMAT2 scores compared to MIBG non-avid tumors (median 216 vs. 45; $p = 0.04$). VMAT1 expression did not correlate with MIBG avidity. **Conclusions:** VMAT1 and VMAT2 are expressed in the majority of neuroblastomas. Expression correlates with clinical and biological features. Expression of VMAT2 but not VMAT1 correlates with avidity for MIBG.

10044 Poster Session (Board #114), Sun, 8:00 AM-11:30 AM

Meta-analysis of effects of demographic and treatment variables on outcome for localized paratesticular rhabdomyosarcoma (PT RMS) in North America and Europe. *First Author: David Walterhouse, Ann and Robert H Lurie Children's Hosp of Chicago, Chicago, IL*

Background: Treatment recommendations for localized PT RMS differ based on clinical trials conducted by cooperative groups in North America and Europe. We conducted a meta-analysis to identify effects of demographic features and treatment choices on outcome for patients with localized PT RMS. **Methods:** We analyzed demographic and treatment variables from 12 studies conducted by the Children's Oncology Group (COG; n = 416), Cooperative Weichteilsarkom Studiengruppe (CWS; n = 106), European paediatric Soft Tissue Sarcoma Group (EpSSG; n = 99), Italian Cooperative Group (ICG; n = 64), and SIOP Malignant Mesenchymal Tumor Group (MMT; n = 159) that enrolled 844 eligible patients with localized PT RMS from 1988-2013. Categorical and continuous variables were checked for association. Event-free survival (EFS) and survival (S) were compared among groups using univariate and multivariate analyses. **Results:** Mean patient age at enrollment differed among the cooperative groups (7 yrs [MMT] – 11 yrs [EpSSG]; $p < 0.05$). Patients ≥ 10 yrs were more likely to have tumors > 5 cm (60%; $p < 0.05$), enlarged nodes (N1) (17%; $p < 0.05$), and pathologically involved nodes (33%; $p < 0.05$) than younger patients. 89% of N1 nodes and 19% of N0 nodes were pathologically involved in patients ≥ 10 yrs. With a median follow-up of 7 yrs, 87.5% of patients were event-free and 94.9% were alive. Variables that impacted EFS ($p < 0.05$) were cooperative group, era of enrollment, age, IRS group, T-stage, tumor size, and surgical assessment of nodes in patients ≥ 10 yrs with tumors > 5 cm. Using a stepwise variable selection procedure on a proportional hazards regression model starting with all demographic and treatment variables, the EFS model selected era, age, size, and surgical assessment of regional lymph nodes ($p < 0.05$) and the S model selected era, age, size, and histology ($p < 0.05$). **Conclusions:** Localized PT RMS has a favorable prognosis using approaches of North American and European cooperative groups. Surgical assessment of regional nodes is important in boys ≥ 10 yrs as this impacts EFS (but not S), and in younger boys with N1 disease. Clinical lymph node staging is otherwise sufficient to guide therapy.

10045 Poster Session (Board #115), Sun, 8:00 AM-11:30 AM

Treatment outcomes of pediatric and young adult sporadic desmoid tumors. *First Author: Sara Helmig, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH*

Background: Desmoid tumor (DT) is a non-malignant soft-tissue neoplasm of children and adults that is often treated with surgery, radiation and/or chemotherapy. DTs may recur even after complete resection, and the benefit of medical therapy is unpredictable. Data driven DT therapy guidelines are lacking for children and young adults. **Methods:** A retrospective review of DT patients treated at a single institution between 2003 and 2014. **Results:** Twenty-three patients, aged 3 months to 25 years of age at diagnosis, were identified from a complex patient population that included 7 patients with congenital deformity or syndromes. Anatomic locations included extremity (15), head/neck tumors (2), and trunk/abdomen (6). Both head/neck and 5 of 6 trunk patients demonstrated no evidence of disease (NED) at last follow-up, whereas only 1 extremity patient was NED ($p = 0.0001$). Of the 23 patients, all but 2 patients had at least one surgical resection. Six patients required a single surgery only: R0 (n = 4), R1 (n = 1), and R2 (n = 1). Eight patients received vinblastine and methotrexate (VBL/MTX), 5 received sorafenib, and tamoxifen (TAM) with sulindac, hydroxyurea, and liposomal doxorubicin were each administered to 1 patient. One VBL/MTX patient experienced a partial response while 3 others experienced prolonged stabilization (> 36 months). Two of four patients treated with sorafenib experienced stabilization (> 24 months). The single patient treated with TAM/sulindac experienced prolonged stabilization. Five patients received radiation therapy, with one developing a secondary sarcoma and two others stabilizing without further sequela. There were no deaths related to DT. **Conclusions:** Our findings demonstrate that a subset of tumors can be adequately treated with a single surgery. Head/neck and trunk tumors were more likely to be rendered NED than extremity tumors. Another subset of unresectable/recurrent tumors treated with mild medical therapy stabilized without significant morbidity, although RECIST response was rare in this complex cohort. Given the unpredictable benefit of therapies for unresectable/recurrent disease, genome directed approaches and observation-only strategies merit further exploration in this age group.

10046 Poster Session (Board #116), Sun, 8:00 AM-11:30 AM

The prognostic significance of MIBG uptake in left supraclavicular lymph nodes in high risk neuroblastoma patients. *First Author: Shifra Ash, Pediatric Hematology Oncology, Schneider Children's Medical Center of Israel, Petah-Tikva, Israel*

Background: Metastatic MIBG localization in the soft tissues of the left supraclavicular (LSC) region is occasionally seen in children with high risk (HR) neuroblastoma. The purpose of the study was to evaluate the prognostic significance of this uptake. **Methods:** We performed a retrospective analysis of MIBG studies and clinical data of 77 HR neuroblastoma patients treated at Schneider Children's Medical Center of Israel between 1998 – 2015. The median age was 2.8 years (0.1-7.6) and the median follow up was 39 months (1-202). HR was defined as patients diagnosed as stage 3 with MYCN amplification and stage 4. Treatment consisted of induction chemotherapy, surgery, autologous bone marrow transplantation, local radiation and retinoic acid with or without immunotherapy. MIBG studies included whole body surveys, SPECT or SPECT/CT with the supraclavicular regions in the field of view. **Results:** LSC uptake was identified in 13/77 children (17%). All children with LSC MIBG uptake had abdominal primary tumors. Patients with LSC uptake had a 5y relapse free survival (RFS) of only 16%±14 as opposed to 42%± 7 for patients with no uptake ($p = 0.021$). Five year overall survival (OS) was 0% in children with LSC uptake and 57%±7 in those without ($p = 0.001$). Within the group of 46/77 patients without MYCN amplification, 5y OS was 0% in 8 children with LSC uptake and 51%± 9 in 38 without ($p = 0.014$). On multivariate analysis for survival, only LSC MIBG uptake was found to be a poor independent prognostic factor, with an increased risk of 3.69 fold (95% CI 1.6-8.3, $p = 0.002$). **Conclusions:** Avid metastases identified by MIBG in the LSC region can identify HR patients with worse prognosis. This phenomenon resembles metastatic spread to Virchow nodes from gastric cancer and can be used as a prognostic factor. Cross sectional imaging with MIBG (or other modalities) should always include the left supraclavicular region. The presence of left supraclavicular disease should be considered for therapy planning.

10047 Poster Session (Board #117), Sun, 8:00 AM-11:30 AM

Comparison of ^{18}F-FDG-PET-CT and bone scintigraphy for evaluation of osseous metastases in newly diagnosed and recurrent osteosarcoma. *First Author: Caitlin Hurley, St. Jude Children's Research Hospital, Memphis, TN*

Background: Bone scintigraphy (BS) is routinely used to detect osseous metastases in osteosarcoma. The use of ^{18}F-fluorodeoxyglucose positron emission tomography-computed tomography (^{18}F-FDG-PET-CT) to assess tumor extent in pediatric sarcomas has increased recently. We compared the sensitivity, specificity, and diagnostic accuracy of PET-CT and BS for detection of osseous metastases in osteosarcoma. **Methods:** We retrospectively reviewed 39 patients with osteosarcoma who underwent paired PET-CT and BS at diagnosis and/or first recurrence between 2003 and 2012. PET-CT and BS studies were independently reviewed by 2 pediatric imaging specialists who were blinded to results of the opposing modality and reference standard. Reviewers categorized lesions as benign, malignant or indeterminate. Reference standard for lesion histology was biopsy or clinical follow-up. Diagnostic performance of PET-CT, BS, and combined modalities were determined. **Results:** Forty-two examinations from 39 patients were reviewed and 123 bone lesions were evaluated. Median age was 11 years (range 5-19 years). Four patients had 13 osseous metastases at diagnosis (3 biopsied, 10 clinically), and 3 had 9 osseous metastases at recurrence (2 biopsied, 7 clinically). For all sites combined, sensitivity, specificity and diagnostic accuracy were 92%, 76%, and 84% respectively for PET-CT, 77%, 94%, and 85% for BS, and 98%, 69%, and 84% for PET-CT and BS combined. For metastatic sites alone, sensitivity, specificity and diagnostic accuracy were 77%, 76% and 76% for PET-CT, 41%, 94% and 80% for BS, and 96%, 69% and 76% for combined modalities. Improved sensitivity of PET-CT for metastatic sites compared to BS was borderline significant ($p = 0.077$). PET-CT and BS combined did not improve sensitivity over PET-CT alone ($p = 0.125$), but was significantly higher than BS alone ($p < 0.001$). BS specificity was superior to both PET-CT ($p = 0.02$) and combined imaging ($p < 0.001$). **Conclusions:** ^{18}F-FDG-PET-CT is at least as sensitive as BS in detecting osseous metastases in osteosarcoma; combined use with BS further increases sensitivity. Our findings support the use of both ^{18}F-FDG-PET-CT and BS for staging of osteosarcoma.

10048 Poster Session (Board #118), Sun, 8:00 AM-11:30 AM

ImmunoPET compared with conventional imaging modalities for the detection of Ewing sarcoma metastases in a preclinical model. *First Author: Allison Frances O'Neill, Department of Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Ewing sarcoma is a solid tumor arising from bone and the soft tissues that affects approximately 250 children and adolescents each year. Localized disease confers a favorable 75% 5-year survival, but the prognosis for metastatic disease remains dismal with only a 20% 5-year survival. The ability to accurately diagnose disease extent is therefore crucial. Conventional imaging modalities provide high-resolution anatomic data but lack specificity. The goal of this preclinical study was to compare the detection of metastatic Ewing sarcoma using a ^{89}Zr-labeled anti-CD99 antibody (Ab) with conventional imaging modalities including MRI and [^{18}F]FDG-PET. **Methods:** NOD scid gamma mice were injected via tail vein with luciferase-transduced TC32 Ewing sarcoma cells and monitored for tumor growth by bioluminescence imaging until development of 2-3 mm liver metastases at 4 weeks. Disease burden and lesion distribution were assessed by MRI and [^{18}F]FDG-PET. Mice were then injected with the ^{89}Zr-labeled anti-CD99 Ab and imaged from 16 to 144 h post-injection. **Results:** Liver metastases were detected by immunoPET from 16 h to 144 h post-injection with the maximum tumor-to-background ratio observed at 72 h (SUVmax = 12.5 for tumor and 4 for local normal tissues). Liver metastases of 2-3 mm diameter were identified on MR images guided by immunoPET data, but were not detected using [^{18}F]FDG. Autoradiography data demonstrated a ^{89}Zr-Ab metastases-to-liver uptake ratio of 13:1. **Conclusions:** The ^{89}Zr-labeled anti-CD99 Ab PET probe out-performed [^{18}F]FDG and MRI in the detection of Ewing sarcoma metastases, validating our prior work with a ^{64}Cu-labeled anti-CD99 probe. The longer half-life of ^{89}Zr allowed imaging at later time points (72 h) than ^{64}Cu yielding a tumor-to-background ratio that was two-fold higher. The more sensitive and specific detection and monitoring of metastatic disease may have tremendous implications for the clinical care of patients with Ewing sarcoma. In light of existing safety data for the imaging of adult solid tumors with ^{89}Zr-labeled Abs, this study supports next steps for translation to pediatrics.

10049 Poster Session (Board #119), Sun, 8:00 AM-11:30 AM

Analysis of prognostic factors of clinical outcome in children and adolescents enrolled in phase I trials: a multicentre European collaborative study. *First Author: Fernando Carceller Lechon, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Phase I trials play a key role in the evaluation of novel agents for pediatric patients with advanced cancer. One of the major challenges remains the selection of patients who are most likely to benefit from investigational treatments and have a life expectancy ≥ 8-12 weeks. Two clinical scores have been validated in adult oncology to optimise patient selection: the Royal Marsden (RM) score (albumin, lactate dehydrogenase (LDH), number of metastatic sites); and the MD Anderson Cancer Centre (MDACC) score (RM score plus performance status (PS) and gastrointestinal tumor type). These scores have not been validated for children/adolescents enrolled in phase I trials. **Methods:** Retrospective study of patients aged < 18 years, with solid tumors, enrolled in phase I trials at Innovative Therapies for Children with Cancer (ITCC) centres between 2000-2014. Descriptive and uni/multivariate analyses of overall survival (OS) were carried out. **Results:** 172 patients were studied; median age 9 years. Tumor types included: primary central nervous system 42%, bone sarcomas 23%, neuroblastoma 10%, others 25%. Best response: complete/partial in 21 patients (12%); stable disease in 42 (24%). Overall, 30 and 90-day mortality on study were, respectively, 8% and 29%. Median OS (months) as per RM score was: 15.2 ± 2.4 for scores 0-1 *Vs* 5.7 ± 1.7 for scores ≥ 2 (p = 0.015); and, as per MDACC score, 15.9 ± 2.6 for scores 0-1 *Vs* 7.7 ± 2.3 for scores ≥ 2 (p = 0.022). In univariate analysis, tumor type, PS, school/work attendance at inclusion, use of opioids, creatinine above upper limit of normal (> ULN), total bilirubin > ULN, LDH > ULN, albumin < 35 g/dl, prior radiotherapy, and prior autologous stem cell rescue (ASCR) significantly correlated with OS. In multivariate analysis, poor PS, LDH > ULN and no prior ASCR correlated with lower OS. **Conclusions:** The RM and MDACC scores select patients with an inferior OS in pediatric phase I studies, but cannot be deemed fully fit for purpose in children. Clinical characteristics which independently predict impaired survival will identify children who are unlikely to benefit from participation in phase I trials and improve the efficiency of these studies.

10050 Poster Session (Board #120), Sun, 8:00 AM-11:30 AM

Efficacy in six courses of nonmethotrexate three-drug chemotherapy and surgery in osteosarcoma: 25-year experience. *First Author: Rejin Kebudi, Istanbul University, Oncology Institute and Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, Istanbul, Turkey*

Background: Chemotherapy and surgery are the mainstay of osteosarcoma (OS) treatment. Using 2-4 drugs and short or long duration in chemotherapy protocols have been evaluated in various trials. A metaanalysis (Anninga JK, 2011) has reported, 3-drug regimen is better than 2, but not inferior than 4-drug. Our study aims to evaluate the outcome of Osteosarcoma (OS) patients treated with a nonmethotrexate 3-drug regimen and surgery. **Methods:** Children and adolescents with oteosarcoma treated between January,1990- January,2015 at Istanbul University, Oncology Institute were retrospectively evaluated in terms of demographic features and survival outcomes. The patients recieved 6 courses of a 3 drug regimen comprising of ifosfamide 1.8 g/m2/d x 3 days, epirubicin 90 mg/m2/d and sisplatinum 100mg/m2/d administered 3-pre and 3-postoperatively. Methotrexate was not in the protocol because drug levels could not be monitored in the 1990's at our center. Since 2012, mifamurtide was added to the protocol postoperatively for nonmetastatic patients. **Results:** 189 children (105 boys, 84 girls) with a median age of 12 years (3-18yrs) were evaluated. 151 (80%) were non-metastatic and 38 metastatic. Median follow-up was 3,6 years (1mo.-24 yrs). 91.5 % had limb salvage surgery. Relapse/progressive disease was observed in 69 patients at a median 15 months (1mo-63 mo). The 5 and 10-year overall survival and event free survival for the whole group were (OS) 63.1% and 60.5%, and (EFS) 58.8% and 57% respectively. In non-metastatic and in metastatic patients, 5-year OS was 73.8 and 23.9% , 5-year EFS was 69.4% and 20.8%; respectively (p = 0.0001). In 25 nonmetastatic patients recieving chemotherapy and mifamurtide 2-year OS and EFS were 90.9% and 85.5% respectively at a median of 20 months. **Conclusions:** A 3-drug combination of cisplatin,epirubicin,ifosfamide given for 6 courses is an effective, reasonably well tolerated regimen for osteosarcoma; and combined with surgery in experienced hands results in survival rates comparable to other studies in the literature. Longer follow up is needed to assess the contribution of mifamurtide on outcome. Presence of metastasis is associated with poor outcome.

10051 Poster Session (Board #121), Sun, 8:00 AM-11:30 AM

Comparison of clinical features and outcomes in patients with extraskeletal versus skeletal localized Ewing sarcoma: A report from the Children's Oncology Group. *First Author: Thomas Cash, Emory Univ/Children's Healthcare of Atlanta, Atlanta, GA*

Background: The prognostic significance of having extraskeletal Ewing sarcoma (EES) using modern chemotherapy protocols is unknown. The purpose of this study was to compare the clinical characteristics and outcomes for patients with extraskeletal and skeletal Ewing sarcoma. **Methods:** Patients had localized Ewing sarcoma and were treated on two consecutive protocols using 5-drug chemotherapy (INT-0154 and AEWS0031). Patients were analyzed based on having an extraskeletal (n = 213) or skeletal (n = 826) site of tumor origin. Patient characteristics were compared using Wilcoxon rank sum, Fisher exact, and chi-square tests. Event-free survival (EFS) was estimated using the Kaplan-Meier method and compared using the log-rank test. Relapse, death, or second malignancy were considered events. **Results:** Age of diagnosis and sex did not differ according to tissue of origin. Patients with EES were less likely to be white (80.8% vs. 87.7%; p = 0.02), and were less likely to have tumors > 8cm (22.3% vs. 36.3%; p = 0.01) compared to patients with skeletal Ewing sarcoma. There was a trend to suggest superior EFS for patients with EES compared to skeletal tumors (hazard ratio 1.34; p = 0.053). Among patients with extraskeletal tumors, the EFS was inferior for those patients who were not white (p = 0.005) and who were > 18 years of age (p = 0.02). The distribution of event types experienced by each group did not differ. **Conclusions:** Clinical characteristics differ between patients with extraskeletal and skeletal localized Ewing sarcoma and outcomes may be superior for patients with EES. The origin of these differences requires further investigation.

10052 Poster Session (Board #122), Sun, 8:00 AM-11:30 AM

A phase I study of sirolimus in combination with metronomic therapy in children with recurrent and refractory solid/CNS tumors. *First Author: Muna Qayed, Emory Univ, Atlanta, GA*

Background: Sirolimus, an oral mTOR inhibitor, has anti-tumor effects mainly by blocking signals which drive cells from G1 to S phase. It has antiangiogenic activity and has shown antitumor activity in pediatric solid tumor xenografts. At higher doses, with prolonged exposure, sirolimus has been shown to inhibit mTORC2 thereby inhibiting feedback loops that could lead to tumor growth. The safety of combining escalating doses of sirolimus with low dose metronomic chemotherapy was tested in a phase I trial. **Methods:** Patients ≤ 30 years of age with recurrent or refractory solid (including CNS) tumors were eligible. Treatment consisted of continuous sirolimus and celecoxib (100 mg twice a day), oral etoposide (50 mg/m^2/day, maximum dose 100mg) alternating every 21 days with oral cyclophosphamide (2.5 mg/kg/day, maximum dose 100mg) in 42 day cycles. The starting dose of sirolimus was 1 mg/m^2 daily and was escalated by 0.5 mg/m^2, following a Bayesian method of Escalation With Overdose Control. Samples for MTOR pathway evaluation in peripheral blood mononuclear cells were obtained during cycle 1. **Results:** 18 patients were enrolled: four on dose level (DL)1(one patient not evaluable), four on DL2, eight on DL3, and two on DL4. Median age was 11.0 years (2.3 – 19.4 years). Diagnoses included Ewing sarcoma, osteosarcoma, MPNST, rhabdoid tumor, retinoblastoma and CNS tumors (GBM, DIPG, high grade glioma, medulloblastoma, ependymoma, astrocytoma, PNET, GCT). One DLT (grade 4 neutropenia) was observed on DL2, two DLTs (grade 3 abdominal pain-,grade 3mucositis) on DL3, and two DLTs (grade 3 dehydration, grade 3 mucositis) on DL4. The recommended phase II dose was determined to be 2 mg/m^2 (DL3). Additional ≥ grade 3 regimen-related toxicities during cycle 1 were leukopenia, lymphopenia, thrombocytopenia, febrile neutropenia and vomiting. Best response was stable disease (SD) in 8 patients and partial response (PR) in one patient with GBM. One patient with high grade glioma was removed from study with SD due to toxicity and developed a PR without further therapy. **Conclusions:** The combination of sirolimus with metronomic chemotherapy is well tolerated in children. A phase II trial of this combination is planned. Clinical trial information: NCT01331135.

10053 Poster Session (Board #123), Sun, 8:00 AM-11:30 AM

A phase I/II clinical trial of veliparib (ABT-888) and radiation followed by maintenance therapy with veliparib and temozolomide in patients with newly diagnosed diffuse intrinsic pontine glioma (DIPG): A Pediatric Brain Tumor Consortium Interim Report of Phase I Study. *First Author: Patricia Ann Baxter, Texas Children's Cancer Center, Baylor College of Medicine, Houston, TX*

Background: We report the results of the dose escalation component of a phase 1/2 trial in children with newly diagnosed DIPG designed to determine the maximum tolerated dose (MTD) and toxicities of veliparib in combination with radiation therapy (XRT) as well as the optimal dose for veliparib and TMZ post-XRT. We also evaluated the pharmacokinetics (PK) of veliparib and its impact on poly(ADP-ribose) (PAR) levels in PBMCs. **Methods:** Veliparib was given daily x 5, BID, during XRT (6-7 wks) followed by maintenance therapy with daily TMZ and twice daily veliparib for 5 days, every 28 days for up to 10 cycles. The veliparib starting dose during XRT was 50 mg/m2/dose BID. Maintenance therapy began at week 10 with veliparib 25 mg/m2/dose BID and 135 mg/m2/day TMZ. Blood for PK studies was obtained pre- and post veliparib days 1 and 4 of XRT. PAR levels, as measured using an ELISA assay, were assessed on days 1 and 3 to 5 of XRT. **Results:** 18 patients were enrolled in the phase 1 portion of the trial. Dose-limiting toxicities (DLT) during the XRT phase were a grade 2 intra-tumoral hemorrhage (n = 1), grade 3 maculo-papular rash (n = 2), and grade 3 nervous system disorder (generalized neurologic deterioration) (n = 1). The RP2D for veliparib was 65 mg/m2/dose BID during radiation therapy. After completion of veliparib and radiation, patients received veliparib at 25 mg/m2/dose BID and TMZ at 135 mg/m2/day for 5 days every 28 days, which was the RP2D from preceding PBTC027, a phase I trial in children with recurrent CNS tumors. Intra-patient escalation of TMZ during maintenance was attempted but was not feasible due to hematologic DLT. **Conclusions:** Veliparib, 65 mg/m2/dose BID, plus radiation therapy, followed by veliparib plus TMZ was reasonably well tolerated in children with newly diagnosed DIPG. A phase 2 trial is ongoing to study the efficacy of this treatment in children with newly diagnosed brainstem gliomas. Clinical trial information: NCT01514201.

10054 Poster Session (Board #124), Sun, 8:00 AM-11:30 AM

Pharmacogenetic markers for efficacy and toxicity of chemotherapy in osteosarcoma patients. *First Author: Hanneke I. Vos, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Despite multiagent chemotherapeutic treatment, osteosarcoma patients relapse frequently and survival has reached a plateau in the past decades. A poor response to chemotherapy is considered as risk factor for an unfavourable outcome. We have previously identified genetic markers predictive of treatment outcome in genes of cisplatin and doxorubicin metabolic pathways. However, the complex metabolism of the drugs used in osteosarcoma treatment involves a broader range of drug metabolic enzymes and transporters. Therefore we have performed large scale screening of 1,936 genetic variants in 231 genes known to be involved in drug metabolism and transport. **Methods:** From two cohorts of osteosarcoma patients (n = 139 and n = 177), germline DNA was genotyped using the DMET Plus array. Associations between genetic variants and ototoxicity (SIOP grade 1-4), histological response (HR) to preoperative cisplatin and doxorubicin based chemotherapy, and 5-year Disease Free Survival (DFS) were assessed by logistic regression models in PLINK and Cox proportional hazards models in GenABEL respectively. **Results:** 689 markers and 136 patients (cohort 1), and 669 markers and 174 patients (cohort 2) passed quality control (call rates > 0.9, minor allele frequency > 0.01). Upon meta-analysis, 16 markers were significantly associated (P< 0.05) with ototoxicity, including *AOX1* encoding a protein involved in homeostasis of reactive oxygen species. A total of 14 variants showed association with HR, and 23 markers with 5-year DFS, with an overlapping marker in the energy metabolism gene *SLC25A27*. In addition, a previously detected association between an *ABCC5* variant and DFS was confirmed. **Conclusions:** To the best of our knowledge, this is the first pharmacogenetic study in osteosarcoma patients studying a large number of drug metabolism and transporter genes. We have detected significant associations of treatment response and ototoxicity with genes previously unknown to be related to cisplatin and doxorubicin metabolism and transport. Upon replication, biological validation and prospective testing, these markers are of potential interest for the development of new treatment strategies and optimizing current therapy.

10055 Poster Session (Board #125), Sun, 8:00 AM-11:30 AM

Developmental pharmacokinetics of topotecan (TPT), a renally excreted drug, in infants and young children with brain tumors. *First Author: Vinay M. Daryani, St. Jude Children's Research Hospital, Memphis, TN*

Background: We investigated TPT pharmacokinetics (PK) in a clinical trial evaluating risk adapted therapy for infants and young children with brain tumors (NCT00602667). During consolidation, TPT is administered over 4 hrs to high risk patients on days 1 – 5; the initial dosage is based on age (patients < 6, 6 – 11.9, and > 12 months receive 2, 2.5, and 3.5 mg/m^2, respectively). **Methods:** PK studies are performed using a limited sampling strategy (time points: pre-infusion, 5 mins, 1, and 3 hours post infusion). TPT lactone concentrations are measured by HPLC-UV using a CLIA-approved assay. We use a PK-guided approach to individualize the TPT dosage to achieve a daily target plasma $AUC_{0-\infty}$ of 120 – 160 ng/mL*h. In this report we analyzed the individual TPT data from 38 patients using a population PK approach. A two-compartment PK model was fit to the TPT concentration-time data using nonlinear mixed effects modeling to estimate population PK parameters and inter- and intra-subject variability. Estimated PK parameters included volume of the central compartment (V_c), total systemic clearance (Cl_t), and intercompartmental rate constants (K_{cp}, K_{pc}). **Results:** In the 38 patients, we collected and analyzed 396 samples. The median (range) age, body surface area (BSA), and actual weight are 22.6 months (6 – 42 months), 0.54 m^2 (0.31 – 0.69 m^2), and 12 kg (5.4 – 16.9 kg), respectively. The population mean (RSE%) estimates of plasma TPT lactone Cl_t and V_c were 25.7 (4.8) L/h/m^2 and 24.2 (5.8) L/m^2, respectively, with interindividual variability (%CV) of 24% for Cl_t and 22% for V_c. The median (range) TPT Cl_t in 9 patients < 12 months old was 20.6 L/h/m^2 (10.8 – 29.9 L/h/m^2) and was significantly lower (Mann-Whitney p < 0.0001) compared to 29 patients ≥ 12 months old with a median (range) TPT Cl_t of 28.3 L/h/m^2 (16.7 – 45.1 L/h/m^2). **Conclusions:** TPT Cl_t exhibits an age-dependency independent of BSA and the increase in TPT Cl_t parallels the physiological maturation in renal function that occurs during infancy. These results validate our use of lower initial TPT dosages in infants and point to incorporation of a maturation function on clearance to further refine our dosing approach for TPT in infants and young children with brain tumors. Clinical trial information: NCT00602667.

10056 Poster Session (Board #126), Sun, 8:00 AM-11:30 AM

Haploidentical stem cell transplantation and subsequent immunotherapy with antiGD2 antibody for patients with relapsed metastatic neuroblastoma. *First Author: Peter Lang, University Children's Hospital, Tübingen, Germany*

Background: Pediatric patients with relapsed metastatic neuroblastomas have a poor prognosis and additional therapeutic strategies are needed. We present results of a phase I/II-trial with subsequent immunotherapy with an anti-GD2mAb (CH14.18/CHO) after HLA mismatched, haploidentical stem cell transplantation (SCT). **Methods:** T- and B-cell depleted stem cells from parental donors were used in combination with Melphalan140mg/m^2, Thiotepa10mg/kg, Fludarabin160mg/m^2 and ATG-F. Infusions with CH14.18/CHOmAb were started on day 60-180 posttransplant: 6 cycles with 20mg/m^2/day x 5 days; in cycles 4-6, 1x10^6 U/m^2 Interleukin 2 (IL2) was given additionally. The disease status was evaluated with whole body MRI, MIBG scan and bone marrow aspirates. **Results:** 34 patients with 1st or 2nd metastatic relapse were enrolled. During antibody infusions, endogenous secretion of IL2 was increased (928U/ml prior vs. 1690U/ml post, $p < 0.001$), which resulted in significantly increased numbers of activated CD69+ Natural Killer (NK) cells (3 vs. 13% $p < 0.01$). In 5/7 investigated patients, effective ADCC and complement mediated (CDC) anti-tumor effects against neuroblastoma cells were detectable in vitro (85% specific lysis, E:T-ratio = 20:1, BATDA-release). 14/34 patients did not reach the end of the protocol (due to side effects, n = 2; TRM, n = 1; progression or relapse, n = 11). 8/34 patients could maintain a CR, 9/34 patients improved their partial remission and achieved CR, 3/34 patients had stable disease. Thus, success of treatment defined as stable disease or improvement was shown in 59%. Progression free survival at 2 and 3 years was 55% and 38% (median follow up: 550 days). Frequent side effects were pain, fever and CRP elevation; rare side effects comprised SIRS/capillary leak syndrome, seizures, and accommodation disturbances. Only 1 patient developed transient acute GvHD grade II. **Conclusions:** CH14.18/CHO infusions after haploidentical stem cell transplantation appear to be feasible without increased risk of inducing GvHD. Results of our study also suggest an anti tumor effect of the new, donor-derived immune system in vitro and in vivo. Clinical trial information: NCT02258815.

10057 Poster Session (Board #127), Sun, 8:00 AM-11:30 AM

Association of pharmacogenetic variants with progressive disease in osteosarcoma patients. *First Author: Hanneke I. Vos, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Despite treatment, some osteosarcoma patients have refractory/progressive disease and a very poor prognosis. We have previously identified genetic markers predictive for disease free survival. We hypothesize that osteosarcoma patients with refractory/progressive disease have a pharmacogenetic profile different from patients with recurrent disease. To investigate this, we have analyzed these subgroups of patients using a large scale screening including 1,936 genetic markers in 231 drug metabolism and transport genes. **Methods:** Germline DNA of Dutch osteosarcoma patients treated with cisplatin and doxorubicin-based chemotherapy (n = 316) was genotyped with the DMET Plus array. Patients with refractory/progressive disease (primary tumor growth/ growth or development of new metastases, up to 3 months post chemotherapy) were compared to control patients (without refractory/progressive disease or recurrence), as were patients with recurrent disease (local or distant relapse). Associations between genetic variants and refractory/progressive disease or recurrent disease were assessed by logistic regression models in PLINK. **Results:** 710 markers and 310 patients passed quality control. Of 280 eligible patients, 36 experienced progression and 76 recurrence. In multivariate association analyses of genetic variants and refractory/progressive disease or recurrent disease, adjusted for presence of primary metastases, sex and age at diagnosis, 25 genetic markers were significantly associated ($P< 0.05$) with refractory/progressive disease. Of these, 18 genetic variants in 13 genes were uniquely associated with refractory/progressive disease and not with recurrent disease in this cohort. **Conclusions:** This is the first pharmacogenetic analysis of osteosarcoma patients to distinguish between refractory/progressive disease and recurrent disease. In this exploratory study we have identified genetic variants specifically associated with refractory/progressive disease in osteosarcoma patients. This analysis represents the first step to identify patients for whom chemotherapeutic treatment is ineffective and should be further explored in future studies.

10058 Poster Session (Board #128), Sun, 8:00 AM-11:30 AM

Safety and tolerability of crizotinib in combination with chemotherapy for relapsed or refractory solid tumors or anaplastic large cell lymphoma: a Children's Oncology Group phase I consortium study. *First Author: Emily Gustava Greengard, University of Minnesota, Eden Prairie, MN*

Background: Crizotinib is a small molecule inhibitor of the c-Met/HGFR, ALK, and ROS1 receptor tyrosine kinase (RTK). The Children's Oncology Group (COG) Phase I study of crizotinib determined the recommended phase 2 dose (RP2D) to be 280 mg/m^2/BID. Objective tumor responses in patients with known activating ALK aberrations were demonstrated. This phase I study aims to determine the safety, tolerability and RP2D of crizotinib in combination with conventional chemotherapy for children with refractory solid tumors and ALCL. **Methods:** Pediatric patients with measurable or evaluable solid tumors or ALCL, refractory to therapy were eligible. Using a 3+3 design, crizotinib was escalated in 3 dose levels from 165 mg/m^2/dose to the RP2D of 280 mg/m^2/dose BID. Patients were enrolled on either Part A, crizotinib with topotecan and cyclophosphamide, or Part B, crizotinib with vincristine and doxorubicin. The oral solution of crizotinib was used for all patients. In part C of the study, patients received crizotinib as formulated capsules in combination with topotecan and cyclophosphamide. Pharmacokinetic evaluation prior to the first dose and at steady state were required. Correlative studies for ALK aberrations were performed on patients with neuroblastoma. C-Met expression was performed on non-ALCL, non-neuroblastoma patients. **Results:** To date, 22 eligible patients have enrolled with 17 patients fully evaluable for toxicity. In part A, crizotinib was escalated to 215 mg/m^2/dose, however, two patients experienced DLT of diarrhea and dehydration at 215 mg/m^2/dose. In part B, crizotinib was escalated to 280 mg/m^2/dose, however, two patients experienced DLT of nausea, dehydration and prolonged QT interval at 280 mg/m^2/dose. Due to concerns that toxicities may be due to palatability of the oral solution, Part C subsequently opened and is currently enrolling patients. **Conclusions:** The safety and tolerability of crizotinib with conventional chemotherapy warrants further investigation. The oral solution of crizotinib may not be palatable. Alternative formulations are being developed. Clinical trial information: NCT01606878.

10059 Poster Session (Board #129), Sun, 8:00 AM-11:30 AM

Phase 1 trial of p28 (NSC745104), a non-HDM2 mediated peptide inhibitor of p53 ubiquitination in children with recurrent or progressive CNS tumors: A final report from the Pediatric Brain Tumor Consortium. *First Author: Rishi Ramesh Lulla, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Background: Wild type and mutated TP53 are common in pediatric CNS tumors. p28 is a cell penetrating peptide that preferentially enters cancer cells and binds to wild type and mutant p53 protein inhibiting COP1 mediated ubiquitination and proteasomal degradation. This results in an increase in levels of p53, which induces cell cycle arrest at G_2/M. A Phase I trial in 15 TP53 positive, adult patients with stage IV tumors reported no AEs and 1CR and 3PR with 4 patients alive greater than 40 weeks. Regression analysis suggested that p28 has activity in patients whose tumors express both wild type and mutated TP53. **Methods:** Intravenous p28 was administered 3 times weekly for 4 consecutive weeks of a 6-week cycle at 4.16 mg/kg/dose (the adult MTD) using a rolling 6 study design. TP53 expression status was characterized by immunohistochemistry and serum pharmacokinetics were established on the second dose. **Results:** Of the 18 patients registered on the study, 12 patients (8 males, median age 11 years (range 3-19)) completed the DLT period and are evaluable for toxicity with malignant glioma (n = 4), choroid plexus carcinoma (n- = 2), medulloblastoma (n = 2), pineoblastoma (n = 2), DIPG (n = 1) and AT/RT (n = 1). p28 was well tolerated; 7 patients received 2 or more courses and the most common adverse event attributed to drug was transient Grade I infusional reaction. One patient with metastatic pineoblastoma with bone marrow involvement had 2 DLTs of Grade 4 neutropenia and thrombocytopenia. Pharmacokinetic analysis of 16 patients revealed an overall $t_{½}$ and $t_{½\alpha}$ similar to adults. An increased AUC was observed in pediatric patients, as a result of a higher C_{max} and longer $t_{½\alpha\beta}$. p53 expression in tumor cell nuclei was high in 7 of 12 available tissue samples; correlation with response to p28 will be presented. **Conclusions:** This phase I study demonstrates that p28 is well tolerated in children with recurrent CNS malignancies at the adult MTD. Future combination studies are being explored. Clinical trial information: NCT01975116.

10060 Poster Session (Board #130), Sun, 8:00 AM-11:30 AM

Transcriptome based individualized therapy of refractory pediatric cancer in adolescents and young adults. *First Author: Bushra Weidenbusch, Technische Universität München, Munich, Germany*

Background: Progress in pediatric oncology had little impact on adolescents and young adults (AYAs). Survival rates stagnated and are even worse than in younger and older age groups. Tumor biology in refractory patients is highly heterogeneous inter- and even intra-individually .New approaches are therefore urgently needed. Gene expression analysis may aid in medical decision making in this setting. ***Methods***: We enrolled patients aged 10-40 years for whom standard of care and current clinical trials provided no further treatment options in a one arm open label prospective study to assess survival. Tumor samples obtained for diagnosis underwent transcriptome analysis with Affymetrix arrays. We focused on genes with > 1.5 fold expression vs. normal tissue, identified as drivers by TARGETgene. Targets ranked between 1-100 were considered for therapy. Drug selection criteria were: delivery, no previous use in the patient, citations related to disease, citations related to other cancers, side effects, drug interactions, oral application, approval by German authorities. ***Results***: From 12/12-01/15, 18 biopsies were obtained after informed consent from 16 eligible patients at a single institution (TUM) with a mean age of 15.8 years. Diagnosis was sarcoma in 14 (6 Ewing sarcomas, 4 soft tissue sarcomas, 4 osteosarcoma), and embryonal tumor in 2. Targeted therapy was administered in 10, while in 5 no druggable targets could be identified. One patient was noncompliant. Mean druggable targets per patient was 7.6, with 462 medications assessed. 18 different drugs were recommended with an average of 3 drugs per patient, including PKIs, TKIs, TOP2Is, nucleoside analogs, arsenic trioxide and ATRA. Therapy was well tolerated with no adverse reactions and no side effect-related discontinuation of treatment. In this pilot study survival was at least not inferior to best medical care. ***Conclusions***: Targeted therapy is a feasible alternative to best medical care in refractory cancer in AYAs. In the majority of patients druggable targets can be identified and therapy typically does not cause side effects. Prospective studies to determine potential overall survival benefit are ongoing within the INFORM consortium.

10061 Poster Session (Board #131), Sun, 8:00 AM-11:30 AM

Phase II study of nimotuzumab and radiotherapy in children and adolescents with newly diagnosed diffuse intrinsic pontine gliomas (DIPG). *First Author: Sidnei Epelman, Santa Marcelina Hospital, Sao Paulo, Brazil*

Background: DIPG are amongst the most challenging tumors to treat in childhood with no drug proven to be effective. Standard of care remains focal radiotherapy alone however, rapid disease progression usually occurred. Median overall survival is less than 1 year, and the 2-year survival is less than 10%. **Methods:** Patients with clinically and radiologically confirmed, centrally reviewed newly diagnosed DIPG were eligible for this multicenter phase II study. The anti-epidermal growth factor receptor antibody, nimotuzumab (150 mg/m2) was administered intravenously once weekly concomitant with focal radiotherapy (54Gy) and every 2 weeks until tumor progression. Response evaluation was based on clinical and radiological assessments. Primary objective was to improve survival with a historic cohort that received radiation therapy alone. **Results:** 21 patients entered into this study (7/14, male/female; median age, 7.6 years; range 2-16 years). All received radiotherapy. Treatment was well tolerated. 40/502 cycles had adverse effects related to the drug and very mild. The majority of adverse effects were associated with progression of disease. Disease free survival at 7.3 months was 85.7% (CI95% - 70.7-100). Overall survival at 9 months was 71.4% and at one year, 57.1% (CI95% - 33.8-74) which demonstrated better results when compared with historic trials. **Conclusions:** This trial demonstrated some activity of nimotuzumab in DIPG. It was well tolerated and improved overall survival. A small subset of patients appeared to benefit from this anti-EGFR antibody and can be considered in future trials with synergistic drugs. An upfront biopsy can bring the prospect of a better understanding of DIPG biology and selection of better treatment. Clinical trial information: NTC01145170.

10062 Poster Session (Board #132), Sun, 8:00 AM-11:30 AM

The genomic landscape of anaplastic Wilms tumors with diffuse versus focal anaplasia. *First Author: Gabriel G Malouf, AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Medical Oncology, UPMC Univ Paris 06, Institut Universitaire de Cancérologie GRC5, Paris, France*

Background: Anaplasia is a potent marker for adverse outcome in patients with Wilms tumors (WT). While WT patients with focal anaplasia (FA) have similar survival to those with nonanaplastic intermediate risk WT, patients with diffuse anaplasia (DA) display poor outcomes. Beside *TP53* mutations, the genome-wide genetic basis of WT remains unknown. **Methods:** We performed whole-exome sequencing on genomic DNA derived from 11 WT and matched normal DNA from the same patients, using Agilent human V5 (51Mb) capture and the HiSeq sequencing platform. Overall, 8 and 3 matched pairs with DA and FA were assessed, respectively. Paired-end RNAseq was also performed in the same dataset for fusion transcript detection. Chromosome 17p copy number, where *TP53* is located, was assessed by a MLPA assay. **Results:** Overall, we identified 117 (median 10, range 5-25) non-synonymous somatic single nucleotide variants, of which 47 were predicted to lead to a deleterious protein. No difference was observed in term of total number of mutations between WT with DA and FA, respectively. *TP53* mutations were identified in 4 DAWT. In addition, 2 DAWT and 2 FAWT harbored identical hotspot *DROSHA* mutation (E1147K). Ingenuity Pathway Analysis revealed enrichment for mutations in genes involved in embryonal tumor development (*ARMCX3, BCOR, FLT4, KMT2C, REST* and *TP53*) ($p = 2.7x10^{-4}$). All but one case of DAWT with *TP53* mutations harbored *TP53* deletion; the case without *TP53* deletion had in addition *DROSHA* mutation. The 4 patients with *TP53* mutations died as compared to one out of 7 without mutation ($p = 0.01$). No known or novel fusion transcripts were identified. **Conclusions:** Our results reveal an exceptionally low mutational load in anaplastic WT, consistent with previously reported results in pediatric solid tumors. *DROSHA* and *TP53* are likely to be mutually exclusive mutations in WT. Updated results with an independent validation dataset will be presented at the meeting.

10063 Poster Session (Board #133), Sun, 8:00 AM-11:30 AM

Localized vagina/uterus rhabdomyosarcoma (VU RMS): Results of a pooled analysis from four international cooperative groups. *First Author: Veronique Minard-Colin, Institut Gustave Roussy, Villejuif, France*

Background: VU RMS is rare and recognized as one of the most favorable site of RMS. In an attempt to determine optimal therapy in relation both to cure and to late effects, the experience of four international collaborative groups (Children's Oncology Group [COG], SIOP Malignant Mesenchymal Tumor Group [MMT], Italian Cooperative Soft Tissue Sarcoma Group [ICG], and European pediatric Soft Tissue Sarcoma Group [EpSSG]) was shared at an international workshop. **Methods:** From 1985 to2009, a total of 237 eligible patients were identified from group files (132 from COG, 62 from MMT, 24 from ICG, and 19 from EpSSG). **Results:** Median patient age at diagnosis differed among tumor location (1.9 yrs [vagina = 160 pts]; 4 yrs [uterus corpus = 34 pts]; 13.5 yrs [cervix = 43 pts]). Median follow-up was 8 years. Twenty-seven percent of pts received radiation therapy (RT) as part of primary therapy (21% COG, 27% MMT, 46% ICG, 42% EpSSG), and among those, there were significant differences regarding the use of brachytherapy (BT) between the individual groups (14% in COG, 71% in MMT, 55% in ICG, and 75% in EpSSG).Ten-year event-free (EFS) and overall survival (OS) were 72% and 92%. In univariate analysis, low OS was only correlated with enlarged nodes (N1 = 11 pts). While EFS was slightly decreased in pts without initial RT (EFS, 74% *vs* 82% with RT; p = NS), there was no difference in OS (OS: 93% and 90% without or with initial RT). In total, taking into account total burden of treatment (primary therapy and treatment for relapse), 117 (53%) of the 221 survivors were cured with chemotherapy +/- conservative surgery. **Conclusions:** These analyses show that half of patients with VU RMS can be cured without systematic RT or radical surgery. When RT is indicated, BT should be encouraged to limit late sequelae.

10064 Poster Session (Board #134), Sun, 8:00 AM-11:30 AM

Late outcomes among adult survivors of childhood non-Hodgkin lymphoma (NHL): A report from the St. Jude Lifetime Cohort Study. *First Author: Matthew J. Ehrhardt, St. Jude Children's Research Hospital, Memphis, TN*

Background: Adult survivors of childhood NHL are at risk for chronic conditions likely underestimated by patient reported outcomes. Prevalence and severity based on direct clinical assessment are lacking. **Methods:** Clinical, laboratory, and performance-based evaluations were obtained on 200 adult survivors of pediatric NHL at St. Jude Children's Research Hospital. Chronic conditions were graded per CTCAE criteria. Impaired physical function was defined as performance below the 10^{th} percentile of normative data. Multivariable Poisson regression models were used to investigate associations [relative risk (RR), 95% confidence intervals (CI)] between patient characteristics, therapies, and clinical outcomes. **Results:** Survivors (66% male, 87% white) were a median age of 10 years (range 1-19) at diagnosis and 34 years (20-58) at evaluation. Forty-six (23%) received radiation to the brain, 69(35%) high dose methotrexate, and 161(81%) steroids. Most (93%) had $\geq$ 1 chronic condition, 77% $\geq$ 2 chronic conditions, and 50% a severe/life-threatening (grade 3-4) condition. Most prevalent were overweight/obesity (65%), cognitive impairment (46%), dyslipidemia (41%), and impaired fasting glucose (37%). Most prevalent grade 3-4 conditions were obesity (35%), hypertension (15%), and cognitive impairment (13%). Risk-based screening detected cardiomyopathy in 14(8.5%); 50% grades 3-4. There were 27 second cancers (61% grades 3-4) in 23(12%) survivors. Prevalence of abnormal body composition, measured by waist to height ratio and percent fat on dual-energy x-ray absorptiometry was 72%. Many had impaired aerobic (22%), strength (48%), muscular endurance (36%), flexibility (39%), and mobility (36%) assessments. Adjusting for ages at diagnosis and evaluation, race, and methotrexate, male sex (RR 1.2, CI 1.1-1.5), anthracycline $\geq$ 250mg/m^2 (RR 1.3, CI 1.1-1.6), and radiation (RR 1.3, CI 1.1-1.6) were associated with having $\geq$ 2 chronic conditions. Non-white race (RR 1.6, CI 1.2-2.1) was associated with a grade 3-4 condition. **Conclusions:** Prospective systematic evaluation identified significant chronic conditions and performance limitations in adult survivors of childhood NHL.

10065 Poster Session (Board #135), Sun, 8:00 AM-11:30 AM

Patterns and predictors of psychological distress in adult survivors of childhood cancer: A Childhood Cancer Survivor Study (CCSS). *First Author: Norma Mammone D'Agostino, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Screening for psychological distress is an important part of comprehensive survivorship care. While elevated symptoms of depression and anxiety have been reported, patterns of emotional comorbidity have not been examined. The aims of this study are to identify clusters of distress symptoms and to examine disease, treatment and demographic predictors. **Methods:** Latent profile analysis was conducted using 3 domains (depression, anxiety, somatization) from the Brief Symptom Inventory – 18 in siblings (N = 3085) and 5+ year survivors (N = 16032) from the CCSS. High distress was defined using t-score $>$ 63. Bayesian information criterion and Lo-Mendell-Rubin adjusted certainty were used to select the optimal cluster number. Multinomial logistic regression was used among survivors to identify disease, treatment and demographic predictors of cluster membership stratified by sex. **Results:** Four latent clusters were identified: low distress on all 3 domains (well-adjusted); high distress on all 3 domains (global distress); high somatization relative to anxiety and depression (somatic distress); high anxiety and depression relative to somatization (affective distress). Compared to siblings, fewer survivors were well-adjusted (62% *v.* 74%) and more had global distress (11% *v.* 5%), both p's $<$ 0.0001. Diagnosis-specific patterns of distress were identified (leukemia and bone cancer: global distress, CNS: affective distress, Hodgkin lymphoma and neuroblastoma: somatic distress). More male (66%) than female (58%) survivors were well-adjusted, but more females reported somatic (17% vs 10%) and global (12% vs 9%) distress, all p's $<$ 0.0001. Among females, fair/poor perceived health (OR 30.9, 95% CL 19.4-49.1; compared to excellent health), headache (OR 2.69, 95% CL 2.24-3.24), and antimetabolite chemotherapy (OR 1.31, 95% CL 1.10-1.55) were associated with global distress. Perceived health and pain were associated with global distress in males. **Conclusions:** Results support the conceptual distinction between physical (somatic) versus affective (anxiety and depression) symptoms of distress and highlight sex differences and health-related predictors of distress.

10066 Poster Session (Board #136), Sun, 8:00 AM-11:30 AM

***CELF4* variant and Anthracycline-related Cardiomyopathy (anth-card) – A COG Study (ALTE03N1).** *First Author: Xuexia Wang, University of Wisconsin-Milwaukee, Milwaukee, WI*

Background: Identification of genetic variants that modify anth-card risk can facilitate targeted interventions. **Methods: Discovery:** Case-control approach used to conduct GWAS in non-Hispanic white ($>$ 90% Europeans: Multidimensional Scale) childhood cancer survivors (CCS). Anth-card cases: n = 112; median ejection fraction (EF): 44%; age at ca dx: 7.5y; anth dose: 319 mg/m^2. Ca controls: n = 219; EF: 65%; age ca dx: 7.9y; anth: 180mg/m^2 matched on ca dx, age at ca dx, year ca dx, time from ca dx. 2-step method used to detect anth dose-SNP interaction (*Genet Epidemiol,* 2012; **36**:183). **Replication:** Case-only design used in 54 CCS with anth-card (EF: 41%; all race/ethnicity; age at ca dx: 7.6y; anth: 300 mg/m^2). **Functional analyses**conducted. **Results: Discovery:** No SNP was marginally associated with anth-card at GW level. 2-step GxE: *Step 1:* Top 1000 SNPs with modest main effect retained; 643 independent tests estimated after LD-based SNP pruning. *Step 2:* GxE interactions tested between SNPs retained in Step1 (P= 0.05/643$_{\text{independent tests}}$= 7.77x10^{-5}). SNP rs1786814 on *CELF4* gene passed significance cut-off (*P_ge*= 1.14x10^{-5}). (MAF$_{\text{control:}}$ 0.249; minor allele: A). Multivariable analyses adjusted for anth dose, sex, chest RT: in CCS with AA genotype, anth-card was rare at all anth doses; in CCS with anth $>$ 300mg/m^2, GG genotype conferred 5.4-fold (95%CI, 1.8-16.2, P= 0.003) increased anth-card risk compared to AA/GA. **Replication:** GG genotype in anth $>$ 300mg/m^2: OR = 5.1, 95%CI 1.0-25.2, P = 0.046; ref: AA/GA. **Functional analysis:** CELF is implicated in alternative splicing of cardiac troponin T (cTnT) - a myocardial injury biomarker; $>$ 1 cTnT variants results in temporally split myofilament response to Ca^{2+}, and decreased contractility (seen in dilated cardiomyopathy) (*Circ Res,* 1995;**76**:681-6). DNA from 33 healthy non-anth-exposed hearts genotyped for rs1786814; RNA splice isoforms measured (RT-PCR), and verified (DNA sequencing). Coexistence of embryonic and adult cTnT (n = 23) more likely in GG hearts (GG: 78%; GA: 22%; AA: 0%, P= 0.016). **Conclusions:** We report a modifying effect of an intronic polymorphism of *CELF4* (rs1786814) on dose-dependent anth-card risk, possibly through accumulation of $>$ 1 form of cTnT protein.

10067 Poster Session (Board #137), Sun, 8:00 AM-11:30 AM

Longitudinal evaluation of health status and chronic conditions in aging pediatric astrocytoma survivors: A Childhood Cancer Survivor Study (CCSS) report. *First Author: Karen Elizabeth Effinger, Stanford University, Palo Alto, CA*

Background: Astrocytoma is a common pediatric central nervous system tumor. However, little is known about the health status and chronic conditions and their association with social outcomes in aging survivors. **Methods:** We evaluated 1,073 5-year astrocytoma survivors (median age: 28 years, range 9-56; median time from diagnosis: 21 years, range 7-38) and 4,023 siblings enrolled in the CCSS at up to 3 time points. We estimated the prevalence of poor health status in 6 domains (general health, functional impairment, activity limitation, mental health, cancer-related pain, cancer-related anxiety); severe, disabling, or life-threatening chronic conditions; and social outcomes (marriage, education, employment, income) in those $\geq$ 25 years of age. We compared outcomes between survivors and siblings as a function of attained age using generalized linear models with robust variances adjusted for race, sex, and body mass index. **Results:** Compared with siblings, astrocytoma survivors were more likely to report poor health status across all domains, more chronic conditions, and poor social outcomes. Among survivors, increasing numbers of chronic conditions were associated with lower marriage and employment rates, lower income, and poor health status in all domains. All domains of poor health status were associated with unemployment. **Conclusions:** Pediatric astrocytoma survivors have increased odds of poor health status, chronic health conditions, and poor social outcomes compared with siblings. Chronic conditions impact health status and social outcomes highlighting the need for regular screening and early interventions.

	Survivors (%)	Siblings (%)	Odds Ratio (95% Confidence Interval)
Poor general health	16.0	5.1	3.6 (3.0-4.3)
Functional impairment	32.7	3.7	13.3 (11.1-16.0)
Activity limitation	20.3	5.6	4.6 (3.9-5.5)
Poor mental health	21.0	10.9	2.0 (1.7-2.4)
Cancer-related pain	12.4	NA	-
Cancer-related anxiety	12.8	NA	-
Chronic conditions	47.7	9.9	9.1 (7.7-10.6)
Married	41.3	69.3	0.32 (0.27-0.37)
Graduated college	40.5	55.1	0.61(0.52-0.71)
Employed	64.7	87.1	0.26 (0.22-0.31)
Income > $20,000	79.7	95.0	0.24 (0.19-0.30)

10068 Poster Session (Board #138), Sun, 8:00 AM-11:30 AM

Quality of life assessment in retinoblastoma: A cross-sectional study of 122 survivors. *First Author: Atul Batra, All India Institute of Medical Sciences, New Delhi, India*

Background: Retinoblastoma (Rb) is the most common intraocular tumor in childhood. With current modalities, cure rates are high and hence number of survivors is increasing. However, data on quality of life (QOL) in this population are minimal. **Methods:** We analyzed QOL in 122 retinoblastoma survivors using the PedsQL 4.0 generic core scale in local language, which has been validated in Indian population. The self-reported questionnaire was filled by children of more than 5 years of age who had completed treatment for more than 12 months. The questionnaire consists of 23 questions on physical, social, emotional and school domains on a scale from 0 to 4. This was converted to a scale from 0 to 100, where higher values represented better QOL. The QOL was compared with 50 siblings using student's t-test. Factors predicting the QOL were assessed. **Results:** The median age of Rb survivors was 98 (range, 60-247) months and 68% were males. Seventy-nine percent were International Retinoblastoma Staging System (IRSS) stage1 and 25% had bilateral disease. Fourteen percent had extraocular involvement and 22% received radiotherapy. The overall QOL was significantly poorer in Rb survivors as compared to controls (Table). The emotional health domains of QOL (fear, anger and sleeping) were significantly lower in Rb survivors. Difficulties in maintaining friendships and competing were reported in the social health domain. In school health domain, there was significantly higher absenteeism due to sickness and hospital visits among Rb survivors. However, the physical health domain including household work, exercise and self-care was similar in both the groups. Age, sex, IRSS stage and previous radiotherapy did not affect the QOL. **Conclusions:** QOL is often a neglected aspect in survivors of pediatric solid tumors. We found a significantly poorer QOL in Rb survivors. However, no predicting factors for poor QOL were found in this group. Although a high survival rate has been achieved in early stage Rb, efforts need to be made to improve QOL.

Domain	Rb Survivors (N = 122)	Controls (N = 50)	P value
Physical	79.1 ± 9.1	81.4 ± 10.1	0.14
Social	71.8 ± 13.1	83.9 ± 10.5	< 0.001
Emotional	78.2 ± 9.8	82.5 ± 12.5	0.02
School	79.9 ± 12.3	91.9 ± 4.7	< 0.001
Overall	77.3 ± 8.6	84.9 ± 5.9	< 0.001

10069 Poster Session (Board #139), Sun, 8:00 AM-11:30 AM

Risk stratification to guide long-term follow up of teenage and young adult survivors of childhood cancer. *First Author: Susannah Jane Stanway, Royal Marsden Hospital, Surrey, United Kingdom*

Background: Long term survivors of paediatric cancer have increased over time. Optimal models of long term care must be developed dependent on current and predicted morbidity, which is affected by tumour type and intensity of treatment. Currently, survivors are referred to the long term follow-up (LTFU) clinic 5 years post treatment and are followed indefinately. The aim of this project was to assess use of risk-stratification to guide intensity of LTFU of survivors of childhood cancer. **Methods:** A retrospective review of the Royal Marsden Hospital Childrens' Late Effects (LE) database was performed. Electronic records of survivors aged 13 to 24 seen in clinic between 2000 to 2012 were reviewed. Patients (pts) were divided into Wallace levels depending on tumour type and treatment given. Number and grades of LEs of treatment were documented using NCI CTC version 4. **Results:** 316 survivors were divided into Wallace level 1 (n = 18, 6%), 2 (n = 163, 52%) and 3 (n = 135, 43%). At a median follow up of 10.9 years from end of treatment, there were a total of 21 groups of LEs identified. Total LEs were 7 for level 1 pts, 128 for level 2 and 373 for level 3. There were 0.39 LEs seen per pt in level 1, the majority of which were grade 1 or 2, in contrast to 2.72/pt in level 3. The relative risk of at least one grade 3 LE at level 3 compared to level 2 was 4.16. The number lost to follow up was 37, 70% of which were in level 2. **Conclusions:** All survivors of childhood cancer need a treatment summary and care plan at 5 years post treatment, when the risk of relapse is very small. Stratification using Wallace levels is feasibile and helps define level of care required. Level 1 and 2 pts can be discharged to a primary care colleague informed by a treatment summary and personalised LTFU care plan. Level 3 pts with higher prevalence and grade LEs will need on-going specialist input from a LTFU service.

10070 Poster Session (Board #140), Sun, 8:00 AM-11:30 AM

Long-term outcomes by race/ethnicity in the Childhood Cancer Survivor Study (CCSS) cohort. *First Author: Smita Bhatia, University of Alabama at Birmingham, Birmingham, AL*

Background: Racial/ethnic differences in risk for long-term adverse outcomes in childhood cancer survivors are not well established. **Methods:** Hispanic (H: 750, 5.4%) and African American (AA: 694, 5%) survivors were compared to non-Hispanic whites (NHW: 12,397, 89.6%) for late mortality, subsequent malignant neoplasms (SMN), and CTCAE-graded chronic health conditions. Poisson regression models adjusted for demographic/clinical factors were used to calculate relative rate (RR) and 95% confidence intervals (CI). **Results:** AA and H survivors were younger at diagnosis, and had lower SES. *Mortality:* No racial/ethnic difference was observed (Table). *SMN:* Risk did not differ by race/ethnicity (cumulative incidence 30y from diagnosis: NHW: 9.0%, AA: 6.6%, H: 7.0%, p=0.3). However, risk for non-melanoma skin cancer (NMSC) was very low among irradiated AA and H survivors (Table). *Chronic Health Conditions (grades 3-5):* Compared to NHW, AA were more likely to report cardiac conditions and H endocrine conditions (Table). These differences were attenuated after adjusting for cardiovascular risk factors (CVRF: dyslipidemia, hypertension, smoking). **Conclusions:** By and large, when adjusted for SES and treatment, morbidity/mortality did not differ by race/ethnicity. However, specific morbidities (H: endocrine, AA: cardiac) were more prevalent, and were partially explained by CVRFs. Risk of NMSC was negligible among irradiated AA and H, relative to irradiated NHW. These findings inform targeted intervention opportunities.

Intestinal obstruction in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Arin L Madenci, Brigham and Women's Hospital, Boston, MA*

Background: For adult survivors of childhood cancer, knowledge about the long-term risk of intestinal obstruction from surgery, chemotherapy, and radiotherapy is limited. **Methods:** Intestinal obstruction requiring surgery (IOS) occurring 5 or more years after cancer diagnosis was evaluated in 12,316 five-year survivors from the CCSS cohort (2,002 with and 10,314 without abdominopelvic tumors) and 4,023 sibling participants. Cumulative incidence of IOS was calculated with second malignant neoplasm, late recurrence, and death as competing risks. Piecewise-exponential models assessed the associations of clinical and demographic factors with rate of IOS. **Results:** IOS was reported by 165 survivors (median age at IOS=19 years, range=5-50 years; median time from diagnosis to IOS=13 years) and 14 siblings. Cumulative incidence of IOS at 35 years was 5.8% (95% confidence interval [CI]=4.4-7.3%) among survivors with primary abdominopelvic tumors, 1.0% (95% CI=0.7-1.4%) among those without abdominopelvic tumors, and 0.1% (95% CI=0.1-0.5%) among siblings. Survivors of abdominopelvic lymphoma had the highest 35 year cumulative incidence of IOS, 7.2% (95% CI=2.8-12.5%). Among all survivors, abdominopelvic tumor (adjusted rate ratio [ARR]=3.6, 95% CI=1.9-6.8, $P<0.001$) and abdominal/pelvic radiotherapy within 5 years of diagnosis (ARR=2.4, 95% CI=1.6-3.7, $P<0.001$) increased the rate of IOS, adjusting for year of diagnosis; sex; race/ethnicity; age at diagnosis; age during follow-up (as natural cubic spline); primary cancer type; and chemotherapy, radiotherapy, and surgery occurring within 5 years of diagnosis. Developing IOS increased the subsequent mortality among survivors (ARR=1.8, 95% CI=1.1-2.9, $P=0.016$), adjusting for the same clinical and demographic factors. **Conclusions:** In the decades following diagnosis and treatment, survivors of childhood cancer are at increased risk of developing late-onset IOS, with subsequent increased risk of mortality. These findings underscore the need to promote long-term awareness of these risks among patients and providers, especially for survivors with abdominal or pelvic tumors who have undergone treatment with surgery or radiotherapy.

10072 Poster Session (Board #142), Sun, 8:00 AM-11:30 AM

Neurocognitive, emotional, and quality of life outcomes in long-term survivors of rhabdomyosarcoma: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Melissa Schapiro, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Previous studies of rhabdomyosarcoma (RMS) survivors have focused on outcomes related to chronic health conditions. We evaluated neurocognitive, emotional, and quality of life (QOL) outcomes of > 5-year survivors. **Methods:** 482 survivors diagnosed 1970-1986 (mean age [SD] 7.2 [5.4] years at diagnosis; 24.3 [4.8] years of follow-up) and 393 siblings from the CCSS rated their neurocognition, emotions, and QOL using the Neurocognitive Questionnaire (NCQ), Brief Symptom Inventory-18 (BSI-18), and Medical Outcomes Short Form-36 (SF-36). Based on normative data, impairment was defined as the bottom 10^{th} percentile of performance on the NCQ, the top 10^{th} percentile of symptom prevalence on the BSI-18, and the bottom 15^{th} percentile on each SF-36 subscale. Odds ratios (OR) and 95% confidence intervals (CI) were calculated using multivariable logistic regression. **Results:** Survivors reported more impairment than siblings on NCQ task efficiency ($p < 0.001$), higher symptom prevalence on BSI-18 depression (13.3% vs. 8.1%, $p = 0.020$) and anxiety (7.9% vs. 4.4%, $p = 0.038$), and poorer QOL on all SF-36 subscales: physical (12.5% vs. 3.1%, $p < 0.001$), social (15.5% vs. 9.4%, $p = 0.009$), and emotional (19.2% vs. 13.5%, $p = 0.030$) functioning, pain (12.4% vs. 14.8%, $p = 0.015$), general health (26% vs. 11.5%, $p < 0.001$), vitality (27.6% vs. 20.6%, $p = 0.022$), and role limitations due to physical (17.4% vs. 9.9%, $p = 0.002$) and emotional (21.3% vs. 13%, $p = 0.002$) problems. Among survivors, women were more likely than men to report impaired vitality (OR 2.2, 1.3-3.5) and social functioning (OR 2.3, 1.3-4.3). Adjusting for age at diagnosis and sex, cranial radiation therapy was associated with poorer task efficiency ($p = 0.004$) and greater likelihood of depression (OR 2.0, 1.1-3.8). Survivors with recent use of antidepressants/anxiolytics reported significantly worse task efficiency and poorer QOL on all SF-36 subscales than survivors not using these medications. **Conclusions:** Adult RMS survivors demonstrate substantial long-term impairment of neurocognitive function, emotional status, and QOL, warranting clinical assessment and appropriate interventions.

10073 Poster Session (Board #143), Sun, 8:00 AM-11:30 AM

Adverse fat depots, marrow adiposity, and skeletal deficits in long-term survivors of pediatric hematopoietic stem cell transplantation. *First Author: Sogol Mostoufi-Moab, The Childrens Hospital of Philadelphia, Philadelphia, PA*

Background: Allogeneic hematopoietic stem-cell transplantation (alloHSCT) survivors treated with total body irradiation (TBI) exhibit bone deficits and excess adiposity, potentially related to altered mesenchymal stem cell differentiation into osteoblasts or adipocytes. **Methods:** We examined associations among fat distribution, bone microarchitecture, and insulin resistance in alloHSCT survivors after TBI. This was a cross-sectional observational study of 25 alloHSCT survivors (aged 12-25 years) a median of 9.7 (4.3-19.3) years after alloHSCT compared to 25 age-, race-, and sex-matched healthy controls. Vertebral MR spectroscopic imaging and tibia micro-MRI were used to quantify marrow adipose tissue (MAT) and trabecular microarchitecture. Additional measures included DXA whole-body fat mass (WB-FM), leg lean mass (Leg-LM), trunk visceral adipose tissue (VAT), and CT calf muscle density. Insulin resistance in alloHSCT survivors was estimated by HOMA-IR. **Results:** AlloHSCT survivors had lower Leg-LM ($p< 0.001$), and greater VAT ($p< 0.01$), MAT ($p< 0.001$) and fat infiltration of muscle ($p= 0.04$) independent of WB-FM, vs. matched-controls; BMI did not differ. Survivors had lower bone volume fraction and abnormal microarchitecture including greater erosion and more rod-like structure vs. controls (all $p= 0.04$); 14 had vertebral deformities and two had compression fractures. Greater WB-FM, VAT, MAT and muscle fat infiltration were associated with abnormal trabecular microarchitecture ($p< 0.04$ for all). AlloHSCT HOMA-IR was elevated, associated with younger age at transplantation ($p< 0.01$), and positively correlated with WB-FM and VAT (both $p< 0.01$). **Conclusions:** Long-term survivors demonstrate sarcopenic obesity, insulin resistance, and vertebral deformities. The markedly increased marrow adiposity, abnormal bone microarchitecture, and abnormal fat distribution highlight the risks of long-term treatment-related morbidity and mortality in alloHSCT recipients after TBI. Future studies are needed to identify strategies to prevent and treat metabolic and skeletal complications in this growing population of childhood alloHSCT survivors.

10074 Poster Session (Board #144), Sun, 8:00 AM-11:30 AM

Temporal changes in treatment exposures in the Childhood Cancer Survivor Study (CCSS). *First Author: Ann Mertens, Emory University, Atlanta, GA*

Background: Well-designed epidemiologic investigations of pediatric cancer survivors inform clinical practice guidelines and future clinical trials. Expansion of the CCSS cohort to include survivors diagnosed across three decades (1970-99) affords the opportunity to evaluate associations between key temporal changes in survivor and treatment characteristics and risk for subsequent adverse health outcomes. **Methods:** We analyzed cancer and treatment characteristics of 24,000 CCSS participants. Treatment exposures were abstracted from medical records. Trends across 5 year intervals were evaluated using logistic regression models with weights to account for sampling probabilities. **Results:** Within the expanded CCSS, the use of chemotherapy significantly increased overall (Table, T1-T6) for all diagnoses except leukemia which was always 100%. Exposure to radiation (RT) decreased overall and for all diagnoses except soft tissue sarcoma. Overall, chest RT exposure was reduced and notably, exposures of ≥ 30 Gy declined from 85% to 6% (T1 to T6) for Hodgkin lymphoma. Alkylating agent use increased by 15% overall, and among leukemia, lymphoma and sarcoma patients proportions were on the order of 40% higher at T6 than at T1. Use of anthracyclines (ANT) increased significantly, predominantly for doses lower than 250 mg/m^2. **Conclusions:** The expansion of the CCSS cohort provides a unique resource to evaluate the impact of historical changes in primary cancer therapy, including reduction of therapeutic intensity for low- and standard-risk populations, as well as intensification of specific therapies for high-risk populations on health and psychosocial outcomes.

10075 Poster Session (Board #145), Sun, 8:00 AM-11:30 AM

Longitudinal smoking patterns in survivors of childhood cancer: A Childhood Cancer Survivor Study (CCSS) update. *First Author: Todd M. Gibson, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of pediatric cancer have elevated risks of mortality and morbidity. Many morbidities associated with cancer treatment (e.g. second cancers, cardiac and pulmonary disease) are associated with cigarette smoking, suggesting survivors who smoke may be at higher risk for these adverse health conditions. **Methods:** We examined self-reported smoking status in 10,430 CCSS participants (age ≥ 18 years) across 2 questionnaires, at a median time of 7.9 years (range 1.4-11.9) apart. Smoking prevalence was compared among survivors, siblings, and the U.S. general population (standardized by age, sex, race/ethnicity and calendar time). Among a subgroup of survivors who also completed an additional follow-up questionnaire (N = 3908) a median of 12.5 years (range 4.3-16.3) after the first questionnaire, multivariable regression models evaluated characteristics associated with longitudinal smoking patterns. **Results:** At baseline, 19% of survivors were current smokers, compared with 24% of siblings and 29% in the standardized U.S. general population. At first follow-up, 17% of survivors were current smokers, compared to 21% of siblings and 24% of the U.S. population. Characteristics associated with consistent "never smoking" over all three questionnaires included higher household income (RR 1.17, 95% CI 1.08-1.25 for ≥ $60,000 versus < $20,000 per year), higher education (RR 1.36, 95% CI 1.26-1.47 for > high school versus ≤ high school), and receipt of cranial radiation therapy (RR 1.10, 95% CI 1.05-1.16). Among "ever smokers", higher income (RR 1.22, 95% CI 1.09-1.38) and education (RR 1.26, 95% CI 1.13-1.40) were associated with quitting, whereas cranial radiation was associated with not having quit (RR 0.85, 95% CI 0.76-0.96). Development of an adverse health condition was not associated with smoking patterns. **Conclusions:** Although smoking prevalence may be declining, the substantial number of consistent, current smokers reinforces the need for continued development of effective smoking interventions for survivors.

10076 Poster Session (Board #146), Sun, 8:00 AM-11:30 AM

The effect of sociodemographic factors and therapy on survival in pediatric liver cancers: A SEER population study. *First Author: Minzhi Xing, Division of Interventional Radiology, Department of Radiology, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: To investigate long-term survival in pediatric primary liver cancers, including hepatoblastoma & hepatocellular carcinoma (HCC) based on sociodemographic factors & therapy in a large-scale population study. **Methods:** The Surveillance, Epidemiology and End Results (SEER) database was queried for pediatric cancer patients with the liver as the primary site (C22.0), diagnosed 1973-2011. Overall survival (OS) was stratified by tumor & patient characteristics. Analysis of OS via therapy was further stratified based on socio-demographic factors. Kaplan-Meier & Cox proportional hazard models were used to assess independent predictors for OS. **Results:** Of 1145 newly diagnosed pediatric cancer patients with liver as primary site, 1012 had primary liver cancers, of whom 725 had hepatoblastoma and 287 had HCC, median age 2yrs, 60.47% male. Overall median OS was 210.7±6.4 mo. Median OS significantly correlated with younger age at diagnosis ($<$ 2 vs. $\geq$ 2yrs, 240.7 vs. 159.7 mo, $p <$ .001), ethnicity (white, black, other; 193.1, 81.6, 166.5 mo; $p = .0136$), geographic location (Alaska, East, Northern Plains, Southwest, Pacific Coast; 106.2, 91.6, 173.1, 112.0, 144.3; $p = .0144$), median family income ($\geq$ \$75k vs. $<$ \$75k/year, 194.1 vs. 184.5 months, $p = .013$), and regional education levels (% bachelor degree or above, $\geq$ 25% vs. $<$ 25%, 198.5 vs. 191.5 months, $p < .0247$). Surgery was performed in 684 patients (67.6%), 40 patients received radiation (3.95%), 15 patients received both surgery and radiation (1.48%), and 274 patients received best supportive care (27.0%). OS was significantly lower in patients who received best supportive care (22.6 mo) compared to surgery (275.4 mo, $p <$ .001), radiation (77.3 mo, $p <$ .001), or both surgery & radiation (171.3 mo, $p <$ .001). Favorable sociodemographic factors significantly correlated with higher therapy rates. **Conclusions:** In pediatric primary liver cancers, socio-demographic factors including younger age at diagnosis, white ethnicity, higher family income & higher regional education levels correlated with prolonged survival. Significantly higher survival with treatment was observed; favorable socio-demographic factors predicted higher treatment rates.

10077 Poster Session (Board #147), Sun, 8:00 AM-11:30 AM

Palonosetron vs ondansetron: Prevention of chemotherapy-induced nausea and vomiting in pediatric patients in a multicycle study. *First Author: Edita Kabickova, Department of Paediatric Haematology and Oncology, Charles University 2nd Medical School, Prague, Czech Republic*

Background: Palonosetron (PALO) has been shown to be non-inferior to ondansetron (OND) at preventing chemotherapy-induced nausea and vomiting (CINV) in adult patients (pts) receiving moderately/highly emetogenic chemotherapy (MEC/HEC). **Methods:** This phase III study evaluated the efficacy/safety of two PALO doses (10, 20 μg/kg) vs OND (3 $\times$ 150 μg/kg) in pediatric pts receiving up to 4 MEC/HEC cycles. For the primary objective statistical analysis was used to show non-inferiority for PALO (δ = -15%) vs OND from complete response rates (CR, no emesis/rescue medication) in the acute phase (0–24h after first MEC/HEC dose) of cycle 1. Secondary objectives included CR rate in the delayed (>24–120h) and overall (0–120h) phases and safety. **Results:** In 493 pts aged 64 days–16.9 years the CR rate was highest in the PALO 20 μg/kg group in all phases of cycles 1, 3 and 4 with statistical non-inferiority shown for this dose vs OND in the acute phase of cycle 1 (see table). In cycles 1–4 treatment-emergent adverse events (TEAEs) were fewer in the PALO 20 μg/kg group (69.3%, 64.4%, 55.9%, 48.4%) vs the PALO 10 μg/kg (80.2%, 76.2%, 72.1%, 75.0%) and OND (81.7%, 82.6%, 68.2%, 72.2%) groups. Drug-related TEAEs (cycles 1–2 only) were comparable although highest in the OND group (4.7%). TEAEs in cycles 3–4 plus all study withdrawals and fatal TEAEs were not considered drug-related. Laboratory and ECG evaluations, inclusive of the QT interval raised no concerns. **Conclusions:** In pediatric pts receiving up to 4 MEC/HEC cycles palonosetron 20 μg/kg was non-inferior to OND in the acute phase of cycle 1, numerically superior to OND across all cycles and presented no significant safety risks. Clinical trial information: NCT01442376.

10078 Poster Session (Board #148), Sun, 8:00 AM-11:30 AM

Risk assessment in children presenting with fever and chemotherapy-induced neutropenia. *First Author: Kristen Schratz, Department of Pediatrics, Columbia University Medical Center, New York, NY*

Background: Febrile neutropenia (FN) is a common complication of cancer treatment and predisposes children to develop severe infections. The purpose of this study was to identify clinical and laboratory factors predictive of a serious infectious complication in pediatric cancer patients with FN. **Methods:** A retrospective cohort study was performed in 188 children admitted for management of 381 episodes of febrile neutropenia. The primary outcome was development of a severe infectious complication (SIC), which included an infection diagnosed by clinical exam, a proven bacterial infection of the blood, urine or other sterile site or a radiologically diagnosed infection. Twenty-five variables assessable at the time of presentation to the oncology clinic or emergency department were analyzed for significance, and included patient-specific, treatment-related and episode-specific variables, as well as complete blood count results. **Results:** The cohort's mean age was 8.4 years. The underlying diagnosis was a solid tumor in 57.1%, and a hematologic malignancy in 42.9% of patients. The rate of SIC was 30.6% with the most prevalent complication being bacteremia in 49% of those. Of the episodes of bacteremia gram-negative bacilli were isolated in 58.6%. Factors identified in univariate analysis to be significant predictors were maximum temperature, leukocyte count, hemoglobin level, platelet count, baseline disease activity and hypotension. Multivariate regression analysis identified relapsed or advanced disease status, presence of hypotension and degree of leukopenia as significant predictors for a SIC. **Conclusions:** This study identifies several predictors of SIC in pediatric patients with FN, which will enable the development of a prediction model to distinguish patients at low risk of developing SIC. Risk stratification will allow for the design of a prospective safe outpatient management for the low-risk group.

TPS10079 Poster Session (Board #149a), Sun, 8:00 AM-11:30 AM

A multicentric study of interval compressed multiagent chemotherapy and metronomic chemotherapy for patients with Ewing sarcoma family of tumors: The Latin American Pediatric Oncology Group trial. *First Author: Lauro José Gregianin, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Large cooperative group studies have shown the efficacy of risk-adapted treatment for Ewing sarcoma (ES). However, validation and local adaptation by national cooperative groups is needed. A multicenter protocol to determine the efficacy and safety of adapted regimen was developed by the Latin American cooperative group (GALOP). The primary endpoint is investigate the feasibility and progression free survival (PFS) of combined modality therapy that incorporates interval-compressed VDC/IE as shown by the AEWS0031 study, and metronomic chemotherapy (CT). Secondary endpoints include safety, overall survival and duration of response. **Methods:** Induction (Indct) CT consisted of alternating cycles of VDC (vincristine 1.5 mg/m2 d1, doxorubicin 37.5 mg/m2 d1 and d2, cyclophosphamide 1.2 g/m2 d1) and IE (ifosfamide 3 g/m2 d1, d2 and d3, and etoposide 165 mg/m2 d1, d2 and d3), followed by local control. Pts with localized disease received 6 cycles at Indct and 8 at consolidation (Cons), and pts with metastasis received 9 at Indct and 5 at Cons. The time interval between cycles at Indct and Cons are 14 and 21 days, respectively. After Cons, pts with metastasis received metronomic CT, which consisted in oral cyclophosphamide (25 mg/m2/day, continuously) and vimblastin (3 mg/m2, weekly), for 1 year, while pts with localized disease are randomized (1:1) to receive or not metronomic CT according to the following risk factor: , age above versus (vs) below 14-years-old, pelvic vs non-pelvic primary tumor, tumor size more vs less than 8 cm, and male vs female. Toxicity is assessed following cycles of CT according to the CTC criteria. Enrollment began in April 2010, and, as of January 2011, 234 pts (107 with metastasis) have been recruited across 37 centers from Argentina, Brazil, Chile, and Uruguay. Statistical design: Target enrollment is 500 subjects; 200 pts with metastasis, and 300 pts with localized disease, of which 150 is randomized to the metronomic CT arm and 150 receive no further CT, in order to identify a difference in 5-years PFS of 15% (power 0.80, 2-tail type 1 error of 0.05).

TPS10080 Poster Session (Board #149b), Sun, 8:00 AM-11:30 AM

Long-term infusion of anti-GD2 antibody ch14.18/CHO in combination with interleukin-2 (IL2) activity and efficacy in high-risk relapsed/refractory neuroblastoma patients. *First Author: Holger N. Lode, University Med Ctr of the Ernst-Moritz-Amdt Universitat Greifswald, Greifswald, Germany*

Background: Long-term infusion (LTI) of anti-GD_2 antibody ch14.18/CHO may improve outcome in patients (pts) with high risk relapsed/refractory neuroblastoma (NB). **Methods:** 97 pts received 6x10^6 IU/m^2 sc IL2 (d1-5; 8-12), LTI of 100 mg/m^2 ch14.18/CHO (d8-17) and 160 mg/m^2 oral 13-cis-RA (d19-32) in an ongoing SIOPEN Phase II study (APN311-202) (NCT01701479) (44 pts) and a closed single center program (53 pts) (APN311-303). Response assessments followed INRG criteria. Fcγ-receptor polymorphisms FCGR2A (H131R), -3A (V158F) and -3B (NA1/NA2) were determined. **Results:** A decreasing degree of morphine usage and low pain scores were observed. Clinical overall responses were 30% (APN311-303) and 31% (APN311-202). The survival update of the APN311-303 cohort revealed a 1-y & 4-y OS of 94.2±3.2% & 60.9±9.0% (median FU 2.9y [0.7-5.2y]) and a 1-y & 4-y PFS of 54.4±6.9% & 32.3% ±6.9% (median FU 2.8y [0.7 - 4.9y]). Median TTP was 571d (95% CI: 232.7d). The comparator is the reported historical gold standard with 1-y & 4-y PFS of 19±2% & 8±3% and OS of 56±3% & 14±4% and a median TTP of 63 d (95% CI: 56.8d). NB pts with high affinity FCGR alleles and an increase in ADCC (cut off 15%) are associated with longer PFS and OS rates ($p < 0.03$; $p < 0.005$), which supports NK-cell mediated ADCC as the mechanism of action. Parameters of immune modulation (CDC, and WBT) and pharmacokinetics (PK) of ch14.18/CHO were comparable between APN311-202 and -303 cohorts. PK of ch14.18/CHO was analyzed in cycle 1: C_{max}= 12.2±0.4μg/ml, $t_{½}$= 8.4±1.1 d, AUC = 145.3± 5.8 μg*d/ml, Vd = 9.3±0.5L/m^2. A pro-inflammatory cytokine response (IL-2, IL-6, IL-8, IFNγ) translated into the expansion of effector NK- (3x) and T-cells (2x). We observed HACA in 17/97 pts (17.5%) of which only 9/97 (9.3%) were neutralizing with respect to the inhibition of CDC and WBT activity. In HACA negative patients, levels of ch14.18/CHO and functional parameters (CDC, WBT) analyzed before subsequent treatment cycles indicate persistent anti-NB activity for the entire treatment period. **Conclusion:** LTI of ch14.18/CHO is active and effective in high-risk relapsed/refractory NB. Clinical trial information: NCT01701479.

TPS10081 Poster Session (Board #150a), Sun, 8:00 AM-11:30 AM

A phase II study of pazopanib in children, adolescents, and young adults with refractory solid tumors. *First Author: Alice Lee, Columbia University, New York, NY*

Background: Pazopanib (VOTRIENT; GlaxoSmithKline) is an angiogenesis inhibitor targeting VEGFR-1, -2, and -3; PDGFR-α and -β; and c-Kit, and is indicated for the treatment of adults with advanced RCC and advanced soft tissue sarcoma. Data from adults with sarcoma support the study of soft tissue and bone sarcomas, as well as embryonal tumors, in pediatric subjects. The current Phase II study undertaken by the Children's Oncology Group (COG-ADVL1322/ VEG116731) was preceded by a Phase I trial of pazopanib tablets and powder for oral suspension (PfOS) in children (N = 51). The maximum tolerated dose (MTD) for tablets was 450 mg/m^2/dose and 160 mg/m^2/dose for the PfOS, with two dose-limiting toxicities (DLTs) seen at 225 mg/m^2 of the PfOS. Hematologic and non-hematologic toxicities were generally mild. One subject each with hepatoblastoma or desmoplastic small round cell tumor had a partial response; 8 had stable disease ($\geq$ 6 cycles); 7 of these had sarcoma (Glade Bender; J. Clin. Oncol. 2013; 31:3034). Given these findings, this Phase II trial will further evaluate efficacy, safety, pharmacokinetics, and pharmacodynamics in children. **Methods:** This is a multi-center study of pazopanib in US and Canadian subjects age 1 to 18 years with solid tumors relapsed or refractory to prior therapy. Tumor types include rhabdomyosarcoma, non-rhabdomyosarcomatous soft tissue sarcoma, Ewing sarcoma, osteosarcoma, neuroblastoma, and hepatoblastoma. Subjects will be stratified by tumor type, and the response rate to pazopanib will be assessed for each of the six disease strata using a two-stage design. Pazopanib will be administered orally once daily as a tablet at 450 mg/m^2 or as PfOS at 225 mg/m^2. The phase I PfOS MTD of 160 mg/m^2 may result in suboptimal exposure. Given that the toxicity at 225mg/m^2 was isolated and reversible, the first 6 patients receiving PfOS will be dosed at 225 mg/m^2 and assessed for first-cycle DLTs and PK. The study will also evaluate pazopanib pharmacokinetics and toxicity in this pediatric population and will assess the relationship between efficacy and levels of cytokines and angiogenic factors, and VEGF and KDR polymorphisms. Four of 77 subjects have been enrolled. (NCT01956669) Study funded by GSK. Clinical trial information: NCT01956669.

TPS10082 Poster Session (Board #150b), Sun, 8:00 AM-11:30 AM

A randomised phase IIb trial of BEvACizumab added to Temozolomide ± IrinOtecan for children with refractory/relapsed Neuroblastoma - BEACON-Neuroblastoma, a European Innovative Therapies for Children with Cancer (ITCC) - International Society of Paediatric Oncology Europe Neuroblastoma Group (SIOPEN) trial. *First Author: Lucas Moreno, CNIO, Spanish National Cancer Research Centre, Madrid, Spain*

Background: Current therapy for relapsed/refractory high-risk neuroblastoma is not evidence based and long-term disease control is poor. Advances in frontline therapy have been achieved through randomised clinical trials. BEACON-Neuroblastoma trial is designed to identify a backbone chemotherapy regimen to be combined with targeted agents and determine if inhibiting angiogenesis with bevacizumab(B) adds to the activity of chemotherapy. It is the first randomized European study for refractory/relapsed neuroblastoma **Methods:** BEACON-Neuroblastoma is a factorial phase 2, multicentre, international, randomized clinical trial (EudraCT 2012-000072-42, sponsored by the University of Birmingham). Patients 1-21 years with relapsed/refractory high-risk neuroblastoma are randomised to 1 of 4 arms: T (temozolomide), IT (irinotecan-temozolomide), BT (B-T) or BIT (B-IT). The trial tests whether B added to chemotherapy (T or IT) demonstrates activity and whether the addition of I to T increases activity. Primary endpoint is best response at any time during trial treatment. During 2015, whether the addition of topotecan to T increases activity will be addressed by changing to 3 x 2 design with 6 arms and requiring 160 patients. The trial incorporates functional imaging (FI) to elucidate the role of anti-angiogenic therapy in neuroblastoma; a biomarker study measuring neuroblastoma mRNAs and molecular characterisation. This work is supported by Cancer Research UK [grant number CRUK/11/056] and Imagine for Margo. 21 sites in 7 countries are open (11 further sites are to open). From Jul-2013 to Jan-2015, 30 patients have been included. BEACON-Neuroblastoma is the recommended approach for relapsed/refractory neuroblastoma in SIOPEN/ITCC. The trial will answer 2 randomised questions in a small population and has developed a European network of centres performing biomarker and FI studies. It will be the foundation of a European multi-arm multi-stage trial to evaluate new drugs in the future Clinical trial information: NCT02308527.

TPS10083 Poster Session (Board #151a), Sun, 8:00 AM-11:30 AM

Early detection of transformation of plexiform neurofibromas to malignant peripheral nerve sheath tumors in neurofibromatosis type 1. *First Author: Sucharita Bhaumik, Children's Natl Med Ctr, Washington, DC*

Background: Neurofibromatosis 1 (NF1), an autosomal dominant genetic disorder, is characterized by development of benign plexiform neurofibromas (PN) and malignant peripheral nerve sheath tumors (MPNST) that often develops from malignant transformation in a preexisting PN. Complete surgical resection is only curative treatment, making early detection of malignant transformation an important goal. A preliminary study by Meany et al [Pediatr Blood Cancer. 2013, 60(1): 59-64] using ^{18}Fluoro-deoxy-glucose positron emission tomography (FDG-PET) to identify concerning lesions, described high FDG uptake in both malignant and benign PN.^{18}F-3′-fluoro-3′-deoxy-L-thymidine (FLT) PET measures cell cycling and proliferation. We hypothesize that FLT-PET may be more sensitive and specific in the identification of malignancy. This pilot study in NF1 patients with lesions concerning for MPNST will evaluate 1) feasibility of FLT-PET 2) ability of FLT-PET to distinguish benign from malignant and 3) perform comprehensive genomic analyses from tumor and blood samples. **Methods:** Trial design: Fifteen patients with NF1 and lesions concerning for malignant transformation are eligible. Patients undergo clinical evaluation of NF1 manifestations, whole body MRI with volumetric analysis of tumor burden, FDG and FLT-PET, guided biopsies of the concerning lesion and of adjacent presumably benign PN for detailed pathologic analysis. Germline blood samples, tissue samples from concerning lesion and surrounding presumably benign PN (Trios) will undergo genomic analysis. The reader of the PET studies will be blinded to the pathologic diagnosis. Exploratory statistical methods will be used to evaluate the differences in uptake between the two groups (FDG and FLT), followed by logistic regression to identify uptake values most associated with benign versus malignant classification. Clinical, imaging, histopathologic, and genomic features will be correlated in an exploratory fashion, to describe features associated with malignant transformation. This single institution trial (NCT02211768) is open for enrollment at the NCI, and has enrolled the first patient. Clinical trial information: NCT02211768.

10500 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

GeDDiS: A prospective randomised controlled phase III trial of gemcitabine and docetaxel compared with doxorubicin as first-line treatment in previously untreated advanced unresectable or metastatic soft tissue sarcomas (EudraCT 2009-014907-29). *First Author: Beatrice M. Seddon, University College Hospital, New Malden, United Kingdom*

Background: Standard first-line treatment of locally advanced/metastatic soft tissue sarcoma (STS) is Dox. GemDoc has activity in STS and is used in relapsed STS after failure of at least one line of chemotherapy. Our aim was to compare GemDoc with Dox as first-line treatment of locally advanced/metastatic STS. **Methods:** Patients (pts) from 24 UK sites and 1 Swiss site were randomised to receive 6 cycles of Dox 75 mg/m^2 intravenously (IV) day 1 every 3 weeks, or Gem 675 mg/m^2 IV days 1 and 8 and Doc 75 mg/m^2 IV day 8 every 3 weeks (wks). Pts had locally advanced/metastatic STS, Trojani grade 2 or 3, disease progression prior to enrolment, no prior chemotherapy for sarcoma, no prior Dox, WHO performance status 0-2, age $\geq$ 13 years. Pts were stratified by age ($\leq$ 18 or $>$ 18 years) and histological subtype (uterine leiomyosarcoma [uLMS], synovial, pleomorphic, and other). Primary endpoint was progression free survival (PFS) rate (PFR) at 24 wks. Results: From Dec 2010 - Jan 2014, 257 pts were randomised (n = 129 Dox; n = 128 GemDoc). Median follow up was 19 months. 61% of pts were female; median age was 55 years. Baseline characteristics were balanced. Histology was 27% uLMS, 4% synovial, 12% pleomorphic, 56% other. PFR at 24 wks was 46.1% v 46.0%, median PFS was 23 v 24wks, for Dox v GemDoc, but the hazard ratio (HR) was 1.28 (95% CI 0.98-1.67, P = 0.07) in favour of Dox. Median OS was 71 v 63 wks (HR = 1.07; 95% CI 0.77-1.49) for Dox v GemDoc. Although the PFS Kaplan-Meier curves did not violate the proportional hazards assumption (p = 0.53), they initially overlapped, and then separated after 24 wks in favour of Dox. Best response (CR/PR/SD) was 65.9% (Dox) v 58.6% (GemDoc). Mean dose intensity was 94.6% (Dox) v 83.3% (GemDoc). 46% (Dox) v 61% (GemDoc) of pts had at least one dose delay; 1 pt (2%) on Dox v 13 pts (16%) on GemDoc stopped treatment early due to toxicity. Conclusions: Although the PFR at 24 wks was the same for Dox and GemDoc, the HR indicated superiority of Dox. Dox was less toxic and easier to deliver than GemDoc, and should remain standard first-line treatment for locally advanced/metastatic STS. Clinical trial information: ISRCTN07742377.

10501 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized phase Ib/II study evaluating the safety and efficacy of olaratumab (IMC-3G3), a human anti-platelet-derived growth factor α (PDGFRα) monoclonal antibody, with or without doxorubicin (Dox), in advanced soft tissue sarcoma (STS). *First Author: William D. Tap, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Options for patients (pts) with unresectable/metastatic STS are limited. While Dox is standard of care, Dox combinations have yet to improve overall survival (OS) over Dox alone. Olaratumab (IMC-3G3), a fully human monoclonal antibody, selectively binds PDGFRα (a signaling pathway implicated in STS), blocks ligand binding, and enhances Dox activity in preclinical sarcoma models. **Methods:** We conducted a phase Ib, open-label, randomized phase II study of Dox $\pm$ olaratumab in unresectable/metastatic STS (NCT01185964). Pts received Dox (75 mg/m^2 Day 1) with (Arm A) or without (Arm B) olaratumab (15 mg/kg Days 1 and 8, every 21 days), a dose and schedule confirmed safe in phase Ib, for up to 8 cycles. In Arm A, olaratumab monotherapy continued after Dox until disease progression; in Arm B, pts could cross over to olaratumab at progression. The primary endpoint was progression-free survival (PFS; target hazard ratio [HR] = 0.67, 80% power, α = 0.2) with OS as a secondary endpoint. **Results:** Of 133 pts randomized, 129 (97%) were treated (64, Arm A; 65, Arm B). Demographics were balanced. Final PFS analysis (103 events) revealed medians of 6.6 months (Arm A) and 4.1 months (Arm B) (stratified HR; 95% confidence interval [CI]: 0.672 [0.442-1.021]; p = 0.0615). Interim OS analysis (83 deaths) revealed medians of 25.0 months (Arm A) and 14.7 months (Arm B) (HR = 0.44; p = 0.0005). Objective response rates were 18.8% (Arm A) and 12.3% (Arm B) (p=0.3407). The following Grade $\geq$ 3 adverse events (AEs) occurred in $\geq$ 5% of the population: Arm A $>$ Arm B, neutropenia (51.5% vs 33.8%), anemia (12.5% vs 7.7%), fatigue (9.4% vs 3.1%), thrombocytopenia (9.4% vs 7.7%); Arm A $<$ Arm B, febrile neutropenia (12.5% vs 13.8%), infections (6.3% vs 10.8%). **Conclusions:** This study of olaratumab in combination with Dox met its primary PFS endpoint and achieved an improvement of 10.3 months in median OS that was highly statistically significant (HR = 0.44; p = 0.0005). Olaratumab is the first agent added to Dox to improve OS in advanced/metastatic STS in a randomized trial. Clinical trial information: NCT01185964.

LBA10502 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Randomized, open-label, multicenter, phase III study of eribulin versus dacarbazine in patients (pts) with leiomyosarcoma (LMS) and adipocytic sarcoma (ADI). *First Author: Patrick Schöffski, University Hospital Leuven, Leuven, Belgium*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 30, 2015, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2015, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

10503 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized phase III study of trabectedin (T) or dacarbazine (D) for the treatment of patients (pts) with advanced liposarcoma (LPS) or leiomyosarcoma (LMS). *First Author: George D. Demetri, Dana-Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: This phase III multicenter trial compared T with D in pts with advanced LPS or LMS previously treated with an anthracycline and at least one additional systemic therapy. **Methods:** Pts were randomized to T or D in a 2:1 ratio. Dosing of T and D were q 3 wks IV infusion: T (1.5 mg/m^2 over 24 hr) vs D (1 g/m^2 over 20-120 min). The primary end point was overall survival (OS), and secondary end points were progression-free survival (PFS), time to progression (TTP), objective response rate (ORR), duration of response (DOR), symptom severity and safety. Cross-over to T after disease progression (PD) on D was not allowed until revision after this planned interim analysis (IA) of OS (50% events). The study is ongoing for final OS. Final results of secondary endpoints are presented. **Results:** The IA included 518 pts (T = 345, D = 173), 73% with LMS and 27% with LPS. Treatment with T resulted in a 45% reduction in the risk of PD or death compared with D (hazard ratio [HR] = 0.550; P $<$ 0.0001; Median [M] 4.2 vs 1.5 months [mo], respectively), with benefit observed across all subgroups, and validated by independent radiologists audit. Other end points demonstrated improved efficacy of T: TTP (HR = 0.522, p $<$ 0.0001; M = 4.2 vs 1.5 mo), clinical benefit rate (CR+PR+SD $\geq$ 18wks) (34.2% vs 18.5%; Odds Ratio[OR] = 2.291; p = 0.0002), ORR (9.9% vs 6.9%; OR = 1.467; p = 0.3269), DOR (HR=0.471, p = 0.1415; M = 6.5 vs 4.2 mo). The IA of OS (64% censored) demonstrated a 13% reduction in risk of death in T arm compared with D (HR = 0.872, p = 0.3741; M = 12.4 vs 12.9 mo). 34% of T and 17% of D pts received $\geq$ 6 cycles. The safety profiles were consistent with the well-characterized toxicities of both agents, with the most common grade 3-4 toxicities in T vs. D arm being ANC (40% vs 25%), platelets (19% vs 20%), increased ALT (29% vs 1%), and drug-related death (2.1% vs 0%). Patient-reported outcomes were similar across the arms, with low symptom scores during treatment. **Conclusions:** This phase III trial demonstrates improved disease control with T vs. D in advanced LPS and LMS, and confirms the acceptable benefit-risk profile of T from the prior randomized Phase 2 study (STS-201). T is a meaningful treatment option for pts with advanced LPS and LMS. Clinical trial information: NCT01343277.

10504 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Activity of regorafenib (RE) in leiomyosarcomas (LMS) and other types of soft-tissue sarcomas (OTS): Results of a double-blind, randomized placebo (PL) controlled phase II trial. *First Author: Olivier Mir, Institut Gustave Roussy, Villejuif, France*

Background: RE is a multikinase inhibitor that has demonstrated activity in gastrointestinal stromal tumors. We investigated its activity and safety in anthracycline pretreated metastatic soft tissue sarcomas (STS). **Methods:** REGOSARC (NCT01900743) consisted of four independent cohorts of patients (pts) with LMS, OTS, synovial, and adipocytic sarcomas who were randomized (1:1) to receive either RE (160 mg/d, 21/28 d) or PL, with optional cross-over. Key-eligibility criteria were age $\geq$ 18, measurable progressing STS not amenable to curative-intent surgery, $\leq$ 3 previous lines of treatment for metastatic STS. The primary endpoint was progression-free survival (PFS) with blinded central radiological review. Statistical assumptions for LMS and OTS cohorts were PFS = 1.6 months (mo) with PL, PFS = 4.6 mo with RE, 1-sided $\alpha = 0.1$ and $\beta = 0.05$. **Results:** From July 2013 to July 2014, 57 LMS and 53 OTS pts were enrolled (55 with PL, 55 with RE). The two most common OTS types were Undifferentiated Pleomorphic Sarcomas (n = 21, 40%) and Solitary Fibrous Tumors (n = 7, 13%). Eighty-four (77%) tumors were grade 3. In both cohorts, the most common primary sites were retroperitoneum and uterus (n = 23, 21%, each). There were 48 men (44%). The median age was 60 (20-81) years. The median number of prior lines was 2 (1-3): 106 (97%), 59 (54%), 39 (35%) and 4 (4%) pts were previously treated with doxorubicin, ifosfamide, trabectedin and pazopanib, respectively. Both arms in each cohort were well balanced. The most common Gr 3 AEs were hypertension (10 vs 2 pts; RE vs PL), skin toxicity (9 vs 1), asthenia (9 vs 3) and diarrhea (6 vs 2). There was no Gr5 AE and 1 Gr4 AE (anemia in RE arm). The median PFS of LMS pts was 4.0 mo with RE versus 1.9 mo with PL (HR = 0.49; 95CI 0.27-0.89; p = 0.017). The median PFS of OTS pts were 4.6 and 1.0 mo, with RE and PL respectively (HR = 0.38, 95CI 0.20-0.74; p = 0.002). The 6-mo OS rate of LMS pts was higher in the RE arm (87.0% vs 75.9%; HR = 0.25; 95CI 0.08-0.81; p = 0.013), this difference was not significant in the OTS cohort (79.0 vs 62.0%; HR = 0.64, 95CI 0.23-1.74; p = 0.4). **Conclusions:** RE demonstrates promising activity and an acceptable toxicity profile that warrant further clinical evaluation in LMS and OTS pts. Clinical trial information: 2012-005743.

10505 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Three vs. 1 year of adjuvant imatinib (IM) for operable high-risk GIST: The second planned analysis of the randomized SSGXVIII/AIO trial. *First Author: Heikki Joensuu, Comprehensive Cancer Center, Helsinki University Hospital, and University of Helsinki, Helsinki, Finland*

Background: Three years of adjuvant IM is recommended after surgery for patients (pts) with high-risk GIST with an IM-sensitive mutation. This recommendation is based on the findings from the SSGXVIII/AIO trial that compared 1 year (Arm A) to 3 years (Arm B) duration of administration of adjuvant IM. After a median follow-up of 4.5 yrs, 3 yrs of IM resulted in superior recurrence-free survival (RFS) and overall survival (OS), but the OS benefit was based only on 37 events. **Methods:** Pts with high-risk GIST according to the modified NIH risk stratification who had GIST resected macroscopically completely were eligible. The pts were randomly assigned 1:1 to Arm A or B, and were scheduled to receive IM 400 mg/day either for 12 or 36 months after surgery. Tumor histology was reviewed centrally after randomization. The study protocol was amended in October 2006 to exclude pts who had completely resected metastatic disease from the study. We now present the second planned analysis of the trial based on a median follow-up time of 7.5 years. **Results:** 400 patients were entered to this multicenter, open study between February 4, 2004, and September 29, 2008. The 397 pts who provided informed consent formed the Intention-To-Treat (ITT) population (A, 199; B, 198 pts). Pts who did not have GIST at central pathology review (n = 15) and those with metastatic GIST at study entry (n = 24) were excluded to form the Efficacy Population (i.e. "the true adjuvant GIST population"; A, 181; B, 177). In this second analysis, 171 recurrences and 68 deaths were detected (ITT). Pts assigned to 3 yrs of IM had longer RFS (HR 0.60, 95% CI 0.44 - 0.81; P $<$ 0.001) and longer OS (HR 0.61, 95% CI 0.38 - 1.00; P = 0.046) than those assigned to 1 yr of IM in the ITT population, and also in the Efficacy Population (HR 0.62; 95% CI 0.45-0.85; P=0.003; and HR 0.54, 95% CI 0.31-0.96; P = 0.032, respectively). 5-year OS was 86.8% and 93.4% in the 1-year and 3-year groups, respectively, despite the high-risk features of GISTs (Efficacy Population). The frequency of cardiac events (A, 10; B, 6) and the numbers of second cancers (A, 18; B, 23) were similar in the groups. **Conclusions:** Three years of adjuvant IM resulted in superior RFS and OS as compared to 1 year of IM. Clinical trial information: NCT00116935.

10506 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Final results of the multicenter randomized phase II PAZOGIST trial evaluating the efficacy of pazopanib (P) plus best supportive care (BSC) *vs* BSC alone in resistant unresectable metastatic and/or locally advanced gastrointestinal stromal tumors (GIST). *First Author: Jean-Yves Blay, Centre Léon Bérard, Department of Medicine, Lyon, France*

Background: GIST is the most common mesenchymal neoplasm of the gastrointestinal tract. Imatinib followed by sunitinib then regorafenib is the usual sequence in advanced setting. P is effective in soft tissue sarcomas; it has never been evaluated in a randomized setting in GIST. **Methods:** Eligible patients (pts) were randomized (1:1; stratification on number of prior drugs (2 *vs* $\geq$3)) to receive P+BSC or BSC. Primary endpoint was Progression-Free Survival (PFS). 80 pts were planned to detect an improvement in the 4-month PFS rate (PFS-4m) from 15% (BSC) to 45% (P+BSC) with 5% two-sided α and 80% power. Secondary objectives included Best Overall Response (BOR), Overall Survival (OS), safety and trough plasma P concentrations (Ct). **Results:** From Apr 11 to Dec 13, 81 pts (P+BSC: 40, BSC: 41) were randomized. Arms were well balanced; median age: 63y (27-85), 70% males and 54% with $\geq$ 3 prior drugs. The intent-to-treat analysis based on investigator-assessed progressive disease (PD) showed an improved PFS with PFS-4m of 45.2% (95% CI 29.1-60.0) for P+BSC *vs* 17.6% (95% CI 7.8-30.8) for BSC (HR: 0.59, 95% CI 0.37-0.96; p = 0.03). 36 pts out of 41 switched to P following investigator-assessed PD (median P duration: 3.5 months (0.1-19), main reasons for discontinuation: PD (52.8%) and toxicity (22.3%)). Centrally-assessed BOR showed stable disease in 84.2% *vs* 70.7% and PD in 15.8% *vs* 26.8% of pts in P+BSC and BSC arms. Among all pts treated with P (n = 76), 72.4% experienced grade $\geq$ 3 related adverse events (AE) (hypertension: 36.8%), including 25% of related serious AE (pulmonary embolism, 9.2%). At the time of analysis, 29 *vs* 31 pts had died in the P+BSC and BSC arms (OS HR: 0.94, 0.56-1.56). 1 toxic death occurred (hepatic cytolysis). Preliminary results showed a higher median Ct at steady state in pts progression-free at 4 months *vs* progressive: 25 (2-63) vs 17 (8-35) μg/ml (n = 43; p = 0.08). **Conclusions:** P combined to BSC improves PFS in advanced GIST resistant to imatinib and sunitinib. In the context of a high switch rate, no difference in OS was found. Further PK analyses are ongoing. Clinical trial information: NCT01323400.

10507 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

A phase Ib/II study of MEK162 (binimetinib [BINI]) in combination with imatinib in patients with advanced gastrointestinal stromal tumor (GIST). *First Author: Ping Chi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ETV1, a lineage-specific survival factor for GIST and its precursor interstitial cells of Cajal, represents a promising therapeutic target in GIST. In preclinical models, MEK inhibition with BINI, synergizes with imatinib in destabilizing ETV1 protein and suppressing GIST tumorigenesis and progression. Combined MEK and KIT inhibition therefore represents a novel therapeutic approach for patients with GIST. **Methods:** The phase Ib portion of the imatinib (400 mg daily) plus BINI was performed in patients (pts) with imatinib-resistant advanced GIST. A standard 3+3 dosing schema was utilized to determine the recommended phase II dose (RP2D) of this combination. Additional pts were enrolled on an expansion cohort at the RP2D. Responses were assessed by RECIST1.1 and Choi criteria every 8 weeks. Custom targeted next-generation sequencing with the Integrated Mutation Profiling of Actionable Cancer Targets (IMPACT) was performed on archived tumor samples for all pts. **Results:** Eighteen pts enrolled to the phase I portion, with 9 pts each in the dose escalation and the expansion cohorts. Median age 60 (range 30-74), 44% women, median prior therapy 3 (range 1-6, 14/18 pts had $\geq$ 3 prior therapies). Imatinib 400 mg daily with BINI 45mg BID was established as the RP2D. Dose limiting toxicity (DLT) was asymptomatic grade 4 Creatinine Phosphokinase (CPK) elevation (1/6 pts at RP2D). The most common non-DLT grade 3/4 toxicity was asymptomatic CPK elevation (12/18 pts). Other common Grade 2 toxicities include peripheral edema (5/18), rash (3/18). No unexpected toxicities observed. Of the 15 pts with evaluable CT scans, 5 pts (33%) had Choi PR; and 9 pts had RECIST SD at 8 weeks. Seven pts remain on trial at data cutoff (range 4-53 weeks). Median progression free survival is not reached. Correlation of outcome with IMPACT is forthcoming. **Conclusions:** BINI and imatinib combination is well-tolerated and has clinical activity in imatinib-refractory GIST. Phase II study is on-going in untreated GIST pts and a larger clinical trial in the imatinib-resistant GIST population is warranted. Clinical trial information: NCT01991379.

The somatic mutational landscape in soft tissue sarcoma: Early results from TCGA data. *First Author: Andrew Scott Brohl, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The widespread use of next-generation sequencing has uncovered the genomic landscape in many tumor types. Given the disease rarity and histologic diversity, much less is known about the somatic mutational landscape in soft tissue sarcoma. **Methods:** Publicly available whole exome sequencing data from the Cancer Genome Atlas (TCGA) sarcoma project was downloaded and processed using well-established bioinformatics pipelines. Recurrent mutations were analyzed for statistical significance and potential oncologic relevance. Pan-sarcoma and histology-specific mutational frequencies were calculated. **Results:** Matched tumor-normal whole exome sequencing was available for 242 patients at the time of analysis. The disease histologies include 92 leiomyosarcoma, 51 dedifferentiated liposarcoma, 44 undifferentiated pleomorphic sarcoma, 24 myxofibrosarcoma, 9 malignant peripheral nerve sheath tumor, 8 synovial sarcoma, 1 desmoid tumor, and 13 lacking clinical annotation at the time of analysis. There were a median 475 high-confidence somatic variants detected [range 127-7153]. Statistically significant recurrent mutations include recurrent inactivating mutations in 3 well-established tumor suppressors, *TP53, ATRX,* and *RB1*, found in 27.3%, 8.7% and 6.2% of the total cohort respectively. Differential mutational frequency of these genes was noted between histological subtypes. Additional statistically significant recurrent mutations in genes of less clear oncologic significance are noted, as are additional recurrent mutations in other known cancer genes, but found in frequencies not meeting statistical significance. **Conclusions:** To our knowledge this is the first attempt to analyze the somatic mutational landscape in soft tissue sarcoma from TCGA whole exome sequencing data. We report statistically significant recurrent mutation in three tumor suppressor genes with clear oncogenic implication. Additional recurrent mutations of interest due to either mutational frequency or mutational impact in other cancer types are noted. A comprehensive analysis of genomic data is underway by the TCGA sarcoma analysis group.

10509 **Poster Discussion Session; Displayed in Poster Session (Board #153), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM**

Next generation sequencing of synovial sarcomas. *First Author: Myrella Vlenterie, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Over 95% of synovial sarcoma (SS) share the t(X;18) translocation. Despite this similarity, they show heterogeneous tumor behavior and differ in therapy response. Treatment options are limited and depending on age, 50-90% of patients with localized disease survive 5 year. Therefore we tried to identify targetable mutations in SS. **Methods:** Mutation sequence analysis including copy number variation was performed on 26 tumors from 22 patients (age 11-78 years), using the comprehensive cancer panel (LifeTechnologies) on the Ion Torrent. We sequenced paired samples from 4 patients: 3 primary tumors with corresponding metastasis and 2 metastases of 1 patient responding divergently to pazopanib. In total, we analyzed 17 primary tumors, 6 metastatic lesions and 3 local relapses. Nonsynonymous variations in coding regions were included. Mutations were filtered for known single nucleotide polymorphisms and earlier found variations in our own research database. The remaining variations were verified by Sanger sequencing and compared to matching normal DNA. All research was performed in agreement with the medical ethical committee. **Results:** 8 somatic mutations were found in 8 samples. These mutations have not yet been reported in SS. Two are established mutations in oncogenes previously described in carcinomas: *KRAS* in colon and lung carcinomas and *CCND1* in endometrial cancer. Other somatic mutations, with unknown oncogenic character, were found in *RNF213*, *SEPT9*, *KDR*, *CSMD3*, *MLH1* and *ERBB4*. Similar mutations were found in the paired samples. Chromosomal aberrations, e.g. partial loss of chr 3 or gain of chr 8, were detected in 50% of SS. A loss of chr 6q was seen in the pazopanib resistant lesion and not in the matching lesion responding to pazopanib. **Conclusions:** To our knowledge this is the largest reported cohort of extensively molecularly analyzed SS. We observed a variety of mutations, the *CCND1* mutation being potentially druggable. A possible correlation between 6q loss and pazopanib resistance is subject of ongoing study. The diversity in mutations found underlines the diversity in SS genotypes beyond the known fusion gene. This potentially explains the heterogeneous behavior and emphasizes the challenge in finding new druggable targets in this disease.

10510 **Poster Discussion Session; Displayed in Poster Session (Board #154), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM**

Clinical application of prognostic gene expression signature in fusion gene-negative rhabdomyosarcoma: A report from the Children's Oncology Group. *First Author: Pooja Hingorani, Phoenix Childrens Hosp, Phoenix, AZ*

Background: Pediatric rhabdomyosarcoma has two common histological subtypes: embryonal (ERMS) and alveolar (ARMS). *PAX/FOXO1* fusion gene status is a more reliable prognostic marker than alveolar histology while fusion gene-negative (FN) ARMS patients are clinically similar to ERMS patients. A five-gene expression signature (MG5) previously identified two diverse risk groups within the fusion-gene negative RMS (FN-RMS) patients but this has not been independently validated. The goal of the current study was to test whether expression of the MG5 metagene, measured using a technical platform that can be applied to routine pathology material, would correlate with outcome in an unrelated cohort of patients with FN-RMS. **Methods:** A series of cases were taken from the Children's Oncology Group (COG) D9803 study of children with intermediate-risk RMS and gene expression profiling for the MG5 genes was performed using the nCounter assay. The MG5 score was correlated with clinical and pathological characteristics as well as overall and event-free survival. **Results:** MG5 standardized score showed no significant association with any of the available clinical-pathological variables. The MG5 signature score showed a significant correlation with overall (N = 57; HR 7.3 95%CI[1.9-27.0], p = 0.003) and failure-free survival (N = 57; HR 6.1 95%CI[1.9-19.7], p = 0.002). **Conclusions:** This represents the first, validated molecular prognostic signature for children with FN-RMS who otherwise have intermediate-risk disease. The capacity to measure the expression of a small number of genes in routine pathology material and apply a simple mathematical formula to calculate the MG5 metagene score provides a clear path toward better risk stratification in a future, prospective clinical trial.

10511 **Poster Discussion Session; Displayed in Poster Session (Board #155), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM**

The who and what of imaging in sarcoma and correlation with survival. *First Author: Vadim S Koshkin, University of Michigan, Ann Arbor, MI*

Background: Response and progression are surrogates for survival that inform clinical decisions. Comparison of anatomic and functional imaging modalities in a large prospective clinical trial can suggest the optimal method of selecting patients who benefit from further therapy. **Methods:** 115 patients with metastatic, chemo-refractory Ewing's Sarcoma were treated with R1507, a human monoclonal antibody directed at IGF-1 receptor, as part of SARC011 study (J Clin Onc vol 29). Each pt had anatomic imaging with CT or MR at baseline and 6-week intervals and FDG-PET at baseline and on day 9. Anatomic imaging results were reported by each of the 31 sarcoma centers using WHO criteria. An expert central radiology group performed an independent review and volumetric analysis on 76 pts. Using log-rank analysis we defined the optimal volume cut points for progression and response at 6 wk imaging which correlated with OS, and compared this model to previously established criteria including WHO (both central and local), RECIST and PERCIST. **Results:** Volume increase of 175% for prior lesions at 6 wks was the optimal cutoff for decreased OS ($p < 0.001$) and thus progression. Optimal cutoff for response was a 45% volume decrease. OS of patients with PD at 6 wks was significantly reduced compared to non-progressors based on Volume ($R^2 = 0.17$) as well as other criteria: RECIST ($R^2 = 0.17$), WHO_Central ($R^2 = 0.16$), WHO_Local ($R^2 = 0.14$). Patients with PMD by PERCIST on day 9 had reduced OS vs. non-progressors ($p = 0.001$). Progression type impacted survival, as pts with new lesions and enlarging prior lesions had decreased OS compared to pts with either variable alone. **Conclusions:** In a large clinical trial we identified pts with decreased OS based on multiple anatomic imaging criteria at week 6 and functional imaging by PERCIST as early as day 9. A new model using volumetric analysis with cutoffs different from those extrapolated from RECIST or WHO was introduced, and its utility should be assessed in a prospective clinical trial. Clinical trial information: NCT00642941.

Event-free survival and overall survival in 2,253 patients with osteosarcoma registered to EURAMOS-1. *First Author: Sigbjorn Smeland, Oslo University Hospital, The Norwegian Radium Hospital, Scandinavian Sarcoma Group, Oslo, Norway*

Background: EURAMOS-1 (NCT00134030) is an international study in osteosarcoma including two Phase III randomized controlled trials that investigated postoperative treatment optimization on the basis of histological response to preoperative chemotherapy (CT). One study aim was to report outcomes from diagnosis for all registered patients in this large, intergroup study. **Methods:** Patients (pts) were eligible for registration if: < 30 days from diagnostic biopsy; age ≤ 40yrs; with localized or primary metastatic, high-grade extremity or axial osteosarcoma; resectable disease; fit for treatment and follow-up. Treatment was preop CT with methotrexate, doxorubicin, cisplatin (MAP), surgery and then post-op MAP-based CT according to response and optional randomization. The primary outcome measure was event-free survival (EFS), defined as time from diagnostic biopsy until the earliest of: death, local recurrence, new metastatic disease, progression of metastatic disease or secondary malignancy, or date of last contact; a secondary outcome measure was overall survival (OS). Standard statistical methods were used. **Results:** 2260 pts from 17 countries & > 300 centres were registered from 2005 to 2011; this analysis excludes 7 ineligible pts. The site was 13% proximal femur or humerus, 82% other limb site, 5% axial skeletal; 16% had definitive metastases. 92% had conventional osteosarcoma. Median age was 14yrs (quartiles 11, 17). 1334 (59%) were randomized; 919 (41%) were not, mostly for non-consent. Median follow-up was 5.2 yrs. 1000 EFS events and 634 deaths were reported. From biopsy, 5-yr EFS = 54% (95%CI 52%, 57%), and 5-yr OS = 71% (95%CI 69%, 73%). In 1881 pts with localized disease, 5-yr EFS = 59% (95%CI 57%, 62%) and 5-yr OS = 75% (95%CI 73%, 77%); in 357 pts with metastases 5-yr EFS = 29% (95%CI 24%, 34%) and 5-yr OS = 46% (95%CI 41%, 52%); metastases were unreported for 15 pts. Prognostic models will be presented. **Conclusions:** EFS and OS rates in this multinational study were comparable to centres' reported series. We used broader eligibility criteria than most osteosarcoma studies, by including patients with axial or metastatic disease. However, this extends recruitment and relevance of our findings. Clinical trial information: 67613327.

Forty years of randomized trials in advanced/metastatic soft tissue sarcoma (STS): Endpoint selection, surrogacy and quality of reporting. *First Author: Alona Zer, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: Randomized controlled trials (RCTs) in STS have utilized varying endpoints. Surrogacy of intermediate endpoints such as progression-free survival (PFS), response rate (RR), 3 month progression free survival (3moPFS) and 6 month progression free survival (6moPFS) with overall survival (OS) has not been established. The quality of reporting of efficacy and toxicity also remains uncertain. **Methods:** A systematic review of MEDLINE and EMBASE identified RCTs of systemic therapy in STS. Surrogacy between intermediate endpoints and OS was explored using meta-regression comprising a linear regression weighted by study sample size for the hazard ratio (HR) for OS with the HR for PFS or the odds ratio (OR) for RR, 3moPFS and 6moPFS. Quality of reporting of efficacy and toxicity were defined as described previously (Vera-Badillo et al, Ann Oncol 2013) and trends over time evaluated using simple linear regression. **Results:** Of 3329 articles initially identified; 52 RCTs published between 1974 and 2014 and comprising 9762 patients met the inclusion criteria. There was a moderate correlation between PFS and OS and between RR and OS (Table 1). The correlation between 3moPFS and 6moPFS with OS was however, weak. Only 44% of studies defined the primary endpoint clearly, but this deficiency improved over time (p for trend < 0.001). There has been a significant reduction in the use of RR as the primary endpoint over time, favouring time-based events (p for trend = 0.02). In 14% of RCTs, despite the primary endpoint not being met, the concluding statement suggested benefit from the experimental therapy. Toxicity was comprehensively reported in just 52% of RCTs while 17% reported toxicity poorly. Quality of toxicity reporting has not changed significantly over time (p = 0.70). **Conclusions:** In advanced STS RCTs PFS is a better surrogate for OS than RR. The correlation between 3moPFS/6moPFR and OS is weak and its use should be reconsidered. Although the quality of RCT reporting has improved over time, toxicity reporting and interpretation of results remain suboptimal.

Surrogate endpoint	Correlation coefficient with OS
HR for PFS	0.61
OR for RR	0.51
OR for 3moPFS	0.27
OR for 6moPFR	0.31

A phase Ib dose-escalation study of TRC105 (anti-endoglin antibody) in combination with pazopanib in patients with advanced soft tissue sarcoma (STS). *First Author: Steven Attia, Mayo Clinic, Jacksonville, FL*

Background: The VEGFR inhibitor pazopanib is approved for the treatment of advanced STS. Resistance to pazopanib is a challenge in the treatment of STS, and endoglin (CD105) activation may be an important resistance mechanism. Endoglin is an angiogenic receptor expressed on proliferating tumor vessels, which is upregulated following VEGF inhibition and expressed on certain STS subtypes, including angiosarcoma. A phase Ib study of TRC105, an anti-endoglin antibody, in combination with pazopanib was performed in patients (pts) with advanced STS. **Methods:** Heavily-pretreated STS pts with leiomyosarcoma (11); angiosarcoma (2); synovial sarcoma (2); epithelioid sarcoma (1); myxofibrosarcoma (1); epithelioid hemangioendothelioma (1); and unclassifiable high grade sarcoma (2), ECOG PS 0-1, were treated with infusional TRC105 weekly in two cohorts (8mg/kg and 10mg/kg). TRC105 was initiated following a 2 to 4 week lead-in period of pazopanib starting at 800 mg PO daily. **Results:** Twenty pts (median age = 57; M:F 9:11; median prior regimens = 2) were treated. Eighteen of twenty pts tolerated pazopanib alone in cycle 1 and received TRC105 beginning with cycle 2. TRC105 dose escalation proceeded from 8 mg/kg (n = 3) to 10 mg/kg (n = 15) without dose limiting toxicity. Grade 1-2 adverse events (AEs) characteristic of each drug were not increased in frequency or severity during concurrent dosing of the two drugs. The most common TRC105 AEs included grade 1-2 telangiectasia (with associated epistaxis and gingival bleeding), while the most common pazopanib AEs included grade 1-2 fatigue and diarrhea. One patient with cutaneous angiosarcoma is ongoing with a complete response, and 5 of 18 pts (28% of those evaluable for efficacy) exhibited > 10% tumor reduction by RECIST 1.1. Duration of therapy ranged from 2 to 12.3+ months. Efficacy endpoints will be correlated with endoglin expression by immunohistochemistry. **Conclusions:** TRC105 was well tolerated at its recommended phase 2 dose of 10 mg/kg weekly, in combination with daily oral pazopanib, in pts with advanced STS, and the combination exhibited evidence of activity. A multicenter phase 2 trial of TRC105 + pazopanib is ongoing. Clinical trial information: NCT01975519.

A phase II study of tivozanib in patients with metastatic and non-resectable soft tissue sarcomas. *First Author: Mark Agulnik, Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: Despite a multi-modality approach, many patients (pts) with early stage soft tissue sarcomas (STS) will develop recurrent or metastatic disease. Treatment options for these pts are limited, thus necessitating new antitumor agents. VEGFR1, VEGFR2 and VEGFR3 are high affinity receptor tyrosine kinases localized in the endothelium of tumor vasculature and are involved in tumor angiogenesis. VEGFR tyrosine kinase inhibitors (TKI) block phosphorylation of the VEGFR and inhibit activation of angiogenesis and, indirectly, tumor growth. Tivozanib is a potent and selective VEGFR 1,2 & 3 TKI with a long half-life, and thus a potential novel agent in the treatment of metastatic STS. **Methods:** A multicenter phase II study of tivozanib in pts with metastatic and non-resectable STS was conducted through the Midwest Sarcoma Trials Partnership. Adequate performance status, organ function, measurable disease (RECIST 1.1) and 1-4 prior therapies were required. Tivozanib 1.5 mg PO daily was given in 28 day cylces (21 days on, 7 days off) until disease progression (PD) or unacceptable toxicity. The primary endpoint was progression-free survival (PFS), assessed at 16 weeks. Secondary endpoints include overall response rate (ORR), clinical benefit rate (CBR), OS, laboratory correlates and safety and tolerability. A Simon 2-stage design was used. **Results:** A total of 56 pts were enrolled at 3 sites, with 53 evaluable for response. Median age was 58 (range 21-82); 57% were female; 73/27% were ECOG PS 0/1; 34/20/21/25% had 1/2/3/4 prior therapies, including 24 pts who received prior VEGF inhibitor therapy. The most common histologies included LMS (46%), pleomorphic sarcoma (14%), liposarcoma (9%) and MPNST (9%). PFS at 4 months is 34.6% with a median PFS and OS of 3.4 and 9.2 months, median follow-up 5.5 months (0.9-18.3). 2 confirmed PR, 28 SD and 22 PD were observed. ORR and CBR are 4 and 58%, respectively. Common grade 3-4 adverseevents included (%): hypertension (22), decreased EF (9) and fatigue (7). **Conclusions:** Tivozanib was well tolerated in this study of highly pretreated patients with multiple sarcoma histologic subtypes. Median PFS and PFS at 4 months are promising. Tivozanib warrants further study in sarcoma. Clinical trial information: NCT01782313.

A phase I/II clinical trial of belinostat (PXD101) in combination with doxorubicin in patients with soft tissue sarcomas (STS). *First Author: Joanna Vitfell-Rasmussen, Department of Oncology, Herlev hospital, Herlev, Denmark*

Background: Belinostat is a novel histone deacetylase (HDAC) inhibitor. This study assessed the MTD and DLTs of the combination of belinostat and doxorubicin in solid tumours (phase I) and efficacy as measured by response rate (RR) in advanced STS (phase II). **Methods:** Belinostat was administered as a 30-minute IV infusion on Day 1-4 and on Day 5 in combination with doxorubicin. It was dose escalated using a belinostat starting dose of 600 mg/m^2 combined with 50 mg/m^2 doxorubicin (cohort 1), in subsequent cohorts doxorubicin was administered at 75 mg/m^2 with 600 mg/m^2 belinostat (cohort 2), 800 mg/m^2 (cohort 3) and 1000 mg/m^2 (cohort 4). A phase II trial was then performed in STS patients (pts) using the doses in cohort 4. A stopping rule determined that the phase II trial was stopped if no more than 2 responses (CR/PR) were seen among the 20 pts within the first 2 treatment cycles. The following pharmacokinetic parameters were determined: elimination half-life ($t_{1/2}$), maximum concentration (C_{max}), time to maximum concentration (t_{max}), area under the curve ($AUC_{0\text{-}tf}$ and AUC_{∞}), elimination rate constant (λz) and volume of distribution (Vc and Vss). **Results:** A total of 41 pts were included (25 in phase I, 20 in phase II (including 4 pts with STS from cohort 4). Common drug-related toxicities included: fatigue (95%), nausea (76%) and alopecia (63%). One DLT was observed, Rash - Hand and Foot Syndrome, CTC grade 3, in cohort 3 on Day 22. The MTD was declared the highest tested dose level: belinostat 1000 mg/m^2 combined with 75 mg/m^2 doxorubicin. Dose normalised $AUC_{0\text{-}tlast}$ and Cmax appeared relatively consistent across the different cohorts on both Days 4 and 5 indicating that belinostat exhibited linear pharmacokinetics across the dose range and that doxorubicin had no effect on belinostat exposure. Two responses were observed in phase I at cycle 4 (2 PR, RR of 8% (95% CI, 1 - 26%)) and in the phase II trial there were 2 responses (1 PR (cycle 4) /1 CR (cycle 2), RR of 13% (95% CI, 2 - 38%)) and 9 SD, hence the trial was stopped after 20 pts were enrolled. **Conclusions:** The combination of belinostat and doxorubicin was well tolerated and showed activity in 12/20 pts with advanced STS in the MTD population, which warrants further investigation. Clinical trial information: NCT00878800.

10517 **Poster Discussion Session; Displayed in Poster Session (Board #161), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM**

Detection of *KIT* mutants in circulating tumor DNA (ctDNA) and their association with ponatinib anti-tumor activity in patients (pts) with advanced gastrointestinal stromal tumors (GIST). *First Author: Michael C. Heinrich, Knight Cancer Institute and Portland VA Medical Center, Oregon Health & Science University, Portland, OR*

Background: Ponatinib is a multi-targeted tyrosine kinase inhibitor with potent preclinical activity against a broad range of clinically relevant *KIT* mutants, including primary-activating (especially exon 11) and secondary-resistance (including exons 17/18) mutants. Ponatinib is being evaluated in a phase 2 trial (NCT01874665), in which TKI-resistant metastatic GIST pts are enrolled in 2 cohorts based on the presence (A) or absence (B) of *KIT* exon 11 mutations in tumor specimens. We used ctDNA to explore the association between *KIT* mutation status and anti-tumor activity of ponatinib. **Methods:** Plasma samples were collected at baseline (BL) and every 8 wks, and a subset analyzed for 7 primary (exons 9, 11, 13) and 20 secondary (exons 13, 14, 17, 18) mutations using BEAMing. The primary trial endpoint was clinical benefit rate (CBR = CR+PR+SD at 16 wks) using modified RECIST 1.1 in cohort A. Associations between changes in ctDNA levels and tumor burden (RECIST lesions) were assessed by calculating an odds ratio (OR) and *p*-value. Data as of Dec 1, 2014, based on 32 evaluable pts of 45 enrolled pts. **Results:** 21 pts in cohort A had a BL sample, with secondary mutations detected in 11. All 11 pts had 1 (n = 6) or multiple (n = 5) detectable mutations in exon 17/18, commonly involving residues D820, N822, or Y823 – 1 pt also had a gatekeeper mutation in exon 14 (T670I); the CBR in these pts was 55% (6/11). 11 pts in cohort B had a BL sample, with a secondary mutation (A829P) only detected in 1.Overall (A+B), 15/23 pts (65%) with BL and post BL samples had at least 1 primary or secondary mutation detected. In these pts, a post BL decrease in mutant *KIT* ctDNA was associated with a reduction in tumor burden at that time point (OR = 13.6; p= 0.035). Additional analyses are ongoing. **Conclusions:** Primary and/or secondary *KIT* mutations were detected in ctDNA from a majority of TKI-resistant GIST pts and their levels were associated with tumor burden over time. Importantly, antitumor activity of ponatinib was observed in pts with exon 17/18 mutants detectable by ctDNA. Further exploration of the utility of ctDNA *KIT* mutation analysis for monitoring responses in GIST is warranted. Clinical trial information: NCT01874665.

Plasma sequencing to detect a multitude of secondary KIT resistance mutations in metastatic gastrointestinal stromal tumors (GIST). *First Author: Sebastian Bauer, Universitaetsklinikum Essen-Innere Medizin-Essen, Essen, Germany*

Background: Resistance to kinase inhibitors is associated with a marked genomic heterogeneity of secondary mutations of KIT in metastatic GIST which is poorly represented in single tumor biopsies. We sought to evaluate plasma sequencing (plasma seq) as a novel approach to detect or monitor the spectrum of resistance mutations in GIST. **Methods:** We prospectively collected 30 plasma samples from 22 patients with metastatic GIST (incl. corresponding tumor from same time point: n = 13; median pretreatment: n = 2). Circulating free DNA (cf DNA) and tumor DNA were sequenced on an Illumina MiSeq platform using a custom designed targeted sequencing panel. Mutations with a percentage < 0.5% of total reads were excluded. **Results:** We detected 87 non-synonymous KIT mutations in plasma samples with various percentages of total reads (0.5-20% of cf-DNA). Primary mutations were found in 41% (all matching the tumor analysis), resistance mutations were seen in 86% of pts including patients responding to imatinib. Mutations in exon 17 were the most common resistance mutations. Resistance mutations detected in tumor samples were infrequently matched by plasma DNA. Notably, p53 mutations were detected in 77%, mutations of RAS or RAF in 59% of patients albeit at low levels. A comparator group of 19 plasma samples from pts with NSCLC harboured 6 low level KIT mutations at levels of 0.9% fc-DNA (median). Extended storage time, high storage temperature and mechanical stress negatively impacted the purity of cf-DNA. **Conclusions:** Plasma seq in pts with metastatic GIST detects a multitude of resistance mutations of KIT and other genes. Future validations should incorporate comprehensive sequencing of corresponding tumor tissue. Handling of plasma samples should be standardized in order to maximize the yield of mutant DNA. The clinical value of plasma seq should be tested in randomized trials.

10519 **Poster Discussion Session; Displayed in Poster Session (Board #163), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:30 PM-5:45 PM**

An NGS assay strategy with FFPE and cfDNA to determine primary and secondary mutations across the initial diagnosis and subsequent recurrence/progression of patients with localized, recurrent and metastatic GIST. *First Author: Nagavalli Somasundaram, National Cancer Centre, Singapore, Singapore*

Background: Primary and secondary mutations in GIST affect prognosis and treatment response and impacts treatment decision making. A single driver mutation (primary) is found amongst exons of KIT, PDGFRA and less commonly BRAF, KRAS and NRAS. Sequencing multiple genes may be required to determine the primary mutation and the amount of FFPE diagnostic biopsy material can be limiting. Upon disease progression on Imatinib, 1 or more secondary mutations in exons 13,14,15,17 or 18 in KIT can simultaneously develop, affecting response to subsequent therapy. Determining the secondary mutations at progression is limited by the need to test several possible mutations, small sample amount and sampling error from inter and intra-lesional heterogeneity. **Methods:** We developed a strategy employing next generation sequencing (NGS) tools on FFPE and cfDNA. Tumor FFPE and blood (plasma) samples from GIST patients and subjects without GIST were obtained, the latter as negative controls and serial spike-in analytical titrations. DNA from Fresh Frozen Tumor samples, where available were also obtained. **Results:** Initial FFPE samples and subsequent blood (plasma) samples were obtained from a cohort of 96 patients with localized or metastatic GIST and 24 control (non-GIST) patients. Primary mutations are determined from FFPE material and secondary mutations from plasma material. From 100ng of DNA in a multiplexed targeted NGS panel, we can determine the primary mutations from exons 9 and 11 of KIT and exons 12,14 and 18 of PDGFRA, exon 15 of BRAF and exons 2,3,4 of KRAS and NRAS simultaneously. From plasma, using just 10 ng of cfDNA, we are able to simultaneously determine the presence or absence of secondary mutations across exons 13,14,15,17 and 18 of KIT down to a variant allele frequency of 0.1%. **Conclusions:** We have developed a clinically deployable NGS assay strategy to determine primary and secondary mutations across the initial diagnosis and subsequent recurrence/progression of patients with localized, recurrent and metastatic GIST.

10520 Poster Session (Board #164), Sun, 8:00 AM-11:30 AM

A phase II trial of sorafenib (SO) in advanced chordoma patients (pt). *First Author: Eric Amela, Centre Oscar Lambret, Lille, France*

Background: To report in a hypothesis-generating phase II study the activity and safety of SO in advanced chordomas. **Methods:** Pts received SO 800 mg/d until progression, intolerance or up to 9 months (mo) and intolerance. The primary endpoint was progression-free survival according to RECIST 1.1. Secondary end-points were RR, OS and toxicity. **Results:** From 07/2011 to 01/2014, 27 pts were enrolled (median age 64, range 30-86), including 17 men and 10 women. The primary tumor locations were sacrum (21, 77.7%), rachis (4, 14.8%) and clivus (3, 11.1%). Metastasis was present in 14 pts (58.3%). Twenty-six pts (96.3%) had received prior treatment, including surgery (18, 66.7%), radiotherapy (18, 66.7%) and prior systemic therapies (MTT; 12, 44.4%; median number of lines 1, range 1-3). The duration of SO treatment was 4.9 months (range, 0.5-10.1). The median relative dose-intensity was 1 (range, 0.43-1). Because of toxicity, treatment was temporarily discontinued for 11 pts (40.7%) and dose-reduction was necessary in 10 cases (37.0%) A 6 mo, we have observed 1 delayed RECIST-based partial response confirmed at 9 mo. The median follow-up was 8.7 mo (1.2-31.0 mo). The 12 month-PFS rate was 57.4% (95CI 34.7-74.7) in the whole population, and 63.6% (32.7-83.3) and 47.1% (15.2-74.1) in pts naïve to and those previously treated by MTT, respectively. The 12 month-OS rate was 86.5% (55.8-96.5). Three (11.1%) and 14 (51.8%) pts experienced grade (Gr) 4 and Gr 3 toxicities. The Gr 4 toxicities were thyrotoxicosis (1 case), skin toxicity (1 case) and arterial hypertension (1 case). The most common Gr 3 toxicities were arterial hypertension (5), skin toxicity (5) and diarrhea (5, 18.5%). One keratoacanthoma occurred during follow-up. **Conclusions:** This trial showed a promising activity of SO in advanced chordoma. Further clinical explorations (e.g. randomization trial with discontinuation design) are warranted. Clinical trial information: 2009-017020-59.

10521 Poster Session (Board #165), Sun, 8:00 AM-11:30 AM

Patient-reported outcome instruments meaningful and relevant for tenosynovial giant cell tumor (TGCT): A qualitative study. *First Author: Heather Gelhorn, Evidera, Bethesda, MD*

Background: Tenosynovial giant cell tumor (TGCT), a rare locally aggressive neoplasm of the synovium of joints and tendon sheaths, is associated with inflammation, pain and swelling in part due to CSF1R-bearing macrophages recruited to the tumor by genetic elevation of CSF1 activity. Most common treatment is surgery; pharmacological treatments are in development. Patient Reported Outcome (PRO) instruments are potential critical endpoints to demonstrate treatment benefit in clinical trials. Symptoms and other PROs meaningful to TGCT patients have not been formally researched, and instruments to evaluate such outcomes do not exist. **Methods:** PRO instruments of potential relevance were evaluated by literature review and by clinical and PRO experts. TGCT patients were recruited through clinical sites and the internet for participation in qualitative research interviews to identify predominant symptoms and to test relevance and content validity of selected PRO measures. **Results:** 22 subjects participated: 73% female, mean age 42.5 (range 27-56); 19 (86%) diffuse, 3 (14%) localized TGCT; 50% prior surgery. Tumors were located in knee (n = 15), hip (n = 3), ankle (n = 2), elbow (n = 1), forearm (n = 1). Most common symptoms cited were pain (82%), stiffness (73%), swelling (86%), reduced range of motion (64%) and joint instability (64%), which were consistent with clinical expert input and with instruments chosen by PRO experts. The Brief Pain Inventory (BPI) worst pain numeric rating scale (NRS), PROMIS physical functioning items and WOMAC items identified from the literature, as well as a worst stiffness NRS developed for TGCT, were confirmed as meaningful measures of TGCT patient symptoms and were well understood in qualitative interviews. These measures are currently being piloted in an ongoing Ph1 clinical trial of PLX3397, a small molecule inhibitor of CSF1 receptor kinase, in TGCT (NCT01004861). **Conclusions:** Pain, stiffness and physical functioning are important treatment outcomes in TGCT patients. We have identified potentially reliable and valid PRO measures of these concepts, which are being tested in phase I and will be further evaluated in a phase III TGCT clinical trial with PLX3397. Clinical trial information: NCT01004861.

10522 Poster Session (Board #166), Sun, 8:00 AM-11:30 AM

Pilot trial of vigil immunotherapy in Ewing's sarcoma. *First Author: Maurizio Ghisoli, Mary Crowley Cancer Research Centers, Dallas, TX*

Background: Ewing's sarcoma is the second most common primary bone malignancy in children and adolescents. While front-line intensive multimodality treatment significantly improves survival in first line treatment, the prognosis for metastatic patients with either disease relapse within two years of initial therapy or initially resistant to chemotherapy is very poor with few long-term survivors and 1-year survival generally less than 20%. **Methods:** We implemented a Phase I trial of 12 metastatic Ewing's sarcoma patients who were either multiply recurrent (n = 11) or had failed frontline treatment within 2 years (n = 1). Patients received Vigil (previously called FANG) vaccine dosed between $1x10^6$, $4x10^6$, $1x10^7$ or $2.5x10^7$cells/intradermal injection/month for ≥ 4 months. Vigil is comprised of irradiated autologous tumor transfected with a dual DNA plasmid expressive of GMCSF and bi-shRNA furin components. Knockdown of furin down regulates both downstream TGFβ1 and TGFβ2 expression. Safety and clinical responses were monitored. Patient immune responsiveness to unmodified tumor cells was assessed by sequential IFNγ-ELISPOT assay using whole blood mononuclear samples starting at baseline (pre-treatment) and sequentially after treatment. **Results:** None of the 12 patients (47 vaccinations) developed Grade 2/3/4 drug related toxicity. Median product release GMCSF expression was 1858 pg/10^6 cells; median knockdown of TGFβ1 and TGFβ2 was 100% and 99%, respectively. Eight patients have been sequentially assessed for circulating mononuclear cell IFNγ-ELISPOT response, all of whom were IFNγ-ELISPOT negative at baseline. In all eight, follow up IFNγ-ELISPOT at month 1 or month 4 (one patient) post-Vigil converted to positive (> 10 spots/10^6cells and > 2x baseline). One patient achieved a partial tumor response (38% tumor reduction, RECIST 1.1). The estimated Kaplan-Meier median survival of these 12 patients at Year 1 was 75%. **Conclusions:** In this phase 1 study in patients with Ewing's sarcoma, Vigil immunotherapy was well tolerated, elicited a tumor-specific systemic immune response in all patients, and was associated with favorable 1-year survival. Further clinical testing is warranted. Clinical trial information: NCT01061840.

10523 Poster Session (Board #167), Sun, 8:00 AM-11:30 AM

Perioperative chemotherapy with cisplatin (CP) and doxorubicin (DOX) with and without high-dose methotrexate (HDM) in adult osteosarcoma (AOT): Is methotrexate warranted? *First Author: Lucila Soares Da Silva Rocha, Instituto Do Cancer Do Estado De Sao Paolo, Sao Paulo, SP, Brazil*

Background: treatment of AOT consists of perioperative chemotherapy and surgical resection. Standard chemotherapy in AOT consists of CP and DOX. Although considered standard of care in the pediatric population, the use of HDM remains controversial in adults. In addition, it is associated with greater toxicity rates, leading many specialized centers to drop it. This study aims to review treatment efficacy in localized AOT treated at our institution to ascertain the role of HDM in this disease. **Methods:** this retrospective study included consecutive patients with localized AOT treated at the Instituto do Cancer do Estado de São Paulo (ICESP) from 2008 to 2014 that received at least one perioperative chemotherapy cycle. Chemotherapy regimens consisted of DOX and CP (group 1). A subgroup of patients also received HDM (group 2). Analysis of overall survival (OS), disease free survival (DFS) and treatment toxicities were performed. **Results:** final analysis included 26 patients, 16 treated in group 1 and 10 in group 2. Most patients presented ECOG performance status 0-2 (93.8 and 80%) and lower extremity primary tumours (62.5 and 80.0%), for group 1 and group 2 respectively. Despite lower average age (35.0±12.1 and 18.9±2.1 y), group 2 presented more grade (G) 3/4 thrombocytopenia (0 and 15.8%) and G3/4 mucositis (0 and 21.1%), while group 1 presented more neutropenia G3/4 (46.6 and 26.3%). Both groups presented no G3/4 renal toxicities. Two grade 5 toxicities occurred in group 2 (bleeding and neutropenia), both after the first HDM cycle. Efficacy analysis revealed no difference in DFS (4.38±0.61 and 2.3±0.54y, p = 0.228) and OS between groups (4.70±0.56 and 2.52±0.57y, p = 0.107), with a trend to better outcomes in group 1. The 4-year OS was 65.6 and 32.8% for group 1 and 2 respectively. **Conclusions:** HDM chemotherapy was associated with greater severe and lethal toxicity when added to CP and DOX perioperative chemotherapy in AOT. In addition, it does not seem to impact on efficacy. This data does not support the use of HDM in the treatment of AOT.

10524 Poster Session (Board #168), Sun, 8:00 AM-11:30 AM

Prognostic relevance of miRNA let-7e in localized intestinal GIST: A Spanish Group for Research on Sarcoma (GEIS) Study. *First Author: Javier Martin Broto, Hospital Universitario Virgen del Rocio, Sevilla, Spain*

Background: Risk estimation of recurrence in localized GIST relies on factors as mitosis, size, site or capsule rupture. Recently, genotype has shown to add prognostic value at least in intermediate risk group. Nevertheless, there is a remarkable lack of molecular prognostic variables in localized GIST. We had previously performed miRNA arrays in a subset of localized intestinal GIST comparing relapsed vs no-relapsed patients. We identified let-7e (FC = – 1163.9; $p < 0.0001$) and miR-550 (FC = +204.2; $p < 0.0001$) as the most significantly downregulated and upregulated miRNAs respectively. Here we analyze the prognostic role of these miRNA in a validation set (VS) of intestinal GIST **Methods:** Selection criteria used for VS were intestinal GIST, R0 surgery, no tumor rupture, no adjuvant imatinib and size larger than 2 cm. RNA extraction was performed using the RecoverAll Total RNA Extraction kit (Ambion). The expression of miRNAs was determined by means qRT-PCR using specific Taq-Man probes. let-7e and miR-550 expression levels were categorized as above or below median values. Kaplan–Meier and log-rank test were the statistics used and relapse free survival (RFS) was the clinical endpoint **Results:** A subset of 112 patients was selected as VS, 23 of which were excluded (metastatic, tumor rupture, etc). Thus, 89 patients were selected, 58 of whom recurred after median follow of 117 months. Median of size and mitoses were 10 cm and 10 x50hpf. In univariate analyses, let-7e showed statistically significant difference in median of RFS: 26 (19.5-32.6) vs 50 (24.6-39.7) months for below and above median values respectively ($p = 0.011$). For miR-550 no significant differences were seen 35 vs 29 months ($p = 0.99$). Mitosis $\leq 5/ > 5$ with 162 vs 26 months ($p = 0.002$) and size $\leq 10/ > 10$ with 37 vs 29 months ($p = 0.05$) showed also prognostic relevance. In multivariate analysis, mitosis HR 2.7 (1.4-5.3; $p = 0.004$) and let-7e HR 2.1 (1.2-3.8, $p = 0.009$) were independent prognostic factors for RFS **Conclusions:** miRNA let 7-e has demonstrated to be a relevant prognostic factor for RFS in intestinal GIST patients and deserves to be explored for targeting purposes. A further analysis is planned in a larger series of GIST including also gastric cases

10525 Poster Session (Board #169), Sun, 8:00 AM-11:30 AM

Stem cell rescue from irradiation of multiple tumor sites combined with high-dose chemotherapy, followed by reduced intensity conditioning and allogeneic stem cell transplantation in patients with advanced pediatric sarcomas: Preliminary results of the MetaEICESS 2007 protocol. *First Author: Stefan Burdach, Technische Universität München, Munich, Germany*

Background: Advanced pediatric sarcomas are associated with poor prognosis. These truly rare diseases include Ewing's sarcomas (ES), metastatic to more than one bone or early relapse as well as stage IV rhabdomyosarcomas (RMS). We assessed toxicity, relapse free survival (RFS) and overall survival (OS) of advanced ES and RMS patients treated a single institution with the MetaEICESS 2007 protocol. **Methods:** From 2007 to 2015, 9 patients, 7 with ES ($\geq$ three bones/organs or marrow involved at diagnosis, $n = 4$ or relapse < 24 months after diagnosis, $n = 2$) and 2 with stage IV RMS patients were enrolled. The protocol comprised induction-chemotherapy, whole-body MRI/PET directed radiotherapy to the primary tumor and to all metastases, surgery, tandem high-dose chemotherapy with autologous rescue and allogeneic stem cell transplantation (allo-SCT). Data was censured on februay 1st 2015. Radiotherapy was delivered to the primary tumor ($n = 8$, total dose 50-60 Gy), to the lungs ($n = 4$, 15-18 Gy), and to lymph node and osseous metastases ($n = 3$ and $n = 7$, 45-50 Gy). Target volumes ranged from 453 – 9.407 cm^3 (median of 2.762 cm^3). One patient received proton, all others photon irradiation. **Results:** 5 patients are surviving in CR at a median of 27 months (range 0-62) after allo-SCT. Median RFS after allo-SCT was 17 months (range 0-62). 8 patients had reached complete remission (CR) before allo-SCT, three of whom relapsed thereafter, predominantly outside the radiotherapy treatment fields. 4 patients received donor lymphocyte infusions (DLI), of whom two patients showed clinical responses. One patient had to be retransplanted after initial graft rejection, 3 patients suffered ADV reactivation, 3 patients developed acute- and 1 patient chronic GvHD. **Conclusions:** The MetaEICESS 2007 protocol constitutes a feasible option for patients with advanced pediatric ES and RMS. A larger cohort is mandatory to verify OS or RFS improvement over current protocols.

10526 Poster Session (Board #170), Sun, 8:00 AM-11:30 AM

Prognostic factors analysis of extraskeletal osteosarcoma: Updated results of an EMSOS study. *First Author: Alessandra Longhi, Instituto Ortopedico Rizzoli, Bologna, Italy*

Background: Extra Skeletal Osteosarcoma (ESO) account 1% among soft tissue sarcomas. There is no agreement on the best strategy of treatment. **Methods:** An EMSOS collaborative study was performed and data of patients treated for an ESO at different EMSOS centers were collected. **Results:** 147 cases were evaluable. Median age was 53 years(13-84). There were 95 males, 52 females. 114 had localized disease and 32 were metastatic, 1 unknown. Median tumor size was 10 cm, median interval from symptoms onset to diagnosis was 4 months. Primary tumor site was lower limb in 73 patients , upper limb in 33 patients,12 were in viscera. 109/114 with localized disease had surgical resection of primary tumor , 80 had R0 resection, 23 R1, 6 unknown. Among 114 patients with localized disease 79 received chemotherapy: 61 received a bone osteosarcoma-like chemotherapy regimen and 12 a soft tissue sarcoma like regimen;6 unknown type . 34/114 patient with localized disease received RT. Median follow up for all patients was 30 months (1-384 ms), 87 patients were alive and 60 dead at last FUP; median follow up for 87 survivors patients was 51 ms (1-384ms).. 5yrs overall survival (OS) for all 147 was 55%, 62% for patients with localized disease and 28% for those with metastatic disease. Among 114 patients with localized disease, local relapse occurred in 29/114 (25%) , distant metastases in 41/114 (36%). In patients with localized disease the probability of 5-yr OS according to tumor and treatment variables is reported in the table below. **Conclusions:** 5yr OS and prognostic factors (age,size,margins,surgical remission) are similar to soft tissue sarcoma group. Only a positive trend was seen for chemotherapy at univariate analysis but not at multivariate analysis.

	5-yr OS	p-value
Age	71%	0.07
18-40 (23)	67%	
41-65 (59)	47%

10527 Poster Session (Board #171), Sun, 8:00 AM-11:30 AM

High dose ifosfamide in metastatic high-grade osteosarcoma, after failure of standard multimodal chemotherapy. *First Author: Emanuela Palmerini, Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: Although there are many reports on post-relapse survival for osteosarcoma,studies on validated clinical outcome measures (progression-free survival at 6 months [6-mo PFS], complete response [CR], partial response [PR], stable disease [SD]) are lacking. We explored high dose ifosfamide (HDIFO) activity in patients (pts) with relapsed osteosarcoma. **Methods:** Pts progressing after standard treatment and with measurable disease were eligible. Treatment consisted of ifosfamide 3 gr/m^2/day, day 1–5, continuous infusion, every 21 days, until progression or unacceptable toxicity. Overall response rate (ORR: CR + PR), SD, 6-mo PFS, and overall survival (OS) were assessed. **Results:** Fifty-one pts were enrolled. Median age was 19 (7-68): 21 pts pediatric, 30 pts adult. Female/Male: 18/33. Forty-eight pts were ECOG 0, 3 pts ECOG 1. Line of treatment: 46 pts were in 1^{st}line; 5 pts in $\geq$ 2nd line. 32/51 had already been treated with lower doses of ifosfamide for the primary tumor. Pattern of metastases: 35 pts lung only, 13 multiple sites, 3 bone only. 23/51 patients underwent metastasectomy after HDIFO, achieving surgical complete remission (CR2). ORR: CR: 0/51, PR: 11/51 (22%); SD 28/51 (55%), progressive disease (PD) 12/51 (23%). Median duration of response was 6 months (range: 0-192 months). PRs were mainly observed in pediatric pts (9/21 [43%]) and in pts with lung only disease (9/35 [26%]). 6-mo PFS rate was 53%. 6-mo PFS was significantly better for pts receiving HDIFO in 1^{st}line (6-mo PFS: 1^{st}line 52% vs $\geq$ 2nd line 0%; $p= 0.04$), while there was no difference according to age, gender or pattern of metastases. 1- and 2-year OS were 60% and 31%, respectively, with increased survival for non-progressing pts (1-year OS: PD 25% vs SD 40% vs PR 45%; $p= 0.001$), and for pts undergoing metastasectomy (1-year OS: CR2 96% vs no CR2 33%, p 0.0001). **Conclusions:** HDIFO demonstrated activity in osteosarcoma, especially in 1^{st} line, pediatric pts and lung only disease. This series also confirms the important role of surgical complete remission in this subset of pts.

10528 Poster Session (Board #172), Sun, 8:00 AM-11:30 AM

Sustained response of complex giant cell tumors with denosumab: Single center 8-year experience. *First Author: Neal Shiv Chawla, Sarcoma Oncology Center, Santa Monica, CA*

Background: GCTB are aggressive osteolytic tumors, which are characterized by local bone destruction and soft tissue invasion. There have been limited non-surgical treatments, including radiation therapy. However, an unacceptable rate of post radiation sarcomas has been well established. Such tumors have osteoclast like giant cells/stromal cells that express surface RANK ligand. Denosumab is an FDA approved drug used in the treatment of unresectable GCTB or GCTB with severe morbidity related surgery. It is a monoclonal antibody that targets the RANK ligand characteristic to GCTB. We report our 8-year experience in the treatment of complex GCTB using denosumab. **Methods:** Review of 43 skeletally mature patients (N = 43) who were treated with subcutaneous (SC) denosumab for the treatment of GCTB, in whom surgery was not feasible without severe morbidity. Denosomab was dosed at 120 mg on days 1, 8, 15, 29, and every 4 weeks thereafter. CT, PET/CT, or MRI was used to determine radiographic disease burden, along with clinical examination assessing symptoms of disease and side effects of treatment. **Results:** Average best response per RECIST 1.0 criteria was stable disease. Patients received denosumab on average 159 weeks (range: 12 - 310 weeks), with few complications. 5% (2/43) of patients developed mandible infections, 7% (3/43) of patients developed osteonecrosis of the jaw (ONJ), and 2% (1/43) of patients developed an atypical traumatic fracture during treatment. Overall, as a treatment of GCTB, denosumab proved safe and efficacious over prolonged use, with very low rates of complications and a sustained disease response. **Conclusions:** This study represents the longest reported single center use of denosumab in the treatment of GCTB. Overall, it shows the safety and efficacy in the use of denosumab in the treatment of GCTB.

10529 Poster Session (Board #173), Sun, 8:00 AM-11:30 AM

Functional and clinical long-term outcome of Ewing sarcoma treatment*. *First Author: Andreas Ranft, Pediatric Hematology and Oncology, University Hospital, Muenster, Germany*

Background: Since 1980 patients with Ewing sarcoma have been treated according to consecutive protocols (CESS) of the German Society of Pediatric Oncology and Hematology (GPOH). Rising survival rates have raised the question of the quality of long-term survivorship. Objective and subjective measurement tools are used to evaluate the actual health status and daily-life activity level as an indicator for restitution of function. **Methods:** Long-term outcome of 603 survivors of the CESS 81, CESS 86, EICESS 92, and EURO-E.W.I.N.G. 99 trials, run by the GPOH, diagnosed between 1980 and 2009, was assessed by the Toronto Extremity Salvage Score (TESS), Short-Form Health Survey (SF-36), and Brief Symptom Inventory (BSI) questionnaire scales, and by the StepWatch Activity Monitor (SAM) accelerometer device. Prospective data were correlated retrospectively with standardized primary trial data. A 1:2 non-random peer control group was selected to compare results with healthy individuals. Median age of former patients was 28.7 years, 56% were males. Median observation time was 12.9 years (range 3.7-31.2). **Results:** Former patients were less active than the control group, contributing to a mean step count difference of 1758 steps per day (10394 vs. 12152; $p < .01$), but have reached the recommended level for an active life-style (> 10000). Negative prognostic factors were pelvic tumors (9265; $p < .01$) and primary metastatic disease (9322; $p < .05$). Correlations between self-reported scales and the step measurement were rather low ($r < .30$). The TESS score (> 90), BSI somatization, anxiety and depression scales (raw values < 0.50), and the SF-36 (Physical/Mental Component Summary scores = 47.9/49.7) showed no major clinical or functional limitations. Around 15% of former patients rated their health status as less good or poor compared to 2% of the controls. **Conclusions:** The present study comprised a follow-up period of up to 30 years after the treatment of Ewing sarcoma. Former patients seemed to return to a normal lifestyle with minor limitations. The outcome is an encouraging signal to patients with this severe disease. *supported by BMBF/DLR 01ER0807

10530 Poster Session (Board #174), Sun, 8:00 AM-11:30 AM

Phase II trial of gemcitabine plus rapamycin as second line in advanced osteosarcoma: A Spanish Group for Sarcoma Research (GEIS) Study. *First Author: Javier Martin Broto, Hospital Universitario Virgen del Rocio, Sevilla, Spain*

Background: There are few reports focusing on systemic treatment in osteosarcoma (OS) patients progressing after most active drugs. Preclinical data showed activity of rapamycin in xenograft murine models of OS and in a phase II trial testing m-TOR inhibitor; 4/5 partial responses were seen in OS patients. Likewise, gemcitabine exhibited some activity in retrospective series in OS. Additionally, our group had conducted a phase I trial with gemcitabine (G) plus rapamycin (R) in sarcomas with biological inhibition of m-TOR at recommended doses. All these together supported the design of a phase II trial in advanced progressing OS with G and R combination. **Methods:** Main endpoint was progression free survival rate (PFSR) at 4 months, defining P1 as 40% and P0 as 20%. A minimax Simon's two-stage design was applied with an estimation sample size of 33 evaluable patients. Most relevant inclusion criteria were as follows: Non-resectable locally advanced or metastatic disease; age 2-80 y; ECOG 0-2 and measurable progressing disease after receiving at least cisplatin, doxorubicin and methotrexate. The scheme consisted of G 800 mg/m2 i.v. d1 and 8 every 21 days administered at 10 mg/m2/min and R 5 mg/day p.o. **Results:** From September 2012 to November 2014, 36 patients were enrolled in 12 hospitals of GEIS network with a median age of 24 y (4-60). Two patients were non-eligible for this analysis (chondrosarcoma and early finish of trial drugs). Male/Female distribution was 21/15 and ECOG distribution was 30%, 58% and 12% for 0, 1 and 2 respectively. Overall, 115 cycles were administered with median follow-up for alive patients of 5 (1-17) months. Hematologic grade 3/4 toxicity was neutropenia 42%, thrombocytopenia 25%, anemia 14%, febrile neutropenia 8% and most relevant non-hematologic toxicity was fatigue 14% and transaminitis 5%. There were 2 (6%) PR, 13 (39%) SD and 18 (54%) PD. Regarding the main endpoint, PFSR at 4 months was 44% (27-61) and at 6 months was 28% (13-44). Median of PFS and OS were 2.3 months and 11.2 months respectively **Conclusions:** The trial met the PFSR expectations with low to mild toxicity and therefore deserves further investigation. Translational associated research is ongoing. Clinical trial information: 2012-001106-26.

10531 Poster Session (Board #175), Sun, 8:00 AM-11:30 AM

Clinical Characteristics and Treatment Outcomes of Clear Cell Chondrosarcomas: MD Anderson Cancer Center Series. *First Author: Anthony Paul Conley, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clear cell chondrosarcomas (CChs) represent 2% of all chondrosarcomas and are defined by cells with abundant clear vacuolated cytoplasm surrounded by a cartilaginous matrix. Understanding clinical characteristics and treatment patterns may improve outcomes. We reviewed our institutional experience with this rare disease. **Methods:** With IRB-approval, CChs patients (pts) treated at MD Anderson Cancer Center from 1994 to 2013 were identified through Tumor Registry and Sarcoma Pathology Database. Descriptive statistics, survival analysis (RFS, OS), and Cox proportional hazards regression models were performed including Kaplan-Meier plots were provided for OS and RFS. All statistical analyses were performed using SAS 9.3 for Windows. **Results:** 15 pts were identified. Median age at diagnosis was 42 years (range 25 to 74 years). 80% were male. Ethnicity included Caucasians (12 pts; 80%), Asians (2 pts; 13%), and Hispanics (1 pt, 7%). The most common presenting symptom/sign was pain (10 pts; 67%) followed by fracture (3 pts; 20%). The most common site of disease was proximal humerus (7 pts; 47%). All pts had MSTS stage I disease. Primary therapy included radical resection in 12 (80%), curettage/resection in 1 (7%), and curettage in 2 (13%) pts. Of 12 pts, 11 had R0 resection. Median tumor size was 5 cm (range, 2.5 cm to 9.6 cm). Local relapse (LR) occurred in 4 (27%) pts; 1 also had distant relapse (DR). 2 pts had DR alone. DR sites included lungs, liver, and bone. 2 LR were associated with intra-lesional procedures, 1 LR with decompressive laminectomy, the LR+DR had fracture at diagnosis while 2 pts with DR occurred despite radical resection with R0 margins. 1 of 3 DR pts received systemic therapy. Median follow-up time from treatment was 55.1 months (range, 10.4 months to 202.1 months). Median RFS was 102.2 months with 95%CI (33.2 months to 200.2 months). Median OS was 185.8 months. Of 3 deaths only 1 was disease-specific. No significant predictors of RFS or OS were identified. **Conclusions:** CChs is a rare tumor for which complete surgical resection can be curative. Relapse may occur years later so long-term follow up is advised. Understanding predictors of metastasis may require a collaborative effort.

10532 Poster Session (Board #176), Sun, 8:00 AM-11:30 AM

Anti-tumor effects of dovitinib in patient-derived gastrointestinal stromal tumor (GIST) xenograft models. *First Author: Yemarshet Kelemework Gebreyohannes, Laboratory of Experimental Oncology, Department of Oncology, KU Leuven, and Department of General Medical Oncology, University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Advanced GIST is treated with the tyrosine kinase inhibitors imatinib, sunitinib and regorafenib, but the majority of patients develop heterogeneous resistance to these agents. In an attempt to overcome such resistance, we tested the efficacy of dovitinib which acts against VEGFR, FGFR, FLT3, PDGFRB and KIT, using patient-derived GIST xenograft models. **Methods:** NMRI *nu/nu* mice (n = 47) were transplanted bilaterally with the human GIST xenografts UZLX-GIST2 (*KIT* p.A502_Y503dup) or -GIST9 (*KIT* p.P577del+p.W557LfsX5+p.D820G) and were treated in 4 cohorts: control (untreated), imatinib (50 mg/kg/bid p.o.), imatinib (100 mg/kg/bid p.o.) and dovitinib (30 mg/kg/qd p.o.). Efficacy was assessed by tumor volume measurement (3x/week), histopathology, immunohistochemistry [Ki67, phospho-Histone H3 (pHH3), cleaved PARP] and Western blotting analysis of KIT signaling. Histologic response (HR) was graded according to Antonescu et al. *Clin Cancer Res* 2005; 11:4182-90. Microvascular density (MVD) was assessed by counting CD31 positive vessels. Mann Whitney U test was used for statistical analysis. **Results:** After three weeks of treatment, dovitinib caused tumor volume reduction (to 37% of baseline) in UZLX-GIST2 and disease stabilization in -GIST9. It induced grade 2-3 HR in $>$ 50% of tumors in both models. Compared to control, dovitinib reduced mitotic activity by 22.6 fold ($p < 0.0001$) in UZLX-GIST2, whereas no significant difference was observed in the other model. Results were confirmed by pHH3 and Ki67 stainings. Apoptotic activity was decreased in dovitinib treated UZLX-GIST2 tumors compared to control. MVD was reduced in both UZLX-GIST2 (1.6 fold; $p < 0.05$) and -GIST9 (1.3 fold; $p = 0.059$) under dovitinib. Furthermore, it partially inhibited KIT, AKT and 4EBP-1 phosphorylation in UZLX-GIST2. **Conclusions:** Dovitinib showed anti-tumor efficacy in GIST xenograft models, with more pronounced effects in *KIT* exon 9 mutant disease. The decrease in MVD in both models suggested that the anti-tumor effects were at least partially mediated by the anti-angiogenic capacity of dovitinib. These results support ongoing and planned GIST trials (NCT01478373, 02268435, 01440959 and 01831726).

10533 Poster Session (Board #177), Sun, 8:00 AM-11:30 AM

ReGISTry Study of High Risk GIST Patients After Complete Resection:The adjuvant therapy and pathological diagnosis in Japan. *First Author: Toshirou Nishida, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Although three-year imatinib adjuvant therapy is recommended by GIST guidelines, there is a lack of clinical data regarding use of adjuvant therapy, adherence, and indications. A prospective registry study for high-risk GIST progressing in Japan examined reality of adjuvant in clinical practice. **Methods:** Between Dec. 2012 and Dec. 2014, 398 pts with histologically-confirmed high-risk GIST in local site were registered. There were 214 males and 184 females with median age of 64 yrs. In the central, H&E, immunohistochemistry, and genotyping were done. **Results:** Disease was located in the stomach (n = 238), small intestine (n = 122), large intestine (n = 26), or others (n = 12). Median tumor size was 8.0 cm and median mitosis (local pathology) was 10/50HPF. Tumor rupture was seen in 52 pts (13%) and 49 pts had received neoadjuvant therapy. After surgery, adjuvant therapy was administered for 304 pts (76%) and withheld for 82 pts (21%). PS of pts with adjuvant therapy was 0 (258 pts), 1 (37 pts) and $>$ 2 (2 pts). Tumor cell type included spindle (n = 327), epithelioid (n = 14) and mixed (n = 33) histology by pathological test at each hospital. Central pathological review was done for 272 pts: KIT was positive in 263 pts (97%), DOG1 in 262 pts (96%), and CD34 in 228 pts (84%). Mutations were analyzed in 260 pts including 209 KIT exon 11 mutations, 15 KIT exon 9 mutations, 8 other KIT mutations, 10 PDGFRA exon18 mutations, 1 PDGFRA exon 12 mutations, and 6 wild type GISTs. Although KIT immunoreactivity was consistent between central and local (concordance = 92%), CD34 immunoreactivity showed lower concordance (76%) and 10 pts (3.7%) were diagnosed as non-GIST in the central review. There was significant correlation between local and central mitotic counts, but median mitotic count by central review (5/50 HPF) was significantly lower than local values, which resulted in 46 pts (18%) was not diagnosed as high-risk in central. **Conclusions:** Adjuvant imatinib was used for 76% of high risk GIST pts locally diagnosed. There are some disparities in the pathological review of high risk GIST between local and central pathologists, which may indicate requirement of improvement in pathological concordance of GIST. Clinical trial information: UMIN000009531.

10534 Poster Session (Board #178), Sun, 8:00 AM-11:30 AM

Selective indications of surgery in esophageal gastrointestinal stromal tumors: A retrospective study of the French Sarcoma Group (FSG). *First Author: Florence Duffaud, La Timone University Hospital, Marseilles, France*

Background: Esophageal GIST (ESOGIST) are rare tumors, accounting for less than 1% of all GISTs, requiring special consideration regarding evaluation, diagnosis, perioperative treatment and conduct of operation. **Methods:** Through a national multicenter retrospective study in the FSG, 17 patients (pts) with localized ESOGIST were identified between 2000 and 2014 in 9 FSG centers. **Results:** Characteristics of pts were: 11 females, 6 males, median age of 69 years (36-81). Weight loss (n = 6), dysphagia (n = 5) were the most common symptoms. Eight (47%) tumors (T) occurred in the lower third of the esophagus, 5 (29%) in the gastro-oesophageal junction, 2 in the superior third, and 2 in the middle third. All pts underwent oesophagoscopy and/or endoscopic ultrasound (EUS) and CT scan. 15 had a pretherapeutic biopsy guided by EUS. Median T size was 70 mm (3-150). Nine pts received imatinib (IM) therapy as 1st treatment resulting in 6 PR, 3 SD, and permitting T resection in one. Tumors were resected in 8 (47%) pts, 7 upfront, one after IM; with enucleation in 4 [median size 4 cm (3-7)], oesophagectomy in 4 [median size 10 cm (0.5-15)]. Resections were R0 in 2, R1 in 6 pts. 9 pts were not operated (4 with age $>$ 75 and multiple co-morbities, 4 due to advanced T, 1 still on neoadjuvant IM). One patient was never treated. T characteristics were: KIT+ (n = 15), CD34+ (n = 8), mitoses/50 HPF $\leq$ 5 (n = 2), mitoses /50 HPF $>$ 5 (n = 6), and mitoses count unknown for 9. Mutations were documented in 11/17 cases, usually in KIT exon 11 (82%). Five pts received adjuvant IM. With a median follow-up of 19 months (7-99), 12 pts are alive, 5 died (4 due to other cause). Two pts relapsed after enucleation, with metastases in one. Among 12 pts alive, 5 are in CR, 7 with measurable disease (4 in PR, 3 with SD) still on IM for 5, on other TKI for 1, and 1 never treated. **Conclusions:** ESOGIST must be differentiated from leiomyoma and can be reliably identified pre-operatively by EUS-guided biopsy. Surgery for ESOGIST is either enucleation or oesophagectomy depending on tumor size**.** Preoperative IM therapy may improve resectability and is an efficient alternative when surgery is contraindicated

10535 Poster Session (Board #179), Sun, 8:00 AM-11:30 AM

Ponatinib efficacy and safety in patients (pts) with advanced gastrointestinal stromal tumors (GIST) after tyrosine kinase inhibitor (TKI) failure: Results from a phase 2 study. *First Author: Michael C. Heinrich, Knight Cancer Institute and Portland VA Medical Center, Oregon Health & Science University, Portland, OR*

Background: The oral TKI ponatinib has potent pre-clinical activity against mutant KIT and PDGFRA, including clinically relevant mutants resistant to available TKIs. We hypothesized that ponatinib might be effective in GIST after prior TKI treatment failure. **Methods:** This phase 2, single-arm study (NCT01874665) evaluated efficacy and safety of ponatinib 45 mg qd in advanced GIST after TKI failure; N = 45. Cohorts were enrolled based on presence (A) or absence (B) of *KIT* exon 11 mutations. Primary endpoint is clinical benefit rate (CBR = CR + PR + SD) at 16 wk by modified RECIST 1.1 in Cohort A. Secondary endpoints include CBR (Cohort B and overall) and objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety. Due to arterial occlusive events in other ponatinib trials, enrollment criteria were revised in early 2014 to include only pts in whom all 3 TKIs approved for GIST had failed. **Results:** Enrollment is complete (Cohort A, 30 pts; B, 15 pts). Median age was 59 y. Most pts (76%) received $\geq$4 anticancer regimens; 36% received 2 and 58% received 3 approved TKIs. Median time since diagnosis was 6 y. At 10-mo median follow-up (data as of Dec 1, 2014), 9 pts were ongoing; 15 discontinued for progressive disease per RECIST, 9 for AEs, and 12 for other reasons. Cohort A CBR was 37% (10/27); ORR 7% (2/27). Best responses: PR 2; SD 16. Median PFS/OS: 4.3 mo/15.0 mo. Cohort B CBR was 14% (2/14); ORR 0%. Best response: SD 6. Median PFS/OS: 2.0 mo/13.5 mo. Treatment-emergent AEs (TEAEs) in $\geq$40% of pts: rash 58%; fatigue 51%; constipation 42%; headache 42%; myalgia 40%. Myocardial ischemia, cerebrovascular accident, peripheral artery stenosis, deep vein thrombosis, and pulmonary embolism occurred in 1 pt each; 4 pts had evidence of ventricular dysfunction. Serious TEAEs (other than disease progression) in $\geq$2 pts: abdominal pain 9%; pneumonia 7%; fatigue, nausea, small intestinal obstruction, vomiting, 4% each. Two deaths, from pneumonia and pulmonary embolism, were considered possibly ponatinib-related. **Conclusions:** Ponatinib has clinical activity in advanced GIST pts after TKI failure, particularly pts with *KIT* exon 11 mutations. Clinical trial information: NCT01874665.

10536 Poster Session (Board #180), Sun, 8:00 AM-11:30 AM

Clinicopathological impact of protein phosphatase 2, regulatory subunit A, alpha mutations in gastrointestinal stromal tumors. *First Author: Midori Ishii, Department of Orthopaedic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

Background: Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors in gastrointestinal tract. Approximately 85-90% of GISTs are harboring oncogenic mutations in *KIT* or *PDGFRA*, and the tyrosine kinase inhibitor (TKI) drastically improved the prognosis of GISTs patients. On the other hand, a subset of GISTs acquire secondary resistance to TKI or show primary resistance to TKIs. Recent studies report that the disorder of the protein phosphatase 2, regulatory subunit A, alpha (*PPP2R1A*) is responsible for the constitutive phosphorylation of its substrates including TKs, and the constitutive phosphorylation of TKs plays an important role in the tumorgenesis and the progression of ovarian and uterine carcinomas. The aim of this study was to elucidate the frequency of *PPP2R1A* mutations and their impact on the clinicopathological factors in GISTs. **Methods:** Ninety-six cases of GISTs (formalin-fixed paraffin-embedded material) with prognostic information were collected. These cases were examined for *PPP2R1A* mutations (exon 5 and 6) by PCR followed by direct sequences, and the impacts of *PPP2R1A* mutations on the clinicopathological features were examined. In addition, *PPP2R1A* mutated GISTs were also examined for the mutation status of *KIT, PDGFRA* and *KRAS*. **Results:** Seventeen cases (17.7%) of GISTs harbored mutations in *PPP2R1A*, and types of mutations were various. Among 17 cases, 15 cases (88.2%) harbored either *KIT* or *PDGFRA* mutations, and one case had point mutations in both *KIT* and *PDGFRA*. Among two cases of *KIT/PDGFRA* mutation-negative GISTs, one cases showed *KRAS* mutation. GIST cases with *PPP2R1A* mutations had a tendency for shorter disease free survival (DFS) and overall survival (OS) rate, respectively ($p < 0.05$; DFS, $p < 0.05$; OS). **Conclusions:** These results suggest that *PPP2R1A* mutations play an important role in the tumor progression of GISTs. The effect of *PPP2R1A* alterations on the phosphorylation status of TKs including KIT and PDGFRA are under evaluation.

10537 Poster Session (Board #181), Sun, 8:00 AM-11:30 AM

Adjuvant imatinib (IM) for patients (pts) with primary gastrointestinal stromal tumor (GIST) at significant risk of recurrence: PERSIST-5 planned 3-year interim analysis. *First Author: Chandrajit P. Raut, Division of Surgical Oncology, Brigham and Women's Hospital, Boston, MA*

Background: Adjuvant IM treatment improves survival in pts with primary GIST with significant risk of recurrence. However, optimal treatment duration has not been determined. The ongoing PERSIST-5 trial is evaluating 5 years of adjuvant IM treatment. **Methods:** Beginning in 2009, this single-arm trial has included pts at significant risk of recurrence, defined as either primary tumor $\geq$ 2 cm at any site and $\geq$ 5 mitoses/50 high-power fields or nongastric primary GIST $\geq$ 5 cm. After complete resection of primary KIT+ GIST, pts received IM 400 mg/day for 5 y or until progression, relapse, or intolerance. The primary endpoint was recurrence-free survival (RFS). We report data from a planned 3-y interim analysis. **Results:** Of 91 eligible pts (median age 60 y; range, 30-90 y), median tumor size was 6.5 cm (range, 2.3-30.0 cm), 55% had gastric GIST, and 99% underwent R0 resection. In 85 evaluable pts, the most common GIST genotypes were *KIT* exon 11 (68%) and *PDGFRA* exon 18 (9%). Median time from resection to first IM dose was 9.6 wk (range, 3.1-12.3 wk).As of the data cutoff (May 9, 2014), median treatment duration was 34.2 mo (range, 0.5-55.8 mo). Overall, 4 pts (4%) recurred. There was 1 death; this pt had an IM-resistant *PDGFRA* D842V mutation. No pts without this resistant mutation who stayed on IM recurred. All 3 surviving pts who recurred discontinued (D/C) IM prior to recurrence (range, 7.3-23.1 mo between D/C and recurrence). The most common reasons for D/C (n = 33) were adverse events (AEs; n = 13) or consent withdrawal (n = 13). Grade 3/4 AEs leading to D/C were elevated liver enzymes, alveolitis, and renal cell carcinoma (n = 1 each). The most common AEs were nausea (67%), diarrhea (53%), and fatigue (44%). Dose reduction, occurring in 31 pts (34%), was most frequently due to AEs (n = 22), most commonly neutropenia, nausea, and hypophosphatemia (n = 3 each). **Conclusions:** Adjuvant IM was associated with high rates of survival and RFS.Most recurrences occurred after IM D/C. Data support 3 y of adjuvant IM for higher-risk pts. Additional follow-up will evaluate whether longer treatment improves outcomes. Clinical trial information: NCT00867113.

10538 Poster Session (Board #182), Sun, 8:00 AM-11:30 AM

Treatment of advanced gastrointestinal stromal tumors (GIST): Are results of second-line sunitinib therapy related to duration of response of first-line imatinib? *First Author: Daniela Katz, Hadassah Medical Center, Jerusalem, Israel*

Background: Imatinib (IM) revolutionized the outcome of patients with advanced GISTs; however, disease progression eventually occurs due to IM resistance or intolerance. Sunitinib (SU) is an oral multi-targeted tyrosine kinase inhibitor, approved for second line treatment of advanced GIST after IM failure. Clinical trials have shown that clinical activity of SU after IM failure is significantly influenced by both primary and secondary mutations in the predominant pathogenic kinases. However, since mutational status is not mandatory in the workup of GIST patients, it is difficult to predict response to second line SU. The aim of this study was to explore whether results of SU therapy after IM failure, might be related to the duration of IM treatment. **Methods:** All patients with advanced GIST that are insured by Clalit Health Services, Israel's largest health-care organization were identified. Only patients, who progressed on second-line SU, after receiving IM as first-line therapy, were included. Last date of patient recruitment was Dec 31, 2014. A linear regression model was used to identify the relation between first-line IM duration of response (the independent variable) and duration of response of second line SU. **Results:** We identified 31 consecutive patients with advanced GIST treated with IM and SU, consequently. There were 18 male and 13 female patients, with median age at the start of SU therapy 63.5 years (range: 34-85). Only 7% of patients (n = 3) received adjuvant IM therapy, prior to their metastatic disease. Median duration of response was 25.8 months (2.3-67.4) for IM and 5.2 months (0.8-32.7) for SU. The linear model predicted duration of second-line SU therapy (Y) in relation to duration of IM first-line therapy (X) best with: $Y = 2.36+0.282X$, ($R^2 = 20.6\%$, $p < 0.01$). **Conclusions:** In our study, results of SU therapy in advanced GIST patients were found to positively relate with the duration of first line IM treatment. This relation may serve as a handy estimate for SU duration in the clinic. However, further studies in wider cohorts of patients are needed to confirm this observation.

10539 Poster Session (Board #183), Sun, 8:00 AM-11:30 AM

Identification of therapy options for rare and resistant gastrointestinal stromal tumors (GIST). *First Author: Rebecca Feldman, Caris Life Sciences, Phoenix, AZ*

Background: GISTs are predominantly defined by KIT/PDGFRA mutations which are targetable with a range of kinase inhibitors, however the majority become TKI-resistant (TKI-R). Double (KIT/PDGFRA) wildtype (D-WT) GISTs represent a rare subset of GIST patients in need of treatment options. We investigated a commercial database of theranostic biomarkers for the identification of novel therapy options for GIST. **Methods:** 217 GIST cases were evaluated for D-WT and TKI-R. A multiplatform approach of biomarker testing was used and included a combination of sequencing (NGS, Sanger), protein expression (IHC) and gene amplification (ISH). **Results:** D-WT (n = 15) and TKI-R (n = 23) (including 7 with resistance mutations in the absence of a primary, activating KIT mutation and 4 PDGFRA D842V) were studied for additional targetable alterations. IHC and ISH tests revealed no overexpression or amplification in cMET, EGFR, or HER2. PTEN was intact (positive expression) in the majority of GISTs (92.9% (13/14) D-WT; 100% (19/19) TKI-R). Mutational screening revealed variants in 6/47 genes (excluding cKIT and PDGFRA), most of which are potentially targetable with therapies currently available, or in clinical trials: PIK3CA, ABL, cMET, JAK3, RB1, and VHL. ABL and JAK3 mutations were exclusively found in the TKI-R subgroup. PD-1 positive tumor infiltrating lymphocytes were found in 33% (1/3 D-WT) and 60% (3/5 TKI-R), while PD-L1 tumor expression was found in 67% (2/3 D-WT) and 40% (2/5 TKI-R). Although chemotherapy has historically elicited poor responses in GIST (non-selected patient trials), we observed a high frequency of low expression of predictive markers for gemcitabine (RRM1) and paclitaxel (TUBB3) (77%, 90%; 57%, 73% for D-WT and TKI-R, respectively) and high frequency of TOPO1 overexpression for irinotecan (57%, 32% in D-WT and TKI-R, respectively) which were recently shown to be cytotoxic in TKI-R GIST cell lines (Boichuk, 2014). **Conclusions:** A multiplatform approach of theranostic biomarkers identified non-cKIT/PDGFRA therapy options for rare and resistant GIST. Opportunities for investigating new targetable agents and potentially re-visiting cytotoxics with biomarker guidance in these subpopulations are warranted.

10540 Poster Session (Board #184), Sun, 8:00 AM-11:30 AM

Does aggressive local treatment have an impact on survival in children with metastatic rhabdomyosarcoma? *First Author: Myriam Weyl Ben Arush, Technion Faculty of Medicine, Haifa, Israel*

Background: Due to the extensive initial distant tumour spread in metastatic rhabdomyosarcoma, the importance of local treatment is sometimes underestimated. A retrospective study was conducted to identify the prognostic value of aggressive local treatment in paediatric metastatic rhabdomyosarcoma. **Methods:** Patients with metastatic rhabdomyosarcoma age 1 to 21 treated in France from 1998 to 2011 according to European protocols MMT-4-89, 4-91, 98 and recent national guidelines were selected. Survival comparison were performed between patients with "aggressive local treatment" (surgery and radiotherapy) and exclusive surgery or radiotherapy, after exclusion of patients with early progression. Endpoints were event-free and overall survival (OS). **Results:** A total of 101 children, median age 9 years, with majority of primaries in unfavourable sites (73 patients, pts), T2 tumours (66 pts), alveolar subtypes (65 pts) and large tumours (> 5cm, 83 pts) received various chemotherapy regimens. On univariate and multivariate analysis, OS was better after "aggressive local treatment" (49 pts; 44.3 ± 8%), than after exclusive surgery (10 pts; 18.8% ± 15.5%) or exclusive radiotherapy (29 pts; 16.1 ± 7.2%, $P < 0.006$). Moreover, OS was better in the case of surgery with complete resection (41.1 ± 10.2%) or microscopic residue (56.4 ± 14.9%) than macroscopic residue (20.0 ± 12.6%; $P < 0.03$). **Conclusions:** In this large retrospective analysis, OS appeared to be better for patients receiving "aggressive local treatment" even after adjustment for the initial patient and tumour characteristics. Isolated debulking surgery is associated with a very poor outcome and should be avoided. Aggressive local treatment in patients with rhabdomyosarcoma, even with metastasis, should be seriously considered.

10541 Poster Session (Board #185), Sun, 8:00 AM-11:30 AM

Combined sunitinib and IMRT for preoperative treatment of locally advanced soft tissue sarcoma: Results of a phase I trial of the German Interdisciplinary Sarcoma Group GISG 03. *First Author: Jens Jakob, University Medical Center Mannheim, Department of Surgery, Mannheim, Germany*

Background: Experimental data indicate that concurrent treatment with anti-angiogenic substances such as sunitinib improves the efficacy of irradiation. The aim of this phase I trial was to establish the safety profile and recommended dose of sunitinib combined with irradiation as preoperative treatment for soft tissue sarcomas. **Methods:** Patients with locally advanced, non-metastatic soft tissue sarcomas received sunitinib (orally, continuous dosing, 3+3 study design, dose level 1: 25 mg, dose level 2: 37.5 mg, NCT01498835) two weeks prior and during preoperative intensity modulated radiation therapy (25 x 1.8 Gy for retroperitoneal tumors, 28 x 1.8 Gy for extremity tumors). Surgery was performed 5 to 8 weeks after neoadjuvant treatment. Primary endpoint was the recommended dose for subsequent trials. Toxicity was scored according to CTCAE 4.0 criteria. Secondary endpoints were postoperative morbidity and treatment response. **Results:** Nine patients with a median age of 52 years were enrolled in dose level 1 (6/9) and 2 (3/9). Median tumor size was 11 cm. Tumors were located in the retroperitoneum (4/9), lower leg (3/9) or trunk (2/9). Most frequent toxicities of any grade were hematological (8/9), skin (6/9) and oral (5/9) toxicity. At dose level 1, 1/6 patients developed dose limiting grade 4 lymphopenia but recovered completely after discontinuation of sunitinib. At dose level 2, 0/3 patients developed dose limiting toxicity. 5/9 patients required dose adjustments due to toxicity. Skin toxicity within the radiation field did not exceed grade 2. All patients underwent tumor resection (8/9 R0 and 1/9 R1). 2/9 patients had postoperative complications requiring re-intervention. Treatment response according to RECIST was as follows: partial response 1/9, stable disease 7/9, progressive disease 1/9. Pathological examination revealed ≥ 95% tumor necrosis in 3/9 resected specimens. **Conclusions:** Combined preoperative treatment of extremity and retroperitoneal soft tissue sarcoma with irradiation and sunitinib is tolerable and warrants further investigation. The recommended dose of sunitinib for further testing is 37.5 mg. Clinical trial information: NCT01498835.

10542 Poster Session (Board #186), Sun, 8:00 AM-11:30 AM

Activity of crizotinib (C) in patients (pts) with clear cell sarcoma (CCSA) in EORTC phase II trial 90101 "CREATE". *First Author: Patrick Schoffski, University Hospitals Leuven, Leuven, Belgium*

Background: This phase II trial assesses the safety and activity of the ALK/MET inhibitor C in 6 different *ALK*- or *MET*-driven tumor types including CCSA, an orphan, treatment-refractory malignancy. The chimeric *EWS-ATF1* and *EWSR1/CREB1* fusion genes are hallmarks of CCSA and activate *MET* through the melanocyte master transcription factor. **Methods:** Pts with local diagnosis of advanced/metastatic CCSA consented for shipment of a non-returnable tumor tissue block and were screened for trial participation after central confirmation of the diagnosis and Vysis EWSR1 break apart FISH (Abbot Molecular). Eligible pts received C 250 mg twice daily p.o. A Simon's optimal two stage design was implemented independently in each disease-specific study cohort. If at least 2 out of the first 12 MET+, eligible and evaluable CCSA pts achieved a confirmed RECIST 1.1 PR or CR, a maximum of 35 pts were to be enrolled and treated to assess the activity of C, with no interruption of recruitment planned between the two stages. The abstract presents CCSA enrollment characteristics and activity according to the Simon's design stopping rule. Updated activity/safety results of the fully recruited cohort will be available at ASCO. **Results:** Between 01/2013 and 12/2014, 16 investigational sites in 8 European countries recruited 43 pts, of whom 32 had a centrally confirmed diagnosis of MET+ CCSA (tissue blocks available from 97.7% of pts). Central histological and molecular work-up took a mean lab turnaround time of 4 days (range, 2-10) after receipt of unstained slides. Among the first 12 eligible and evaluable MET+ cases, no RECIST responses were observed; best response was SD in 7 and PD in 5 pts. The mean duration of treatment was 6-7 cycles (range, 2-14; cycle length 3 weeks). **Conclusions:** EORTC is able to perform molecularly driven screening phase II trials in orphan malignancies with mandatory collection of tumor tissue and real time confirmation of diagnosis and genetic profiling. C did not meet prespecified response rates in MET+ CCSA, but achieved long-lasting disease control in a clinically relevant subset of pts, which prompted ongoing correlative studies using available tissue, genetic and clinical data. Clinical trial information: NCT01524926.

10543 Poster Session (Board #187), Sun, 8:00 AM-11:30 AM

High-risk soft tissue sarcoma of extremity and trunk wall: A retrospective comparison of local control in patients treated with or without radiation therapy at a single reference center. *First Author: Marco Fiore, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Wide resection plus RT has been considered in the past 3 decades standard treatment for high-risk STS of extremity and trunk wall. The potential for avoiding RT has been explored in limited groups of patients (pts), e.g. small STS. We retrospectively explored the role of RT in high-risk STS treated at a reference institution over a more recent time spam. **Methods:** Consecutive pts affected by primary, localized, extremity and trunk wall STS surgically treated between 2000 and 2012 were reviewed. All tumors were ≥ 5 cm, deep, and G2-G3 according to FNCLCC grade. Ewing/pPNET and pediatric STS were excluded. Two groups were identified: Group A, pts who received adjuvant/neoadjuvant RT; Group B, pts who did not. Local recurrence-free survival (LRFS) was analyzed. **Results:** Study population included 404 pts. Median follow up was 53 months for alive pts (IQR, 30-85). Median size was 10 cm. In Group A, 319 pts received RT (106 preoperative, 211 postoperative, 2 pre- and post). In Group B, 85 pts did not receive RT for individualized reasons. No significant differences were found between groups according to tumor size, age, sex, histotypes. Margins in Group A were R0/R1 in 252 (78.9%), and 67 (21%) cases, respectively; in Group B, 63 (74.1%) and 22 (25.9%), respectively (P value = .380). Group A and Group B were different for: G3 tumors (80.6% and 68.2%, respectively; P value = .0184); trunk tumors (7.5% and 20%, respectively; P value = .0013); (neo-)adjuvant chemotherapy (57.7% and 38.8%, respectively; P value = .002). Five-years LRFS was 83.91% in Group A, and 81.11% in Group B (P value = .1302). No differences in LRFS were found neither between R0 pts treated in Group A and B (P = .1417), nor between R1 pts treated in Group A and B (P = .6971). **Conclusions:** Local outcome of high-risk STS in pts individually treated without radiation therapy was not significantly different compared to those treated by surgery plus RT. Further studies are needed to investigate which subgroups of high-risk STS may benefit from surgery alone, possibly distinguishing between extremity and trunk sites, as well as between G2 and G3 tumors.

10544 Poster Session (Board #188), Sun, 8:00 AM-11:30 AM

Association of hematological toxicity (tox) and outcome to doxorubicin (DOX) in advanced soft tissue sarcoma (STS): A retrospective analysis of the EORTC-Soft Tissue and Bone Sarcoma Group database. *First Author: Stefan Sleijfer, Erasmus MC, Rotterdam, Netherlands*

Background: DOX pharmacokinetics vary substantially between patients leading to large differences in systemic drug levels. Given potential dose-effect relations, patients with the greatest tox may also have the best outcome. We assessed whether severity of hematological tox during treatment is associated with outcome in advanced STS patients treated with first-line DOX (monotherapy; 75 mg/m2 q 3 weeks). **Methods:** Worst tox (anaemia, leukopenia, neutropenia and thrombocytopenia) scored during treatment according to CTCAE v4.0 was included in this analysis. Differences in overall survival (OS), progression free survival (PFS) and response rate (RR) between patients with or without high haematological tox (grade 0-2 vs 3-4) were assessed using conventional statistical tests in landmarked subsets, to avoid bias from patients stopping treatment early. Potential confounders were collected including relative dose intensity (RDI), patients' and tumor characteristics. **Results:** In 557 patients eligible for this analysis, 32% were between 50-60 years, 51% female, 72% had a grade II/III tumor. Leiomyosarcoma (28%) and liposarcoma (15%) were the most common subtypes. 47.2% of the patients received at least 6 cycles of treatment; 45% stopped treatment early due to progression, 3% because of tox. RDI was constant over the cycles. During treatment, grades 3/4 anemia, leukopenia, neutropenia and thrombocytopenia were observed in 6.1%, 35.9%, 51.9%, and 1.6%, respectively. After cycle 1, grade 3 tox occurrence was constant over the diverse cycles, grade 4 tended to decrease after cycle 1 (21.0% at cycle 2, 12% at cycle 3). OS and PFS did not differ between patients experiencing high versus low tox at the end of cycles 1, 2 and 3. Also for RR, no association was seen with severity of haematological tox. **Conclusions:** In this large series, there was no association between outcome and haematological tox during DOX. This information may be useful to reassure advanced STS patients that failure to experience haematological tox during treatment does not equate to undertreatment.

10545 Poster Session (Board #189), Sun, 8:00 AM-11:30 AM

Metastatic soft tissue sarcoma, an analysis of systemic therapy and impact on survival. *First Author: Samuel John Harris, The Royal Marsden Hospital, London, United Kingdom*

Background: Patients (pts) with metastatic Soft Tissue Sarcoma (STS) are known to have poor outcomes with median overall survival (OS) reported to be circa 12 months. Recent publications have reported median OS circa18 months. We performed a retrospective analysis of all pts with metastatic STS treated at the Royal Marsden between 1991-2010 to examine OS trends. **Methods:** Adult pts with metastatic STS from 1991-2010 were studied, excluding pts with GIST, those referred for a second opinion or lost to follow-up within 2 months. Pts were grouped into time periods of 5 years: T1-T4. Pts were censored at 4 years from diagnosis. OS rates were calculated using Kaplan-Meier and log-rank tests. An univariate analysis of age, sex, systemic therapy, tumour grade, time to metastatic disease and histology was performed. **Results:** 2747 pts were identified: 54% female, 75% $<$ 65yrs, median age 53 yrs. Leiomyosarcoma was the commonest diagnosis: 28%; pleomorphic sarcoma: 9%; liposarcoma: 8%. Median OS was 17.5 months. The median OS of T1-T4 was 14.8, 17.9, 18.4 and 17.3 mths. The only significant difference was T1 to T3 ($p = 0.026$). Nearly 60% of pts in T1-T3 had $\geq$ 1 line systemic therapy, which fell to 50% in T4. The percentage of elderly pts increased from 18 to 31% in T4. Systemic therapy was associated with a highly statistically significant increase in median OS from 12.5 to 19.3 mths (HR 0.63 $p = 0.0003$). Higher grade, shorter time to metastatic disease (except if synchronous) and age $>$ 65 were associated with significantly poorer outcomes. Endometrial stromal sarcoma and low grade fibromyxoid sarcomas had the best outcomes, median OS $>$ 10 yrs. Pleomorphic sarcoma, angiosarcoma & sarcoma NOS had the worst outcomes, OS $<$ 12 mths. **Conclusions:** The median OS of 17.5 months was longer than previous estimates of circa 12 months, consistent with recent reports, and demonstrates improvement compared to the 1980's and early 1990's. However, no further improvements in OS were seen over the past 15 years, in part due to increasing numbers of elderly patients. Although subject to multiple biases, especially fitness for treatment, the substantial improvement in OS in patients receiving treatment is encouraging and may be evidence for a benefit from systemic therapy in patients with metastatic STS.

10546 Poster Session (Board #190), Sun, 8:00 AM-11:30 AM

Longer term cardiac safety of aldoxorubicin. *First Author: Sant P. Chawla, Sarcoma Oncology Center, Santa Monica, CA*

Background: Aldoxorubicin (6-maleimidocaproic acid hydrazide) is a novel prodrug of doxorubicin that binds to the thiol group of cysteine-34 amino acid in circulating albumin. The circulating albumin-drug conjugate preferentially accumulates within tumors, bypassing uptake by most normal tissues, including the heart, liver, kidneys and GI tract. Doxorubicin is released in the acidic tumor environment, either intra-or extra-cellularly, thus avoiding the cumulative toxicity that can occur with doxorubicin treatment. **Methods:** Aldoxorubicin has been investigated in clinical trials since 2011. We reviewed data on the cardiotoxicity of aldoxorubicin from 3 phase I studies and 1 phase IIb study (142 patients). Both MUGA and echocardiograms were administered at baseline then periodically thereafter (usually every 2 months) until either study withdrawal or death. All patients had normal cardiac function at baseline with LVEF $>$ 45% in some studies and 50% in others. Prior exposure up to 225 mg/m^{2}of doxorubicin was permitted. **Results:** The dose range of aldoxorubicin was 175-350 mg/m^2 administered i.v every 3 weeks (equivalent to 130-260 mg/m^2 doxorubicin per cycle). There were 126 evaluable patients who received 1-21 cycles of treatment. While 14% of patients demonstrated a $\geq$ 10% drop in LVEF, 21% had a $\geq$ increase in LVEF. No patient exhibited a decrease in LVEF that was below 50% of their institution's normal value. Where it was collected, 3.9% of patients exhibited QTc $>$ 500 msec. No patient had a clinically significant increase in troponin concentrations. Patients have received up to 5,439 mg/m^2 of doxorubicin equivalents, or 12 times the peak cumulative dose of standard doxorubicin, without any evidence of cardiotoxcity. **Conclusions:** Despite administering cumulative doses of over 1,500 mg/m^2 to the majority of the 126 evaluable patients in these clinical studies, aldoxorubicin has shown no evidence of cardiotoxicty, distinguishing it from doxorubicin itself.

Surrogate properties of survival endpoints in metastatic soft-tissue sarcoma: A meta-analysis. *First Author: Marion Savina, INSERM U897 (Cancer Axis), ISPED, Bordeaux, France*

Background: Alternative endpoints to overall survival (OS) such as progresion-free survival (PFS), time-to-progression (TTP) or time-to-treatment failure (TTF) are increasingly used to assess treatment efficacy in randomized controlled trials (RCT) to reduce inclusions and trials' duration. Their properties in terms of surrogate markers need to be assessed to ensure that they can adequately replace OS. **Methods:** We conducted a literature review to summarize by cancer type studies evaluating surrogate endpoints for OS. In the absence of data for soft-tissue sarcoma (STS), we assessed surrogate properties for OS of PFS, TTP and TTF in advanced STS. We relied on a meta-analytical framework to estimate individual-level association (association between the candidate surrogate endpoint and OS) and trial-level association (association between the treatment effects on the candidate surrogate and on OS). Statistical methods included weighted linear regression (WLR) and the two-stage method introduced by Burzykowski et al., which relies on the joint modeling of 2 survival endpoints with a copula function and a regression model. **Results:** Individual data of 2020 patients from 10 European RCTs were analyzed. We censored OS at 2 years and PFS, TTP and TTF at 1 year. Regardless of the method, the highest individual-level association was observed for PFS ($R^2 = 0.62$ IC95% [0.27; 0.76]; Kendall's tau = 0.43 IC95% [0.40; 0.46]). Even if WLR suggested that PFS had the highest trial-level association, it was not significant for any of the two methods (WLR: $R^2 = 0.44$ IC95% [0.00; 0.69]; two-stage model: $R^2 = 0.01$ IC95% [-0.46; 0.48]). **Conclusions:** Out of the 3 endpoints, PFS had the best surrogate properties. Associations with OS were however moderate and cannot validate PFS as a surrogate for OS. This could be partly explained by a lack of precision due to our small sample size in terms of patients and trials. STS are rare tumors ($<$ 2% of all cancers) which explains the low number of available trials with usually smaller sample sizes compared to other cancers. We are however collecting additional trials to improve these estimations and complementary analyses are ongoing to validate our regression models on external data.

10548 Poster Session (Board #192), Sun, 8:00 AM-11:30 AM

Cost-effectiveness analysis of preoperative versus postoperative radiotherapy in resectable extremity soft tissue sarcoma. *First Author: Melody Xuan Lu Qu, Cancer Centre of South Eastern Ontario, Kingston, ON, Canada*

Background: Preoperative and postoperative radiotherapy (RT) for extremity soft tissue sarcoma (STS) have similar recurrence and overall survival outcomes. However, side effect profiles, costs and long-term functional outcomes are different. The aim of the study was to determine the optimal sequencing of RT in these patients through decision analysis. **Methods**: A cost-effectiveness analysis was conducted using a Markov model, with quality adjusted life years (QALYs) as the primary outcome. Utility values, rates of acute and chronic complications, transition probabilities and cost data were extracted from the published literature. Overall and progression free outcomes were internally validated. One-way and two-way sensitivity analyses were performed to determine the thresholds at which each strategy would be preferred. Probabilistic sensitivity analysis was performed for complication rates and costs to assess the robustness of this model. The time horizon was 5 years with a cycle length of 3 months. QALYs and costs were discounted at a rate of 3%. **Results**: Preoperative RT is a more cost effective strategy ($9,760/QALY) when compared to postoperative RT ($11,752/QALY). Preoperative RT is the preferred strategy for all acute wound complication rates tested on one-way sensitivity analysis. Postoperative RT is the preferred strategy when chronic complications with this modality is less than 17%, or when the rate seen in preoperative RT is greater than 61%. On probabilistic sensitivity analysis, preoperative RT is the preferred strategy in 75% of cases at a willingness to pay threshold of $50,000. **Conclusions**: Our model suggests that preoperative RT is more cost-effective than postoperative RT in the management of resectable extremity STS, primarily due to the lower incidence of chronic wound complications.

10549 Poster Session (Board #193), Sun, 8:00 AM-11:30 AM

Epidemiology, treatment (tx) patterns and outcomes in Asian soft tissue sarcoma (STS) patients: Results from the Soft Tissue Sarcoma in the Asia Pacific Region (STAR) study. *First Author: Richard Hong Hui Quek, National Cancer Centre, Division of Medical Oncology, Singapore, Singapore*

Background: There is a paucity of STS epidemiology and tx pattern information in the Asia Pacific region, with published data only from small or single country studies. STAR, a large multicountry observational study, was initiated to describe epidemiology, tx patterns and clinical outcomes in STS patients (pts) diagnosed in 2006–2010 at tertiary referral centers in Hong Kong, Indonesia, the Philippines, Singapore and Thailand. **Methods:** Data were collected by retrospective chart review. Kaposi's sarcoma, gastrointestinal stromal tumor, dermatofibrosarcoma protuberans, bone sarcoma and extraskeletal osteosarcoma were excluded. Demographics, tumor characteristics and tx patterns were analyzed descriptively. Overall survival (OS) and progression free survival (PFS) were estimated by the Kaplan Meier method. **Results:** STAR included 635 adult pts, 25% of whom presented with metastatic STS. Main histological subtypes: leiomyosarcoma (19%), liposarcoma (19%), undifferentiated pleomorphic sarcoma (UPS; 18%), synovial sarcoma (9%) and angiosarcoma (7%). Of 230 pts who had chemotherapy (CTx), 32% had neoadjuvant or adjuvant CTx only and 68% had palliative CTx. In the palliative setting, most pts had 1 (57%) or 2 (27%) lines of systemic tx. Combination CTx was more common than monotherapy (54% vs 47% of regimens). The most common first line (1L) regimens were doxorubicin/ifosfamide (36%) and paclitaxel (10%). The most common 2L regimens were gemcitabine/docetaxel (29%), gemcitabine (9%) and trabectedin (9%). Median PFS (95% CI) for 1L, 2L and 3L palliative CTx were 3.8 (2.2–5.5) months, 4.0 (2.1–5.8) months and 1.9 (1.3–2.6) months, respectively. Median OS of pts who presented with metastatic STS was 11.7 (8.9–14.5) months. **Conclusions:** STAR is the first large observational study to capture STS epidemiology, tx patterns and outcomes across Asia. UPS prevalence was similar to published data, suggesting acceptable pathologic quality, while angiosarcoma prevalence appeared slightly higher than in Western studies. During this period, most CTx regimens were combinations and palliative CTx beyond 2L was uncommon. Funding: GlaxoSmithKline.

10550 Poster Session (Board #194), Sun, 8:00 AM-11:30 AM

Targeted next generation sequencing in well-differentated/dedifferentiated liposarcoma (WD/DD LPS): Multiple gene amplifications but few mutations. *First Author: Neeta Somaiah, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: WD/DD LPS is a common soft tissue sarcoma with approximately 1500 new cases per year. Surgery is the mainstay of treatment but recurrences are frequent and limited systemic options make treatment challenging. 'Tumor genotyping' is becoming more common in clinical practice as it offers the hope of personalized targeted therapy. We wanted to evaluate the results and the clinical utility of available tumor genotyping panels in WD/DD LPS. **Methods:** MDACC patients (pt) who had their tumor analyzed by either Foundation One (FM) (244 gene panel for solid tumors, tumor only) or the institutional T200 panel (202 gene panel, tumor and normal) were included. There were 124 overlapping genes in these panels. FFPE sections were sequenced on the T200 panel using the Illumina HiSeq2000 platform. On average, the cutoff for calling variants on the T200 is 1%-5% for high coverage data (> 500x) and 10-15% for lower coverage(< 200x). **Results:** Total of 20 pt samples were identified, 7 on T200 (1 WD+6 DD) and 13 on FM (5 WD+8 DD). Significant copy number alterations (CNA) were identified in all samples. Only recurrent, potentially clinically actionable CNA (out of the 166 identified) are tabulated below. In the 7 pt samples on T200, 27 mutations were detected: 8 genes (*CTNNB1, MECOM, ZNF536, EGFR, EML4, CSMD3, PBRM1, PPP1R3A*) were identified as deleterious (on Condel, PolyPhen and SIFT) and a truncating mutation was found in *NF2*. Of these only the *EGFR* and *NF2* are known driver mutations and potentially actionable. These mutations have not been reported previously in DD LPS. On the FM panel, *ZNF536, CSMD3 and PPP1R3A*were not evaluated (NE) and no mutations were reported. **Conclusions:** In this series, 20/20 (100%) of the WD/DD LPS had *MDM2* and *CDK4*amplified. Additional recurrent novel deleterious genetic changes were identified, but further studies are needed to determine their therapeutic and pathogenetic significance.

10551 Poster Session (Board #195), Sun, 8:00 AM-11:30 AM

A retrospective analysis of patients with soft tissue sarcoma treated long-term with trabectedin. *First Author: Elizabeth J. Davis, University of Michigan, Ann Arbor, MI*

Background: Treating STS with systemic therapy beyond six months is challenging due to cumulative toxicity. Trabectedin (T) has demonstrated efficacy and tolerability in STS and became available in 2005 through an expanded access program (EAP). Results of the EAP noted better overall survival and response rates in patients (pts) with leiomyosarcoma (LMS) and liposarcoma (LPS) compared to other histologies. Multiple cycles of T were tolerable with 30% of pts receiving ≥ 6 cycles and 7% of pts receiving ≥ 1 year of therapy, but descriptions of pts receiving T beyond one year are limited. **Methods:** We performed a retrospective analysis of pts with STS at the University of Michigan and M.D. Anderson Cancer Center who received long-term (≥ 10 cycles) T. We further subdivided pts into those treated for more than one year (≥ 18 cycles) and two years (≥ 35 cycles). Variables evaluated included age, gender, histology, site of primary tumor, number of prior treatments, number of dose reductions, and reason for discontinuation of T. **Results:** Four hundred and twenty-two pts treated with T were identified. Sixty-two pts (15%) received ≥ 10 cycles; 95% of these pts were treated on the EAP. Twenty-two pts (5%) were treated for ≥ 1 year and seven pts (2%) for ≥ 2 years. All pts treated for ≥ 1 year had LMS or LPS. Five pts (23%) treated for ≥ 1 year did not require a dose reduction. The primary reason for discontinuation of T was sarcoma progression. **Conclusions:** Trabectedin is a tolerable long-term therapy for a subset of pts with STS. Pts with LMS and LPS may derive the most benefit from long-term treatment, but further study is needed in a larger number of pts. Clinically relevant toxicities leading to T discontinuation beyond 1 year were fatigue and myelosuppression.

Multimodal treatment of pulmonary artery sarcoma: A single center experience. *First Author: Simona Secondino, Medical Oncology, Fondazione IRCCS PoliClinico San Matteo, Pavia, Italy*

Background: Pulmonary artery sarcoma (PAS) is a rare disease arising from the endothelial cells of the pulmonary artery wall, generally presenting with pulmonary hypertension (PI). The therapeutic approach, mainly based on surgery, either pneumonectomy or pulmonary endarterectomy (PEA), depends on the extension of the disease and the patient's clinical condition. The prognosis is extremely poor as survival rarely exceeds 1 year from diagnosis. **Methods:** From October 2010 to December 2014, 8 patients (pts) referred to our Institution for symptoms of acute or chronic pulmonary thromboembolic disease were diagnosed to have PAS. Five pts had PI, one with severe hemodynamic instability requiring emergency surgical treatment. Median age was 64 years (range 32-77), 5 pts were female. In 6 pts the disease was bilateral, and 3 had lung metastases. **Results:** All pts underwent PEA, none having life threatening complications from surgery. Pathology showed 4 high grade and 4 intermediate grade sarcomas. Following PEA and a short course of cardiopulmonary rehabilitation, 7 pts were able to received conventional chemotherapy (CT) with doxorubicin and ifosfamide, starting a median of 42 days (range 22-69) from surgery. Two pts also received radiotherapy after completion of the CT program. Four pts have died for disease progression at 6, 6, 8, and 26 months from surgery while 4 are alive, three being disease free at 8, 15, and 40 months. **Conclusions:** In pts with PAS a multimodal approach including PEA, CT and radiotherapy is feasible. Other than improving quality of life, it appears to considerably extend life expectancy.

10553 Poster Session (Board #197), Sun, 8:00 AM-11:30 AM

Metastatic dermatofibrosarcoma protuberans (DFSP) and fibrosarcomatous DFSP (FS-DFSP): Sensitivity to imatinib (IM) and gene expression profile. *First Author: Silvia Stacchiotti, Istituto Nazionale Tumori, Milan, Italy*

Background: We report on IM activity in patients (pts) with metastatic DFSP/FS-DFSP and on the gene expression profile (GEP) analysis of pure DFSP versus FS-DFSP, aimed at identifying prognostic markers **Methods:** All pts treated with IM at our institution from 2007 to 2014 for metastatic DFSP/FS-DFSP were selected. To estimate the PFS, pts progressing after IM discontinuation who responded after restarting IM were considered PD at the time of definitive PD on IM. Path and cytogenetics of the primary lesion and metastases were compared. We performed RNA Sequencing of 5 DFSP and 5 FS-DFSP (3 metastatic) on HiScanSQ platform. In 2 pts the analysis was done on samples taken before and after IM. GEP analysis was done with Python function htseq-count, differential expression with Bioconductor package edgeR, hierarchical clustering and Principal Component Analysis (PCA) with Multiple Array Viewer. SNV, Ins/del, fusion transcript analyses are ongoing **Results:** 10 pts were identified, all evaluable for response. All showed a FS component in the metastatic tumor, 7/10 in the primary lesion. COL1A1-PDGFb was detected in all cases. Best RECIST response was: 8 PR, 1 SD, 1 PD. 5 pts received complete surgery after IM (4 while under response, 1 after PD) with evidence of path response in 4 (with aspects depending on surgical timing, affecting tumor cells and pericytes). All pts relapsed. IM was restored in 4 pts with a new response. Median PFS was 11 mos (range 2-14+). By PCA all DFSP displayed a unique GEP, clearly different from FS-DFSP. At the supervised analysis, FS-DFSP were marked by over-expression of potential biomarkers such as MCAM and TGM2 (involved in metastatic process and chemoresistance). Many genes were upregulated in pure DFSP, reflecting the enrichment in neural markers and cell adhesion molecules **Conclusions:** All metastatic cases were FS-DFSP. Most pts responded to IM but PFS was shorter than reported in series including all DFSP. All pts who were operated after IM relapsed, suggesting that IM cannot eradicate metastatic DFSP/FS-DFSP and the role of surgery is limited. Restart IM after surgery, as done in GIST, is to be evaluated. DFSP and FS-DFSP presented a clearly different GEP

10554 Poster Session (Board #198), Sun, 8:00 AM-11:30 AM

Natural history and outcome in a large series of primary dermatofibrosarcoma protuberans (DFSP) treated at a reference institution. *First Author: Andrea Pierluigi Fontana, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: DFSP is a rare sarcoma, characterized by an indolent course, although local recurrences (LR) and occasional distant metastases (DM) are described. We sought to investigate its natural history and prognostic factors in a large series of patients (pts). **Methods**: All consecutive pts affected by primary DFSP, located at any sites, treated at Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, from January 1993 to December 2012, were retrospectively reviewed. Overall Survival (OS), surgical margins status, LR and DM were analyzed. **Results**: 270 pts were identified, 246 (91.1%) affected by classic (C)-DFSP and 24 (8.9%) by fibrosarcomatous (FS)-DFSP. All pts are alive at a median follow-up (FU) of 6 yrs (range 1-15), save for two of them, dead for other diseases. All pts underwent macroscopic complete surgery. Microscopic margins were negative in 247 cases (91.5%), positive (PM) in 23 (8.5%). Overall, LR occurred in 4 pts (1.5%), 2/21 C-DFSP with PM, 2/2 FS-DFSP with PM, respectively. 3 of the LR were located to the scalp, 1 in the groin. A wider resection was repeated on 3 pts, who are disease-free (DF) after 2, 4 and 8 yrs, respectively. One pt refused surgery, her disease is under control with imatinib (IM) after 3 yrs. DM occurred in 3 pts (1.1% of the whole series; 12.5% of FS-DFSP), all affected by FS-DFSP (2 lung and 1 pancreatic metastases). 2 pts were treated with a lung wedge resection. One was DF after 78 mos, the other recurred again after 14 mos and was further treated with a combination of IM and a second surgery. He is still on IM and DF after 6 mos. The last metastatic pts is also on IM and progression-free after 4 mos. **Conclusions**: Negative margin resection is always curative for C-DFSP, as the observed metastatic risk is nil. PM may be accepted, when cosmesis is an issue, because LR risk remains low and salvaged by a subsequent wider resection. FS-DFSP has a more aggressive course, LR being highly predictable by PM and DM occurring in as many as 12.5% of pts. This should be used to inform treatment decision for the two DFSP variants.

	pts	PM	LR	LR/PM	DM
C-DFSP	246	21 (8.5%)	2 (0.8%)	2/21 (9.5%)	0 (0%)
FS-DFSP	24	2 (8.3%)	2 (8.3%)	2/2 (100%)	3 (12.5%)
Total	270	23 (8.5%)	4 (1.5%)	4/23 (17.4%)	3 (1.1%)

10555 Poster Session (Board #199), Sun, 8:00 AM-11:30 AM

The lipogenic phenotype reprograms the epigenome in sarcomas. *First Author: Warren Allen Chow, City of Hope, Duarte, CA*

Background: The "lipogenic phenotype of cancer" enhances the metastatic potential of cancers by promoting the *de novo* synthesis of fatty acids (FAs) to maintain their enhanced metabolism. Further, epigenetic reprogramming also promotes the malignant sarcoma phenotype. We hypothesized that development of the "lipogenic phenotype" reprograms the sarcoma epigenome to enhance their malignant potential. **Methods:** Soft-tissue (STS) and bone sarcoma cell lines (SK-UT-1 leiomyosarcoma, HT1080 fibrosarcoma, and Saos-2 osteosarcoma) were transduced with a fatty acid synthase (FASN)-expressing retrovirus. FASN catalyzes the synthesis of long-chain FAs from acetyl-CoA. Acetyl-CoA is generated from pyruvate, the excess end-product of aerobic glycolysis, better recognized as the "Warburg effect." FASN-expressing clones were subjected to proliferation, migration, and immunoblot assays. Transcriptome-wide sequencing and DNA methylation arrays were also performed. Finally, FASN expression was detected in STS clinical specimens by immunohistochemistry (IHC). **Results:** FASN overexpression increased sarcoma proliferation (35-47%), enhanced migration (scratch-wound assay), and increased methylation and acetylation of selected histone 3 lysines (H3K9me3 and H3K27ac). Whole transcriptome sequencing demonstrated multiple up- and downregulated genes, which generally correlated with the methylation status of their respective promoters. Finally, FASN expression was detected 1-3+ by IHC in 14/18 STS tumors by a blinded pathologist. **Conclusions:** FASN overexpression induces histone modifications that repress and induce genes that may enhance the malignant phenotype in sarcoma cell lines. Further, FASN is variably expressed in a majority of STS. Therapeutic targeting of FASN and epigenetic reprogramming may be a novel therapeutic approach to recurrent sarcomas.

10556 Poster Session (Board #200), Sun, 8:00 AM-11:30 AM

Primary high-grade myxofibrosarcoma/pleomorphic malignant fibrous histiocytoma: Percent myxoid component to improve outcome prediction. *First Author: Ann Yeelin Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Myxofibrosarcoma and pleomorphic malignant fibrous histiocytoma (PMFH) are aggressive genetically complex sarcomas. We investigated the association of percent myxoid component (MC) with disease-specific (DSS) and distant recurrence-free survival (DRFS) in primary high-grade myxofibrosarcoma and PMFH and determined the optimal %MC cutpoints for defining subgroups. **Methods:** Review of a prospective database identified 200 patients with primary, high-grade extremity/truncal myxofibrosarcoma or PMFH treated during 1992-2013. Histology was reviewed and %MC determined for each case. Optimal %MC cutpoints were determined from minimum p-value analysis of the entire cohort. DSS and DRFS were analyzed using the Kaplan-Meier method, log-rank test and Cox regression. **Results:** Median follow-up for survivors was 5.8 years. Median tumor size was 9.5 cm (range 2.5-30 cm). The optimal %MC cutpoints for both DSS and DRFS were 5% and 70%. Sarcomas with $\geq$ 5% MC were classified as myxofibrosarcoma (n = 128) and $<$ 5% MC (n = 72) as PMFH. The 5-year DRFS was 64% for $>$ 70% MC myxofibrosarcoma, 49% for 5-70% MC myxofibrosarcoma, and 23% for PMFH. %MC, tumor size, and age were independently associated with DSS, while %MC and size were associated with DRFS (Table). **Conclusions:** Percent MC is an important predictor of DSS and DRFS in primary high-grade myxofibrosarcoma and PMFH. Histology-based classification of %MC improves stratification of patient outcome and will aid in selection of patients for systemic therapy and clinical trials.

Multivariate analysis of clinical and pathological variables associated with DSS and DRFS.

Variable	DSS: Multivariate HR (95% CI)	DSS: *p* value	DRFS: Multivariate HR (95% CI)	DRFS: *p* value
MC 5-70% (vs > 70%)	1.6 (0.9-3.0)	0.11	1.9 (1.1-3.3)	0.03
MC < 5% (vs > 70%)	2.8 (1.7-4.8)	<0.001	3.6 (2.2-6.0)	<0.001
Size (> = 8 cm vs < 8 cm)	2.5 (1.5-4.0)	<0.001	2.3 (1.5-3.6)	<0.001
Age (> = 65 years vs < 65 years)	1.6 (1.0-2.5)	0.03		

10557 Poster Session (Board #201), Sun, 8:00 AM-11:30 AM

Postoperative morbidity and mortality in a large series of primary retroperitoneal sarcoma (RPS) treated at 8 tertiary centers: A study from the Transatlantic RPS Working Group. *First Author: Dirk C Strauss, The Royal Marsden Hospital, London, United Kingdom*

Background: To explore postoperative morbidity and mortality of patients (pts) with primary retroperitoneal sarcoma (RPS) undergoing surgery at 8 high volume centers (the Transatlantic RPS working group). **Methods:** All consecutive pts with primary RPS treated at 2 North American and 6 European centers between 2002 and 2011 were included in a retrospective analysis. Postoperative adverse events according to Common Terminology Criteria for Adverse Events (CTCAE) and mortality at 30, 60 and 90 days were analyzed. Overall survival (OS), local recurrence (LR) and distant metastasis (DM) calculated. Multivariate analysis performed exploring risk factors for postoperative complications considering age, size, number and type of resected organs, preoperative chemotherapy and radiotherapy. **Results:** Total of 1007 pts were included in the database. Median follow-up was 58 months (range 36-90mo). Five and 10yr OS, LR and DM were 67% and 46%, 26% and 35%, 21% and 22% respectively. Postoperative complications of CTCAE grade $\geq$ 3 were observed in 207 pts (21%); grade 3 complications in 128 pts (12.7%), grade 4 in 52 pts (5.2%) and grade 5 for 19 pts (1.9%). The postoperative complication rate varied from 14.4 to 37.0% among centers. The re-operation rate was 10.5%. Most common complications were postoperative bleeding/hematoma (3.0%), bowel anastomotic leak/fistula (2.6%) and bowel obstruction/ileus (2.3%). The 30, 60 and 90-day mortality rate were 1.8 (95% CI 1-2.6), 2.9 (95% CI 1.8-3.9) and 4.1% (95% CI 2.9-5.3) respectively. In multivariable analysis, the occurrence of a postoperative complication was significantly associated with worst OS (HR 1.54, 95% CI 1.08-2.19, p = 0.016) and higher LR rate (HR 1.59, 95% CI 1.09-2.30, p = 0.015) while it was not significantly associated with a worst DM rate (HR 1.33, 95% CI 0.90-1.98, p = 0.153). **Conclusions:** Data about short-term morbidity are consistent with previous studies on RPS and comparable to those other major abdominal cancer surgery. The balance between the expected morbidity and the possible improvement in oncologic outcome should be factored in the management algorithm and tailored to the patient.

10558 Poster Session (Board #202), Sun, 8:00 AM-11:30 AM

Validation of the Royal Marsden Hospital (RMH) prognostic score in 100 patients with advanced sarcoma enrolled in early phase clinical trials at a major cancer center. *First Author: Michael Wagner, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Standard therapy refractory, metastatic and advanced sarcoma patients (pts) have few therapeutic options, and may benefit from enrollment in early stage clinical trials. The Royal Marsden Hospital (RMH) score predicts survival in pts prior to enrollment in Phase I clinical trials. We sought to validate the RMH score as a predictive marker in this population, and to assess if the presence of chromosomal translocations would predict benefit in Phase I clinical trials with targeted agents. **Methods:** Data from medical records of pts referred for enrollment in predominantly VEGF/VEGFR/mTOR inhibitor based Phase I clinical trials at M.D. Anderson Cancer Center were systematically reviewed. Pts were stratified according to RMH score (albumin, LDH, and number of metastatic sites), and the presence or absence of chromosomal translocations. **Results:** Among the 100 sarcoma pts [soft tissue (STS) (n = 79); bone (n = 21)] analyzed, the median age at trial enrollment was 48 (range 14-80). 46 pts (46%) were male. 26 pts (26%) had identifiable chromosomal translocations (17 with EWSR1 rearrangements). Clinical trial enrollment included 31 pts on VEGF agent alone, 16 pts on mTOR inhibitor alone, 13 pts on VEGF+mTOR, 11 pts on VEGF+chemotherapy, 6 pts on VEGF+mTOR+chemotherapy and 23 pts on other targeted agents. Median OS of pts with an RMH score of 0, 1, or 2 or greater was 18.9 mos, 7.5 mos, and 4.0 mos, respectively [HR 2.1 (1.5, 2.9) p $<$ 0.0001]. Median PFS in pts with a translocation was 3.8 mos, and without was 3.5 mos [HR 0.97 (0.60, 1.57), p = 0.89]. Median OS in pts with translocation was 9.5 mos and without was 10.1 mos [HR 1.19 (0.74-1.94), p = 0.48]. Median PFS in STS pts was 4.2 mos (2.8-6.3), and bone sarcoma pts was 2.8 mos (2.0-7.6). Median OS in STS pts was 10.2 mos (95%CI: 8.4-15), and in bone sarcoma pts 7.8 mos (95%CI: 6.5-29). Clinical benefit rate (CR+PR+SD $>$ 6 mos) across all Phase I trials was 35 % (4 PR+ 31 SD $>$ 6 mos). **Conclusions:** RMH score is a significant predictor of overall survival in metastatic sarcoma pts treated on Phase I therapies. The presence of a chromosomal translocation had no effect on outcomes on sarcoma pts enrolled in Phase I trials.

10559 Poster Session (Board #203), Sun, 8:00 AM-11:30 AM

The benefit of adjuvant radiotherapy in high-grade retroperitoneal sarcoma: A SEER analysis. *First Author: James Edward Bates, University of Rochester Medical Center, Rochester, NY*

Background: There is significant controversy surrounding the use of adjuvant radiotherapy (RT) in patients with retroperitoneal sarcoma (RPS). Grade is a prognostic factor in RPS and high-grade disease is associated with decreased local control (LC) and overall survival (OS). Adjuvant RT has been demonstrated to improve LC but not OS. In extremity sarcomas, recent evidence suggests that the benefit of RT is most significant for high-grade sarcomas. We hypothesized that any benefit in OS for RPS would most likely exist in those with high-grade tumors. **Methods**: The Surveillance, Epidemiology, and End Results (SEER) database was used to identify patients with pathology-confirmed retroperitoneal soft tissue sarcoma from 1973 to 2010. Clinical characteristics and outcomes were investigated via Kaplan-Meier and Cox proportional hazards analyses. OS was defined as time to death or last follow-up. **Results**: A total of 483 patients with RPS were identified; 144 (29.8%) of who received postoperative radiation, the rest received surgery alone. Patients who received adjuvant RT had improved median OS (36 mo) compared to those who did not (27 mo, HR = 0.79, p = 0.023). On multivariate analysis the use of adjuvant RT (HR = 0.80, 95% CI: 0.65 – 0.97, p = 0.025), male gender (HR = 1.33, 95% CI: 1.10 – 1.60, p = 0.003), patient age greater than 65 years (HR = 1.34, 95% CI: 1.11 – 1.62, p = 0.002), and increasing SEER historical stage (HR = 1.45, 95% CI: 1.21 – 1.75, p $<$ 0.001) were all statistically significant prognostic factors for OS. **Conclusions**: In a retrospective analysis of a large national cancer database, post-operative RT improved OS in high-grade RPS patients. As such, adjuvant RT should be strongly considered in all patients with high-grade RPS. The current standard of care is to administer radiation prior to surgery in order to minimize potential radiation morbidities. A multi-national EORTC study is currently accruing patients to validate this approach in a prospective manner.

10560 Poster Session (Board #204), Sun, 8:00 AM-11:30 AM

A phase II study of temsirolimus and liposomal doxorubicin for patients with recurrent and refractory bone and soft tissue sarcomas. *First Author: Christian Frederick Meyer, Johns Hopkins Hosp, Baltimore, MD*

Background: Sarcomas are a heterogeneous group of connective tissue malignancies with limited palliative treatment options in the unresectable, metastatic setting. Standard chemotherapy treatment offers progression free survival (PFS) benefit measured in months while a significant impact from targeted therapy has not yet been realized. We conducted a phase I/II study of liposomal doxorubicin with temsirolimus in soft tissue and bone sarcomas based on preclinical data showing synergy against sarcoma stem cells. . We previously reported the phase I dose finding data. Here, we report the results of patients treated at the recommended phase II dose. **Methods:** 18 patients were treated at liposomal doxorubicin 30 mg/m^2 monthly with temsirolimus 20 mg/m^{2}weekly. A variety of subtypes were enrolled including 5 rhabdomyosarcomas, 3 leiomyosarcomas, and 2 mesenchymal chondrosarcomas. 11 of the 18 patients had prior doxorubicin exposure and a median of 2 prior lines of chemotherapy. **Results:** PFS was 315 days (range 27-799) and event free survival (EFS) was 119 days. Response rate, defined as stable disease (SD) or better for 60 days (2 cycles) was 53% (8 of 15) at the recommended phase II dosing (RP2D) and 56% (10 of 18) including the subjects treated with the higher dose of temsirolimus. Those who responded to therapy (defined as SD or better at first evaluation) tended to have prolonged responses, with median PFS for this group of 358 days (range = 75 – 799) and median EFS of 249 days. Pharmacodynamic analysis of target inhibition in 12 evaluable patients revealed concordance between inhibition of pS6K and response in 8 patients and inhibition of pAKT and response in 9 patients. The treatment was well-tolerated with only 4 patients experiencing a significant change in their ECOG performance status. **Conclusions:** Overall, the synergy of this combination bears further investigation of both metabolic and traditional chemotherapeutic agents in sarcomas. Clinical trial information: NCT00949325.

10561 Poster Session (Board #205), Sun, 8:00 AM-11:30 AM

Imatinib mesylate (IM) activity in patients (pts) with locally advanced tenosynovial giant cell tumor/pigmented villonodular synovitis (TGCT). *First Author: Philippe Alexandre Cassier, Centre Léon Bérard, Department of Medicine, Lyon, France*

Background: TGCT is a rare disease affecting the synovium and tendon sheaths of young adults. This usually benign neoplasm is driven by overexpression of CSF1, in some cases as a result of fusion of the CSF1 gene to the COL6A3 promoter in the t(1;2) translocation. The bulk of the tumor is made of CSF1 receptor (CSF1R) expressing cells. We previously reported on the activity of IM in this disease, here we present updated results. **Methods:** This is a multi-institutional retrospective study to assess the activity of IM in locally advanced/metastatic TGCT. **Results:** Forty-nine pts from 10 centers from Europe, Australia and the US were included. There were 31 females, median age was 38 (range 13-76) at diagnosis and 47 (range 21-80) at the time IM was started. The knee (n = 27; 55%), ankle (n = 9; 18%) and hip (n = 5; 10%) were the most common sites of disease. Most pts had locally advanced disease and/or local relapse (n = 47) and 2 pts had metastatic disease (lung and bone). The median number operations before IM was 2 (range 0-9), and only 4 patients never had surgery prior to IM. All but one pts were treated with IM 400 mg/day. Median follow-up was 18 (range 3-78) months and all pts were evaluable for response: 2 pt (4%) had a CR, 8 (16%) had a PR (ORR 20%) and 69 (37%) had SD. The two pts with metastatic disease had no response to imatinib. Ten patients were operated after a median of 6 (range 1-10) months of IM. Forty patients had symptoms at baseline of which 31 had symptom improvement on IM. The median progression-free survival was not reached. In 11 patients who had symptom improvement and stopped IM before PD, symptom control persisted beyond IM interruption (mean 27 months, median not reached). The most common side effects were grade 1 or 2 fatigue and edema, both seen in 19 (38%) pts, followed by nausea and skin toxicity reported in 8 (16%) and 5 (10%) pts respectively. Five patients had grade 3-4 events and overall, 7 patients (14%) discontinued treatment because of poor tolerance. **Conclusions:** These data confirm the value of IM in patients with advanced symptomatic TGCT, in some patients symptom control may persist beyond IM interruption.

10562 Poster Session (Board #206), Sun, 8:00 AM-11:30 AM

Sunitinib malate in advanced alveolar soft part sarcoma (ASPS): A final update after the closure of the named use program. *First Author: Nadia Hindi, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background:We already reported on the activity of sunitinib (SM) in 9 patients (pts) of ASPS. This series is an update. In addition, based on recent evidence demonstrating a role for lactate metabolism in ASPS pathogenesis, we explored the role of MCT1 and MCT4 lactate transporters in SM response **Methods**: From July 2007 to September 2013, 16 pts with progressive, advanced ASPS (M/F: 10/6; median age: 28 yrs; site of primary: extremities 14, other 2; site of metastases: lung 15, brain 4, bone 3; pretreated with chemotherapy: 10) were put on continuous SM 37.5 mg/day, on a named-use program. Response was evaluated at 2 mos from baseline, then every 3 mos by CT and/or MRI, by RECIST. The expression of MCT1 and MCT4 was analyzed by qRT-PCR in 8 of these cases (7 responders, 1 non-responder) **Results**:All pts are evaluable for response. 14 pts stopped SM: 9 for PD observed while receiving SM 37.5, 4 for PD observed while receiving SM at a low dose (25 or 12.5 mg/day; SM had to be definitively reduced due to leukopenia and/or renal failure), 1 for definitive surgery. Best response was 1 CR, 9 PR, 4 SD, 2 PD. Median OS has not yet been reached, with 6 pts dead at the time of the present analysis. At a median FU of 32 mos (range 7-75), the median PFS was 13 mos (range 2-59), 9 pts being disease-free at > 12mos. One pt underwent complete surgery plus RT after 6 mos of SM; she is progression-free at 19 mos. Four pts progressed to the CNS, being stable to all other sites of disease, and underwent radiotherapy (RT) of brain lesions; 2 of them continued on SM with no further evidence of progression after 18 and 22mos (these pts were considered PD at the time of CNS progression). Two pts who had to stop SM for progression occurring after reducing SM due to toxicity responded to the rechallenge of SM after having been treated with a MET inhibitor; they are still on SM and progression-free at 5 and 2mos, respectively. The role of MCT genes in response to SM is currently assessed **Conclusions**:SM is confirmed to be active in ASPS, with long-lasting, dimensional responses. Near 70% of pts maintained responses for > 6mos. Almost 30% of progressions were isolated to CNS. Re-challenge with SM could be an option in previously responding pts who had to stop their therapy due to toxicity

10563 Poster Session (Board #207), Sun, 8:00 AM-11:30 AM

Phase II trial of PF-03084014 in adults with desmoid tumors/aggressive fibromatosis. *First Author: Shivaani Kummar, Phase I Clinical Research Program Stanford University School of Medicine, Stanford, CA*

Background: Desmoids are rare, invasive, slow growing soft tissue tumors that are sporadic or associated with familial genetic syndromes, such as familial adenomatous polyposis. Desmoids are characterized by stabilization and abnormal nuclear localization of β-catenin. Mutations in the *CTNNB1* gene are found in 85-90% of desmoids. Gamma-secretase cleaves intracellular Notch resulting in Notch signaling. PF-030844014 (PF) is an oral reversible γ-secretase inhibitor (GSI) that is well tolerated. Based on encouraging data from a phase I trial, we conducted a phase II study of PF in patients (pts) with symptomatic desmoid tumors progressing following at least one line of therapy. Objectives: determine the response rate (RR); assess symptom measures and perform genotyping for germline/somatic mutations in *APC* and *CTNNB1* genes. **Methods:** PF was administered orally at 150mg BID; for 21 day cycles. Archival samples were sequenced for germline and somatic mutations in *APC* and *CTNNB1*genes. Dynamic contrast-enhanced MRI (DCE-MRI) was obtained at baseline and restaging. Single stage; 90% power to rule out unacceptably low RR of 10% in favor of 35% RR. The validated MD Anderson Symptom Inventory (MDASI) was used to assess symptoms. **Results:** Accrual completed. 13/17 pts (76.4%) remain on study; 4 pts stopped treatment by choice/co-morbid conditions. No pt has progressed to date. Median follow-up time is 10 months (range 2-14), 6 pts remain on study ≥ 1year. Grade 3 toxicities include hypophosphatemia (3 pts, 17.6%) and diarrhea (1 pt, 5.8%). Dose reduction to 100mg BID daily occurred in 2 pts. 16 pts (94%) have stable disease with 1 (5.8%) unconfirmed PR. In 15/17 pts (88.2%), a somatic or germ line mutation was identified. DCE-MRI and symptom scale analysis ongoing. **Conclusions:** PF is active at the selected dose, with a manageable side effect profile. Copy number analysis, transcriptome sequencing and DNA methylation analysis of archival samples as well as 2 paired biopsies obtained on study is ongoing. Clinical trial information: NCT01981551.

10564 Poster Session (Board #208), Sun, 8:00 AM-11:30 AM

A phase I trial of the human double minute 2 (HDM2) inhibitor MK-8242 in patients (pts) with advanced solid tumors. *First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA*

Background: HDM2 binds and inhibits wild-type (WT) p53 thereby promoting oncogenesis. MK-8242 is a potent, orally bio-available, small-molecule inhibitor of the HDM2:p53 protein-protein interaction under development as a novel cancer therapy. **Methods:** A multi-center, 2-part (dose escalation/Part I and confirmation/Part 2; using modified TPI design) Phase I study of MK-8242, administered p.o. BID on days 1-7 in 21 day cycles, was performed to determine the safety, tolerability, and recommended Phase 2 dose (RP2D) in pts with advanced solid tumors with WT p53. RP2D was based on tolerability, plasma pharmacokinetics (PK), and pharmacodynamics (PD) in tumor/blood, including expression of the p53 target PHLDA3. Other objectives were characterizing PK/PD relationship, correlation of biomarkers with response, and assessment of tumor response (RECIST v1.1). **Results:** 47 pts received MK-8242 across 8 dose levels ranging from 60 mg to 500 mg. Initially, 6 pts developed DLTs (G2 nausea at 120 mg; G3 fatigue at 250 mg; G2 nausea and G4 thrombocytopenia at 350 mg; G3 vomiting and G3 diarrhea at 500 mg). DLT criteria were revised to permit management of GI toxicity, and 4 additional DLTs were observed (G4 neutropenia and G4 thrombocytopenia at 400 mg; G4 thrombocytopenia [2 pts] at 500 mg). Other drug-related G3-4 events included anemia, leukopenia, pancytopenia, nausea, hyperbilirubinemia, hypophosphatemia, and anorexia. The RP2D was established at 400 mg as tolerability (i.e., 2 DLTs in 14 evaluable pts), PK, and PD targets were achieved at this dose level. Plasma PK analysis of 400 mg on Day 7 found $AUC_{0\text{-}12hr}$ of 16.7 μM*hr, C_{max} 3.1 μM, T_{max} 2-6 hr, and $T_{1/2}$ 6.5 hr. Blood concentration of PHLDA3 correlated with drug exposure ($R2 = 0.69$, $p < .0010$). In 41 pts who had post-baseline scans, 31 showed SD, 2 achieved PR (both with liposarcoma [LPS], at 250 mg and 400 mg), 8 had PD. 7 pts with LPS remain on study. In total, 27 pts had LPS and their median time-to-progression was > 300 days. **Conclusions:** At the RP2D of 400 mg BID, MK-8242 activates the p53 pathway with an acceptable tolerability profile. Preliminary evidence of clinical activity with PR and prolonged PFS was seen providing impetus for further study of HDM2 inhibitors in LPS pts. Clinical trial information: NCT01463696.

10565 Poster Session (Board #209), Sun, 8:00 AM-11:30 AM

Clinical pattern and implication of PD-L1 expression in soft-tissue sarcoma. *First Author: Chan Kim, Yonsei Cancer Center, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: PD-1/PD-L1 axis plays a paramount role in tumor immune escape by negative regulation of T-cell functions. Recently, immune checkpoint inhibitors targeting this axis displayed promising anti-tumor activity with durable response, and the predictive role of PD-L1 expression is being investigated in various solid tumors. In the present study, we aimed to characterize the PD-L1 expression pattern and its clinical implication in soft-tissue sarcomas (STS). **Methods:** We analyzed PD-L1 expression in 82 STS patients with 5 subtypes including rhabdomyosarcoma (n = 32), synovial sarcoma (n = 19), Ewing sarcoma (n = 18), epithelioid sarcoma (n = 7), and mesenchymal chondromsarcoma (n = 6). PD-L1 expression was evaluated using anti-PD-L1 antibody (clone 130021, R&D System), and PD-L1 positivity was defined as more than 10% of PD-L1 staining in tumor cells. PD-L1 expression was compared with other clinicopathologic variables. **Results:** Median age at diagnosis of patient cohort was 26 (range: 1-78) and male-to-female ratio was 1.6. Initial disease presentation was locoregional disease in 80% of patients and metastatic disease in the remaining 20%. PD-L1 expression was identified in 43% of STS patients. Histologic subtype of STS was significantly associated with PD-L1 expression ($p = 0.004$). Proportion of PD-L1 expressing tumors was highest in epithelioid sarcoma (100%, 7/7), followed by synovial sarcoma (53%, 10/19), rhabdomyosarcoma (38%, 12/32), and Ewing sarcoma (33%, 6/18), while it was not expressed in mesenchymal chondrosarcoma (0%, 0/6). Baseline clinical characteristics other than histologic subtype was not correlated with PD-L1 expression. Patients with PD-L1 expression had worse overall survival compared with those without PD-L1 expression (5-year survival rate: 48% in PD-L1 positive vs. 68% in PD-L1 negative, $p = 0.015$). Moreover, this negative prognostic role of PD-L1 expression in STS was also confirmed by multivariate analysis with Cox regression model (HR: 2.67, $p = 0.017$). **Conclusions:** PD-L1 is not only expressed in STS but also stand as an independent negative prognostic factor for overall survival of STS patients. Thus, PD-L1 needs to be pursued as a potential therapeutic target in patients with STS.

10566 Poster Session (Board #210), Sun, 8:00 AM-11:30 AM

Time to secondary resistance (TTSR) after rechallenge with trabectedin (T) in myxoid round cell liposarcoma (MRCLPS) patients. *First Author: Roberta Sanfilippo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, Milan, Italy*

Background: To explore the time to secondary resistance after rechallenge with T in MRCLPS patients who were responding to T at the time of discontinuation. **Methods:** Since September 2002, 62 patients with recurrent myxoid liposarcoma received T at our institution. According to RECIST, 2/62 patients had a complete response (CR), 34/62 a partial response (PR) (CR+PR = 58%), 18/62 (29%) a stable disease (SD) and 8/62 (13%) a progression disease (PD). Median PFS was 14 months. Among the 54/62 patients who obtained a stable disease or a partial response after the first assessment, 28/54 interrupted treatment in absence of progression, while 26/54 patients received T until progression disease. Time to secondary resistance was defined as time from the first cycle of T to progression, whenever it occurs (including under T reintroduction). **Results:** In the 28 pts in whom Trabectedin was interrupted (11 for surgery of the residual disease, 1 for radiotherapy , 3 for toxicity and 13 for shared decision with clinician) , this was done after a median of 14 cycles (range = 6-21) and the median PFS was 24 months. 17 of them resumed treatment at the time of progression (F = 8, M = 9, median age = 51, range = 32-76). After rechallange, no PD was seen at first assessment, and time to secondary resistance was 48 months. In the 26 pts who went on with T until progression, PFS (i.e., time to secondary resistance) was 11 months. **Conclusions:** Rechallenge with T may be successful in selected patients with myxoid liposarcoma primarily responding to the drug and stopping it after a while. In this series, the choice to continue or stop the drug after response was of course at the discretion of the clinician, and selection biases are likely. Prospective studies on optimization of treatment strategy with T in MRCLPS are worthwhile.

10567 Poster Session (Board #211), Sun, 8:00 AM-11:30 AM

Pazopanib for soft tissue sarcoma (STS) in the first- line setting with denosumab. *First Author: Hiroyuki Narahara, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan*

Background: We established the Japan Sarcoma Association and hold the Japan-United States International Workshop on the Sarcoma Research and Therapy in December 2014. **Aim**: We conducted a retrospective analysis on pazopanib for STS in order to examine the relationships of PFS with denosumab, also from the viewpoint of the first-line setting for metastatic diseases. **Methods:** In this study, the patients with metastatic STS treated with pazopanib from November 2012 till January 2015, consecutively, were retrospectively analyzed. Among first 4 months, the starting dose was fixed at 800mg, but later changed to 400mg because of severe adverse events. **Results:** Eighty seven patients (43 leiomyosarcomas, 8 liposarcomas, 36 other subtypes) were identified. Median age was 56 years old (range 17-84), 69 females and 18 males, 50 pts were treated in the first-line setting and 37 pts were in the second or later-line setting, and 26 pts with multiple bone metastases were all treated with denosumab. Remarkable severe toxicities (G 3/4) were observeded as pheumothorax, hyperbilirubinemia, bladder perforation and perianal abscess, but the rates were infrequent (< 2.2%). All hypertension was manageable by antihypertensive medication and cardio-echogram showed no decrease of EF and it was definitly < 10%. But seum BNP increaseded in some pts. No pts showed symptomatic heart failure in the observation period (median: one year). All the pts, included till July 2014, were evaluable by RECIST 1.1, and 37 pts were evaluated as PR/SD and 31 pts showed PD/NE. Median OS reached 16.9 months (95%CI: 9.7-ND) and median PFS was 2.6 months (95%CI: 2.2-3.7). From the viewpoint of PFS with response, PFS in PR and that in SD were similar. PFS showed no differences between 800mg vs 400mg, leiomyosarcoma vs liposarcoma vs others, PS 0/1 vs 2/3 and 1st line vs later line. But PFS in PR/SD was longer (4.9 months, 95%CI: 2.8-7.1) than that in PD/NE (1.7 months, 95%CI: 1.1-2.3, $p < 0.0001$). PFS with denosumab was not inferior to that without denosumab. **Conclusions:** Pazopanib including first-line setting for metastatic STS is effective and comparable with EORTC trials. The combination chemotherapy of pazopanib with denosumab is promising and further investigations are warranted.

10568 Poster Session (Board #212), Sun, 8:00 AM-11:30 AM

A new simple low-cost multiplexed targeted sequencing assay to detect recurrent fusion genes in sarcomas. *First Author: Emilie Angot, Department of Pathology, University Hospital, Rouen, France*

Background: Sarcomas represent a heterogeneous group of tumors comprising more than 50 histological different types. Ten to fifteen percent of sarcomas are characterized by specific translocations which are routinely used as molecular markers for diagnosis, providing crucial information for prognosis and therapeutic decision. Today, translocations are detected by FISH or RT-PCR. However, these methods can only detect a limited number of transcripts simultaneously. Since the development of high throughput sequencing, the number of specific translocations continues to grow and it seems that we have reached the limits of this molecular "one-shot" approach. **Methods:** We have developed a simple low-cost (less than 6 dollars per patient) assay based on multiplex ligation-dependent RT-PCR for simultaneous screening of more than 50 rearrangements present in sarcomas. To validate this assay, we selected 42 formalin fixed and paraffin embedded (FFPE) sarcomas with known molecular alteration. In the case of non-contributive results, we repeated the analyses with snap-frozen tissue. **Results:** We detected fusion transcript for 9 synovial sarcomas (9/9), 9 alveolar rhabdomyosarcomas (9/9), 4 Ewing sarcomas (4/6), 2 Ewing like sarcomas with *BCOR-CCNB3* fusion transcript (2/2), 6 myxoid liposarcomas (6/7), 2 desmoplastic small round cell tumors (2/2), 1 dermatofibrosarcoma protuberans (1/2), 1 clear cell sarcoma (1/1), 2 angiomatoid fibrous histiocytomas (2/2), 1 infantile fibrosarcoma (1/1) and 1 solitary fibrous tumor (1/1). For 7 tumors, sequence quality was only reached using cryopreserved tissue. We did not detect transcript for 2 primary bone Ewing sarcomas and 1 dermatofibrosarcoma protuberans. Unfortunately, for these latter tumors we did not have cryopreserved tissue. One myxoid liposarcoma transcript was not detected using FFPE and cryopreserved tissue. **Conclusions:** We have developed a multiplexed assay which can reveal a very large number of gene fusions in sarcomas with good sensitivity and excellent specificity. These promising results provide an opening for this new rapid simple low-cost multiplexed targeted sequencing assay as an alternative method to FISH and RT-PCR for routine diagnosis.

10569 Poster Session (Board #213), Sun, 8:00 AM-11:30 AM

A phase 1b study with selinexor, a first in class selective inhibitor of nuclear export (SINE) in patients with advanced sarcomas: An efficacy analysis. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Sarcomas are a heterogeneous group of malignancies with diverse genetic abnormalities. Selinexor is a first-in-class, oral, inhibitor of XPO1, (nuclear exportin protein 1) with potent anti-tumor activity in multiple sarcoma cell lines and in murine liposarcoma xenografts. Here we report results from a Phase 1b dose expansion trial of selinexor in sarcoma patients (NCT01896505). **Methods**: Patients (pts) with advanced, refractory sarcomas with radiographic progression received oral selinexor at 50 mg/m^2 twice weekly per 28 day cycle. Pharmacokinetics (PK, n = 12) was assessed in the fasted and fed state. Pharmacodynamic studies were performed on fresh tumor biopsies. Response was evaluated every 2 cycles (RECIST 1.1). **Results**: 36 pts (14 M / 22 F, ECOG 0/1: 19/17, median age 57.5 years [range 18–86], median lines of previous treatments: 3 [range 1–9]). Disease subtypes include liposarcoma (LPS; N = 12), leiomyosarcoma (LMS; N = 8) and other sarcomas (N = 16). Grade 3 drug related adverse events (AEs) occurring in ≥ 2pts included: fatigue (17%), leucopenia (17%), anemia (11%), hyponatremia (8%) and vomiting (6%). One pt had reversible, grade 3 sensory and autonomic neuropathy and two pts had grade 4 thrombocytopenia (6%). Of the 33 evaluable patients, stable disease was seen in 21/33 (64%) of pts along with decrease of tumor burden (ranging from 5 – 23%) in 7 patients. There were 12 pts (36%) that progressed. In pts with progressive LPS and LMS, the median progression free survival (mPFS) on selinexor was 4.2 months (mo) and 3.7 mo, respectively. PK was similar to previously published results and there was better absorption in the fed state compared to fasting and fat content did not affect bioavailability. Matched pre- and post-tumor biopsies (N = 6) showed target inhibition of XPO1 by nuclear localization of p53, apoptosis by increased cleaved caspase, marked reduction in cellularity and Ki-67 and increase in stroma. **Conclusions**: Oral selinexor administered twice weekly was well tolerated with manageable toxicities. Selinexor demonstrated durable stable disease in various soft tissue and bone sarcomas. Based on promising results a larger study is planned. Clinical trial information: NCT01896505.

10570 Poster Session (Board #214), Sun, 8:00 AM-11:30 AM

Pattern of relapse in limb/girdle low-grade liposarcoma/atypical lipomatous tumor (ALT) during guidelines-suggested follow up (FU). *First Author: Raimondo Piana, Department of Orthopaedic Oncology and Reconstructive Surgery, Azienda Ospedaliero Universitaria Città della Salute e della Scienza, CTO Hospital, Torino, Italy*

Background: In soft tissue sarcomas (STS) after complete (marginal/wide/radical margins) surgery, surveillance should be tailored to individual patient's (pts) risk that depends on histotype, grading and site of origin. Unfortunately there is a substantial lack of evidence to personalize FU and most guidelines (GL) suggest both clinical (history and physical examination) and imaging procedures (X-rays, CT, US, MRI) taking into account two broad categories (low- and high-grade STS) but ignoring histotype heterogeneity. We reviewed our prospectively collected STS database to assess ALT pattern and risk of relapse in order to improve our future FU policy. **Methods:** In 2001 our regional-based health system adopted a STS GL (www.reteoncologica.it) suggesting the following FU: pts examination every 4-6 months in the first 3 years, every 6 months until the 5th year, then yearly. Pts underwent local and chest imaging (either CT or X-rays). Average cost and exposure to X-rays were computed for the entire FU. We searched for pts affected by ALT with complete clinical records (centrally reviewed histology, surgical record, and at least 3-year FU). ALT-specific overall survival (OS), relapse-free survival (RFS) and local-RFS (LRFS) were estimated according to Kaplan-Meier method. **Results:** Between 2001 and 2011 we took care of 163 patients affected by LGL. Complete records were available in 152 (93%) pts. Adherence to FU was considered adequate in 127 (78%) pts (median age 58, IQR 50-67; median size 14 cm, IQR 8-19). Median FU was 117 months (95% CI 95-140). Ten-year OS, RFS and LRFS were 100%, 74% and 74%, respectively. Among the 13 (10%) relapsed pts, we observed 13 local relapses and no distant metastases. All relapses were surgically amenable. Two pts died during their FU and none because of systemic progression. The chest X-rays estimated 10-year FU cost is 450 euros per pts with an average total exposure of 0.9 mSv. **Conclusions:** Until a hardly foreseeable randomized trial on FU will be performed, our study, though retrospective, does not support the systematic use of chest imaging in ALT FU that adds apparently needless costs and low, but not negligible, ionizing radiation risks.

10571 Poster Session (Board #215), Sun, 8:00 AM-11:30 AM

Primary chest wall soft tissue sarcomas: predictors of survival following surgical resection in a large population cohort. *First Author: Sadiq Rehmani, Mount Sinai St. Luke's Hospital, New York, NY*

Background: Primary soft tissue sarcomas (STS) of the chest wall are rare entities with limited information regarding treatment and oncological outcomes. The aim of this study is to evaluate the outcomes of surgical treatment in malignant primary chest wall STS and identify factors affecting survival using the Surveillance, Epidemiology, and End Results (SEER) database. **Methods:** We conducted a retrospective analysis using the SEER database (1988 -2010) and queried for all patients with primary chest wall STS. Only adult patients with histologically confirmed single primary tumor undergoing curative surgical resection were included in the study. Primary outcome was overall survival; covariates included demographics, tumor pathology, radiation and type of surgical procedure as coded in SEER (Simple/Partial or Total/Radical). Chi-square tests were performed to analyze categorical variables. Kaplan-Meier and Cox regression analyses were used to evaluate overall survival. **Results:** A total of 1053 cases of surgically resected, histologically confirmed, primary chest wall STS were identified. Mean age was 56 years and male to female ratio was 1.33:1. Out of 1053, 57% patients underwent Simple/Partial resection while 43% underwent Total/Radical. A total of 42% patients received radiation therapy. The mean overall survival of the entire cohort was 126.6 (± 8.284) months. After adjusting for covariates using Cox's proportional hazards regression, higher tumor grade (grade3: HR = 4.934 {CI: 2.599-9.365}, $p < 0.001$; grade4: HR = 4.895 {CI: 2.629-9.117}, $p < 0.001$) and tumor size (5-10 cm: HR = 1.77 {CI: 1.216-2.560}, $p < 0.005$; > 10cm: HR = 3.72 {CI: 2.538-5.458}, $p < 0.001$) were found to be independently associated with poor survival. **Conclusions:** Primary chest wall soft tissue sarcomas are uncommon tumors. Using the SEER database, we present the largest cohort reported to date. In this analysis, both advanced tumor grade and size are poor predictors of survival. Further studies are required to validate these findings and to direct adjuvant therapy.

10572 Poster Session (Board #216), Sun, 8:00 AM-11:30 AM

Local control following resection of primary retroperitoneal sarcoma with and without preoperative radiotherapy. *First Author: Carol Jane Swallow, Department of Surgery, University of Toronto, Toronto, ON, Canada*

Background: Retroperitoneal sarcoma (RPS) represents a therapeutic challenge due to its typically advanced stage at presentation, with local failure a harbinger of death from sarcoma following resection of primary RPS. Preoperative external beam radiotherapy (Pre-op RT) offers the potential for sterilization of margins and better local control. We present mature outcomes according to histologic subtype and treatment of patients with primary RPS managed at our center. **Methods:** All patients presenting with primary RPS between 01/96 and 06/11 identified from a prospective database were eligible. Distant metastases or unresectability at presentation, receipt of pre-op chemotherapy or post-op radiotherapy were exclusion criteria. All biopsy and resection specimens were re-analysed by an expert pathologist and mdm2 status used to facilitate histologic subtyping. Cumulative-incident rate curves were constructed for local and distant recurrence (LR, DR). **Results:** All 120 included patients underwent total gross resection. In this cohort, overall survival was 75% and 64% at 5 and 10 yrs, median 206 mos, and disease specific survival was 85% and 76% at 5 and 10 yrs, median 209 mos. Pre-op RT was given to 101 patients while 19 had surgery alone. Surgical approach, histologic subtype (80% liposarcoma, LPS) and follow-up (median 59 mos) did not differ between treatment groups; median size was larger (28 vs. 19 cm) and histologic grade lower in the surgery alone group. For the 120 patients, DR occured in 12 at a median 23 mos (range 2-131) postoperatively and varied significantly by histology (4/65 DD-LPS; 0/31 WD-LPS; 7/17 LMS; 1/7 other; $p < 0.01$), but not treatment group. LR occured in 24 at a median 22.5 mos (range 2-103) and varied significantly by histology (22/65 DD-LPS; 2/31 WD-LPS; 0/24 other; $p = 0.01$). For the entire cohort, LR rate was 20% and 28% at 5 and 10 yrs. LR at 5 yrs varied significantly by treatment group (16% for pre-op RT, 51% for surgery alone, $p < 0.01$). **Conclusions:** Pre-op RT was associated with improved local control compared with a contemporaneous control. Participation in the EORTC randomized trial of pre-opRT vs. surgery alone is essential to determine the true benefit of pre-op RT in primary RPS.

10573 Poster Session (Board #217), Sun, 8:00 AM-11:30 AM

Phase 2 study of gemcitabine, docetaxel, and doxorubicin in patients with advanced, unresectable, and/or metastatic sarcoma who have failed prior therapies. *First Author: Andrew Eugene Hendifar, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Gemcitabine and docetaxel chemotherapy protocols have proven efficacy in the treatment of metastatic soft tissue sarcomas. Doxorubicin is also a commonly used treatment both as a single agent and as a part of combination therapies. This phase 2 study was designed to assess the efficacy and safety of a combination regimen of gemcitabine, docetaxel , and doxorubicin. **Methods:** This is a single institution study of advanced sarcoma pateints who were refractory to 1st line chemotherapy. Adequate performance status, organ function, and measurable disease (RECIST v1.1) were required. Patients received Gemcitabine (400 mg/m2), Doxorubicin (20 mg/m2) and Docetaxel (20 mg/m2) on days 1 and 8 of a 21 day cycle, and must have completed 2 cycles in order to be evaluable. Disease assessment was completed using the RECIST 1.1 criteria and toxicity was evaluated using the NCI CTCAE version 4.2. **Results:** A total of 32 patients were enrolled from 08/2011 - 08/2014 and 31 patients received at least 2 cycles of therapy. Pts with leiomyosarcoma (n = 7) liposarcoma (7) synovial sarcoma (2), chondrosarcoma (2), bone tumors (6), and others (8). The majority of patients (n = 21, 66%) previously received doxorubicin and many (n = 8, 25%) had previously received gemcitabine and docetaxel in combination. The average number of previous regimens was 3 previous chemotherapies (range, 1 to 7). The median age was 49 (range, 21 – 69). A median of 5 cycles of gemcitabine, docetaxel and doxorubicin were given (range, 1-12). A partial response was seen in 16 % of patients (5/31), and stable disease > 3 months in 39% (12/31). Clinical benefit (CR+PR+SD > 3months) was 17/31 55% (95% CI .36 -0.7) Grade 3 and 4 hematologic toxicities were observed in 14 patients (thrombocytopenia 12 pts, and neutropenia 2 pts) however, no patients were discontinued for toxicity. **Conclusions:** The combination of gemcitabine, doxorubicin, and docetaxel is an active regimen with a manageable toxicity profile in patients with advanced and pre-treated soft tissue and bone sarcomas.

10574 Poster Session (Board #218), Sun, 8:00 AM-11:30 AM

Metastatic Non-Uterine Leiomyosarcoma: Prognostic factors, Overall Survival and chemotherapy outcomes. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Non-uterine Leiomyosarcoma (LMS) is an aggressive, malignant tumor of mesenchymal origin whose natural history is poorly defined. We sought to evaluate clinical and treatment outcomes in patients (pts) with metastatic (met) disease. **Methods**: In a retrospective study using an institutional sarcoma database, we identified all pts with met non-uterine LMS treated at Memorial Sloan Kettering Cancer Center between 1983-2011 and collected their correlative clinical information.Kaplan-Meier method and Cox's proportional-hazard models were used to determine overall survival (OS) from time of met and prognostic factors. Hazard ratios (HR) are listed with their 95% confidence intervals (CI). Objective responses to 1st chemotherapy were determined by RECIST 1.1. **Results:** We identified 214 pts: median age 56 (range 23-85), 80 (37%) male. Median OS was 2.6 years (yr) (range: 0.04-17 yr) with 14 yr of follow-up. Independent factors predictive of improved OS included age < 56, HR 0.70 (0.52-0.97) p = 0.03; primary tumor site in the retroperitoneum, HR 0.56 (0.34-0.93) p = 0.03; and < 3 met sites, HR 0.65 (0.47-0.9) p = .009. Most common regimens included anthracycline+alkylator (n = 47), gemcitabine-based regimens (n = 58), liposomal doxorubicin (dox) (n = 17) and dox (n = 15). Rates of complete response (CR) + partial response (PR), stable disease (SD), and progressive disease (PD) were 18%, 56% and 25%, respectively. Pts with CR/PR and SD had improved OS compared to those with PD, HR 0.25 (0.13-0.49, p < 0.001) and HR 0.46 (CI 0.28-0.76) p = 0.002, respectively. Regimen type did not impact OS. **Conclusions:** LMS is an aggressive malignancy with poor prognosis. Age < 56, primary tumors arising in the retroperitoneum and < 3 met sites were associated with improved OS. Patients with CR/PR/SD to first line chemotherapy had improved OS regardless of type of chemotherapy used. Molecular analysis of select pts with long-term OS may be warranted

TPS10575 Poster Session (Board #219a), Sun, 8:00 AM-11:30 AM

A randomized phase II/III study, comparing perioperative adriamycin plus ifosfamide versus gemcitabine plus docetaxel for operable high grade soft tissue sarcomas in extremity or trunk: JCOG1306. *First Author: Kazuhiro Tanaka, Oita University, Yufu, Oita, Japan*

Background: Based on the results of JCOG0304, which showed sufficient efficacy of perioperative chemotherapy with adriamycin plus ifosfamide (AI) for operable high-grade soft tissue sarcomas (STS), AI has been considered acceptable as standard regimen for operable STS in Japan. Recent studies have reported gemcitabine plus docetaxel (GD) is effective for advanced STS. A new clinical question has thus arisen of whether less toxic GD has a compatible efficacy to AI as perioperative therapy. Therefore, we have commenced a phase II/III trial to confirm the non-inferiority of perioperative GD to AI. **Methods:** Eligibility criteria include operable, histologically proven STS, primary tumor (T2bN0M0 or anyTN1M0) based on the 7th AJCC/UICC-TNM or first local recurrent tumor, arising in the extremities or trunk, FNCLCC grade 2 or 3, and aged 20 to 70. Patients are randomized to the AI or the GD. Patients in the AI arm receive preoperative 3 courses and postoperative 2 courses of adriamycin at 30 mg/m^2 on days 1-2 and ifosfamide at 2 g/m^2 on days 1–5, every 3weeks. Patients in the GD arm receive preoperative 3 courses and postoperative 2 courses of gemcitabine at 900 mg/m^2 on days 1 and 8, and docetaxel at 70 mg/m^2 on day 8, every 3 weeks. In the phase II part, the primary endpoint is the proportion of completion of preoperative chemotherapy without progressive disease in the GD arm. The planned sample size is 28 patients in the GD arm, which was calculated based on an expected proportion of completion of preoperative GD without progressive disease of 85% and a threshold of 65%, with a one-sided alpha of 0.1 and a beta of 0.2. In the phase III part, the primary endpoint is overall survival. The sample size was calculated as a total of 140 patients with a one-sided alpha of 0.1, power of 0.7 and a non-inferiority margin of 8% at 3 year survival, assuming 3 year survival of AI to be 85% and that of GD as 87%. The accrual period is 6 years and the follow-up period is 5 years. This trial has started in February 2014 and the current enrollment is 18 as of January 2015 (UMIN000013175). Clinical trial information: 000013175.

TPS10576 Poster Session (Board #219b), Sun, 8:00 AM-11:30 AM

EPAZ: A randomized phase II trial comparing pazopanib with doxorubicin as first line treatment in elderly patients with metastatic or advanced soft tissue sarcoma of the Working Group Medical Oncology (AIO) and German Interdisciplinary Sarcoma Group (GISG). *First Author: Viktor Gruenwald, Medical School of Hannover, Hannover, Germany*

Background: 1/3 of STS patients are 60 years and older. Single agent doxorubicin is the mainstay of therapy in metastatic disease, which is frequently associated with hematological toxicity (grade 4 neutropenia in 34%; febrile neutropenia in 9%). We assume that comorbidities in the elderly population may limit tolerability of doxorubicin and novel agents may improve health-related quality of life (HR-QoL), while maintaining efficacy. **Methods:** This is a randomized, open-label, multicenter phase II study that compares pazopanib 800 mg OD to doxorubicin 75 mg/m^{2}as first line treatment in elderly patients with metastatic or advanced STS (NCT01861951). A total of 120 patients will be recruited and randomized 2:1 to receive either pazopanib or doxorubicin, stratified by performance status (0-1 vs. 2) and histological subtype. HR-QoL (QLQ-C30) and comprehensive geriatric assessment (elderly minimal dataset of EORTC ETF) is determined throughout the course of the study, in order to assess the impact of treatment on the patient's quality of life and daily living. Key inclusion criteria: age $\geq$ 60 years; progressive intermediate or high grade STS; ECOG PS 0-2; measurable disease (RECIST 1.1); availability of archived STS tissue; adequate organ function; no prior therapy for metastatic disease. Primary endpoint: Progression free survival (PFS) based on local tumor assessment according to RECIST 1.1. Key secondary endpoints include the incidence of grade 4 neutropenia and febrile neutropenia. For the latter endpoints, sensitivity analyses will be conducted to adjust for primary prophylaxis of granulocytopenia or febrile neutropenia. Other secondary endpoints include: HR-QoL, geriatric assessment, safety and tolerability, overall survival, objective response rate, PFS rate at 12 and 26 weeks, time to onset of response, and predictive biomarkers. The first patient was randomized on October 12, 2012. Currently, a total of 85 patients have been randomized. Clinical trial information: NCT01861951.

TPS10577 Poster Session (Board #220a), Sun, 8:00 AM-11:30 AM

A study of the safety and efficacy of the combination of gemcitabine and docetaxel with ontuxizumab (MORAb-004) in metastatic soft tissue sarcoma. *First Author: Sant P. Chawla, Sarcoma Oncology Center, Santa Monica, CA*

Background: Ontuxizumab is a humanized immunoglobulin G-1-kappa monoclonal antibody (mAb) that is the first clinical stage agent to target endosialin. Endosialin (TEM-1/CD248) is a cell surface glycoprotein expressed on cells involved in the development of tumor vasculature, but has generally limited expression in normal tissue. In some tumors, such as sarcomas, endosialin is expressed directly by the tumor cells and therefore soft tissue sarcomas (STS) may be a suitable treatment target. **Methods:** This Phase 2 multicenter study in subjects with metastatic STS (0-2 prior regimens) is being conducted in two sequential parts. Part 1 was an open label, dose-escalation, safety lead in: 4, 6 and 8 mg/kg ontuxizumab (administered on days 1 and 8 of a 21 day cycle) combined with gemcitabine and docetaxel (G/D) (900 mg/m^2 on days 1/8 and 75 mg/m^2 on day 8, respectively)). Based on the observed safety profile in Part 1, 8 mg/kg was utilized in Part 2 efficacy design. In Part 2 subjects are randomized in a double-blind 2:1 ratio to G/D plus ontuxizumab (8 mg/kg) or G/D plus placebo. Using an adaptive population finder design, randomization is stratified by four histological cohorts (liposarcoma, leiomyosarcoma, undifferentiated pleomorphic sarcoma (UPS) and myxofibrosarcoma, and other STS). An independent unblinded statistical committee (ISC) monitors the trial adaptations for futility, success, or maximal cohort sizes (60). Primary objective is progression-free survival (PFS) by RECIST1.1. Secondary objectives include overall survival (OS), overall response rate (ORR), and predictive/ response biomarkers. Enrollment ended in August 2014 with 209 subjects randomized. Primary result analysis is anticipated in December, 2015. Clinical trial information: NCT01574716.

TPS10578 Poster Session (Board #220b), Sun, 8:00 AM-11:30 AM

SARC 028: A phase II study of the anti-PD1 antibody pembrolizumab (P) in patients (Pts) with advanced sarcomas. *First Author: Melissa Amber Burgess, University of Pittsburgh Physicians, Pittsburgh, PA*

Background: Immune checkpoint inhibition with antibodies (abs) to cytotoxic T-lymphocyte antigen-4 (CTLA-4), programmed death 1 (PD-1), and programmed death ligand 1 (PD-L1) have made a significant therapeutic impact in metastatic melanoma. Abs targeting the PD-1/PD-L1 axis also exhibited clinical activity in solid tumors that are not considered "immunogenic", e.g., lung and bladder cancer. The significance of the PD-1/PD-L1 axis is currently being elucidated in sarcoma. Over 150 sarcomas of various histologic subtypes have been analyzed for PD-L1 tumor expression and the presence of PD-1+ tumor infiltrating lymphocytes (TIL): up to 65% of sarcomas expressed PD-L1 which, along with PD-1 TIL positivity, correlated with poorer overall survival and aggressive tumor features. We seek to determine the efficacy of PD-1 blockade with the anti-PD-1 ab pembrolizumab in pts with advanced soft tissue (STS) and bone sarcomas. **Methods:** This is an open label, multicenter, single stage, phase II study of P in pts with advanced STS (Arm A) or bone sarcomas (Arm B). P will be given intravenously at 200 mg every 3 weeks. The primary efficacy endpoint is objective response rate (ORR) by RECIST 1.1. 40 pts/arm will provide 82% power to detect an improvement in ORR from 10 to 25% with a one-sided type I error of 4.2%. This design will also have 87% power to detect an improvement in the 4-months progression-free survival rate from 20% to 40% with a one-sided type I error of 4%. Key eligibility criteria include $\geq$ 12 years of age, ECOG PS of 0 or 1, up to 3 prior therapies, and at least one tumor site accessible for biopsy. Exclusion criteria include low grade sarcoma, prior immunotherapies, and chronic use of corticosteroids or other immunosuppression. Secondary endpoints are safety, overall and progression free survival, and response rates by immune-related response criteria (ir-RC). Mandatory tumor biopsies pre and post-treatment will be obtained to determine PD-L1 expression as well as to perform immune monitoring in the tumor microenvironment. Peripheral blood will also be collected for immune monitoring in the circulation. Enrollment will occur at 10 SARC participating institutions and is expected to be completed in 2015. NCT02301039. Clinical trial information: NCT02301039.

11000 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Identifying somatic oncogenic mutations in leukocytes that infiltrate primary breast cancers. *First Author: Elizabeth Anne Comen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the past decade, sequencing studies have delineated somatic mutations in human cancers. Given that cancer cells interact with their microenvironment and the presence of somatic mutations in a subset of elderly individuals with clonal hematopoiesis, we hypothesized that white blood cells within tumors might be characterized by clonally selected mutations in known cancer genes. Here we provide direct evidence of the presence of clonal somatic mutations affecting known cancer genes in tumor-infiltrating leukocytes from breast cancer (BC) patients. **Methods:** We evaluated tumor infiltrating leukocytes in 17 primary BC samples: 13 patients had triple negative BC, 2 had ER+, HER2+ BC, and 2 had ER+, HER2- BC. Fluorescent activated cell sorting was employed to separate CD45-positive hematopoietic cells from CD45-negative epithelial cells. Whole exome sequencing of tumor infiltrating leukocytes revealed candidate somatic mutations in known cancer genes, including BCOR, NOTCH2, TET2, NF1, EZH2 and JAK1. To validate our findings, we expanded our sample size to 20 patients and performed targeted capture massively parallel sequencing of matched tumor-infiltrating leukocytes and germline DNA. Laser-capture microdissected cancer cells were subjected to high-depth sequencing to rule out the presence in cancer cells of the somatic mutations found in leukocytes. **Results:** In 10 of the 20 patients, we identified and validated somatic mutations, including mutations affecting genes associated with leukemia in tumor infiltrating leukocytes but not in laser-capture microdissected BC cells from the same patients. Targeted sequencing indicated that these mutations are enriched in tumor-infiltrating leukocytes as compared to circulating leukocytes. **Conclusions:** We identified clonal somatic mutations in known cancer genes in tumor infiltrating leukocytes. These data suggest a novel relationship between cancer cells and mutant infiltrating leukocytes. Studies are underway to investigate functional interactions between BC cells and hematopoietic cells harboring somatic mutations.

11001 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

White adipose tissue inflammation and breast cancer progression. *First Author: Neil M. Iyengar, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Obesity is a poor prognostic factor for breast cancer (BC) survivors. White adipose tissue (WAT) inflammation (WATi) occurs in the breasts of most obese/overweight individuals, and also in some who are normal weight. We demonstrated that breast WATi is associated with several molecular changes including activation of NF-κB and elevated aromatase expression that could contribute to tumor progression. Additionally, WATi correlates with circulating changes including hyperinsulinemia that occur in the metabolic syndrome, a poor prognostic feature for BC. Here we examine the impact of breast WATi on BC progression. **Methods:** We conducted a case-control study nested within a cohort of 610 patients (pts) with invasive BC who underwent mastectomy from 2001 – 2006. Case pts were women who developed distant relapse while control subjects remained free of disease with follow up to 2014. Controls were matched (1:1) on age at diagnosis, BMI, receptor status, grade, T stage, N stage, use of adjuvant therapy, and co-morbidities. WATi, detected by CD68 immunostain, was defined by the presence of dead/dying adipocytes surrounded by macrophages known as crown-like structures of the breast (CLS-B). Distant recurrence free survival (dRFS) was compared by CLS-B status using Cox regression. Risk of distant relapse by CLS-B status was examined by conditional logistic regression analysis. **Results:** Adequate WAT was available for 250 subjects. Among pts who developed distant relapse ($n = 127$), median dRFS was worse for pts with breast WATi (20 months [mo], range 16-26) than those without WATi (26 mo, range 20-34; hazard ratio [HR] 1.44, 95% confidence interval [CI] 1.00-2.06, $P < 0.05$). The association between WATi and shorter dRFS remained significant in multivariable analysis (HR 1.83, 95% CI 1.07-3.13, $P = 0.03$). A higher proportion of pts who developed distant relapse had breast WATi at index mastectomy (52/127, 41%) than those who remained disease free (46/123, 37%), though not statistically significant as the study was underpowered for this endpoint ($P = 0.76$). **Conclusions:** In pts with recurrent BC, breast WATi is an adverse independent prognostic variable. These findings support further study of WATi as a targetable biomarker of BC progression.

11002 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Association of inactivation of *STK11/ LKB1* with a suppressive immune microenvironment in lung adenocarcinoma (LUAC). *First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Little is currently known about how the oncogenotype of LUAC shapes its immune micro-environment. We recently identified that major subsets of *KRAS*-mutant LUAC defined on the basis of co-occurring genomic alterations in *STK11/LKB1*, *TP53* and *CDKN2A/B* display distinct immune profiles. Specifically, inactivation of the LKB1 tumor suppressor is associated with striking lack of immune system engagement. Here, we systematically assess the immune contexture of LUACs in the context of LKB1 inactivation. **Methods:** Our datasets include 431 LUACs from TCGA with available exome sequence and RNA-Seq data, as well as a cohort of 106 early stage tumors collected at MDACC (PROSPECT dataset) with available mRNA (Illumina), phospho-protein (RPPA) expression and quantitative IHC data. The un-paired t test and Wilcoxon's rank-sum test were used for comparisons of mean mRNA expression and Histo-scores respectively. PROSPECT tumors were dichotomized into "LKB1-low" and "LKB1-high" based on LKB1 protein expression. **Results:** Somatic mutation of *LKB1* was associated with wide suppression of cytolytic T cell responses. This included apparent defects in MHC class I and II antigen presentation pathways [HLA-A ($P = 0.057$), HLA-B ($P = 1.55e^{-06}$), HLA-C ($P = 1.28e^{-05}$), B2M ($P = 1.8e^{-03}$), HLA-DMA ($P = 2.8e^{-04}$), HLA-DMB ($P = 6.08e^{-07}$),HLA-DOA ($P = 6.28e^{-07}$), HLA-DOB ($P = 3.5e^{-04}$)] as well as reduced expression of co-stimulatory [CD28 ($P = 3.9e^{-03}$), CD80 ($P = 5.55e^{-07}$), CD86 ($P = 6.79e^{-06}$),CD40 ($P = 5.09e^{-09}$), CD70 ($P = 5.7e^{-04}$), TNFRSF9 ($P = 3.79e^{-05}$), TNFSF9 ($P = 0.007$), ICOS ($P = 3.3e^{-03}$),ICOSLG ($P = 1.2e^{-03}$)] and co-inhibitory [CTLA ($P = 0.034$), PDCD1 ($P = 0.0125$), CD274 ($P = 1.16e^{-08}$), PDCD1LG2 ($P = 8.66e^{-06}$), LAG3 ($P = 0.023$), LGALS9 ($P = 1.65e^{-05}$)] molecules. A number of these were further validated in PROSPECT. In the context of *KRAS*-mutant LUACs, LKB1 inactivation was associated with a lower PD-L1 IHC score ($P = 0.039$) and reduced populations of CD3+, CD8+ and CD45RO+ lymphocytes. Detailed IHC data will be presented at the meeting. **Conclusions:** LKB1 inactivation is associated with a muted tumor immune phenotype and may thus predict for resistance to immunotherapy approaches that incorporate immune checkpoint blockade.

11003 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Discordance between HER2-phenotype on circulating tumor cells and primary tumor in women with advanced breast cancer. *First Author: Amelie Schramm, Universitaetsfrauenklinik Ulm, Ulm, Germany*

Background: In the DETECT study program, women with HER2-negative metastatic breast cancer (MBC) are screened for circulating tumor cells (CTCs) to evaluate eligibility for different DETECT treatment intervention trials based on presence and HER2 phenotype of CTCs. Here we present data on the association of CTC prevalence and positive HER2-status on CTCs with patient and tumor characteristics. **Methods:** As of January 2015, number of CTCS using the FDA-cleared CellSearch System (Janssen Diagnostics, LLC) and their HER2 status have been evaluated in 1052 women with HER2-negative MBC screened for the DETECT Study program. Patients were defined as CTC positive if at least 1 CTC was detected in 7.5 ml of peripheral blood, and the cutoff for HER2 positivity was the presence of at least 1 CTC with a strong (+++) immunocytochemical HER2 staining intensity. **Results:** Overall, CTCs were detected in 661 (62.8%) of the 1052 screened patients (median 7 CTCs, range 1 – 35078). CTC prevalence was associated with a higher proportion of pN2/pN3 tumors (28.0 vs. 20.2%; $p = 0.021$) and a higher proportion of lobular carcinomas (22.4 vs. 9.5%; $p < 0.001$) compared to CTC-negative patients. Among the 661 patients with CTCs, at least one HER2-positive CTC was found in 130 patients (19.7%), indicating a discordance between primary tumor and CTCs with regard to HER2-status. Patients with HER2-positive CTCs had less often G3 tumors (27.7 vs. 39.0%; $p = 0.024$), and more often lobular carcinomas (39.2 vs. 18.3%; $p < 0.001$) compared to patients with only HER2-negative CTCs. In addition, patients with triple-negative tumors were less likely to have HER2-positive CTCs than patients with HER2-negative but hormone-receptor positive tumors (6.6 vs. 22.8%; $p < 0.001$). **Conclusions:** Our data confirm discordance in HER2-status between primary tumor and CTCs in 19.7% of patients with HER2-negative MBC. Interestingly, presence of HER2-positive CTCs was associated with hormone-receptor positive tumors. Awareness of the HER2-phenotype of CTCs may have important implications for further personalized therapy options. Clinical trial information: NCT01619111/NCT02035813.

11004 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Detection rate of actionable mutations in diverse cancers using a biopsy-free (blood) circulating tumor DNA assay. *First Author: Razelle Kurzrock, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: Analysis of cell-free DNA using next generation sequencing (NGS) is a potentially powerful tool for the detection/monitoring of circulating tumor DNA (ctDNA). We report the findings of a biopsy-free NGS ctDNA assay in a series of 103 patients with advanced cancer. **Methods:** Between June 1, 2014 and January 16, 2015, plasma samples from 103 patients with a variety of cancers were analyzed for ctDNA. Single nucleotide variants (SNVs) in 54 genes and copy number variants (CNVs) in 3 genes (*EGFR*, *ERBB2* and *MET*) are reported quantitatively as the fractional mutant allele concentrations in cell-free DNA and the absolute copy numbers of the genes measured, respectively (Guardant360, Guardant Health, Inc.). This ctDNA assay has high sensitivity (detects 85%+ of the single nucleotide variants detected in tissue in advanced cancer patients) and analytic specificity (> 99.9999%). **Results:** Of the 103 patients, there were 40 with breast and 40 with lung cancer; and 23 various other malignancies. Of the total, 78 (75.7%) had at least one detectable mutation (mean = 2.1/patient). In 222 healthy volunteers used to validate that assay, only 1 had an alteration. Within the breast cancer cohort, 22% had 1 alteration; 50%, 2 or more (range 0-12; mean = 2.2/patient). *TP53* alterations were the most common, found in 32.5%. Interestingly, 25% of patients had an *EGFR* alteration (amplification or SNV), higher than previously reported. Mutations in *PIK3CA* were detected in 10 cases. In the 40 lung cancer patients, 82.5% had at least 1 alteration (mean = 2.2/patient). *TP53* alterations were present in 50%; *EGFR* alterations, in 30%; and MET amplification/variation, in 22.5%. Sixty-two of 103 patients (60% of all patients; 80% of patients with an alteration) had alterations that were conceivably actionable by an FDA approved drug and/or an agent in clinical trials. **Conclusions:** In this single institution series, 75.7% of the patients had an alteration on a 54 gene panel ctDNA assay. Importantly, of patients with at least 1 alteration, 80% had alterations actionable by existing drugs. ctDNA testing in blood identifies a high number of potentially actionable abnormalities in a broad range of cancer types.

11005 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Protein expression by genetic mutations identified in gene panels (hotspots) and efficacy of targeted treatments. *First Author: Stephen Charles Benz, Five3 Genomics, Santa Cruz, CA*

Background: Treatment decision support by next generation sequencing of gene panels is currently limited to the analysis of somatic (tumor) data from DNA sequencing without taking into consideration expression of mutated genes. We present here a supercomputer-driven, cloud-based integrated analysis of genomic (DNA) and transcriptomic (RNA) sequencing data to 1) directly identify driver variants between somatic and germline (normal) DNA and 2) to determine expression of identified mutations in a cohort of 3,784 patients, thereby establishing therapeutic relevance of the mutated genes overcoming the limitations of panels. **Methods:** This large scale 3,784 patient genomic (DNA and RNA sequencing) data set from 19 anatomical tumor types was processed to detect DNA variants (germline vs somatic) and RNA expression, and to establish not only the existence but also the expression level of hotspot mutations in the following oncogenes: PIK3CA, KRAS, NRAS, AKT1, BRAF, IDH1, CTNNB1, and IDH2. **Results:** Of the 3,784 patients in this analysis, 720 were found to have mutations in the oncogenes listed above. Remarkably, only 38 (5.3%) of these patients had better than 90% expression by RNAseq, and 36 patients (5.0%) with identified hotspot mutations had no or low (< 10%) expression. For example, mutations at position E545 in the PI3K protein encoded by the PIK3CA gene, which has been targeted by both pan-PI3K and mutant-targeted drugs in clinical trials, showed low or no expression in 12% (5/41) of breast cancer patients and not a single patient showed relatively maximal (> 90%) expression. Similarly of the 204 thyroid cancer patients with a BRAF V600 hotspot mutation, 7.5% (15/204) had low or no expression and none had relatively maximal expression. **Conclusions:** These findings illustrate that genetic mutations in gene panels (hotspots) do not always result in protein expression. Given that many gene mutations were not expressed, we conclude that an informed molecularly-driven clinical treatment decision requires insight into downstream protein expression and not just DNA alterations alone.

11006 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Safety and activity of DCR-MYC, a first-in-class Dicer-substrate small interfering RNA (DsiRNA) targeting MYC, in a phase I study in patients with advanced solid tumors. *First Author: Anthony W. Tolcher, START, San Antonio, TX*

Background: MYC, an oncoprotein deregulated in over half of all human malignancies, has thus far been considered "undruggable" with conventional approaches. RNA interference (RNAi), a therapeutic approach that can be used to silence the *MYC* oncogene, has been shown to inhibit cancer growth in animal models. Synthetic DsiRNA with specificity for *MYC* have demonstrated highly potent activity in vitro (picomolar IC_{50}), and anti-MYC DsiRNA formulated in EnCore lipid nanoparticles (DCR-MYC) have demonstrated activity in vivo across various tumor models. DCR-MYC is the first MYC-targeting siRNA to enter clinical trials. **Methods:** This phase I, dose-escalation study (3+3 design) evaluated the safety, pharmacokinetics (PK), pharmacodynamics (PD) and clinical activity of DCR-MYC in patients (pts) with advanced solid tumors, multiple myeloma or lymphoma. DCR-MYC is administered as a 2-hr IV infusion on Day 1 and 8 of a 21 day cycle. Given the role of MYC in tumor metabolism, FDG-PET is obtained after cycle 1 to assess early metabolic response, while RECIST response is assessed after every 2 cycles. **Results:** Nineteen pts have been treated across 5 dose levels (0.1, 0.125, 0.156, 0.2, 0.3 mg/kg): 8M/11F, median age 58 yrs, ECOG PS 0(5), 1(14). Tumor types include NET (4), MBC (4), CRC (3), Ovarian (2), Appendiceal (2), other (4). The most common treatment-related AEs (all grades/grade 3) include fatigue (7/0), nausea (5/0) and infusion reactions (3/1). A pt with PNET treated at 0.1 mg/kg experienced DLT (transient grade 3 AST) and fatigue. This pt experienced a complete metabolic response (based on FDG-PET) after cycle 1 which has been sustained for > 8 months without further treatment. Metabolic responses after cycle 1, as well as evidence of tumor shrinkage have been observed in multiple patients. Preliminary PK analysis from the first two dose levels shows dose proportional changes in AUC and Cmax. **Conclusions:** DCR-MYC, a novel MYC inhibitor, is well tolerated and shows promising initial clinical and metabolic responses across various dose levels. These data support early validation of MYC as a therapeutic target. Updated results from the ongoing study will be presented. Clinical trial information: NCT02110563.

11007 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Comprehensive genomic profiling (CGP) of advanced cancers to identify MET exon 14 alterations that confer sensitivity to MET inhibitors. *First Author: Garrett Michael Frampton, Foundation Medicine, Cambridge, MA*

Background: Amplifications and activating mutations in the c-MET proto-oncogene are known oncogenic drivers that have proven responsive to targeted therapy. Alterations affecting the splice sites of *MET* exon 14 have been identified, which cause exon skipping, MET activation, and predict sensitivity to MET inhibitors in vitro. We undertook comprehensive genomic profiling (CGP) of a large series of advanced cancers to identify MET exon 14 alterations. **Methods:** DNA was typically extracted from 40 microns of FFPE sections from 34,735 cases examined between April 2012 and January 2015. CGP was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of > 500x. All classes of genomic alterations (GA) were evaluated. **Results:** CGP of 34,735 patients identified 200 cases harboring METex14 alterations. The alterations had diverse sequence composition, with > 100 distinct sequence variants represented. The 200 patients had a median age of 68.2 years (range 15-83), with 86 males and 114 females. The cases were comprised of lung carcinoma (173), carcinomas of unknown primary (14), brain glioma (6), and one each of adrenal cortical carcinoma, hepatocellular carcinoma, melanoma, Merkel cell carcinoma renal cell carcinoma, rhabdomyosarcoma, sarcoma NOS, and synovial sarcoma. The majority were stage IV. Identification of this alteration via CGP in routine clinical care has led to treatment with MET inhibitors such as crizotinib, and to durable partial responses or better exceeding 3 months in histiocytic sarcoma (1), sarcomatoid lung carcinoma (1), and nsclc (1+). Multiple patients (5+) have initiated treatment on either crizotinib or MET inhibitors in clinical development, and additional outcome data will be reported. **Conclusions:** MET exon 14 alterations define a hereto unrecognized population of advanced cancers. Early reports of patients demonstrate cases harboring such alterations are responsive to multiple small molecule MET inhibitors. This finding expands the population of advanced cancer patients who can derive benefit from MET-targeted therapies.

11008 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Altering the tumor microenvironment: A phase II study of copper depletion using tetrathiomolybdate (TM) in patients (pts) with breast cancer (BC) at high risk for recurrence. *First Author: Eleni Nicole Nackos, New York Presbyterian Hosp-Weill Cornell, New York, NY*

Background: Bone marrow derived endothelial progenitor cells (EPCs) and copper-dependent pathways are critical components to remodeling the tumor microenvironment and creating the pre-metastatic niche. Copper depletion (CD) inhibits tumor metastases in preclinical models. We hypothesized that TM-associated CD would reduce EPCs and other copper dependent processes in the pre-metastatic niche in BC pts at high risk for relapse. We investigated the relationship between CD and its effect on EPCs and other components of the tumor microenvironment including lysyl oxidase (LOX). **Methods:** In this single arm, phase II study, BC pts at high risk for recurrence, defined as node+ triple negative (TN), stage 3 and 4 with no evidence of disease (NED) were enrolled on a trial of CD with TM. We utilized TM to maintain ceruloplasmin (Cp) between 5-17 mg/dl until end of treatment or relapse. The primary endpoint was change in EPCs measured by flow cytometry before and during treatment with TM. Secondary endpoints included tolerability, safety, and its effect on other markers including LOX. **Results:** We enrolled 75 pts. The study treatment duration was 24 cycles (28 days each). Over 2021 cycles have been administered. The median age is 51 (range 29-66). 45 pts have Stage 2/3 BC and 30 are Stage 4 NED. 48% of pts have TNBC, and 40% of pts are Stage 4 NED. Median Cp level decreased from 28 at baseline to 16 ($p < 0.0001$) after one cycle. Copper depletion was most efficient in TNBC. TM was well tolerated and the only grade 3/4 toxicities were reversible neutropenia (2.5%) and anemia (0.04%). CD was associated with a significant decrease in EPCs ($p < 0.001$) and LOX ($p < 0.001$) in the 2 year analysis; the 5 year analysis is ongoing. The PFS for all 75 pts from the start of TM treatment was 81% including a PFS of 94% for all stage 2/3 pts with TNBC at median f/u of 5.6 yrs. The hazard ratio for relapse is zero at two years. **Conclusions:** TM is safe, well tolerated and appears to affect multiple components of the tumor microenvironment creating an inhospitable environment for tumor progression. This seems to be most striking in TNBC. Further phase III trials are warranted. Clinical trial information: NCT00195091.

Next-generation sequencing to reveal somatic mutations that confer sensitivity to everolimus. *First Author: Sun Min Lim, Yonsei Cancer Center, Seoul, South Korea*

Background: Using targeted ultradeep sequencing, we aimed to explore genomic alterations that confer extreme sensitivity to everolimus. **Methods:** We collected formalin-fixed paraffin-embedded tumor/normal pairs from 38 patients (21 with exceptional clinical benefit, 17 with no clinical benefit) who were treated with everolimus across various tumor types (13 gastric cancers, 15 renal cell carcinomas, 2 thyroid cancers, 1 lacrimal gland cancer, and 7 sarcomas). Ion AmpliSeq Comprehensive Cancer Panel was used to identify alterations across all exons of 409 target genes. **Results:** Tumors were sequenced to a median coverage of 605x. Cancer genomes are characterized by 203 somatic single-nucleotide variants (186 missense, 10 nonsense, 7 splice-site) and 51 frameshift insertions/deletions, with a median of 3.9 mutations per Mb (0 to 14.8 mutations per Mb). Overall, genomic alterations with activating effect on mTOR signaling were identified in 8 of 21 patients with clinical benefit and these include *mTOR, TSC1, TSC2, NF1* and *PIK3CA* mutations. In a patient with ductal adenocarcinoma of the lacrimal gland in whom everolimus achieved a partial response (PR) for 8 months, a novel *NF1* missense mutation (D1644A) and a novel *TP53* frameshift deletion (A39fs*5) were revealed. Three *mTOR* missense mutations (K1771R, N1421D, I1973F) were found in patients with gastric cancer, renal cell carcinoma and angiosarcoma. A mutation in the helical domain of *PIK3CA* (E542K) was found in a renal cell carcinoma patient and a mutation in AKT1 (H238Y) was observed in a sarcoma patient with malignant fibrous histiocytoma. Lastly, a patient with anaplastic thyroid cancer harbored a nonsense mutation in *TSC1* (p.Trp103*) and a renal cell carcinoma patient had a *TSC1* splicing variant (c.1029+1G > A). Recurrent mutations in chromatin remodeling gene (*BAP1;* n = 2, 12%) and receptor tyrosine kinase signaling (*FGFR4;* n = 2, 12%) were noted only in patients without clinical benefit. **Conclusions:** Regardless of different cancer types, mTOR-pathway-activating mutations confer sensitivity to everolimus. Targeted sequencing of mTOR pathway genes facilitates identification of potential candidates for mTOR inhibitors.

11011 **Poster Discussion Session; Displayed in Poster Session (Board #223), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM**

Next generation sequencing (NGS) to identify targetable recurring mutations and exceptional responders in relapsed and high-risk childhood and adolescent/young adult (AYA) malignancies. *First Author: Brian Turpin, Cincinnati Children's Hosp Medcl Ctr, Cincinnati, OH*

Background: NGS has been rapidly introduced into routine clinical care for select adult malignancies, and the National Cancer Institute genomic precision medicine initiatives (e.g. M-PACT, NCI-MATCH) seek to use genetic sequencing-based treatment to improve response rates in select adult populations. However, the applicability of this technology in pediatric and AYA tumors has yet to be established. **Methods:** In an IRB-approved retrospective analysis of focused exome sequencing of 190 relapsed and high risk pediatric and AYA malignancies, 67 hematologic malignancies, 38 sarcomas, 34 neuroblastomas, 21 CNS, 7 liver, 6 renal, and 17 "other" tumors were analyzed. DNA was sequenced to high, uniform coverage (Illumina HiSeq) and analyzed for genomic alterations (GAs) (Foundation Medicine, Cambridge, MA). **Results:** Population included 156 patients with relapsed/refractory cancer and 34 with de novo high-risk disease (median age 7 yrs; range 3 mos to 34 yrs). GAs were identified in 82% of patients (median of 2 mutations; range 0-15) and included 142 cancer related genes. TP53 was the most frequently identified GA (17% of patients). GAs were identified in multiple "actionable" pathways, including cell cycle regulation/DNA repair (36% of patients), RAS/RAF/MEK (22%), and epigenetic pathways (20%), frequently independent of histology. The number of mutaions ($p = 0.03$) and the presence of a mutation in TP53 ($p = 0.035$) or a cell cycle regulation pathway ($p = 0.004$) was associated with older age. Eceptional responses were observed with GA-based assignment of therapies with RAS/RAF/MEK and epigenetic pathway GAs. Forty percent of patients had gene mutations eligible for the adult M-PACT study. **Conclusions:** High risk and relapsed pediatric and AYA cancer patients have frequent tumor GAs amenable to targeted therapeutics, with the most common actionable pathways being cell cycle regulation/DNA repair, RAS/RAF/MEK, and epigenetic pathways. Formal prospective study of targeted therapy in pediatric and AYA cancer patients, analogous to the NCI-MATCH trial, should be feasible and informative.

Skeletal tumor burden on baseline ^{18}F-fluoride PET/CT to predict bone marrow failure after radium-223. *First Author: Elba Etchebehere, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The purpose of this study is to evaluate if skeletal tumor burden on whole-body 18F-sodium fluoride PET/CT (Fluoride PET/CT) is able to predict bone marrow failure Radium-223 therapy (Ra-223). **Methods:** We retrospectively reviewed 76 histologically confirmed hormone-refractory prostate cancer patients (43-89 y old; mean 71 ± 9 yrs.) with bone metastases who underwent Fluoride PET/CT either prior to, during and/or 3 months after therapy with Ra-223. Bone marrow failure (BMF) was the primary end point. BMF was defined as: (1) the development of hematologic toxicity (WHO Grades 3 or 4) associated with no recovery after 6 weeks, or (2) death due to BMF after the last Ra-223 dose. The following parameters were evaluated: Fluoride PET/CT skeletal tumor burden (TLF_{1O} < 12,000 *vs* ≥ 12,000), the total number of Ra-223 doses the patients received (Ra_{Tot}), the use of chemotherapy during and after Ra-223, serum hemoglobin concentration (HBG < 10 *vs* ≥ 10g/dl), serum alkaline phosphatase (AP < 147 *vs* ≥ 147UI/L), and serum PSA (< 10 *vs* ≥ 10 ng/ml). **Results:** Forty-one patients underwent a baseline Fluoride PET/CT prior to Ra-223 and were eligible for analysis. The number of Ra-223 administrations ranged from 2 to 6 (mean = 5). Of the 41 patients, 16 developed BMF (G3 = 12; G4 = 4). A significant increased risk of developing BMF was observed for patients with $TLF_{1O} \geq 12{,}000$ (OR = 40.0; p = 0.0013), fewer Ra_{Tot} (OR = 0.51; p = 0.0190), HGB < 10 g/dl (OR = 51.0; p = 0.0137) and AP ≥ 147UI/L (OR = 9.50; p = 0.0025). Chemotherapy used concomitant to or after Ra-223 was not found to increase risk of BMF (OR = 0.79; p = 0.71), nor was PSA (OR = 1.17; p = 0.83). Moreover, in a multivariable analysis including all evaluated parameters, TLF_{1O} was the only independent predictor of BMF (OR = 8.74; p = 0.0450). **Conclusions:** Bone marrow failure may occur after Ra-223 treatment, and high skeletal tumor burden as quantified by Fluoride PET/CT is a significant risk factor.

11013 **Poster Discussion Session; Displayed in Poster Session (Board #225), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM**

Imaging peritoneal metastasis of gastric cancer with PET/CT and the radiotracer ^{18}F-fluorothymidine (^{18}F-FLT):Proof-of-concept study. *First Author: Yoshitaka Honma, Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan*

Background: Peritoneal metastasis (PM) is the most frequent form of metastasis in gastric cancer (GC), especially in diffuse type adenocarcinoma (DTAC). Microscopic PM can be identified accurately only in laparoscopic staging. The utility of metabolic imaging for GC is limited because DTAC are not 18F-fluorodeoxiglucose (FDG) avid, and the sensitivity of detecting PM by FDG/PET is known to be low in GC.18F-fluorothymidine (18F-FLT) was developed for imaging cellular proliferation, and its physiological accumulation to the intestinal tract is known to be less than FDG. In previous reports, 18F-FLT-PET had higher sensitivity than FDG and could visualize primary lesion or lymph node metastasis of GC with sufficient contrast, even in DTAC. In this proof-of-concept study, we explored the capability of 18F-FLT PET/CT for detecting macroscopic PM of GC. **Methods:** The key eligibility criteria were: (i) histologically proven gastric adenocarcinoma; (ii) PM detected by CT imaging; (iii) PS: 0-2; and (iv) sufficient organ function. 18F-FLT PET/CT was performed at the National Cancer Center Hospital, and the PET/CTs were interpreted by two independent radiologists who were not informed of the patient background. Detection sensitivity (DS) was defined as proportion of patients for whom 18F-FLT PET/CT noted at least one of the lesions detected in CT. **Results:** Twenty patients were enrolled in this study. One patient was diagnosed as gastric lymphoma by pathological review, who was excluded from the analysis. Fifteen of 19 patients (78.9%) had DTAC. PM was detected by 18F-FLT PET/CT in 14 of 19 patients (SUVmax: 1.697-13.21, DS = 73.7%). Classifying the patterns of PM into omental-cake-type (oPM) and nodule-type (nPM), seven of 19 patients (36.8%) had oPM, all of which were detected by 18F-FLT PET/CT (SUVmax: 1.771-13.21, DS = 100%). Meanwhile, in a total of 42 nodules detected by CT in the 12 patients with nPM, 20 nodules were detected by 18F-FLT PET/CT (SUVmax for positive cases: 1.697-6.524, DS = 47.6%). **Conclusions:** This proof-of-concept study clear the criteria of DS by 18F-FLT PET/CT for proceeding to the future study investigating clinical utility of 18F-FLT PET/CT for PM of GC. Clinical trial information: UMIN000009329.

Phenotypic correlation of tumor uptake of exogenous glutamine radiotracer versus tumor mutational status. *First Author: Mark Dunphy, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Fluoroglutamine (FGln) is a positron emission tomography (PET) clinical tumor imaging radiotracer now in a first in human trial. Glutamine metabolism in several cancer models has been linked both to aggressive tumor phenotype and specific oncogenic mutations. **Methods:** Adults with advanced solid tumors or lymphoma with adequate end organ function are eligible for this phase 1 trial. Microdose radiotracer is given by IV bolus, followed by serial PET scans over a 3-hour period. The primary endpoint is safety, pharmacokinetics, metabolism and bio-distribution of FGln, to be reported separately. Secondary endpoint analysis compares tumor uptake of exogenous glutamine tracer versus tissue-derived tumor biomarkers. **Results:** 20 pts: median age 75 (range 21-75); male 40%; primary tumor site: brain (6), pancreas (3), breast (3), kidney (2), stomach (2), lung (1), large bowel (1), lymph node (1), adrenal gland (1); histology: adenocarcinoma (11), neuroendocrine (2), lymphoma (1), astrocytoma/oligodedriglioma/GBM (6); mean tumor size 2.8cm (range 1.1 to 11.5). Tumor uptake of exogenous glutamine tracer varied between pts with PET-positive tumors (n = 12) and PET-negative (n = 8); tumor uptake expressed as tumor/blood ratio of tracer concentrations, ranged 0.8-4.4. Uptake did not correlate with pre FGln-injection serum glutamine levels (R^2= 0.005); median serum glutamine concentration 610 (range 425-982). 14 pts with tumoral DNA sequencing available or pending were identified. Mutations in TCA cycle genes occurred in 6 of 14 pts (2 with IDH R132H, 1 with FH F402L, 3 with SDH-A/B alterations). Highest observed tumor uptake of exogenous glutamine radiotracer and the longest retention of tracer were observed in 2 pts with tricarboxylic acid (TCA) cycle mutations. **Conclusions:** Fluoroglutamine PET detected tumors in a variety of cancer types, including patients with known mutations affecting tumor metabolism. Clinical trial information: NCT01697930.

Subjects' views on compensation for donating biospecimens. *First Author: Rebecca D. Pentz, Emory University School of Medicine, Atlanta, GA*

Background: Biobanking for research is an increasingly common practice. Ethical concerns regarding ownership of tissue and compensation for donation have arisen as the prevalence of biobanks has increased. **Methods:** Patients eligible for surgical removal of tumors or other tissues at the Winship Cancer Institute were asked to donate tissue by physicians during a surgical oncology clinic as well as by tissue donation staff carrying out a national, multisite NCI biobanking study. We surveyed 101 of these patients, regardless of whether they donated tissue, about informed consent issues surrounding broad future research use of donated tissues. One question queried participants on their preferences regarding compensation for biospecimen donation. Once consented, participants had the option of completing the interview on-site or over the phone. We did not collect any Protected Health Information, other than contact information, which was destroyed upon completion of the interview. **Results:** Of the 140 patient approached, 101 (72%) participated, with 94 (93%) completing the interview over the phone. 19 (14%) patients refused to participate and 20 (14%) were lost to follow up. 52 (51%) were male, 74 (73%) white, and the median age was 62 years. 50 (50%) had a college degree, and the average income bracket was $60,000 - $80,000. Seventy-five (74%) did not think they should be paid for donating tissue. When probed as to their reasons for not wanting payment, most subjects [46 (61%)} provided altruistic reasons. Five noted that biobank participants were not subjected to any additional burden, and three mentioned that the tissue would be destroyed if they had not participated. Seven of the 75 said payment would be appreciated though not expected. Nine (9%) said donors should be paid, with five citing ownership of the tissues. 14 (14%) believed they should only be paid under certain conditions, most commonly referring to tissue use by for-profit companies. Three (3%) had no opinion. **Conclusions:** The majority of subjects did not feel that they should be compensated for tissues provided, viewing it as an opportunity to help others. A small minority believed compensation was due, especially in the case of tissue use by private researchers in for-profit companies.

11016 **Poster Discussion Session; Displayed in Poster Session (Board #228), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM**

Progesterone receptor isoform ratio to define the molecular signature of luminal breast cancers and their antiprogestin responsiveness. *First Author: Maria May, IBYME-CONICET, Buenos Aires, Argentina*

Background: Current therapies for hormone receptor (+) breast carcinomas target the estrogen receptor. Evidence indicates that the progesterone receptor (PR) also participates in cancer growth. In experimental models, we showed that mifepristone (MFP) inhibits the growth of mammary carcinomas when the predominant isoform is PR-A. The aim of our study was to confirm these observations and explore the molecular signatures of breast cancers overexpressing isoforms PR-B or PR-A. **Methods**: Tissue sections from 100 surgical samples were cultured with MFP (10 nM) or vehicle for 48 hs, and embedded in paraffin for Ki-67 staining. Frozen samples were processed for Western blotting (n = 360) or RNAseq (n = 16). Patients were considered PR-A(+) if PR-A/PR-B $\geq$ 1.2, or PR-B(+) if PR-A/PR-B $\leq$ 0.83. The sample size required to detect a 50% difference in MFP response between PR-A+ vs. non PR-A+ samples (type I error: 5%; type II error: 10%) was 19 patients/group. **Results**: MFP only inhibited Ki-67 expression in PR-A+ samples ($p < 0.001$). The 9 ductal HER2 (-) cancer samples analyzed by RNA-Seq with the EBseq algorithm showed 140 transcripts (FC $> \pm 2$; FDR < 0.05); 55 up-regulated in PR-A, and 85 in PR-B. Gene ontology showed functional modules associated with cancer cell proliferation such as 'Aurora B signaling' and the 'FOXM1 transcription factor network' ($p < 0.01$) linked with PR-B up-modulated genes. Intrinsic subtypes and risk score (ROR-S) predicted by the 50-gene PAM50 model were associated with each PR isoform group; 4/4 PR-B cases were Luminal B and 4/5 PR-A were Luminal A ($p < 0.01$). Studies of 140 deregulated transcripts discriminating PR-A from PR-B (TCGA RNASeq breast cancer dataset) demonstrated that a large number of genes up-regulated in PR-B group, remained up-regulated in luminal B and basal-like cancers, compared with PR-A associated genes that are expressed in normal-like and luminal A subtypes. The gene expression signatures associated to each PR isoform are now under validation using an independent cohort of breast cancer samples. **Conclusions:** The PR isoform ratio may define subgroups within the luminal breast cancers: those with PR-A/PR-B $\geq$ 1.2 are candidates for MFP treatment.

A head-to-head comparison of Mammaprint and Oncotype Dx: A McGill University Health Center Experience. *First Author: Ralph Maroun, Department of Oncology, McGill University Health Center, Montreal, QC, Canada*

Background: The Objective of our study was to investigate the concordance of patient results from a single university centre tested with the 21-gene recurrence score assay, Oncotype DX (ODX) when compared to the 70-gene signature Mammaprint (MP), the 80 gene signature of BluePrint (BP) and TargetPrint (TP). **Methods:** Eighty-six consecutive patient-slides node negative hormone positive breast cancer tissue tested with the ODX were enrolled. Based on the ODX recurrence scores (RS) patients were placed either on Chemotherapy and hormonal therapy or hormonal therapy alone. MP was performed on all of the slides previously tested with ODX, and results were reported as either Low or high recurrence risk and were compared with those of the ODX. **Results:** Of the 50 ODX low RS cases, 33 were low risk by MP (66 % agreement) and of the 9 ODX high RS, 7 were high risk by MP (78 % agreement). Of ODX intermediate risk cases (27), 14 of were MP Low risk (52 %), (48 %) 13 were MP high risk. Of BP low risk luminal tumors, 33/49 (67%) were ODX low, 14/49 (29%) ODX intermediate, and 2/49 (4%) ODX high risk (Table). BP class was correlated with ER, PR and HER2 results. Overall agreement between clinical ER, PR, HER2 (IHC+FISH) results with TP results were 98% (81/83), 83% (69/83), 99% (82/83), and percent positive agreement for HER2 was 0/1 (of unequivocally HER2 positive cases identified correctly by TP). **Conclusions:** Results from our institution show that they are real differences in risk assignments between MP and ODX that may affect treatment decisions. There was close correlation between pathologic variables and MP and BP. These results underscore the need for a proper validation of the ODX and MP genetic signatures with outcomes in order to avoid misclassification of both low and high risk patients.

ODx vs. MP.

Circulating tumor cell (CTC) EMT and stem cell biomarker expression predict overall survival (OS) in mCRC by a combined immunomagnetic qRT-PCR approach. *First Author: Yan Ning, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: CTCs harboring epithelial, mesenchymal and stem cells direct the metastatic process. CTC enumeration and biomarker expression have been associated with clinical outcomes in mCRC patients (pts). We developed and validated a combined immunomagnetic qRT-PCR protocol for colorectal CTC characterization based on epithelial, EMT, and stem cell biomarkers with sufficient sensitivity, specificity, and efficiency. The goal of this study was to test whether molecular characterization of CTCs will more effectively predict OS. **Methods:** CTCs were obtained from 94 pts with mCRC [Median age: 56.5 years, Median follow up: 17.3 (1.3, 39.5) mos and OS: 11.4 (9.0, 21.1) mos]. All pts were refractory to standard treatments and were enrolled in clinical trials at USC from 2009 to 2014. Prior to treatment initiation, peripheral blood was collected for CTC isolation. Immunomagnetic qRT-PCR was used for CTC detection based on the presence of CK20 and survivin gene expression. We then selected, based on functional roles and reliability of detection in CTCs, and quantified markers of EMT (PI3Kα, Akt-2) and stem cell (ALDH1) pathway activation in CTC-positive mCRC pts with AdnaGen primer mixture. Cut-off values were determined by Receiver-operating characteristic (ROC) curves. **Results:** 74 of 94 (79%) pts with CTCs based on CK20 and/or survivin gene expression (CTC-positive group) had a significantly worse OS (10 mos v. not yet reached;) compared with the CTC-negative group (21%) in both univariate (HR:3.383 [1.04, 11.01], $P = 0.001$) and multivariate analyses (HR : 4.557 [1.097, 18.926], $P = 0.037$). All CTC-positive pts, which had PI3Kα(57%), Akt-2(56%) and ALDH1(80%) mRNA expression, independently predicted OS based on cut-off values of each marker. Higher gene expression associated with significantly worse OS compared to those with lower gene expression: PI3Kα: 6.4 *v.* 10.4 mos; Akt-2: 8.6 *v.* 23.6 mos; ALDH1: 7.8 *v.* 10.3 mos ($P < 0.001$ for all comparisons). **Conclusions:** Our study is the first to demonstrate the prognostic and predictive significance of this CTC EMT and stem cell gene signature in mCRC pts. This technology may allow real time molecular monitoring of drug efficacy.

Prospective study comparing outcomes in patients with advanced malignancies on molecular alteration-matched versus non-matched therapy. *First Author: Jennifer J. Wheler, Department of Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: With the paradigm shift to precision medicine, we hypothesized that matching patients to therapy based on molecular profile could significantly improve outcomes. **Methods:** Archival tissues from patients treated in MDACC's Phase I clinic were sent to Foundation Medicine, where next-generation sequencing (NGS)-based comprehensive genomic profiling (236 genes) was performed. Patients with actionable molecular alterations were preferentially treated on pathway-matched therapies. A direct match was defined when the drug targeted an alteration or its immediate downstream effector; an indirect match, when the drug targeted a protein > 1 effector removed from the alteration. Based on matching and the number of alterations in patients' tumors, an exploratory scoring system was evaluated; each direct match was given a 1, each indirect match 0.5, and no match a value of zero, normalized by the number of alterations per patient. Progression-free survival (PFS) and overall survival (OS) were analyzed (Kaplan-Meier method; log-rank test). **Results:** Molecular profiling was performed for 339 of 500 patients (68%) consented on the study. Ninety-five percent of those tested (322/339) had ≥ 1 molecular alteration on NGS. Patients (n=175) were treated either on pathway-matched (n = 110, 63%) or non-matched therapy (n = 65, 37%). Matched/non-matched patient characteristics were similar. The most common reasons for not profiling or not treating were inadequate tissue or early death/hospice. Outcomes are shown below. **Conclusions:** Patients treated on matched therapy had significantly improved PFS and OS versus those on non-matched therapy. An exploratory scoring system that included the number of matched therapies in the regimen and molecular alterations in the tumor confirms the above results. Further analyses of response rates and multivariate analyses of factors impacting outcomes are ongoing.

Outcome by therapy and scoring system.

Basis	**Treatment**	**Patients (n = 175)**	**Median PFS (months)**	**p-value**	**Median OS (months)**	**p-value**
Matching	Matched	110	3.9	0.002	10.8	0.018
	Unmatched	65	3.3		7.5	
Scoring system	≥ median score (≥ 0.13)	92	3.8	0.013	11.1	0.026
	< median score (< 0.13)	83	3.3		7.5

Comprehensive genomic profiling of sarcomas from 267 adolescents and young adults to reveal a spectrum of targetable genomic alterations. *First Author: Deborah Morosini, Foundation Medicine, Inc., Cambridge, MA*

Background: Sarcomas comprise nearly 10% of all cancers (CA) in adolescents and young adults (AYA, age 15-39). Despite high unmet clinical need for better treatments, comprehensive genomic profiling (CGP) of AYA sarcomas has not been reported. To identify the genomic alterations (GA) and potential therapeutic targets, we performed CGP on 267 AYA sarcomas. **Methods:** DNA and RNA were extracted from 267 AYA sarcomas. CGP was performed on hybridization-captured libraries to a mean coverage depth of $>$ 500X for 405, 315, or 265 (DNA) and 333 (RNA) CA-related genes, plus select intronic regions frequently rearranged in CA. Results were analyzed for base substitutions, insertions/deletions, copy number alterations, and fusions/rearrangements. We compared pediatric (peds) (n = 51), AYA (n = 267) and $>$ 39yo (n = 853) patients and complex karyotype driven (CKD) versus fusion driven (FD) subtypes. **Results:** In AYA sarcoma, the most common GAs were in *TP53* (25%), *CDKN2A* (16%), and *EWSR1* (12%). An average of 3 GAs/sample was found (range 1-12). Clinically relevant GAs (associated with approved drugs or mechanism based trials) were present in 60% of cases. Cell cycle alterations (*CCND1,2,3, CCNE1, CDK4/6, CDKN2A/B, RB1*) were enriched in $>$ 39 yo (53%) vs AYA sarcomas (33%, $p < 0.001$, Fisher's exact test). Comparison of CKD and FD AYA sarcomas revealed differing frequency by age grouping. CKD sarcomas were less frequent in the AYA group (15%) compared to either the peds (20%) or $>$ 39 yo (22%). FD sarcomas seem more frequent in AYA tumors (5%) vs $>$ 39 yo (0.5%), but less frequent than in the peds (35%). FD tumors were enriched for GA in *EWSR1* and *SS18* corresponding to the frequency of Ewing and synovial sarcoma, respectively, seen in AYA CA. Novel fusions were also found, such as a *LMNA-NTRK1* fusion in a YA with metastatic sarcoma, enabling enrollment in a clinical trial of NTRK-specific therapy. **Conclusions:** A combined DNA and RNA CGP assay can characterize tumor specific GA in AYA sarcomas and guide novel treatment decisions. Further use of CGP in these patients can potentially increase AYA enrollment in clinical trials of targeted therapies and lead to improved outcomes for these aggressive forms of CA.

Comparison of tumor-infiltrating lymphocytes between primary and metastatic tumors in breast cancer patients. *First Author: Rin Ogiya, Tokai University, School of Medicine, Isehara Kanagawa, Japan*

Background: The assessment of tumor-infiltrating lymphocytes (TILs) in primary breast cancer allow to predict prognosis and chemotherapy benefit, particularly in triple-negative (TN) and HER2-positive breast cancer. In the latter, it predicts also benefit from HER2-targeted agents. A little is known about the change of TILs during the metastatic progression. We compared TILs in paired samples from primary and metastatic TN and HER2-positive tumors. **Methods**: We retrospectively identified 25 patients with triple-negative or HER2-positive early breast cancer diagnosed between 1990 and 2010 at a single institution and subsequently experienced a distant recurrence confirmed by tumor biopsy/resection. Hematoxylin- and eosin-stained slides for these paired match cases were evaluated for stromal-TILs as recently recommended (Salgado R Ann Oncol 2014). We defined three groups according to : low-TILs (≤ 5), intermediate-TIL (10-50), Lymphocyte Predominant Breast Cancer (LPBC) ($\geq 60\%$). **Results**: We evaluated 25 breast cancer patients (n = 11 TN; n = 14 HER2+). Primary tumors had 28% (LPBC), 52% (intermediate-TIL) and 20% (low-TIL). Corresponding first metastatic recurrences had 44% (intermediate-TIL) and 56% (low-TIL). Overall, TILs in primary tumors were significantly higher (average 34.6%) than at metastatic recurrences (average 15.7%) (paired t-test, $p = 0.004$). This difference was similar in HER2+ ($p = 0.036$) and TN ($p = 0.06$). In 13/25 (66%) cases the percentage of TILs decreased and in 3/25 increased (difference $> 10\%$). We performed an exploratory analysis of post-progression overall-survival according to TIL at distant site of recurrence. The group with low-TIL had a significantly lower overall-survival than intermediate-TIL (HR = 3.77, CI 95% 0.99-14.9; logrank test $p = 0.038$). **Conclusions**: Tumor at first metastatic recurrence in TN and HER2+ breast cancer have lower infiltrating-lymphocytes compared to primary tumors, supporting a role for immune escape in tumor progression. Low-TIL at recurrences seemed to be associated with worst overall survival suggesting a more aggressive phenotype. These findings warrant independent confirmation.

11022 Poster Session (Board #234), Sun, 8:00 AM-11:30 AM

Complications following immediate breast reconstruction and influence on breast cancer recurrence rates. *First Author: Suzanne M Beecher, University Hospital Galway, Galway, Ireland*

Background: The rate of immediate breast reconstruction has risen over the past number of years. Post-operative infections are more frequent in patients who undergo reconstruction. The inflammatory response to a postoperative infection can increase the risk of tumour recurrence in other forms of cancer through the release of pro-inflammatory mediators. The aim of this study was to assess the relationship between complications and breast cancer recurrence in patients who undergo immediate breast reconstructive surgery. **Methods:** A review of a prospectively maintained database of allpatients who had immediate breast reconstruction between 2004 & 2009 was conducted. All patients had a minimum 5-year follow up. Univariate & multivariate Cox Regression analysis was performed using SPSS v21. **Results:** 229 patients who underwent immediate breast reconstruction were identified. The overall 5-year disease-free survival was 86%. 53 (23%) patients had wound complications. 43 (19%) had a wound infection. There was a significantly greater risk of developing systemic recurrence in patients who experienced a post-operative wound complication compared to those without (HR: 4.94; 95% CI: 2.72 - 8.95; $P < 0.0001$). The five-year disease free survival rate for patients who had a wound complication was 64% compared to 91% in patients without a complication ($p < 0.0001$). **Conclusions:** This study demonstrates that wound complications after immediate breast reconstructive surgery may have survival implications for breast cancer patients. Further research is warranted to confirm this relationship. In addition, strategies are required to minimize the risk of post-operative wound complications in breast cancer patients undergoing reconstruction.

11023 Poster Session (Board #235), Sun, 8:00 AM-11:30 AM

Inhibition of AKT3 to increase migration and metastasis by upregulation of S100A4 protein expression. *First Author: Florian Ewald, University Medical Center Hamburg Eppendorf, Hamburg, Germany*

Background: The treatment of patients with distant metastases represents one of the biggest challenges in modern oncology, and the occurrence of metastases often determines the prognosis of the disease. Therefore, understanding the mechanisms facilitating the development of metastasis is of paramount importance. It was previously shown that activation of the PI3K/AKT pathway is a requirement for the ability of tumour cells to disseminate and form metastases. However, single AKT isoforms (AKT1, AKT2 and AKT3) were shown to have different, and even opposing functions regarding the regulation of cancer cell migration *in vitro*, giving rise to the hypothesis that inhibition of distinct AKT isoforms might have undesirable effects on cancer progression. The aim of this project therefore is to investigate the functions of the specific AKT isoforms regarding migration and metastasis of cancer cells. **Methods:** Three cell lines were used to generate single and double AKT isoform knockdown cells. Migration and invasion of these cells was analysed *in vitro* using live imaging migration, chemotaxis, and invasion assays. Metastatic potential of AKT isoform knockdown MDA-MB-231 cells was evaluated in a subcutaneous xenograft mouse model *in vivo*. **Results:** Knockdown of AKT3, but not AKT1 or AKT2, results in increased migration and scattering *in vitro*, and this effect was even more pronounced in AKT2/AKT3, and AKT1/AKT3 double knockdown cells. Furthermore, we were able to demonstrate that knockdown of AKT2/AKT3 and AKT1/AKT3 results in an increased number of lung metastasis, as detected by Alu PCR and upon histological examination. We found that AKT3 specifically regulates the expression of the metastasis promoting protein S100A4 via regulation of NFAT5 in MDA-MB-231 cells, and knockdown of S100A4 or NFAT5 were able to reverse the AKT3 induced increase in migration. **Conclusions:** Our study provides novel insight into the specific contribution of each AKT isoform to the regulation of migration and metastasis, and our results indicate that inhibition of AKT3 might cause adverse effects on cancer dissemination and progression. Therefore, our results provide a rationale for the development of AKT isoform specific inhibitors.

11024 Poster Session (Board #236), Sun, 8:00 AM-11:30 AM

Evaluation of a novel c-MET based circulating tumor cell (CTC) biomarker in patients with gastrointestinal (GI) and genitourinary (GU) malignancies. *First Author: Tian Zhang, Duke University Medical Center, Durham, NC*

Background: Genetic alterations in the *MET* oncogene exist in many GI and GU malignancies. *MET* amplification is associated with poor prognosis and can arise as a resistance mechanism to EGFR targeting therapies. We aimed to capture and identify CTCs expressing c-MET. **Methods:** We modified the Cellsearchplatform by using nanomagnetic particles conjugated to antibodies against c-MET to capture c-MET-expressing CTCs and stained for c-MET-PE, DAPI, and pan-CK-FITC. CD45 + cells were excluded. The method was validated by spiking *MET*-amplified gastric cancer cells, c-MET-overexpressing, nonamplified cancer cells, and *MET*-negative cancer cells into peripheral blood from healthy volunteers (HVs). Peripheral blood samples were obtained from patients (pts) with refractory metastatic gastric, pancreatic, colorectal, bladder, renal, and prostate cancers. CTC enumeration with c-MET capture was compared to EpCAM capture. After CTC isolation, DNA FISH for *MET* amplification was performed. **Results:** The novel c-MET CTC assay was 80% sensitive for *MET*-amplified cells, 40-80% sensitive for c-MET-overexpressed cells, and 100% specific for c-MET negative cells and in 20 HVs. Of 50 pts tested thus far, we captured c-MET CTCs in duplicate samples from 3 pts, with gastric adenocarcinoma (90 and 52 c-MET CTCs), colorectal adenocarcinoma (7 and 2 c-MET CTCs), and renal cell carcinoma (RCC; 3 and 1 c-MET CTCs). CTC FISH demonstrated polysomy 7 and *MET* amplification in both gastric and colorectal cancer pts and trisomy 7 with gain of *MET* gene copies in the RCC pt. **Conclusions:** The c-MET CTC assay is rapid, non-invasive, sensitive and specific. c-MET expressing CTCs can be detected in gastric, colorectal, and renal cancers but not negative controls. *MET* amplification can be detected using FISH after CTC capture, leveraging this technology as a potential minimally invasive liquid biopsy. This approach may be clinically useful to identify and follow patients who may be candidates for c-MET directed therapies.

11025 Poster Session (Board #237), Sun, 8:00 AM-11:30 AM

Circulating tumor DNA (ctDNA) as a prognostic marker for recurrence in resected pancreas cancer. *First Author: Judy Sing-Zan Wang, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Despite aggressive therapeutic interventions with pancreaticoduodenectomy and adjuvant chemo/chemoradiotherapy, recurrence rates remain high for patients with resectable pancreas cancer. Additionally, current post-operative surveillance methods including tumor marker CA19-9, clinical symptoms, and CT scans lack sensitivity and specificity for early recurrence. Hence, a practical, blood-based biomarker that could identify cancer at an earlier time point, and prompt a change in management, would be clinically important. **Methods:** Using a highly sensitive digital DNA quantification approach, we measured *KRAS* mutation-associated circulating tumor DNA (ctDNA) in the archived sera of 46 resected pancreas adenocarcinoma patients taken 8-10 weeks post-operatively, after confirming the mutational presence in the primary tumor. Approximately 10 years of patient data were available from chart review and clinical databases to assess disease recurrence. A mutant allele fraction $>$ 0.02% was considered positive. **Results:** In a subgroup analysis, patients whose tumor had a p.G12V *KRAS* mutation and who did not have detectable levels of ctDNA had significantly longer time to disease recurrence than did patients with detectable ctDNA ($p = 0.02$; CI 1.037 to 12.77). Amongst patients whose tumor harbored a p.G12R *KRAS* mutation, those with undetectable ctDNA also had significant longer time to disease recurrence as compared to those with detectable ctDNA ($p = 0.01$; CI 1.241 to 36.99). In combination, 14 of the total 46 patients who had undetectable ctDNA following their resection trended, though statistically insignificant, towards longer time to disease recurrence (median time 545 to 471 days; HR = 0.58; $p = 0.3$) including 3 ctDNA-negative patients who still remain disease free. **Conclusions:** This retrospective analysis demonstrates that ctDNA can be detected in peripheral blood, and may be a valuable clinical marker for specific tumor mutations. Additional larger, prospective studies are needed to validate the clinical utility as a prognostic biomarker for recurrence in resected pancreas cancer.

11026 Poster Session (Board #238), Sun, 8:00 AM-11:30 AM

Emergence of *KRAS* mutation in detection of circulating tumor DNA during treatments for metastatic gastrointestinal cancer patients. *First Author: Yuji Takayama, Saitama Medical Center, Jichi Medical University, Saitama, Japan*

Background: It has been reported that molecular alterations in *KRAS* status were observed during treatment in colorectal cancers. The aim of this study was to explore change in *KRAS* status during various treatments for metastatic gastrointestinal cancer patients. **Methods:** One hundred and nineteen plasma samples were collected prospectively in 2014 from 52 patients who underwent chemotherapy due to metastatic gastrointestinal cancer including 46 colorectal and 6 pancreatic cancer patients. *KRAS* mutant circulating tumor DNA (ctDNA) was detected by digital PCR. Less than 0.1% of positive *KRAS* mutant is estimated as negative. **Results:** *KRAS* assessment in tumor tissues showed 22 patients with *KRAS* mutation (MT), 18 without *KRAS* mutation (WT) and 12 patients without *KRAS* information (NI). Among 22 patients with MT, KRAS assessment in ctDNA displayed 10 patients with KRAS mutant ctDNA and 12 patients without mutant ctDNA. While 18 patients with WT did not show any mutant ctDNA before chemotherapy, 3 patients exhibited *KRAS* mutant ctDNA after treatments. They are treated with different regimens such as CapeOX+BEV, CPT+Cmab and Regorafenib, respectively. *KRAS* mutant ctDNA was detectable in the blood of these three patients prior to radiographic detection of disease progression (PD). Among 12 patients with NI, there were 4 patients with *KRAS* mutant ctDNA and 8 patients without mutant ctDNA. Concerning response to chemotherapy, poor outcome was found in patients with *KRAS* mutant ctDNA regardless of *KRAS* status in tumor tissues. **Conclusions:** These results indicated that blood monitoring of *KRAS* status could be required not only to predict outcome of treatments but also to choose optimal regimes.

Subclassification of prostate cancer circulating tumor cells (CTCs) by nuclear size reveals very-small nuclear CTCs in patients with visceral metastases. *First Author: Yi-Tsung Lu, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: In prostate cancer (PCa), morphologic classification remains a standard clinical practice in pathology. It has been shown that nuclear size and shape in tumor sections correlate with distant metastasis and death, but this relationship has not been explored in emerging tissue sources such as CTCs. Using NanoVelcro chip, our group sub-classified CTCs in PCa patients by shape features focusing on nuclear size and related this to clinical information, particularly the lethal progression to visceral metastasis (VM). **Methods:** A total of 148 blood samples were obtained from 57 PCa patients across the spectrum of metastatic states: no metastases, non-visceral (osseous and/or nodal) metastases, and visceral (hepatic and/or pulmonary) metastases. CTCs captured and enumerated on NanoVelcro Chips were subjected to pathologic review including nuclear size. The distribution of nuclear size was analyzed using a Gaussian Mixture Model. Correlations were made between CTC subsets and metastatic status. **Results:** Statistical modeling of nuclear size distribution revealed 3 distinct subsets: large-nuclear ($>$ 15 μm), small-nuclear (snCTCs, 8.54 - 15 μm), and very-small-nuclear CTCs (vsnCTCs, $<$ 8.54 μm). The proportions of the 3 CTC nuclear subsets varied significantly among different metastatic states ($p < 0.001$). snCTC + vsnCTC identified patients with metastatic disease from those without (0.35 $\pm$ 0.66 versus 2.02 $\pm$ 3.36 cells per mL of blood, $p < 0.001$). vsnCTC counts alone were elevated in patients with VM when compared to those without (0.36 $\pm$ 0.69 vs. 1.95 $\pm$ 3.77 cells/mL blood, $p < 0.001$). Serial enumerations suggested the emergence of vsnCTCs prior to radiographic detection of newly developed VM. **Conclusions:** There are morphologic subsets of CTCs that can be identified by fundamental pathologic approaches, such as nuclear size measurement. Our observation strongly suggests that they contain relevant information on disease status. In particular, the detection of vsnCTCs correlated with the presence of VM and should be explored as a putative blood-borne biomarker to identify patients at risk for developing this lethal progression event of PCa.

11028 Poster Session (Board #240), Sun, 8:00 AM-11:30 AM

Molecular profiling of circulating tumor cells in non-metastatic breast cancer. *First Author: Victoria Forte, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Circulating tumor cells are prognostic in all stages of breast cancer (BC), yet few studies have examined their molecular biology in non-metastatic BC. We have previously reported a method for isolation and gene expression profiling of pure CTCs that permits gene expression profiling without background subtraction of leukocytes. We hypothesized that transcriptional profiling of CTCs prior to therapy may predict for pathologic complete response (pCR) to neoadjuvant chemotherapy (NC) in Stage II-III breast cancer. **Methods:** We are currently enrolling patients to a prospective, observational clinical study in which CTCs are enumerated and captured from 20 mL peripheral blood (PB) via immunomagnetic enrichment based on EpCAM followed by fluorescence-activated cell sorting (IE-FACS). CTCs and tumors are profiled with RNA Seq via the Illumina HiSeq (primary predictor); NanoString PAM50 and real-time polymerase chain reaction will be used as validation studies. **Results:** To date, we have isolated CTCs from 29/33 patients (88%). No CTCs were found in 23 healthy controls. The median number of CTCs isolated was 7 (range 0-65). We will analyze our primary endpoint when $n = 20$ and $n = 40$ NC treated patients. Currently 12/33 patients had NC and 21 had no NC; 10/12 patients had CTCs isolated and 5/10 patients had a pCR. RNA Seq of the first 17 patients CTCs shows clear differentiation between CTCs and PB with 253 differentially expressed genes with a fold-change of at least 2 (false-discovery rate adjusted $p < 0.001$). A gene set enrichment analysis of the 17 CTC samples demonstrated up-regulation of cancer related pathways ($p < 0.001$). RNA Seq and validation studies of additional CTC and tumor samples is currently in progress. **Conclusions:** RNA Seq of rare CTCs is feasible in Stage II-III breast cancer and shows evidence of oncogenes and tumor suppressor genes.

11029 Poster Session (Board #241), Sun, 8:00 AM-11:30 AM

Applying a mitotic index to circulating tumor cells and its prognostic significance: A cytological approach to patient stratification. *First Author: Daniel L Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: It has been well documented that enumeration of Circulating Tumor Cells (CTCs) isolated from the peripheral blood of breast cancer patients can be used as a prognostic indicator of survival. Typically, CTC identification relies on immunohistochemical stains used in an absent/present method (i.e. CK+/CD45-). However, the methodology for identification of CTCs is highly subjective, and histological cytology remains the standard identifier of cancer cells. We expand upon our work regarding the cytological criteria of CTCs, Adams et al, Cytometry 2015, to determine if pathological grading criteria can be applied to CTCs. We report the assessment for overall survival of late stage breast cancer in relation to CTC number and presence of active mitosis. **Methods:** A prospective pilot study of 30 single blinded Stage III/IV breast patient samples were provided by Fox Chase Cancer Center and University of Maryland Baltimore. 7.5mL whole blood was diluted in pre-fixation solution and filtered by CellSieve microfiltration. Cells were fixed, permeabilized, and stained with DAPI, an antibody cocktail against CK 8/18/19, EpCAM, and CD45. CTCs were enumerated and identified as described by Adams et al. Cytometry 2015. CTCs were further subtyped by 1) number of pathologically definable CTCs (PDCTCs) and 2) presence of mitotic events, identified by standard visual cues (e.g. prophase, anaphase, etc.). Kaplan-Meier plots and Hazard ratios were determined at 24 months. **Results:** PDCTCs were found in 87% (26 of 30) of patient samples tested. Of the 14 patients who had $\geq$ 5 CTCs/7.5mL, 36% (5 of 14) survived 24 months. Of the 16 patients who had $<$ 5 CTCs/7.5mL, 81% (13 of 16) survived 24 months. By contrast, 12 of the 30 patients who had $\geq$ 1 CTC with a mitotic event, 17% (2 of 12) survived 24 months. Of the 18 patients who had no mitotic CTCs, 89% (16 of 18) survived 24 months. **Conclusions:** Stratification of breast cancer patients based on number of CTCs is a prognostic indicator of patient survival. Our data suggests that prognostic value is increased by subtyping CTCs based on their mitotic index as assessed by overall survival over a 24 month period.

11030 Poster Session (Board #242), Sun, 8:00 AM-11:30 AM

Exploring the intra-patient *PIK3CA* mutational heterogeneity of circulating tumour cells by massive parallel sequencing in patients with metastatic hormone receptor-positive breast cancer. *First Author: Bram De Laere, Center for Oncological Research (CORE) - campus Sint-Augustinus - University of Antwerp, Antwerpen, Belgium*

Background: Circulating tumour cells are a real-time reflection of the *ad hoc* relevant subpopulation in patients with progressive disease. The study comprises the clinical application of a liquid biopsy to assess the *PIK3CA* genotype at a single cell level. **Methods:** Using CellSearch and DEPArray we purified single and groups of CTCs and WBCs from peripheral blood in 29 patients with metastatic hormone receptor-positve breast cancer. Recovered cells were subjected to Ampli1 whole genome amplification (WGA). Temporally-matched circulating cell-free DNA (cfDNA) was purified from plasma. Additionally, gDNA from archival primary tumour (PT) tissue sections was extracted as comparator. Mutation analysis was performed via targeted amplicon sequencing (TAS) of exons 9 and 20. **Results:** Archival PT tissue section showed a high frequency of mutant *PIK3CA* (16/27 (59,2%)), with a poor and fair agreement with cfDNA (n = 21; 43% disparity; κ = 0,113) and CTCs (n = 22; 27% disparity; κ = 0,394), respectively. A concordant *PIK3CA* status between different compartments was observed in 10/18 (56%) samples. At the used sequencing depth, cfDNA failed to the detect *PIK3CA* mutations in 4 cases (22%), of which three were present in the respective PT and corresponding CTCs. Gain of mutation was observed in 4/18 patients (22%), with a wild type PT and mutant CTCs at progression (cfDNA confirmed the MT genotype in three cases). A wild-type *PIK3CA* sequence in recovered WBCs indicates a high specificity and tumorigenic nature of the picked up variants. Intra-CTC analysis reveals *PIK3CA* mutational heterogeneity with the presence of both mutant and wild-type CTCs. Additionally, unique double-mutated CTCs were detected in 10/26 (38%) cases as well. **Conclusions:** PIK3CA mutations are frequent in metastatic HR^+ breast cancer. Intra-patient *PIK3CA* mutational heterogeneity was observed with cases of concordance and discordance when comparing early to advanced disease. The study presents the utilization of a liquid biopsy, thereby paving the way towards the application of a more personalized medicine in the management of patients with metastatic cancer.

11031 Poster Session (Board #243), Sun, 8:00 AM-11:30 AM

Vemurafenib to eliminate BRAF-mutated circulating epithelial tumor cells (CETCs) from blood of patients with malignant melanoma. *First Author: Dorothea Zimon, Transfusion Center Bayreuth, Bayreuth, Germany*

Background: Almost 50% of melanomas harbor mutations in BRAF, mainly V600E. The mutations are usually identified in the primary tumor. However, the primary tumor is often no longer available and metastases not always reflect the characteristics of the primary tumor. In melanoma it is not clear at what stage epithelial antigen is expressed. CETCs are present in peripheral blood in a significant proportion of patients with malignant melanoma. The aim of the present study was to analyze whether these cells belong to melanoma clone due to the presence of the BRAF gene mutation in these cells. For this reason, the analysis of multiple isolated CETCs from individual patients for BRAF gene mutations was performed. **Methods:** Blood from patients with malignant melanoma was analyzed for cells positive for the EpCAM and Melan-A using the maintrac approach, avoiding cell selection and using an image analysis system for detection. Subsequently, between 8-20 EpCAM and Melan-A positive cells from each patient were isolated individually using a semi-automated capillary approach and deposited one by one into micro cups. The DNA of individual cells was amplified by whole genome amplification and assayed using the cobas BRAF V600 mutation test. Furthermore, we performed mutation analysis of cells after magnetic bead enrichment which is known to contain a mixture of CETCs and leukocytes. **Results:** DNA could be amplified from all individually isolated cells. In addition, we analyzed the presence of V600 mutation after magnetic bead enrichment. A BRAF mutation was detected in 20 - 75 % of evaluable cells in patients with BRAF mutation in primary tumor. In advanced stage or metastatic patients under Vemurafenib therapy, we were not able to find mutated CETCs. **Conclusions:** Individually isolated CETCs from the peripheral blood from patients with melanoma allow not only to detect mutations but also to determine the frequency of mutated cells. This proves that at least part of the CETCs is originated from the primary tumor. Furthermore, detection of BRAF mutation in CETCs may be crucial for a successful molecular-targeted therapy.

11032 Poster Session (Board #244), Sun, 8:00 AM-11:30 AM

Folate Receptor-Positive Circulating tumor cell detected by LT-PCR based method as a diagnostic biomarker for non-small cell lung cancer. *First Author: Xiaoxia Chen, Tongji University Medical School Cancer Institute, Shanghai, China*

Background: To investigate the diagnostic performance of folate receptor (FR) positive circulating tumor cells (CTCs) in distinguishing non-small cell lung cancer (NSCLC) from lung benign disease by using a novel ligand-targeted polymerase chain reaction (LT-PCR) detection technique. **Methods:** CTCs were enriched from 3ml peripheral blood by immune-magnetic depletion of leukocytes and then labeled with a conjugate of a tumor-specific ligand folic acid and a synthesized oligonucleotide. After washing off free conjugates, the stripped bound conjugates were analyzed by quantitative PCR. **Results:** 756 participants (473 patients with NSCLC, 227 patients with lung benign disease, and 56 healthy donors) were randomly assigned to a training set and a test set. The CTC levels in patients with NSCLC were significant higher than those with lung benign disease ($P < 0.001$) and healthy donors ($P < 0.001$). Compared with CEA, NSE, and Cyfra21-1, CTCs displayed the highest area under curve (AUC) (training set: 0.815; validation set: 0.813) in the diagnosis of NSCLC, with a markedly sensitivity (training set: 72.46%; validation set: 76.37%) and specificity (training set: 88.65%; validation set: 82.39%). The model combining CTCs with CEA, NSE, and Cyfra21-1 was more effective for the diagnosis of NSCLC than tumor makers alone (sensitivity and specificity in the training set: 84.21%, 83.91%; validation set: 88.78%, 87.36%). In addition, the CTC levels were higher in patients with stage III/IV NSCLC compared with those with stage I/II disease. **Conclusions:** LT-PCR technique was feasible and reliable for detecting FR-positive CTCs in NSCLC patients and CTC levels could be used as a useful biomarker for the diagnosis of NSCLC.

11033 Poster Session (Board #245), Sun, 8:00 AM-11:30 AM

ERCC1 induction after oxaliplatin exposure may depend on KRAS mutational status in colorectal cancer patient: preliminary data from liquid biopsy. *First Author: Mariantonietta Di Salvatore, Medical Oncology Unit, Catholic University of the Sacred Heart, Rome, Italy*

Background: Basing on preliminary observations of OPUS and PRIME studies, our group retrospectively suggested that KRAS mutational status could affect response to oxaliplatin. We further confirmed this evidence in vitro demonstrating that KRAS mutated cell lines were more sensitive to oxaliplatin due to their inability to induce ERCC1 after drug exposure. Using CTCs as a surrogate, dynamic tissue, in this study we sought to confirm in vivo the relationship between KRAS mutational status, ERCC1 inducibility and clinical outcome in oxaliplatin-treated colorectal cancer patients. **Methods:** We collected blood samples from colorectal cancer patients treated with oxaliplatin-based regimen at 0 and 48 hours during the first cycle of chemotherapy. The presence of CTC was detected by AdnaGene system followed by multiplex RT-PCR including ERCC1 transcript. In CTC-positive ERCC1-positive patients, ERCC1 mRNA expression was measured using a quantitative real time RT-PCR method, before and after drug exposure. We evaluated the relationship between ERCC1 induction and KRAS mutational status and we tried to correlate this association with clinical outcome **Results:** On a total of 38 patients enrolled, 19 were KRAS wild type and 19 KRAS mutated. CTCs were detected in 12 (31,5 %) patients. ERCC1 was expressed in 8/12 CTCs-positive patients, 5 KRAS wild type and 3 mutated. After Oxaliplatin exposure, among ERCC1-positive patients, only 3 showed a significant induction of ERCC1 expression; interestingly all of them were KRAS wild-type and experimented a rapid progression of disease. The median PFS of patients with ERCC1 induction was shorter than that observed in patients with stable or reduced ERCC1 (2,5 months vs 7,2 months). Notably none of the KRAS mutated ERCC1-positive CTCs was able to induce ERCC1 and median PFS was 11,6 months. **Conclusions:** Although based on a small sample size,this study could support the relationship between KRAS mutational status, ERCC1 inducibility, and clinical outcome, corroborating our hypothesis that KRAS mutational status could be a surrogate marker of efficacy of oxaliplatin therapy. Further studies are warranted to study this association.

11034 Poster Session (Board #246), Sun, 8:00 AM-11:30 AM

EpCAM-independent isolation of EMT- circulating tumor cells in patients with primary breast cancer who receive primary systemic therapy. *First Author: Fanny Le Du, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tumor cells with amesenchymal phenotype and/or cancer stem-like cells (CSCs) are known to contribute to metastasis. Circulating tumor cells (CTCs) undergoing epithelial-mesenchymal transition (EMT) may not be detected using an anti-EpCAM antibody. We have developedan antibody-independent CTC enrichment platform, *Apostream* that does not rely on EpCAM-based capture, assessing morphologic and dielectric properties gated on CD45- cells. We used this instrument to determine the feasibility and clinical relevancy of measuring EMT-CTCs in breast cancer patients who received primary systemic chemotherapy (NST). **Methods:** Blood samples from newly diagnosed breast cancer patients were prospectively collected before NST (T0), after NST (T1), and after definitive surgery (T2) and processed using the *Apostream* system. Isolated cells were stained with antibodies to leukocytes (anti-CD45), and the DAPI nuclear stain, to identify CTCs. These CTCs were also stained with additional markers and examined on a laser scanning cytometer to measure protein expression levels of various markers to define 4 CTC-phenotypes: epithelial (CK+, EpCAM+, E-cadherin+), EMT (β-catenin,+ vimentin+), combined epithelial and EMT (CK+, EpCAM+, E-cadherin+, vimentin+), and CSC (CD44+, CD24low). Pathological complete response (pCR) was correlated to CTCs and marker expression. **Results:** Of the 15 patients enrolled, 5 patients achieved pCR. Epithelial-CTCs were detected in 60%, 67%, and 77% of the T0, T1, and T2 samples, respectively. EMT-CTCs were detected in 80%, 87%, and 85% of these samples, respectively. The mean number of CTCs with epithelial and EMT phenotype was 32.8 (range, 0-434) and 68.7 (range, 0-687) respectively. Number ofCTCs with epithelial phenotype and CSC phenotype were more likely to decrease, after NST, if N stage (nodes) > or equal 3 ($P = 0.014$) or T stage (primary tumor) > or equal 4 ($P = 0.066$), respectively. Neither EMT ($P = 0.505$) nor epithelial ($P = 0.580$) phenotypes of CTCs seem to predict pCR. **Conclusions:** A*postream* was successful in detecting both epithelial and EMT-CTCs. We will present the final data analysis of 50 patients to conclude on their predictive impact.

11035 Poster Session (Board #247), Sun, 8:00 AM-11:30 AM

Intra-patient genomic heterogeneity of single circulating tumor cells (CTCs) associated to phenotypic CTC heterogeneity in metastatic castrate resistant prostate cancer (mCRPC). *First Author: Mark Landers, Epic Sciences, Inc., San Diego, CA*

Background: Analysis of somatic genomic alterations in primary tumors is often used to define mutational status and guide therapeutic decisions. Selective pressures (including multiple lines of therapy) can lead to tumor evolution through step-wise accumulation of genomic alterations. CTCs from mCRPC pts have shown phenotypic heterogeneity in size, shape, CK expression (exp) and AR exp. Heterogeneity increases with multiple lines of therapy and is associated with treatment resistance. Defining CTC genotype to phenotype correlation may enable identification of emerging resistant clones for which a change in tx may be needed. We performed NGS whole genome CNV analysis at the single CTC level to detect driver somatic alterations associated with CTC epithelial & AR exp profiles. **Methods:** 147 CTCs were individually sequenced from 9 mCRPC pt blood samples and classified as traditional, CK-, or small CTCs and analyzed for AR exp. CTCs were individually isolated, lysed, WGA, library constructed, sequenced, aligned, parsed, normalized, and subtracted from germline CNV. Each pt CTC CNV profile was used to identify distinct sub-clonal populations and characterize CTC genomes. The genomic alterations were associated with CTC phenotypes. **Results:** Within each pt, 2-5 clonal populations were identified. On average, 11 CNV events were detected per CTC, with an intra-patient CTC correlation of 30-59%. The correlation increased 33% within a CTC specific phenotype ($p = 0.013$). The presence of mCRPC driver alterations (Amp- AR, cMYC; Del- TP53, PTEN, RB1) were predominantly in CTC subpopulations of pts not responding to tx. Overall, 59% of CTCs had a single driver alteration. **Conclusions:** Tracking all CTC populations is important to assessing genomic driver alterations. Intra-patient CTC genomic heterogeneity is common and statistically associated with heterogeneity of size, shape, CK & AR exp. CK- & small CTCs, unlike traditional CTCs, often possess loss of tumor suppressors, and are associated with resistance. Actionable alterations may only be observed in rare CTC subtypes and represent a potential new target to delay disease progression.

11036 Poster Session (Board #248), Sun, 8:00 AM-11:30 AM

Centrosome amplification and prognosis in breast cancer. *First Author: Ryan Austin Denu, University of Wisconsin School of Medicine and Public Health, Madison, WI*

Background: Centrosome amplification (CA) has been reported in all human cancers and is thought to result in aneuploidy and chromosomal instability (CIN). CA is associated with deleterious clinical factors such as higher grade and stage, but these reports have not shown how CA affects survival. Here we analyzed centrosome abnormalities in a cohort of 362 patients. **Methods:** A tissue microarray was constructed using triplicate punch biopsies from each patient. Centrosomes were recognized by immunohistochemistry as the overlap of pericentrin and polyglutamylated tubulin, which represent pericentriolar material (PCM) and centriole markers, respectively. We assessed centrosome number, size, shape, and clustering in at least 30 cells from 3 different regions of each patient's tumor. Ploidy and CIN were assessed using 6-chromosome FISH. Survival was analyzed using the Kaplan-Meier method and Cox proportional hazards modeling. Correlations were assessed using Spearman's rank correlation coefficient. **Results:** CA was associated with worse overall survival, both all-cause and breast cancer-specific mortality, as well as recurrence-free survival. Further, greater centrosome size and centrosome clustering were also associated with worse survival. CA was more pronounced in triple negative and HER2-positive subgroups, and also increased with increasing stage and histological grade. Cox proportional hazards modeling using CA, stage, grade, HER2 status, and hormone receptor status revealed that stage and hormone receptor status were the only independent predictors of survival in this cohort. Further, CA correlated with increased ploidy and chromosomal instability in these tumors. Lastly, the presence of acentriolar centrosomes was higher in cases of higher grade and stage. **Conclusions:** CA, centrosome clustering, and increased centrosome size are associated with worse survival and adverse clinical factors in breast cancer and provide important insight and possibly a direct biologic explanation for the clinical behavior of some aggressive cancers. The presence of acentriolar centrosomes was associated with higher grade and stage, which suggests that PCM fragmentation may be one cause of CA, particularly in more aggressive tumors.

11037 Poster Session (Board #249), Sun, 8:00 AM-11:30 AM

***SOD2* rs4880 CT/CC genotype to predict poor survival for Chinese gastric cancer patients received platinum and fluorouracil based adjuvant chemotherapy.** *First Author: Zhi Xu, Department of Oncology, Nanjing First Hospital, Nanjing Medical University, Nanjing, China*

Background: Adjuvant chemotherapy is a standard therapy for gastric cancer patients, however, treatment response is quite heterogeneous. Molecular biomarkers will be highly valuable to guide the therapy. The antioxidant enzymes superoxide dismutase 2 (SOD2) and glutathione S-transferase pi 1 (GSTP1) are involved in oxidative stress and drug detoxification, which modulate the efficacy of anticancer drugs. Here, we investigated the clinical associations of two single nucleotide polymorphisms of *SOD2* and *GSTP1* in stage II-III postoperative gastric cancer patients. **Methods:** *SOD2* rs4880 and *GSTP1* rs1695 were genotyped in 207 patients received postoperative platinum and fluorouracil based chemotherapy and 304 patients who did not. The genotyping were examined in DNA samples extracted from paraffin-embedded tumor tissue. Association of the 2 SNPs with each clinicopathologic feature was analyzed using the Pearson chi square test. Gastric cancer-specific overall survival was analyzed using Kaplan-Meier curves and log-rank tests. Multivariate Cox regression analyses of these SNPs also were performed. **Results:** *SOD2* rs4880 CT/CC significantly associated with decreased median overall survival time of 23 months when compared to the TT genotype (mean overall survival time of 65.2 months, $P = 0.002$) only for patients received adjuvant chemotherapy. Stratification analysis showed *SOD2* rs4880 CT/CC affected most significantly the clinical outcome for patients with tumor arising at gastric body (HR, 5.707, $P = 0.002$), well to moderately differentiated adenocarcinoma (HR, 4.900, $P < 0.001$), tumor of intestinal type (HR, 4.398, $P < 0.001$), or tumor size less or equal to 5 cm (HR, 2.490, $P = 0.004$); while *GSTP1* rs1695 GA/GG was significant decreased overall survival time among patients with tumor arising at fundus or cardia (HR, 3.001, $P = 0.004$), or mucinous or signet-ring cell carcinoma (HR, 4.750, $P = 0.042$). **Conclusions:** The present study suggested the two polymorphisms would affect the adjuvant chemotherapy outcome in specific subtype of gastric cancer. *SOD2* rs4880 could be used as a biomarker to predict the prognosis and response to therapy.

11038 Poster Session (Board #250), Sun, 8:00 AM-11:30 AM

Clinical impact of expanded *BRAF* mutational status on the outcome for metastatic colorectal cancer patients with anti-EGFR antibody: An analysis of the BREAC trial (Biomarker Research for Anti-EGFR Monoclonal Antibodies by Comprehensive Cancer Genomics). *First Author: Satoshi Yuki, Hokkaido University Hospital, Sapporo, Japan*

Background: $BRAF^{V600E}$ mutation has been recognized as a prognostic marker in patients (pts) with metastatic colorectal cancer (mCRC). Several studies have consistently shown a significant association between the presence of $BRAF^{V600E}$ mutation and resistance to anti-EGFR antibody therapy in pts with previously treated mCRC while there are few reports on the clinical impact of minor *BRAF* mutations. **Methods:** The BREAC trial was a multicenter, retrospective study to investigate the novel biomarkers of anti-EGFR antibody therapy. *RAS and BRAF* mutations were detected by targeted sequencing using FFPE materials of mCRC pts who received anti-EGFR antibody after a failure to standard therapies. Progression-free survival (PFS), overall survival (OS), and response rate (RR) were evaluated according to expanded *RAS/BRAF* mutational status. **Results:** Of 184 pts enrolled in the study, *RAS/BRAF* testing was succeeded in 150 pts. Patients characteristics were as follows; male/female 87/63, median age 63.5 years (range, 28-85), PS 0/1/2 81/65/4. Median PFS, OS, and RR were 4.0 months, 12.4 months, and 21%, respectively. Expanded *RAS* and *BRAF* mutations were detected in 40 pts (26.7%, *KRAS/NRAS* 29/11) and in 16 pts (10.7%, $BRAF^{V600E}$/other 9/7), respectively. Observed *BRAF* mutations other than $BRAF^{V600E}$ were located at kinase domain. The clinical outcomes of other *BRAF* mutations were worse similar to those of $BRAF^{V600E}$ and expanded *RAS* mutations (Table). **Conclusions:** Expanded *BRAF* mutations might predict a lack of response for mCRC pts who received anti-EGFR antibody. Further investigation is warranted to confirm the clinical impact of expanded *BRAF* mutations.

11039 Poster Session (Board #251), Sun, 8:00 AM-11:30 AM

TLR6 polymorphism associated with overall survival in metastatic colorectal cancer (mCRC) patients treated with FOLFIRI/bevacizumab enrolled in FIRE3. *First Author: Satoshi Okazaki, University of Southern California/ Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Toll-like receptors (TLRs) play crucial roles in carcinogenesis and evolution of tumor microenvironment. Recent studies have shown that TLR6 dependent stimulation of the mesenchymal stem cells promotes angiogenesis. We tested the hypothesis that genetic variations of TLR6 will predict outcome in patients treated with bevacizumab based chemotherapy. **Methods:** Genomic DNA was isolated from tissue samples from 543 mCRC patients enrolled in the FIRE3 trial and treated in first-line with either FOLFIRI+bevacizumab (n = 265) or FOLFIRI+cetuximab (n = 278) was obtained from tissue samples. Two single nucleotide polymorphisms (SNPs) in the *TLR6*gene, rs5743810 G/A and rs3821985 G/C, were analyzed by PCR-based direct sequencing. These SNPs were tested for the association with tumor response, progression free survival (PFS) and overall survival (OS). Subgroup analyses by gender, tumor location, and Kras status were also analyzed. **Results:** In the FOLFIRI+bevacizumab treated patients, *TLR6*rs3821985 G/G variant showed a trend toward longer PFS (10.5 vs. 10.0 months, HR: 1.24, logrank p = 0.11) and OS (24.8 vs 24.7 months, HR: 1.28, logrank p = 0.10) compared to other variants (C/G and C/C). In the subgroup of Kras-wild type patients treated with FOLFIRI+bevacizumab, the same variant was significantly associated with longer PFS (10.7 vs. 9.9 months, HR 1.34, logrank p = 0.046) and OS (26.1 vs. 23.8 months, HR: 1.45, logrank p = 0.026) which remained significant (HR: 1.42, p = 0.041,) in a multivariate analysis. In the FOLFIRI+cetuximab treated patients, there was no association with outcome. **Conclusions:** This is the first report showing that *TLR6*SNP is associated with outcome in patients with wild type Kras mCRC treated with bevacizumab based chemotherapy.

11040 Poster Session (Board #253), Sun, 8:00 AM-11:30 AM

Stratification markers for the risk of recurrence after curative resection of stage II or III gastric cancer and potential clinical applications. *First Author: Takashi Oshima, Gastroenterological Center, Yokohama City University, Yokohama, Japan*

Background: Standard treatment for stage II or III gastric cancer is curative resection followed by adjuvant chemotherapy. Treatment outcomes are expected to be further improved by individualized therapy based on biomarker analysis. We extracted mRNA from frozen specimens of gastric cancer to establish a cDNA bank and then analyzed markers for stratifying the risk of recurrence after curative resection of stage II or III gastric cancer. We report our currently available findings. **Methods:** The study group comprised 255 patients with stage II or III gastric cancer who underwent curative resection and were followed up for ≥ 5 years after surgery. The patients were divided into 2 groups: a training set consisting of 145 patients and a validation set consisting of 110 patients. A total of 104 genes were selected as candidate biomarkers on the basis of comprehensive screening by DNA microarray, extraction by SAGE library analysis, and the identification of target molecules and related families, including the results of preclinical studies. The relative expression levels of target genes in gastric cancer tissue were measured by quantitative polymerase chain reaction. Genes identified be independent predictors of poor outcomes in the training set were verified in the validation set by Cox proportional-hazards analysis. **Results:** In the training set of stage II or III gastric cancer, 38 genes were evaluated to be independent predictors of poor outcomes. Verification analysis was then performed using the validation set, and the following 12 genes were selected as candidate markers for recurrence risk stratification ($P < 0.2$): SPARC, INHBA, HRBB2, VSNL1, CXCR4, EZH2, CCR7, PDGFRB, P53, MMP11, MRP1, and CEACAM7. Good reproducibility was obtained for 5 of these genes: SPARC, INHBA, HRBB2, VSNL1, and CXCR4 ($P < 0.05$). **Conclusions:** Promising candidate markers for stratification of recurrence risk after curative resection of stage II or III gastric cancer were identified. These candidate markers are now being analyzed at the protein level by tissue microarray, using specimens from about 500 patients each at two high-volume centers, with the goal of developing clinical applications.

11041 Poster Session (Board #254), Sun, 8:00 AM-11:30 AM

Effect of mutant TP53 genotypes on the outcome of breast cancer (BC) patients in different clinical tumor subtypes. *First Author: George Fountzilas, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

Background: Comprehending the clinical utility of the massively produced BC genomic data remains a challenge. Here, we examined the impact of BC genotypes on patient outcome with respect to clinical (immunohistochemical) tumor subtypes and treatment. **Methods:** Paraffin DNA from 1664 tumors (556 Luminal A, 439 Luminal B, 291 Luminal-HER2, 157 HER2-enriched and 221 triple-negative [TNBC]) yielded informative results upon targeted parallel sequencing for 58 genes. Patients had operable BC and had been treated in 4 prospective trials with adjuvant anthracycline-based chemotherapy in the pre- and post-trastuzumab (T) era. Analysis was performed in training and validation sets and in the entire cohort. **Results:** Eligible mutations (mut, n = 3086) were observed in 56 genes and were distributed in various combinations (1 to > 20 mutant genes) in 1043 tumors (63%). PIK3CA mut were found in 466 (44%); TP53 in 420 (40%); GATA3 in 128 (12%); and, CDH1 in 121 (11.5%) tumors. PIK3CA mut were more common in Luminal A/B tumors (49%), while TP53 in HER2-positive (57%) and TNBC (73%) (all $p < 0.001$). Both PIK3CA and TP53 mut were observed in 7% of all tumors. TP53 mut conferred increased risk for relapse in patients with Luminal A/B (HR = 2.00; 95% CI 1.42-2.82; Wald $p < 0.001$) and TNBC (HR = 1.82; 95% CI 1.04-3.20; Wald p = 0.037). In the same context, PIK3CA mut were associated with favorable prognosis in the absence of TP53 mut; this effect disappeared in tumors with mut in both genes. In HER2-positive patients in the pre-T era, TP53 mut alone or in combination with PIK3CA mut did not interfere with outcome. By contrast, these mutant genotypes tended to confer decreased risk for relapse in patients treated with T (HR = 0.51; 95% CI 0.23-1.14; Wald p = 0.101). All described effects were equally significant in the training and validation sets. **Conclusions:** TP53 mutant genotypes are unfavorable prognosticators in Luminal A/B and TNBC patients, but may predict benefit in HER2-positive patients with operable BC treated with T. PIK3CA mut do not seem to interfere with patient outcome in the latter context. If validated in independent large studies, these findings may have important clinical implications.

11042 Poster Session (Board #255), Sun, 8:00 AM-11:30 AM

PI3K/PTEN/Akt/mTOR pathway aberrations and co-incidence of hormone receptors and HER2 in 19,784 diverse solid tumors. *First Author: Sherri Z. Millis, Caris Life Sciences, Phoenix, AZ*

Background: Molecular aberrations in the phosphatidylinositol 3-kinase (PI3K) pathway have been documented across cancers, especially *PIK3CA*mutations and mutation or loss of PTEN. These alterations may be relevant to therapies targeting the PI3K/PTEN/Akt/mTOR signaling pathway. **Methods:** Molecular profiling was performed on 19,784 tumors (> 40 cancer types) at a CLIA-certified laboratory. Tests included next generation sequencing (NGS), protein expression (immunohistochemistry), and gene amplification (FISH or CISH). **Results:** Frequency and type of *PIK3CA, AKT1* and *PTEN* mutations were collated across cancers. Aggregate gene mutation rates (47 genes), protein expression rates (18 proteins), and copy number (5 biomarkers) were measured. Comparison of frequencies and correlations across cancers identified lineage-specific differences, and co-incidences of associated biomarkers, which will be described. Of note, endometrial, breast, cervical, anal squamous cell, and bladder cancers had the highest *PIK3CA* mutation rate (37%, n = 1600; 31%, n = 2282; 29%, n = 284; 28%, n = 67, 22%, n = 303, respectively). Patterns in *AKT1* and *PTEN* mutation rates differed by cancer, as did PTEN loss - hepatocellular, 57%, prostate, 52%, and endometrial 50% loss. Co-mutation of *PTEN* and *PIK3CA* occurred in 1.5% of breast, 0% of prostate, and 12% of endometrial cancers. Of interest, PIK3CA mutations and PTEN loss co-occurred frequently, e.g. 31% of *PIK3CA*mutated patients also have a PTEN loss. PIK3CA mutations across cancers were distributed 43% in exon 9, 33% in exon 20, and 24% in other exons. Distribution of *PIK3CA* mutations by cancer type varied and occurred more frequently in the absence of HER2 protein expression or copy number increase (p= 0.0001) and more frequently in the presence of hormone receptor overexpression (androgen receptor (AR), progesterone receptor (PR), and estrogen receptor (ER)) (p= 0.0335). PTEN loss was seen in 27% of patients with and 30% without HER2 overexpression or amplification (p= 0.004). **Conclusions:** Patterns of biomarker co-alterations across cancers may provide new insights relevant to targeted therapy and may be crucial to optimizing combination treatments.

11043 Poster Session (Board #256), Sun, 8:00 AM-11:30 AM

piRNA-651 as a prognostic marker in surgically resected non-small-cell lung cancer. *First Author: Nuria Vinolas, Hospital Clinic, Barcelona, Spain*

Background: Piwi-RNAs (piRNAs) are small non-coding RNAs (24-32 nt) required to protect the genome in germline cells. Initially they were thought to be expressed only in germline cells, but they have recently been found to be expressed in several tumours. piRNA-651 has been identified as an oncogene in gastric cancer. However, its role in non-small-cell lung cancer (NSCLC) as well as its potential as a prognostic marker have not yet been examined. **Methods:** piRNA-651 expression levels were assessed in tumour and paired normal tissue samples from NSCLC patients. piRNA-651 expression was analyzed from formalin-fixed paraffin-embedded samples by real-time PCR and by chromogenic *in situ* hybridization. Disease-free survival (DFS) and overall survival (OS) were studied by means of Kaplan-Meier, Log Rank and Cox methods. **Results:** A total of 70 patients with stage I-III surgically resected NSCLC between March 1996 and June 2007 in a single institution were prospectively registered. The median follow-up of living patients was 79 months. None of these patients received preoperative or adjuvant treatment. piRNA-651 was overexpressed in tumour tissue compared to normal tissue, and tumour cells showed a marked cytoplasmic expression. Low piRNA-651 expression was associated with shorter disease-free survival (86.8 *Vs* 25.4 months, p = 0.045) and shorter overall survival (116 *Vs* 59.1 months, p = 0.044). The multivariate analysis identified piRNA-651 as an independent prognostic factor for DFS (p = 0.031) and for OS (p = 0.050). **Conclusions:** piRNA-651 expression may well influence prognosis in NSCLC. To our knowledge, this is the first study to find evidence for a prognostic role for piRNAs in cancer.

11044 Poster Session (Board #257), Sun, 8:00 AM-11:30 AM

Does age influence the intrinsic biology of breast cancer? *First Author: Tomo Osako, Department of Molecular Oncology, BC Cancer Agency, Vancouver, BC, Canada*

Background: The incidence of breast cancer and its molecular subtype are age-related. Patient age may be associated with breast cancer biology through subtype-determining genetic factors (e.g. BRCA1 germline mutation) or aging of the tissue of origin (e.g. telomere shortening or epigenetic modifications in breast epithelium). EZH2 catalyzes trimethylation of histone H3 at lysine 27 (H3K27me3), an epigenetic change playing a role in breast cancer development and progression. We investigated if biomarkers including EZH2 and H3K27me3 display age-associated expression in breast cancer and if non-malignant breast epithelium reflects any age-dependent associations. **Methods:** Two independent sets of breast cancer tissues (n = 3,464 and n = 1,537) and a set of normal breast tissues of non-cancer patients who underwent reduction mammoplasty surgery (n = 537) were used to construct tissue microarrays for protein expression analysis using immunohistochemistry (42, 19 and 12 markers analyzed, respectively). A set of breast cancer tumour samples (n = 1,992) was assayed for global gene expression analysis using Illumina HT-12 gene chips. The associations of biomarker expression with patient age were statistically investigated. **Results:** In breast cancer,EZH2 protein and mRNA expression decreased and H3K27me3 marks increased with age at diagnosis. Gene expression analysis showed that more than 10% of genes (2,708 of about 25,000 genes) showed significant age-associated expression, and gene set enrichment analysis showed that these were enriched in 34 pathways. In non-malignant breast epithelium, EZH2, H3K27me3, ER, Ki67, EGFR and FOXA1 showed age-associated trends, which were similar to the trends seen in breast cancer. **Conclusions:** Patient age may influence the biology of breast cancer, and age-associated gene expression data leads us to hypothesize a mechanism involving histone modification by EZH2. Understanding the age-associated biology offers hope for age-specific preventive and therapeutic options.

11045 Poster Session (Board #258), Sun, 8:00 AM-11:30 AM

Identification of novel prognostic markers of glioblastoma using computational strategies on four genomic datasets. *First Author: Haruka Itakura, Stanford Univ Medcl Ctr, Stanford, CA*

Background: We sought to discover novel biomarkers using computational strategies on four genomic/epigenomic datasets to improve prognostication in glioblastoma (GBM). **Methods:** We obtained survival, clinical, gene expression, copy number variation (CNV), microRNA, and methylation data from The Cancer Genome Atlas on GBM subjects. Our study design was to fit Cox proportional hazards regression models using penalized maximum likelihood on the four datasets to predict overall survival, our analysis endpoint. We trained and tested our Cox models using 10-fold cross-validation on combined datasets created by three different integration strategies: concatenation, partial integration with double penalized maximum likelihood, and combination of weighted predictions from each dataset. We compared three, final Cox regression models using: 1) molecular features selected by the highest-performing integration strategy, 2) established risk factors (age, performance status (KPS), IDH1, MGMT, CIMP), and 3) combined molecular and established features. **Results:** 243 subjects, who possessed survival and all four genomic datasets, were included for analysis. Selecting the top 25% varying genes, gene expression data contained 4453, CNV 5770, microRNA 534, and methylation data 4643 features. The integration strategy based on weighted predictions produced the highest performing prediction model ($p = 0.0006$). The final molecular feature-only model yielded a multivariate combination of 17 prognostic features ($p = 3.89x10^{-10}$). The established features model produced three prognostic features ($p = 5.0x10^{-08}$): age, gender, and KPS. In the combined molecular-established risk model, 11 molecular features (one gene expression, three CNV, four microRNA, and three methylation features) and three clinical features (age, CIMP status, and KPS) were prognostic ($p = 1.79x10^{-08}$). **Conclusions:** Using four genomic datasets and novel computational strategies, we identified 11 molecular features that could improve GBM prognostication beyond the current set of established risk factors. These features warrant closer investigation as novel markers for disease prognostication and targets for therapy.

11046 Poster Session (Board #259), Sun, 8:00 AM-11:30 AM

Assessment of circulating free DNA concentration as a prognostic and predictive biomarker in a large cohort of non-small cell lung cancer treated by platinum-based chemotherapy. *First Author: Claire Tissot, Acute Respiratory Medicine and Thoracic Oncology Department Lyon Sud Hospital and Lyon University Cancer Institute, International Agency for Research on Cancer, Molecular Mechanisms and Biomarkers Group, Pierre Benite, France*

Background: Plasma circulating free DNA (cfDNA) has raised interest in oncology because it has been shown to contain tumor DNA and may thus be used as liquid biopsy. In non-small cell lung cancer, cfDNA quantification has been proposed to be useful as prognosis biomarker and for monitoring. However, available studies are limited and need to be confirmed. Our objective was to assess the predictive and prognostic value of plasma cfDNA concentration in a large series of patients with non-small cell lung cancer and treated with a standard chemotherapy regimen. **Methods:** Our study included samples from lung cancer patients who have been recruited in the French PHARMACOGENOSCAN study. CfDNA of 218 patients has been extracted and quantified by fluorometry before and after 2 or 3 cycles of platinum-based chemotherapy. The correlations between baseline or post-chemotherapy concentrations and treatment response assessed by RECIST 1.0 criteria or patient survival were analyzed. **Results:** 176 patients had stage IV disease and 42 patients had stage IIIb disease. We found that patients with high cfDNA concentration (highest tertile) at baseline had a significant poorer median progression free and overall survivals (OS) than those with lower concentrations (lowest and middle tertile) (10 months (95% CI 10.7-13.9) versus 14.2 months (95%CI 12.6-15.8) for median OS respectively, (P 0.001)). In multivariate analysis, increased baseline concentration in cfDNA was significantly associated to OS independently of Performance Status at diagnosis, stage, age, and response rate. However, we did not find any association between cfDNA concentration and response to treatment. **Conclusions:** These results show that cfDNA may be a useful non-invasive marker for prognosis assessment in NSCLC. However, total concentration of cfDNA is not a good biomarker to assess chemotherapy response.

11047 Poster Session (Board #260), Sun, 8:00 AM-11:30 AM

APC mutations in myeloid malignancies: Incidence and impact on leukemogenesis. *First Author: Aziz Nazha, Leukemia Program, Department of Hematology and Oncology, Cleveland Clinic, Cleveland, OH*

Background: Adenomatous polyposis coli (APC) gene is a tumor suppressor gene that plays an integral role in the WNT-signaling pathway. Germline mutations in *APC* are responsible for the autosomal dominant familial adenomatous polyposis, while somatic mutations are are linked to the initiation and progression of colorectal cancer (CRC). Haploinsufficiency of *APC* impairs hematopoiesis in animal models suggesting that loss of *APC* function contributes to the development of myelodysplasia (Wang J,et al. Blood 2010); however, patients (Pts) with germline *APC* mutations are not predisposed to develop myeloid malignancies. It is not known whether somatic mutations in *APC* gene can drive leukemogenesis. **Methods:** We screened our genomic database for the presence of somatic mutations in *APC* genes in pts with myeloid malignancies. A panel of 62 gene mutations obtained by NG targeted deep sequencing was included. Variant allele frequencies adjusted by zygosity were used to define clonal architecture. **Results:** Among 886 pts with myeloid malignancies, 15 (2%) had somatic mutations in *APC*. Of these, 8 had MDS, 4 AML, and 3 MDS/MPN; with median age of 69 years (range 39-84); none had a documented family history or personal history of CRC. In metaphase cytogenetic (MC) analyses, 11 pts had normal karyotype, 2 del(7q), 1 (-7), 1 inv(1q), and none had chr 5 abnormalities by either MC or SNP. Mutations in *APC* included: 8 missense, 3 nonesense, and 4 non-frameshift in/dels. Majority of *APC* mutations showed heterozygous configuration, resulting in the same consequences with hemizygous deletion of the locus. We then compared these mutations to germline variants recorded in the GEO database. No variants matched our data. Clonal architecture analysis showed that *APC* mutations can be either founder or subclonal. In founder cases, *APC* mutations were always accompanied by subclonal mutations described in myeloid malignancies e.g. *SF3B1, TET2, DNMT3A,* and *RUNX1,* etc. suggesting that *APC* alone is not sufficient to drive leukemogenesis. **Conclusions:** Somatic mutations in *APC* gene are rare in myeloid malignancies. They can be either founder or subclonal. In founder cases, a second hit with recurrent myeloid mutations is required to drive leukemogenesis.

11048 Poster Session (Board #261), Sun, 8:00 AM-11:30 AM

Low frequency *KRAS* G12/13 mutations in urine cell-free (cf) DNA from patients with *BRAF* V600E-mutant advanced cancers. *First Author: Filip Janku, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tumor heterogeneity and clonal selection contribute to resistance to molecular targeted therapies. Dynamic tracking of urine cfDNA mutations can offer a noninvasive tool for monitoring therapeutic efficacy. **Methods:** cfDNA was isolated from single or sequential urine samples from patients with advanced cancers and archival tumor tissue with *BRAF* V600E from a CLIA-certified laboratory. Assays for quantitative detection of *BRAF* V600E and *KRAS* G12/13 mutations in urine cfDNA were developed using digital droplet (dd) PCR and next generation sequencing. Analytical sensitivity of *BRAF* V600E and *KRAS* G12/13 assays is 0.03% and 0.006% mutant alleles in wild-type DNA background. **Results:** Urine cfDNA was examined in 34 patients (melanoma, $n = 11$; colorectal cancer, $n = 8$; papillary thyroid carcinoma, $n = 5$; non-small cell lung cancer, $n = 5$; other, $n = 5$) with *BRAF* V600E in tumor tissue. 32 of 34 patients (94%) had the same mutation in urine cfDNA (mutant, $n = 22$; low-mutant, $n = 10$). Longitudinal analysis in 25 (74%) patients (treated with: BRAFi, $n = 23$; MEKi, $n = 1$; none, $n = 1$) showed that changes in *BRAF* V600E cfDNA amounts correlated with percent changes in target lesions on imaging ($r = 0.68$, $p < 0.001$). Patients with decreased *BRAF* V600E cfDNA ($n = 16$) compared to others ($n = 8$) had a trend to a longer median time-to-treatment failure (8.8 months, 95% CI 8.1-9.5 vs. 2.2 months, 95% CI 0.0-5.1; $p = 0.07$) on BRAF or MEK therapy. Moreover, 22 (65%) patients had a low frequency *KRAS* G12/13 mutation (median 3.4 copies/10^5 genome equivalents) in urine cfDNA that was previously undetected in tumor by CLIA, except in one case. 9 of 9 patients with urine examined at the time of progression had detectable cfDNA *KRAS* G12/13. Re-analysis of the retrieved archival tumor tissues from 8 patients found a previously undetected low frequency (1.3%) *KRAS* mutation in one sample by ddPCR. **Conclusions:** Our results suggest that 65% of patients with advanced cancers and *BRAF* mutation in tumor tissue have low frequency *KRAS* G12/13 mutations in urine cfDNA undetected in tumor samples by standard CLIA technologies. Low frequency *KRAS* mutations can plausibly drive resistance to BRAF targeting agents, and these may be detected in urine cfDNA.

11049 Poster Session (Board #262), Sun, 8:00 AM-11:30 AM

Prosigna (PAM50) to predict response to neoadjuvant chemotherapy (NAC) in HR+/HER2- early breast cancer (EBC) patients. *First Author: Begona Jimenez Rodriguez, Hospital Regional Universitario y H. Universitario Virgen de la Victoria, Málaga (Spain), Malaga, Spain*

Background: Prosigna has been clinically validated in 2 large randomized studies to predict the risk of distant and late recurrence in HR+/HER2- patients treated with endocrine therapy.NAC efficacy is evaluated through pathological surrogates such as residual cancer burden(RCB) and pathologic complete response(pCR), and this response has been correlated to improved survival.HR+/HER2- tumors typically have low rates of pathologic response, however,genomic tests may be able to differentiate between patients who would or would not respond to NAC. We evaluate the correlation between ProsignaROR score and response to NAC. **Methods:** Retrospective analysis was performed on FFPE HR+/HER2- breast tumors from EBC patients who were treated with a contemporary NAC regimen (anthracyclines+taxanes)in a multi-center Spanish cohort. The Prosigna assay was performed on the NanoString nCounter Dx Analysis System at HU Virgende la Victoria de Málaga/CIMES-UMA. Univariate analysis was used to evaluate the correlation of ProsignaROR score and intrinsic subtype to pathologic response. RCB was determined centrally and used as the primary endpoint. **Results:** 95.8% (207/216) ofcore biopsy samplesyielded passing results of which 180 had anRCB classification. Medianage was48y.o.(27-75), initial mammographic tumor size was 3.4cm(1-10), and 27% of patients had G3 tumors. The overall rate of RCB-0/Iwas 18.9%. Prosigna subtypes observed: LuminalA n = 54; LuminalB n = 105; Basal-liken = 14;Her2En = 7. Rate of response RCB-0/I(%) according to PAM50 subtypes was LumA = 9.3%, Her2E = 14.2%, LumB = 20%, Basal = 50%. Prosigna ROR was a significant predictor of response to NAC ($p = 0.047$).Luminal A tumors were unresponsive to NAC relative to the other intrinsic subtypes (Odds RatioLumA vs. non-LumA = 0.341, $p = 0.037$). **Conclusions:** Prosigna ROR reliably predicted response to NAC in this HR+/HER2- population. High-risk tumors were significantly more likely to respond to NAC than lower-risk tumors. The intrinsic subtypes were also predictive of chemo-sensitivity with Luminal A tumors being resistant to NAC,supporting the current St. Gallen consensus guideline where intrinsic subtype determines chemotherapy use.

11050 Poster Session (Board #263), Sun, 8:00 AM-11:30 AM

Evaluation of invasive breast cancer using a 12-chemokine gene expression score (CS): Correlation with clinical outcomes. *First Author: Sangeetha Prabhakaran, Moffitt Cancer Center, Tampa, FL*

Background: We derived a unique CS from a metagene grouping with high enrichment for immune-and inflammation-related genes that in various tumors including breast cancer, accurately predicts the degree and type of lymphoid infiltrate close to tumor aggregates and areas of tumor necrosis and shows improved overall survival (OS) in Stage IV melanoma. (Messina JL et. al Scientific Reports 2012). We analyzed the correlation between the CS, clinicopathologic variables and survival in breast cancer patients (pts). **Methods:** A retrospective review was performed on selected Stage I - III breast cancer pts treated at our institution from 1978 to 2011. CS were calculated by principal component analysis. Pts given neoadjuvant chemotherapy were excluded. Pts were divided into 2 groups at the median into high or low CS. Descriptive and survival analyses were performed. **Results:** 366 pts were included, median age at diagnosis was 54.5 years. Pts mainly presented with Stage II disease (51.8 %) with ductal histology (77.6 %) and were ER/PR positive (63.5%). 86.5% received adjuvant therapy after surgery. Mean CS was 0.23 (range -2.2 to 2.1). Median follow-up period was 66.3 months (mths) (range 2.5 - 212.9). 263 pts were alive and 82.5% disease free at analysis. 88 (37 vs. 51) pts recurred in high vs. low CS groups. In comparison with the low CS group, patients with high CS were more likely to be white (172 vs. 159) ($P = 0.03$), with poorly differentiated tumors (112 vs. 59) ($P < .0001$), ER/PR negative (41 vs. 26) and Her2 positive (36 vs. 19) ($P = 0.001$). They had better OS (median 17.5 vs. 13) ($P = 0.88$) and recurrence free survival (RFS) (median not reached vs.11.1) mths ($P = 0.128$) compared to low CS. Higher scores in Her2 positive pts correlated with increased RFS (12.4 vs. 4.4 mths) that trended towards significance ($P = 0.058$). **Conclusions:** Higher scores are associated with high grade tumors and aggressive subtypes. They also correlate with improved OS and RFS. Further studies using larger datasets to repeat these observations and select tumor subtypes could extend the predictive value of this novel CS and potentially identify candidates for immunotherapeutic treatment.

11051 Poster Session (Board #264), Sun, 8:00 AM-11:30 AM

Prognostic significance of stromal versus intratumoral infiltrating CD8+ lymphocytes in resected non-small cell lung cancer. *First Author: Malaka Ameratunga, Austin Health, Heidelberg, Australia*

Background: The prognostic significance of tumor infiltrating lymphocytes (TILs) in non-small cell lung cancer (NSCLC) remains unclear. Immunotherapies in NSCLC have recently shown therapeutic promise. Assays predicting response to PD1/PDL-1 inhibitors have utilized expression of its ligand PDL-1 on tumor cells or the surrounding immune infiltrate. In other tumor types, stromal CD8+- TILs have been reported to be prognostic. We sought to characterize the immune infiltrate in a large series of resected NSCLC to determine their prognostic significance, focusing on intra-tumoral and stromal TILs. **Methods:** A tissue microarray (TMA) was constructed with triplicate cores of primary tumor from 507 NSCLC lobectomy or pneumonectomy cases. Immunohistochemistry was performed for CD8, CD4 and FoxP3. PDL1 was performed using a proprietary assay from BMS. CD8+ TILs were manually counted and assigned global tumoral and stromal scores based on TIL density, with the scorer blinded to clinical outcomes. Cases were categorized: stromal (S), tumoral (T) or other (equal proportions of tumoral:stromal CD8+-TILs). Disease-specific survival (DSS) was correlated with TIL characteristics. **Results:** Most patients were male (69%). Histologically, 50% were adenocarcinoma (AC) and 42% squamous (SQ). Comparisons were stratified by nodal stage: node negative (N0, n = 354) and node positive (N+, n = 153). In N0 there were 24(7%) T, 40(11%) S and 290(82%) other, compared to 16(11%), 11(7%) and 126(82%) respectively in N+ ($p = 0.16$). There were no differences in CD8+ TILs based on histology ($p = 0.73$). In the N0 population, there was no significant difference in DSS, based on TIL characteristics. In the N+ population, the presence of an S infiltrate was associated with significantly increased DSS compared to a T infiltrate (HR 0.36, 95% CI 0.14-0.96; $p = 0.05$) or other (HR 0.36, 95% CI 0.26-0.92; $p = 0.03$). **Conclusions:** In this large patient cohort, the presence of stromal CD8+ TIL infiltrates was not prognostic in N0 NSCLC but was associated with significantly improved survival in node positive NSCLC. Correlation of PDL-1, FOXP3 and CD4+ stains may further define the TILs and will be reported.

11052 Poster Session (Board #265), Sun, 8:00 AM-11:30 AM

Analysis of the prognostic value of the tumor immunologic profile in resectable NSCLC. *First Author: Marta Usó, Fundación para la Investigación del Hospital General Universitario de Valencia, Valencia, Spain*

Background: The analysis of immune features of tumor microenvironment is leading to the development of new immunotherapies and the identification of new biomarkers. In this study, we have investigated the prognostic value of immune markers, especially those related to immune-regulation in resectable NSCLC. **Methods:** RNA was isolated from fresh-frozen lung specimens (tumor and normal lung) (n = 178). RT-PCR was performed to analyze the expression of 20 genes: CCL2, CCL22, CD1C, CD127, CD209, CD25, CD4, CD8, CLEC4, CTLA4, FOXP3, IDO1, IL10, IL23A, LGALS1, LGALS2, NRP1, PD1, PDL1 and TGFB1, by the use of hydrolysis probes. Relative gene expression was assessed by Pfaffl formula and normalized by the use of ACTB, GUSB and CDKN1B as endogenous genes. Statistical analyses were considered significant at $p < 0.05$. **Results:** Unsupervised hierarchical analysis according to gene expression levels classified patients in two clusters. Cluster I (n = 70) was composed by samples showing lower expression levels of the analyzed genes, whilst cluster Cluster II (n = 84) grouped samples that, in general have higher gene expression levels. Survival analysis showed that patients in Cluster II had better OS (NR vs 46.6 months, $p = 0.040$) and longer PFS (81.22 vs 26.28 months, $p = 0.027$) than patients in Cluster I. In order to obtain a more clinically valid biomarker, an expression score based on the regression coefficients from a multivariate model was built: (IL23A x 0.016) + (IL10 x 0.077) + (CCL2 x 0.154) + (PD1 x 0.132) + (CTLA4 x 0.173). Patients with high expression score have longer OS (NR vs 42.9 months, $p = 0.007$) and longer PFS (82.6 vs 23.4 months, $p = 0.011$). Multivariate analysis, including all significant variables found in the study, indicated that the expression score, along with KRAS status, was an independent biomarker of prognosis for OS [HR: 0.368; 95%CI, 0.190-0.715; $p = 0.003$] in our cohort. **Conclusions:** We identified a unique immune-reaction related profile associated with survival which leaded to the creation of an expression score composed by five genes. Furthermore, this expression score was found to be an independent prognostic biomarker in resectable NSCLC. Supported by grants PI1202838 and RD12/0036/0025 from ISCIII.

11053 Poster Session (Board #266), Sun, 8:00 AM-11:30 AM

Wild type *VHL* clear cell renal cell carcinomas: A distinct morphological and clinical entity with PD-L1 expression. *First Author: Laurence Crouzet, Center of Oncology Eugene Marquis, Rennes, France*

Background: Clear cell renal cell carcinoma (ccRCC) is an aggressive tumor and in most of cases, is characterized by an inactivation of the tumor suppressor gene *VHL (Von Hippel-Lindau).* This inactivation causes an overexpression of the target genes of HIF-dependent transcription factor. VHL/HIF/VEGF pathway thus has a major role in oncogenesis and is currently targeted by anti-VEGF therapy. The emergence of resistance leads to the development of immunotherapy. The interaction of programmed death-1 ligand (PD-L1) with its receptor (PD-1) on T cells inactivates antitumor immune responses. PD-L1 expression appears to be associated with poor outcome in ccRCC. The correlation between complete *VHL* status and the expression of PD-L1 has not yet been investigated. **Methods:** In this study, we correlated the complete status of the *VHL* gene in 98 ccRCC cases with pathological criteria, expression of PDL1 and clinical outcome. For these patients, we had 64 months median follow-up. From frozen tumor sections, *VHL* gene deletion, mutation and promoter hypermethylation were screened. PD-L1 expression was analyzed by immunohistochemistry on the highest Fuhrman nuclear grade and considered positive when any membranous tumor cell staining was detected. **Results:** 33.6% of ccRCCs had 0 or 1 alteration (non inactivated *VHL*) *versus* 66.3% with 2 inactivating events (inactivated *VHL*). Non inactivated *VHL* ccRCCs were associated with a higher Fuhrman grade 4 ($p = 0.02$), metastases ($p = 0.04$), sarcomatoid component ($p = 0.01$) and dense lymphocyte infiltrate ($p = 0.013$). Furthermore, in this group, wild type *VHL* tumors (no alteration of the *VHL* gene, 11,2%), were particularly associated with PD-L1 expression ($p < 0,0001$), and had a worse outcome with a median specific survival of 33 months ($p = 0.016$). **Conclusions:** This long-term study is the first to analyze complete *VHL* gene status in ccRCC in association with PDL1 expression. Wild type *VHL* ccRCCs represent a distinct entity with probably different involved oncogenic pathways. Interestingly, they overexpress PD-L1 and may benefit therapies inhibiting PD-L1/PD-1.

11054 Poster Session (Board #267), Sun, 8:00 AM-11:30 AM

Immune response triggered by a novel molecular crosstalk of major hallmarks of cancer: Angiogenesis, mismatch repair, and immune pathways. *First Author: Shannon Graver, University of Wuerzburg Biocenter, Wuerzburg, Germany*

Background: The development of bevacizumab to inhibit VEGF has resulted in extended PFS, however OS has failed to show significant clinical benefit in a number of cancer types. Recent data however, has shown bevacizumab to prolong OS in a subset of patients with MMR deficient tumors in adjuvant CRC. **Methods:** Isolated macrophages were treated with tumor-conditioned media from MMR proficient and MMR deficient tumor cells. Furthermore tumor cells were co-cultured with human monocyte-derived macrophages for analysis of phagocytic activity. Treatment regimens *in vitro* attempted to mimic the clinical setting by inducing DNA damage in tumor cells, and then allowing cells to recover with or without VEGF using bevacizumab treatment for 24 hrs before co-culture or collection of tumor-conditioned media. **Results:** Gene expression changes in macrophages induced by tumor-conditioned media showed *CCL18* to be a bevacizumab regulated gene. MMR deficient tumor cell conditioned media after DNA damage showed a 68% increase in *CCL18* expression compared to the untreated control that was not evident in MMR proficient cells. *CXCR4* expression may demonstrate negative regulation as MMR proficient tumor cells treated with bevacizumab after DNA damage, promoted a 1.4 fold increase in *CXCR4* expression in macrophages with no functional enhancement of macrophage activity detected. The results of this study also showed an increase in the phagocytic activity of macrophages in the presence of bevacizumab that was significantly more apparent in MMR deficient cells and may be attributed to CCL18. DNA damage in MMR deficient cells in addition to bevacizumab treatment reinforced phagocytosis by a further 16.5% ($\pm$3.9%) compared the controls. Moreover, after DNA damage MMR deficient cells treated with bevacizumab released a cytokine mix that reduced monocyte migration in a bevacizumab dependent manner, showing a functional response with the combination of MMR deficiency and bevacizumab. **Conclusions:** CCL18 is a potential marker for the administration of bevacizumab in a clinical setting that is specific to bevacizumab treatment in combination with MMR deficient tumor cells via immune cell modulation.

11055 Poster Session (Board #268), Sun, 8:00 AM-11:30 AM

Detection of rare somatic mutational profiles in metastatic colorectal cancer (mCRC) during routine *RAS* sequencing using next generation sequencing (NGS). *First Author: Jean-Louis Merlin, Institut de Cancérologie de Lorraine, Service de Biopathologie, CNRS UMR 7039 CRAN Université de Lorraine, Nancy, France*

Background: In most patients with mCRC who are being considered for anti-EGFR antibody therapy, *RAS* mutation testing i.e. *KRAS* and *NRAS* exon 2, 3 and 4, is routinely assessed using PCR-based assays only detecting major hotspot mutations of exon (ex) 2 (codon 12 and 13), 3 (codon 59 and 61) and 4 (codon 117 and 146). We performed deep sequencing of the entire exons using NGS as an alternative to detect additional rare mutations profiles with significant frequency of mutated allele (FMA). **Methods:** 188 formalin-fixed paraffin-embedded tumor samples from primary or metastatic lesions of patients (M/F sex ratio 1.27, mean age 69 years, range 32-90) with mCRC (150 colon, 38 rectum) were analyzed. DNA was extracted from macrodissected slides (mean tumor cell content 43.3%, range 5-80). **Results:** *RAS* mutation testing was routinely assessed using NGS in 177 mCRC samples. NGS could not be performed in 11 cases (6.2%) due to the insufficient quantity or quality of DNA. NGS sensitivity was 1% at X1000 depth. *RAS* mutations were found in 103 samples (62%) and relatively distributed as 69.9% *KRAS* ex2, 3.9% *KRAS* ex3, 14.6% *KRAS* ex4, 4.8% *NRAS* ex2, 1.0% *NRAS* ex3, 1.0% *NRAS* ex4 and 4.8% multiple mutations. Uncommon mutational profiles were detected in 10 cases (9.7%): 2 *KRAS* ex2 c.37G > T p.G13C single mutation with FMA > 30%, 5 silent mutations (4 with FMA > 25%), alone ($n = 2$) or combined with other rare mutations ($n = 3$) with lower but significant FMA (> 1%), and 6 multiple mutation profiles among which 2 double hotspot mutation (*KRAS* ex2 c.34G > A p.G12S and *NRAS* ex3 c.181C > A p.Q61K, *KRAS* ex2 c.34G > A p.G12S and *NRAS* ex2 c.38G > T p.G13V), 1 secondary rare mutation associated with a *KRAS* ex2 c.35G > A p.G12D hotspot mutation, and 3 multiple mutations only with rare but potentially deleterious mutations located around the loops responsible for nucleotide (GTP) binding. In only 1 case, the FMA of the secondary mutations was < 1%. As a whole, 7 cases (6.8%) had *RAS* mutations out of hotspots. **Conclusions:** NGS proved accurate, sensitive and suitable for routine *RAS* genotyping in mCRC. It can detect uncommon *RAS* mutation profiles with significant FMA that can potentially impair the patient response to anti-EGFR antibody.

11056 Poster Session (Board #269), Sun, 8:00 AM-11:30 AM

[^{18}F]FMAU for PET imaging in breast cancer patients. *First Author: Peter Conti, University of Southern California, Los Angeles, CA*

Background: To develop a practicable method of synthesizing ^{18}F-labeled 2'-deoxy-2'-fluour-5-methyl-1-β-*D*-arabinofuranosyluracil ([^{18}F]FMAU) for clinical investigation and study [^{18}F]FMAU in patients with known breast cancer to obtain data on safety, circulating metabolite, tumor imaging feasibility, and radiation dosimetry. **Methods:** Various reaction factors, such as time, temperature, and solvent effect, were explored to optimize [^{18}F]FMAU synthesis. A total of nine breast cancer patients were scanned. [^{18}F]FMAU, 10 mCi i.v. injection in saline was administered to the patient through venous line. Multi-bed position PET scans over tumor-bearing region(s) were obtained, along with attenuation correction images, throughout the time period between 1 and 120 minutes post injection. Throughout the procedure, study staff monitored and recorded patient vital signs. **Results:** A simplified synthesis of [^{18}F]FMAU with shorter synthesis time and higher radiochemical yield was achieved as compared to previously reported methods. The total synthesis time was about 90 min from the end of bombardment.Radiochemical purity was > 99% and specific activity was > 400 mCi/μmol. The PET imaging showed excellent primary breast tumor as well as metastatic disease uptake of [^{18}F]FMAU. No adverse reactions were observed for all studied patients. No major circulating metabolites were identified in human blood at 1 h post injection of [^{18}F]FMAU. The preliminary dosimetry of [^{18}F]FMAU was estimated as 5.0 rem in liver (primary organ), 4.2 rem in kidneys (secondary organ), 0.76 rem in whole body, 0.60 rem in active blood forming organs, and 0.45 rem in gonads per single administration. **Conclusions:** A simplified one-pot synthesis of [^{18}F]FMAU has been developed, which is well suitable for clinical investigations. Our pilot trial achieved its goals of obtaining data on safety, circulating metabolite, breast tumor imaging feasibility, and radiation dosimetry of [^{18}F]FMAU in humans. The data provided a solid foundation for proceeding to larger clinical trials to confirm the utility of [^{18}F]FMAU as an *in vivo* cell proliferation marker for non-invasively and serially estimating DNA synthesis in patients with cancer.

11057 Poster Session (Board #270), Sun, 8:00 AM-11:30 AM

Clinical impact of high-throughput sequencing in patients with advanced cancer: Lessons learned from the Michigan Oncology Sequencing Center. *First Author: Erin Frances Cobain, University of Michigain Health System, Ann Arbor, MI*

Background: The molecular aberrations that drive cancer are diverse and multiple defects are often present. Next generation sequencing permits detection of numerous aberrations within a tumor, which may identify targets for therapy. **Methods:** From 5/2011-12/2014, 452 patients (pts) underwent comprehensive next generation sequencing (Illumina) of a primary or metastatic tumor at the University of Michigan under an IRB approved protocol. Somatic and germline mutations, copy number alterations, gene fusions, and gene expression findings were reviewed at an institutional tumor board. Clinically actionable alterations were categorized as follows: rationale for use of an investigational targeted agent, rationale for off-label use of therapy approved in another condition, information predictive of treatment efficacy and germline mutations known to confer increased cancer risk. We report subsequent treatment information for the first 200 patients enrolled. **Results:** Sequencing was successful in 183 samples (92%). Somatic alterations of biological relevance were identified in 176 cases (96%). 100 pts (55%) had potentially actionable results. 79 pts (43%) had alterations providing rationale for use of an investigational targeted therapy and 7 enrolled in a trial informed by results. Somatic alterations provided rationale for off-label use of a drug in 13 cases (7%) and 5 pts received off-label therapy. 22 pts (12%) had alterations predictive of treatment efficacy, prompting treatment change in 3 pts. 5 pts (3%) were found to have germline mutations conferring increased cancer risk. 48 pts (26%) died within 5 months of enrollment. **Conclusions:** These data demonstrate that comprehensive tumor genome analysis can identify potentially actionable somatic aberrations, indicating this approach is useful as a screening tool for clinical trial participation. Early in the course of the study, many pts died shortly after enrollment. This experience led us to employ this strategy earlier in the therapeutic algorithm.

11058 Poster Session (Board #271), Sun, 8:00 AM-11:30 AM

Allowance of tumor-educated platelets for multiclass liquid biopsy-based diagnosis of cancer. *First Author: Myron Best, Department of Neurosurgery, VU University Medical Center, Amsterdam, Netherlands*

Background: Cancer diagnosis is frequently hampered by limited access to adequate tissue of the primary tumor or metastatic lesions. To overcome such limitations, the use of blood-based liquid biopsies has been suggested. Blood represents a biosource of tumor-educated platelets (TEPs) that sequester biomolecules during tumor growth, thereby altering the platelet mRNA profile. **Methods:** Blood platelet samples of 188 cancer patients covering six tumor types (40 non-small cell lung cancer, 39 glioblastoma, 37 colorectal cancer, 35 pancreatic cancer, 24 breast cancer, and 13 hepatobiliary cancer) and of 52 healthy donors were isolated from whole blood by differential centrifugation. RNA was isolated, subjected to SMARTer mRNA amplification and submitted for whole transcriptome mRNA sequencing on the Illumina platform. Healthy donors, pan-cancer, and individual cancer classes were distinguished by a self-learning support vector machine (SVM) algorithm, using transcripts with moderate to high expression. **Results:** The 240 blood platelet samples were successfully sequenced and demonstrated a good intersample correlation of the detected mRNAs. Based on mRNA profiles, all tumor samples were clearly distinguished from healthy donors: the pan-cancer SVM-supported classification test reached a sensitivity of 97% and a specificity of 90% to distinguish cancer patients from healthy donors. Also, all patients without overt metastases were correctly predicted as cancer patients. Moreover, a multiclass cancer diagnostics TEP-test, to distinguish multiple tumor subclasses and healthy donors provided an overall accuracy of 73%, far exceeding random classification. In addition, we distinguished HER2-positive, and mutant KRAS and EGFR tumors from their wild-type counterparts. Also, patients with metastatic tumors in lung, brain, and liver were accurately diagnosed according to the tumor in the tissue of origin. **Conclusions:** Molecular interrogation of TEP-based liquid biopsies may leverage cancer diagnostics. TEPs provide a circulating biosource for pan-cancer, multiclass, and molecular cancer classification. Of interest, this tool might also allow for blood-based highly sensitive early-stage cancer screening.

11059 Poster Session (Board #272), Sun, 8:00 AM-11:30 AM

Improvement in imaging of metastatic breast cancer (BC) with a novel pretargeted immuno-PET targeting CEA: First clinical results. *First Author: Caroline Rousseau, ICO Cancer Center, Nuclear Medicine Department, Saint Herblain, France*

Background: New phenotypic imaging with noninvasive antibody imaging methods targeting membranous antigens have been tested in BC trials. A new generation of immuno-PET comprising anti-CEA x anti-HSG humanized trivalent TF2 bispecific MAb and ^{68}Ga-IMP288 HSG peptide is being assessed. This study aimed to compare the sensitivity of anti-CEA immuno-PET/CT comparing this immune-PET to morphological imaging and FDG-PET/CT in metastatic BC patients. **Methods:** Thirteen patients with metastatic BC enrolled in an optimization immuno-PET study had whole-body immuno-PET/CT at 1h and 2h after injection of 150 MBq of ^{68}Ga-IMP288 pretargeted by 120 nmol of unlabeled TF2 binding CEA and the HSG peptide injected 24h to 30h before. Thoracic-abdominal-pelvic CT and FDG-PET/CT were also performed. The gold standard was determined by follow-up and a lesion detected by at least 2 imaging modalities was considered as positive. **Results:** Median serum CEA was 46.15 μg/L (9.5 to 1359.0). To date, 515 lesions were confirmed as pathologic by the gold standard: 18 in LN, 4 in lung, 94 in liver, 399 in bone, 1 in skin, and 4 in brain. Overall sensitivity of immuno-PET was 93.8%, with 100% sensitivity for bone, liver, skin, and brain, 94% for LN, and 37.5% for lung. Overall sensitivity of CT and FDG-PET/CT was 74.6% and 84.7%, respectively. Bone MRI had 94% sensitivity. Brain lesions were only detected by immuno-PET/CT and confirmed by MRI. Median tumor SUVpeak on immuno-PET at 1h and 2h was 9.58 (3.52 to 24.55) and 11.04 (3.09-34.27), respectively. In half of patients (7/13) an increased tumor uptake between 1h and 2h was observed and no lesion was detected only at 2h. **Conclusions:** These results demonstrate the high accuracy of anti-CEA pretargeted immuno-PET/CT for staging pts with metastatic BC, especially for bone, liver and brain evaluation. Immuno-PET allowed detection of bone lesions in areas not explored by MRI. Clinical trial information: NCT01730612.

11060 Poster Session (Board #273), Sun, 8:00 AM-11:30 AM

Predictive value of coexisting KRAS and TP53 mutations on response to chemotherapy in non-small cell lung cancer (NSCLC). *First Author: Pascale Tomasini, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: *KRAS* and *TP53* are among the most common mutations in NSCLC. The LACE-Bio group evaluated coexisting *KRAS/TP53* mutations in resected NSCLC and found chemotherapy to be deleterious in patients with double mutations. **Methods:** In an attempt to validate these results,NSCLC patients from Princess Margaret Cancer Centre who were tested for *KRAS* & *TP53* mutations and received chemotherapy for any stage NSCLC were selected. Mutation status was analyzed using Mi-SEQ or Sequenom platforms. *TP53* analysis was added for DNA sequenced by Sequenom. Mutation status was correlated with clinical and demographic data. Relapse- or progression-free survival (RFS, PFS) was the main endpoint. **Results:** Among 186 patients identified, 24 had coexisting *KRAS/TP53* mutations, 67 *TP53*, 27 *KRAS;* 68 had no *KRAS* or *TP53* mutation (WT/WT). No difference was seen in age, sex or stage among the 4 populations ($p = 0.09$, $p = 0.23$, $p = 0.36$, respectively). There were significantly more Caucasians (96 *v* 65%, $p = 0.009$), smokers (29 *v* 14%, $p = 0.007$) and adenocarcinoma (96 *v* 73%, $p = 0.046$) in the *KRAS/TP53* group. 5-year overall survival (OS) was higher in the WT/WT group (68%) compared to *KRAS/TP53* 48%, *KRAS* 42%, *TP53 41%* (log-rank $p = 0.02$). However, no significant OS difference was seen for *KRAS/TP53* compared to the other groups (HR 1.41, CI 0.81-2.45, $p = 0.23$). Among 98 patients who received *adjuvant* chemotherapy, there was no significant difference in RFS for the *KRAS/TP53* group *v* all others (HR 1.47, CI 071-3.08, $p = 0.3$). For 30 stage III patients who received concurrent chemo-XRT, there was no PFS difference for the *KRAS/TP53* group *v* all others (HR 0.80, CI 0.30-2.15, $p = 0.65$). For 85 patients who received 1st-line palliative chemotherapy, there was no difference in PFS in the *KRAS/TP53* group *v* the others (HR 1.05, CI 0.59-1.87, $p = 0.87$). Similarly, in 43 patients who received 2nd-line chemotherapy, there was no difference in PFS comparing the *KRAS/TP53* group to the others (HR 1.18, CI 0.45-3.13, $p = 0.73$). **Conclusions:** We could identify no significant difference in OS, RFS or PFS for patients with NSCLC harboring coexisting *KRAS/TP53* mutations who received chemotherapy for any stage compared to patients with *KRAS* or *TP53* mutation or WT/WT tumors.

11061 Poster Session (Board #274), Sun, 8:00 AM-11:30 AM

Detection of low abundant somatic mutations in circulating exosomal RNA and cfDNA with next-generation sequencing. *First Author: Vincent J. O'Neill, Exosome Diagnostics, Cambridge, MA*

Background: Circulating nucleic acids (NA) in the bloodstream of cancer patients are of interest because of their potential to provide tumor mutation status without requiring a tissue sample. Blood plasma contains at least two sources of circulating cell-free NA: circulating free DNA (cfDNA), from apoptotic/necrotic cells, and RNA enclosed in exosomes (exoRNA), which are secreted by living cells through active metabolic processes. However, tumor derived mutated sequences are often of very low abundance against a background of wildtype. Therefore, efficient extraction of all available circulating NA as well as a highly sensitive mutation detection method, are paramount to development of clinically relevant liquid biopsies. **Methods:** We used a single-step isolation platform for both exoRNA and cfDNA from plasma (EXO52) in combination with a quantitative NGS method detecting a panel of actionable mutations (EXO1000). The assay uses a PCR-based selection of 9 mutation hotspots from 6 genes, a custom library preparation protocol and bioinformatics pipeline. We analyzed mutations present in nucleic acids from plasma of patients with various types of cancer including NSCLC, mCRC and melanoma. **Results:** EXO52 columns simultaneously isolate both cfDNA and exoRNA from plasma samples up to 4 mL with close to 100% efficiency, allowing somatic mutations to be readily detected in both exoRNA and cfDNA. The combination of both was found to provide a superior mutation signal and yield compared to cfDNA alone. The EXO1000 actionable mutation panel and associated bioinformatics pipeline were demonstrated to be quantitative, reproducible and highly sensitive. The assay faithfully detected low copy numbers of mutations using clinical plasma samples from 102 patients with different types of cancer. **Conclusions:** We demonstrate the superiority of isolating both cfDNA and exoRNA from plasma for the purpose of detecting circulating somatic mutations in cancer patients. The EXO52 isolation method combined with the EXO1000 actionable mutation panel overcomes current technical limitations by maximizing mutation signal from all sources of circulating NA, thereby enhancing assay sensitivity.

11062 Poster Session (Board #275), Sun, 8:00 AM-11:30 AM

Assessing HER2 testing quality in breast cancer (BC): Variables that influence HER2-positivity from a large, multicenter, observational study in Germany. *First Author: Josef Ruschoff, Institut für Pathologie Nordhessen, Kassel, Germany*

Background: Despite $>$ 10 years of routine HER2 testing in BC, quality is still an issue. It is often assumed that inter- and intra-laboratory variations in testing quality can be assessed by HER2-positivity rates. However, the extent to which patient- or tumor-related factors influence HER2-positivity rates has not been systematically studied. **Methods:** This observational, prospective study in Germany monitored routine HER2 testing to identify patient- or tumor-related factors that influence HER2-positivity rates, and to identify centers with HER2-positivity rates that could not be explained by these factors. Data collected from eligible BC specimens included test result, patient- and tumor-related factors, sample source, and method of retrieval. Factors influencing HER2-positivity rates were identified by multiple logistic regression (MLR) analysis. Center effects were assessed in an extended MLR model by their statistical significance after adjusting for the combined effect of covariates and multiple testing. **Results:** From Jan 2013 to Aug 2014, data were collected from 16,528 BC specimens and 57 centers. Final analyses included 15,332 invasive BC specimens. Tumor grade showed the highest correlation with HER2-positivity, followed by hormone receptor status, carcinoma subtype, age, and nodal status (all $P<$ .0001). No significant correlation was found for specimen source. Overall HER2-positivity rate across centers was 14.4%. Adjusting for patient- or tumor-related covariates and multiple testing, a statistically significant center effect on HER2-positivity rate was identified for three centers and a significant trend toward center effect for a further three. **Conclusions:** This study is the first of its kind, reporting on the multifactorial parameters that can impact on routine HER2-positivity rates. Results highlight that assessing HER2 testing quality by comparing positivity rates only, as recommended, may be insufficient, and that patient characteristics should be considered to assess HER2 testing quality effectively. As therapy options for HER2-positive BC continue to evolve, identifying the right patients is key.

11063 Poster Session (Board #276), Sun, 8:00 AM-11:30 AM

Towards rapid and cost-effective point-of-care detection of TMPRSS2:ERG fusion transcripts in urine via a novel methodology. *First Author: Eugene J.H. Wee, The University of Queensland, Australian Institute for Bioengineering and Nanotechnology, Brisbane, Australia*

Background: The TMPRSS2:ERG gene fusion is a highly-specific prostate cancer biomarker which is present in about 50% of all prostate cancer cases. The present use of serum PSA for prostate cancer screening is controversial due to its lack of specificity as a screening biomarker. In contrast, the presence of TMPRSS:ERG fusions could offer better screening potential. However, current detection methodologies of TMPRSS2:ERG, such as RT-PCR or FISH, are time consuming, expensive and require specialized equipment. Therefore, a new rapid and cost-effective point-of-care detection methodology is needed to enhance and enable the clinical utility of TMPRSS2:ERG and other cancer-related fusion transcripts. **Methods:** We developed a methodology by combining robust isothermal amplification with a novel readout based on amplified DNA-mediated bridging flocculation. This instrument-free visual evaluation of successful amplification complements the binary biomarker characteristic of TMPRSS2:ERG to give a simple positive/negative outcome. **Results:** The method is sensitive to as few as 10^5 copies (single cell level) of TMPRSS2:ERG fusion transcripts. We were also able to detect fusion transcripts in both whole urine and urinary sediments. Finally, to demonstrate clinical utility, the method was applied to 10 metastatic, castration-resistant prostate cancer urine specimens and results were validated with standard PCR-based methods. **Conclusions:** A simple, rapid ($\leq$ 90 min) and inexpensive ($\leq$ $5 USD) assay was developed to detect TMPRSS2:ERG fusion transcripts in urine. The approach may have broader applications in detecting other gene fusion events in prostate cancer or other cancers to enable quick and convenient clinical decisions.

11064 Poster Session (Board #277), Sun, 8:00 AM-11:30 AM

Preliminary direct evidence of a dose-response relationship for [Y-90]-microsphere selective internal radionuclide therapy (SIRT) in hepatic malignancy. *First Author: Dale L Bailey, University of Sydney, Lidcombe, Australia*

Background: [Y-90]-SIRT has an established role in managing patients with primary and secondary hepatic neoplasia. Recently, imaging of the regional distribution of the implanted [Y-90]-microspheres with positron emission tomography (PET), usually imaged on a hybrid device incorporating X-ray CT (PET/CT), has been implemented. Aims: #1 - To determine SIRT dose (in Gy) to liver lesions identified on FDG PET/CT; #2 – to use early follow-up FDG PET/CT to examine metabolic response; and, #3 – to relate metabolic response to SIRT dose. **Methods:** Prospective data collection of baseline and early follow-up FDG PET/CT as well as Y-90 images within 24 hrs of SIRT (SIR-Spheres microspheres, Sirtex Medical, Sydney, AUS) between January 2013 and June 2014. Within a PET-defined volume of interest (VOI) we measured Total Lesion Glycolysis (TLG = lesion volume on FDG PET $\times$ average SUV_{VOI}) for up to 5 target lesions. Fractional change (%) in TLG between baseline and follow-up was determined and compared to the average dose within the FDG-defined target lesion VOIs applied to the Y-90 PET images converted to dose maps. A positive change in TLG reflects a decrease in uptake (*i.e.*, positive response). **Results:** Fifteen patients containing 32 measurable lesions (CRC = 18,HCC = 6,other = 8) were examined. Mean time from treatment to follow-up FDG PET/CT was 62 ± 15 days. The data were fitted with a log function and showed a good correlation between dose and response (R^2= 0.79). A significant metabolic response, defined as change in TLG of $\geq$ 50%, was seen in all lesions receiving a mean dose of $\geq$ 30 Gy. No relationship was observed between site of origin of the malignancy/pathology and response. **Conclusions:** Dose to tumour and normal tissue can be determined using Y-90 PET/CT imaging. The dose delivered correlates with the metabolic response seen. The dose maps can be used to immediately (with 24 hrs) determine if a therapeutic dose of Y-90 SIRT has been delivered on a lesion-by-lesion basis and, if sub-therapeutic, further action can be instigated.

11065 Poster Session (Board #278), Sun, 8:00 AM-11:30 AM

Development of a PD-L1 immunohistochemistry (IHC) assay for use as a companion diagnostic for pembrolizumab (MK-3475) in non-small cell lung cancer (NSCLC). *First Author: Marisa Dolled-Filhart, Merck & Co., Inc., Kenilworth, NJ*

Background: Tumors express PD-L1 to contribute to escape from immunosurveillance. We developed a PD-L1 IHC assay to investigate whether it could predict response to pembro in NSCLC patients (pts) and be used as a companion diagnostic. **Methods:** The assay uses the 22C3 anti–PD-L1 murine monoclonal antibody on the Dako platform. One pathologist scored each tumor sample by 4 methods: percentage of cells staining at any intensity (PS1), percentage of cells staining at moderate/strong intensity (PS2), percentage of cells staining at strong intensity (PS3), and H-score (HS = PS1 + PS2 + PS3). Only cells with at least partial membrane staining were counted. Receiver operating characteristic analysis was used to compare scoring methods and determine a cutoff using data from 146 NSCLC pts treated with pembro in KEYNOTE-001 who had tumor evaluable for PD-L1 expression by IHC and data for response (immune-related response criteria, investigator review). Samples from the first 31 pts were also tested with a prototype assay by a different pathologist who scored the presence or absence of a regional, primarily inflammatory cell or "interface" pattern in addition to the above. PFS and OS were assessed in the 146 pts with measurable disease (RECIST 1.1, central review). **Results:** The various scoring methods are summarized in the table. Incorporating the interface pattern did not improve scoring. Using PS1, 19 (43%) of 44 pts with $\geq$ 50% tumor cell staining responded, versus only 8 (8%) of 102 pts with $<$ 50% tumor cell staining (odds ratio = 8.93). Median PFS and OS were 4.0 mo and not yet reached, respectively, for pts with $\geq$ 50% staining and 2.1 and 6.1 mo, respectively, for pts with $<$ 50% cell staining. **Conclusions:** The PD-L1 IHC assay is potentially useful to enrich trial populations and as a companion diagnostic in NSCLC. While all 4 scoring methods assessed performed similarly, the percentage of cells staining at any intensity with a cutoff of 50% is the simplest and easiest method to implement in practice. Clinical trial information: NCT01295827.

	Area Under Curve	Youden Index	Cutoff	False Positive Rate, %	True Positive Rate, %
PS1	0.743	0.494	50	21.0	70.4
PS2	0.758	0.462	11	16.8	63.0
PS3	0.736	0.445	1	18.5	63.0
HS	0.758	0.502	63	20.2	70.4

11066 Poster Session (Board #279), Sun, 8:00 AM-11:30 AM

[^{18}F]AA-7: PET imaging in patients with suspected glioma. *First Author: Satoshi Nozaki, Novel PET Diagnostics Laboratory, RIKEN Innovation Center (RINC), Kobe, Japan*

Background: Positron emission tomography (PET) imaging with [^{11}C]methionine provides valuable information about amino acid metabolism in brain tumors. In surgical resection or radiotherapy of gliomas, precisely detecting the normal brain tissue–tumor boundary is critically important. However, as [^{11}C]methionine accumulates not only in tumor tissues but also in normal and inflamed tissues, it cannot detect precisely the normal brain tissue–tumor boundary. Hence, the purpose of this study was to develop a tumor-specific PET tracer, targeting the amino acid transporter LAT1, to assess the safety, biodistribution, and dosimetric properties of the novel PET radiopharmaceutical agent, and to preliminarily evaluate its application in the diagnosis of glioma. **Methods:** We have developed the novel LAT1-specific tracer, [^{18}F]AA-7. In preclinical studies, PET imaging with [^{18}F]AA-7 was performed in mice bearing LNZ308 human glioblastoma cell line and also in two mice models of inflammation (turpentine oil-induced myositis model and collagen-induced arthritis model mice). In a clinical study, dosimetry estimations for [^{18}F]AA-7 in healthy volunteers were determined. Patients with glioma received 185 MBq of [^{18}F]AA-7 and underwent PET scan for 45 minutes after the injection. [^{11}C]methionine and [^{18}F]FDG were used as control tracers in both preclinical and clinical studies. **Results:** In preclinical studies, [^{18}F]AA-7 was highly accumulated in LAT1 positive tumors as compared with [^{11}C]methionine[tumor to muscle ratio: 3.3$\pm$0.2 vs 2.1$\pm$0.4]. Moreover, although [^{18}F]FDG was also highly accumulated in inflamed regions, noticeable accumulation of [^{18}F]AA-7 was not observed in the two mice models of inflammation. In a clinical study, three healthy volunteers and five patients were enrolled in the "first-in-human" trial. All subjects had no significant problem. Upon visual examination, PET imaging using [^{18}F]AA-7 resulted in extremely clear images in patients with suspected glioblastoma. **Conclusions:** [^{18}F]AA-7 may be useful as a novel PET tracer for LAT1-positive tumor imaging and imaging for the efficacy evaluation of therapies, which has low accumulation in inflamed tissues. It may be suitable for PET imaging in patients with suspected glioblastoma. Clinical trial information: UMIN000015271.

11067 Poster Session (Board #281), Sun, 8:00 AM-11:30 AM

Non-invasive determination of HER2-expression in metastatic breast cancer by using ^{68}Ga-ABY025 PET/CT. *First Author: Henrik Lindman, Department of Oncology, Uppsala University, Uppsala, Sweden*

Background: In contrast to biopsies, PET imaging gives a complete and quantitative image of all the patient's tumors and all parts of individual lesions. PET imaging of HER2 could select patients for HER2-targed therapy, predict response based on uptake and be used for monitoring. In this pivotal phase I/II study the HER2-binding Affibody molecule ABY025 was labeled with ^{68}Ga for PET to study effect of peptide mass, test-retest variability and correlation of quantified uptake in tumors to histopathology. **Methods:** Sixteen women with known metastatic breast cancer and on-going treatment were included and underwent FDG PET/CT to identify viable metastases. After iv injection of 212$\pm$46 MBq ^{68}Ga-ABY025 whole-body PET was performed at 1, 2 and 4 h. In the first 10 patients, ^{68}Ga-ABY025 PET/CT with two different doses of unlabeled peptide was performed 1 week apart. Six had HER2-positive primary tumors and 4 were included as HER2-negative controls. In the last six patients (5 HER2-pos and 1 HER2-neg primary tumor), repeated ^{68}Ga-ABY025 PET were done as a test-retest of uptake at 2 h in individual lesions. Primary tumors and biopsies from metastases were collected for verification of HER2 expression. **Results:** Scanning with the higher peptide dose at 2-4h provided better discrimination of HER2-pos metastases in all tissues ($p < 0.01$). Sixteen metastases in 12 patients were biopsied and evaluated by immunohistochemistry and in-situ hybridization. Uptake (SUV, mean $\pm$ SD) at 2h in these metastases was 10.9 $\pm$ 5.1 in HER2-pos (n = 7) vs 3.4$\pm$2.1 in HER2-neg (n = 9) ($p = 0.001$). SUV at 4h was 15.0 $\pm$ 3.4 in HER2-pos (n = 6) vs 2.9$\pm$1.9 in HER2-neg (n = 6) ($p < 0.001$, no overlap). The test-retest intra-class correlation was R = 0.996. ^{68}Ga-ABY025 PET led to change in HER2-targeting treatment in 3 of the 16 patients due to receptor up- or down-regulation. Moreover, the PET data indicates occurrence of intra-patient heterogeneity of HER2-expression in several cases. **Conclusions:** ^{68}Ga-ABY025 PET accurately quantifies whole-body HER2-receptor status in metastatic breast cancer. Clinical trial information: NCT01858116.

11068 Poster Session (Board #282), Sun, 8:00 AM-11:30 AM

A prospective evaluation of cell free DNA (cfDNA) genotyping and circulating tumor cells (CTC) in *EGFR* mutant NSCLC patients (pts) treated with erlotinib. *First Author: Masahiko Yanagita, Dana Faber Cancer Institute, Boston, MA*

Background: Genotype directed therapy is now standard of care for advanced NSCLC pts. However, adequate tumor tissue for comprehensive genotyping remains a challenge. Recent research suggests that CTC capture or cfDNA analysis allows for non-invasive diagnosis and monitoring of treatment. This prospective trial was designed to quantify the predictive value of CTC and cfDNA analyses of *EGFR*-mutant NSCLC pts treated with first-line erlotinib. **Methods:** TKI naïve *EGFR* mutant NSCLC pts were enrolled in a phase II trial of erlotinib treatment. Paired blood for cfDNA and CTC analysis was collected at baseline prior to therapy and every 2 months during follow ups. Plasma genotyping was performed by ddPCR for *EGFR*19del, L858R, T790M while CTCs were isolated by CellSearch and analyzed by IF and *MET*-FISH. Repeat biopsies at progression were performed when feasible. **Results:** Between 2/10 and 1/15, 60 *EGFR*mutant pts (L858R:17, 19del:38, other:5) were enrolled. As of 1/15, 44 patients have discontinued therapy (39 for RECIST progression; 5 for adverse events). Blood was available for cfDNA analysis on 53 and 33 pts at baseline and progression respectively, and *EGFR* mutations were detected in 25/53 pts (47.1 %, median: 57 copies/mL plasma, range: 2-1649) and 10/33 pts (30.3% median, 71 copies/mL plasma, range: 5-2530). Blood was available for CTC analysis on 47 and 33 pts and CTCs were detected in 17/47 pts (36.1%, median: 3 CTCs/7.5 mL blood, range: 1-1145) at baseline and 15/33 pts (45.4%, median: 6 CTC/7.5 mL blood, range: 1-328) at progression. *MET*amplification was identified in CTCs of 2 pts. For 18 pts with detectable cfDNA at baseline and $>=$ 3 follow up blood draws, treatment reduced cfDNA levels to non-detectable for $>=$ 4 months in 83.3 % (15/18). In contrast, for 17 pts with detectable CTCs at baseline, CTCs continued to be intermittently detected on treatment in 58.9% (10/17) of pts. **Conclusions:** cfDNA and CTCs are complementary non-invasive assays for *EGFR*mut NSCLC although the low yield of CTCs may preclude genotyping. Serial cfDNA monitoring may be a better predictor of treatment efficacy than CTCs. Funding: R01-CA135257, P50-CA090578, Conquer Cancer Foundation, Genentech

Contrast-enhanced spectral mammography (CESM) compared with breast MRI for breast cancer detection. *First Author: Lydia Liao, MD Anderson Cancer Center at Cooper, Cooper Breast Imaging Center, Voorhees, NJ*

Background: Contrast-enhanced spectral mammography (CESM) is a new study to detect contrast enhancing malignancy that may not be visible on conventional mammogram. Limited studies have shown that adding CESM to diagnostic workup in adjunct with mammogram and breast ultrasound does increase sensitivity for breast cancer detection. More studies are needed to compare the sensitivity of CESM to BMRI to further define the role of CESM in breast cancer diagnosis. **Methods:** This study involved 60 malignant breasts in 58 women retrospectively chosen from of 1020 patients in our institution during the period of October 2012 to October 2014. Both CESM and BMRI were done for each patient within 30 days. The positive findings were confirmed by pathology reports. The number of malignant lesions was quantified. The size of lesions was classified into three categories based on standard of breast cancer stages. The enhancement intensity on both studies has been quantified based on a scale of 0-3. The scores of each case were calculated for average size of index lesion and statistical analysis. Sensitivity and positive predictive value (PPV) were calculated for each study. Morphology consistence was evaluated by the percentage of the consistent findings between CESM and BMRI. The mean study time for each test was recorded and analyzed for statistical significance. **Results:** Both CESM and BMRI are shown to have sensitivity of 98% for breast cancer detection. No statistical significance was identified on the mean size of index cancer ($p = 0.39$). The enhancement intensity of breast parenchyma is significantly lower on CESM than on BMRI ($p < 0.01$). The mean score of enhancement intensity of index lesions on CESM was significantly less than that for BMRI ($p < 0.01$). The smallest cancer can be detected by both CESM and BMRI is less than 0.5 cm. Morphology consistence was 59/60 (98.3%). CESM has a higher PPV than BMRI (98.0% versus 92.6%). The average test time for CESM is significantly shorter than BMRI (10 minutes versus 25 minutes). **Conclusions:** CESM and BMRI are consistent on morphology and equal sensitivity for detection of breast cancer lesions. CESM has less enhancement intensity than BMRI and higher PPV (reflecting a higher specificity) than BMRI.

11071 Poster Session (Board #285), Sun, 8:00 AM-11:30 AM

Identification of novel and potentially targetable receptor tyrosine kinase alterations in colorectal carcinoma using a 341 gene hybrid capture-based next-generation sequencing assay. *First Author: Jaclyn Frances Hechtman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The current mainstay of clinical molecular testing for advanced colorectal carcinoma (CRC) is mutation analysis for *KRAS*, *NRAS*, and *BRAF* to determine anti-EGFR therapy eligibility. However, the growing number and potential of targeted therapies has led to the need for broader molecular panels to triage patients. Here, we report our experience with a next-generation sequencing (NGS) assay that enables the detection as well as molecular characterization of CRC with rare and potentially targetable receptor tyrosine kinase (RTK) alterations. **Methods:** We use a hybrid capture-based NGS assay encompassing all exons of 341 cancer genes (MSK-IMPACT) to sequence tumor against matched normal to detect potentially actionable somatic alterations including point and indel mutations, copy number alterations, and selected structural rearrangements. CRC with hotspot mutations in *KRAS*/ *NRAS* exons 2-4 and *BRAF* exons 11 and 15 were excluded from further analysis as these downstream mutations often lead to primary resistance. **Results:** Seventy four of 164 CRC had wild type *RAS*/*RAF*. Twelve cases (16%) of this subgroup harbored RTK alterations previously reported to be activating and potentially targetable. Hotspot mutations commonly seen in other tumor types were also identified, including one each of *EGFR* p. L858R in a patient also harboring an *ERBB2* p. S310F, *EGFR* p. L861R, and *ERBB2* p. V842I a patient with *ERBB2* amplification. One each of in-frame fusions of RTKs were also detected: *ERBB2-GRB7* in a patient with *ERBB2* amplification, *RET-NCOA4*, and *ETV6-NTRK3*. Additional RTK amplifications were also observed in the absence of other oncogene alterations, including *FGFR1* (n = 3), *ERBB2* (n = 2), *MET* (n = 1) . No *ALK* or *ROS1*fusions were detected in any of the 164 CRC. Of these 12 patients with potentially targetable RTK alterations, 3 have already enrolled in 'matched' targeted therapies. **Conclusions:** Using a broad molecular assay to interrogate potentially actionable mutations, approximately 16% of *RAS*/ *RAF* wild type CRC harbor RTK alterations that are known to be activating and potentially responsive to inhibition.

11072 Poster Session (Board #286), Sun, 8:00 AM-11:30 AM

Analysis of cell-free circulating tumor DNA in patients with glioblastoma and other primary brain tumors. *First Author: David Eric Piccioni, UC San Diego Moores Cancer Center, San Diego, CA*

Background: Glioblastoma is the most aggressive type of primary brain tumor with a median survival of 15 months and limited therapy options. Trials of genomically targeted matched therapies for brain tumors requiring recent tissue samples for next generation sequencing (NGS) has limited progress. Recently, a cell-free circulating tumor DNA (ctDNA) NGS panel of 54 genes has become available. We sought to evaluate whether this biopsy-free approach would allow us to interrogate genomic alterations in glioblastoma and other primary brain tumor patients. **Methods:** Fifty-nine consecutive patients with primary brain tumors were tested prospectively with the Guardant360 ctDNA panel at a CLIA-certified, CAP-accredited clinical laboratory. Single nucleotide variants (SNVs) in 54 genes and copy number variants (CNVs) in 3 genes (EGFR, ERBB2 and MET) are reported quantitatively as the fractional mutant allele concentrations in cell-free DNA and the absolute copy numbers of the genes measured, respectively. The test is sensitive to a single DNA fragment of mutated ctDNA in a 10 ml blood sample and analytic specificity is 99.999%. **Results:** Average patient age was 53 (range 24-87) and 61% were male. Histopathological subtypes tested were glioblastoma (34), astrocytoma (9), meningioma (6), oligodendroglioma (5), glioma NOS (4) and ependymoma (1). 22 (37.3%) of patients had at least one genomic alteration detected and 4(6.8%) had two genomic alterations detected. SNVs detected included *TP53* (7), *NOTCH* (4), *JAK2* (2), and *KIT*, *ERBB2*, *ALK*, *APC*, *ATM*, *EGFR*, *AR* and *HNF1A* (1 each). A single copy number amplification in *MET* was reported. Cell-free DNA was sufficient to complete the sequencing assay in 100% of cases. **Conclusions:** Contrary to other ctDNA studies where it was postulated that ctDNA would not cross the blood-brain barrier and reach the systemic circulation, we found that over one-third of primary brain tumor patients, including glioblastoma patients, had detectable ctDNA with the Guardant360 assay.

11073 Poster Session (Board #287), Sun, 8:00 AM-11:30 AM

Raise and decline of KRAS mutant clones in colorectal cancers (CRCs) treated with multiple rounds of anti-EGFR antibodies. *First Author: Giulia Siravegna, Istituto di Candiolo, Fondazione del Piemonte per l'Oncologia-IRCCS, Candiolo, Italy*

Background: We previously reported that acquired resistance to anti-EGFR antibodies (moAbs) is associated with the emergence of *KRAS* mutations that can be detected in the blood before disease progression (PD) is clinically manifest (Misale S et al. Nature 2012). It is unknown whether and how subsequent therapies affect KRAS clones, which were selected during treatment with anti-EGFR moAbs. **Methods:** We studied blood samples of 16 patients (pts) who responded and then progressed upon anti-EGFR therapy. For all pts, samples were available at baseline, at the time of first PD and at different time-points across subsequent lines of treatment. At least 4 longitudinal blood draws were available for each case. We analyzed the effect of drug withdrawal in populations of CRC cells (DiFi), which had acquired resistance to cetuximab (cmab). **Results:** In 11/16 pts, mutated *KRAS* alleles were detected in blood samples obtained at PD (2 exon 2 and 8 exon 3 mutations; 1 amplification). Mutant fractional abundance (MFA) varied from 0.09 to 23.46%. *KRAS* mutant clones (1 G12D, 1 G13D, 2 Q61H and 3 Q61L) were tracked in the blood of 7 pts who initially achieved benefit and then experienced PD after treatment with an anti-EGFR moAb (partial response maintained for 3-12 months). Mutant *KRAS* alleles, which rise in blood during EGFR blockade, decline upon withdrawal of anti-EGFR moAbs (from 7.3% MFA to undetectable levels) indicating that clonal evolution continues beyond clinical progression. In the blood of pts who benefit from multiple challenging with anti-EGFR moAbs the levels of *KRAS* mutations are dynamic. They raised during the first anti-EGFR treatment, declined and became undetectable when the anti-EGFR moAb was suspended and raised again during re-challenge with EGFR blockade (from 0.31 to 1.27% MFA). Pharmacogenomic analysis of CRC cells (DiFi), which acquired resistance to cmab, revealed that upon antibody withdrawal, KRAS clones decay while the population regains sensitivity to cmab. **Conclusions:** These results reveal that the CRC genome adapts dynamically to intermittent drug schedules and provide a molecular explanation for the efficacy of re-challenge therapies based on EGFR blockade.

11074 Poster Session (Board #288), Sun, 8:00 AM-11:30 AM

The Prospective Epidemiologic Risk Factor (PERF I) Study: A serum biomarker reflecting collagen type I degradation as an early detection tool for cancer. *First Author: Cecilie Liv Bager, Techinical University of Denmark, Lyngby, Denmark*

Background: Matrix metalloproteinase (MMP) mediated degradation of the extracellular matrix (ECM) play an important role in the development of cancer. One of the most abundant ECM proteins is type I collagen, which is commonly dysregulated and degraded in early stages of tumorigenesis. However, MMP mediated tissue destruction has not been quantified in larger prospective cancer outcome studies. The aim of this study was to investigate if a biomarker reflecting MMP-mediated degradation of type I collagen (C1M) could be used for early detection of cancer, in a large prospective study. **Methods:** From 1999-2001, 5,856 women aged 60-85 participated in the Prospective Epidemiologic Risk Factor (PERF I) stud, which addresses age-related diseases. Demographics and serum samples were collected at time of enrollment. Cancer diagnoses were collected from the Danish Cancer Registry ultimo 2014. Serum C1M levels were measured by ELISA and compared to time of diagnosis and to non-cancer diagnosed and non-diseased women (healthy). Women diagnosed with cancer prior to PERF1 enrollment were excluded from analysis. Data was analyzed using one way ANOVA on log transformed data and by Pearson's correlation coefficient. **Results:** A total of 1,154 women were diagnosed with cancer following PERF I enrollment. C1M, at baseline, was significantly elevated in women diagnosed less than 6 months after blood draw compared to healthy women (p=0.016) and to women diagnosed more than 48 months (p=0.016) after blood draw (see table). Furthermore, C1M correlated with time to diagnosis up to 3 years after blood draw (r = -0.143, p=0.0146, n=289). **Conclusions:** The levels of MMP-degraded type I collagen (C1M) were significantly elevated in serum from women diagnosed up to 6 months after enrollment in PERF I and correlated with time to diagnosis up to 3 years after blood draw. Further investigations into C1M as an early detection tool for cancer could be highly relevant.

	Healthy (95% CL) n=3051	<6 months (95% CL) n=81	6-24 months (95% CL) n=121	24-48 months (95% CL) n=176	>48 months (95% CL) n=776
C1M (ng/ml)	50.1 (38.1-39.3)	63.6 (38.9-52.2)	51.0 (45.9-56.1)	53.0 (46.5-59.5)	49.4 (47.1-51.8)

11075 Poster Session (Board #289), Sun, 8:00 AM-11:30 AM

A phase I, first-in-human dose study of the dual PI3K/mTOR inhibitor LY3023414 (LY) in patients (pts) with advanced cancer. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: The phosphatidylinositol 3-kinase (PI3K)/mammalian target of rapamycin (mTOR) pathway is dysregulated in many malignant diseases. LY3023414 (LY) is an oral ATP competitive inhibitor of the class I PI3K isoforms, mTOR and DNA-PK. Based on preclinical results, we investigated LY in patients with advanced solid tumors. **Methods:** In this 3+3 dose escalation phase I study, patients with solid tumors refractory to standard therapies received LY once daily (QD) or twice daily (BID). The primary objective was to determine a recommended phase II dose (RPTD). Additional objectives were to assess LY dosing safety, pharmacokinetic/pharmacodynamic (PK/PD) profiles, drug-drug interaction with midazolam, and to document anecdotal antitumor activity. **Results:** As of September 2014, 47 pts have received LY either QD (at 20, 40, 80, 150, 225, 325, 450 mg) or BID (at 150, 200, 250 mg). Dose-limiting toxicities (DLTs) have been observed for LY QD only at 450 mg and consisted of grade [G] 4 thrombocytopenia, G4 hypotension, G3 hyperkalemia in 3/3 patients treated. For BID dosing, DLTs were observed in 3/4 patients at 250 mg (G4 hypophosphatemia, G3 fatigue, G3 mucositis) and in 1/15 patients at 200 mg (G2 nausea). Common treatment-related adverse events (all grades) included nausea (38%), fatigue (31%), vomiting (27%), and diarrhea (17%). PK analyses showed a dose-proportional increase in LY exposures (AUC) at tolerated dose levels with a half-life of 1.9 hours and a body clearance of 85 L/hr. Midazolam PK data indicated that LY is a weak inhibitor of CYP3A4. Biomarker assessment demonstrated dose-related target inhibition in peripheral mononuclear cells at LY doses $\geq$ 150 mg. Durable partial response according to RECIST was observed in an endometrial cancer patient harboring PIK3R1 and PTEN mutations and 22 additional patients (47%) had stable disease as their best response. **Conclusions**: LY appears to be safe when administered as single agent up to 325 mg QD or 200 mg BID. The RPTD of single-agent LY is 200 mg BID based on safety, tolerability, and PK/PD data. LY is currently studied in tumor-specific expansion cohorts for mesothelioma, breast cancer, indolent Non-Hodgkin Lymphoma and squamous NSCLC. Clinical trial information: NCT01655225.

11076 Poster Session (Board #290), Sun, 8:00 AM-11:30 AM

Lung cancer patients with HER2 mutations treated with chemotherapy and HER2 targeted drugs: Results form the EUHER2 cohort study. *First Author: Julien Mazières, Hôpital Larrey CHU Toulouse, Toulouse, France*

Background: *HER2* mutations are identified in about 2% of non-small cell lung cancer (NSCLC) and behave as an oncogenic driver. Little is known about the efficacy of chemotherapy and of HER2 targeted drugs in this population. We aimed to study therapeutic outcomes of patients harboring *HER2* mutations (HER2+) in order to establish the efficacy of various drug regimens and to orient future clinical trials. **Methods:** We conducted a retrospective cohort study in European centers testing NSCLC patients for HER2. Eligible patients had advanced stage NSCLC, known HER2 exon 20 insertions by local testing, and treatment with chemotherapy and/or targeted drugs. Clinicians had to obtain informed consent and IRB approval according to local regulations, and response were assessed according to RECIST version 1.1. Data were anonymized and analyzed centrally. **Results:** We identified 101 eligible patients from 38 centers. Our population was characterized by a median age of 61 yrs (30-87), a high proportion of women (63 *vs.* 38 men, 62.4%), and of never smokers (61, 60.4%). All tumors were adenocarcinomas. Concomitant EGFR mutation, ALK translocation and ROS translocation were observed in 5, 1 and 1 patients respectively. The median number of treatment lines was 3 (1-11). Overall survival of the whole population (n = 101) was 24 months (m.). Response rate (RR) and median progression free survival (PFS) for patients treated with conventional chemotherapy (excluding targeted therapy) were 43.5% and 5.9 m. in first line (n = 93) and 10% and 4.2 m. in second line (n = 52) respectively. RR to EGFR-TKI (n = 27) was 7.2% and PFS was 3 m. Eighty-six targeted treatments against HER2 were given to 65 patients including trastuzumab (n = 57), neratinib (n = 14), afatinib (n = 9), lapatinib (n = 5) and T-DM1 (n = 1). RR was 18% and PFS 3.9 months for afatinib. RR was 50% and PFS 5.1 m. for trastuzumab (given with vinorelbine n = 24, docetaxel n = 12, paclitaxel n = 12, cisplatinum based combination n = 7, alone n = 2). **Conclusions:** This series, the largest to date, underlines the chemosensitivity of HER2 + NSCLC and the potential interest of anti-HER2-antibodies that deserve to be further evaluated in clinical trials.

11077 Poster Session (Board #291), Sun, 8:00 AM-11:30 AM

Protein tyrosine phosphatase non receptor 11 (*PTPN11*/Shp2) as a driver oncogene and a novel therapeutic target in non-small cell lung cancer (NSCLC). *First Author: Yasir Elamin, Education Centre Beaumont Hospital, Dublin, Ireland*

Background: *PTPN11*/Shp2 somatic mutations occur in 25% of Juvenile myelomonocytic leukemias (JMML) and less commonly in adult solid tumors. *PTPN11*/Shp2 activates the mitogen-activated protein kinase (MAPK) pathway, upstream of KRAS and MEK. Accordingly, *PTPN11* mutations were shown to sensitize leukemia cells to MEK inhibitors. **Methods:** We applied mass-spectrometry based genotyping (Sequenom Inc., Germany) to DNA extracted from tumor and matched normal tissue of 299 NSCLC patients (98 adenocarcinomas and 201 squamous cell (SCC)). *PTPN11* constructs with mutations (E76A, A72D) were generated and stably expressed in IL-3 dependent BaF3 cells and NSCLC cell lines (H1703, H157). The acquisition of MAPK pathway activation was evaluated using western blotting and reverse phase protein array (RPPA). *PTPN11*/Shp2 phosphatase activity was measured in whole cell protein lysates using Shp2 assay kit (R&D Systems). **Results:** Somatic *PTPN11* hotspot mutations occurred in 3 (3.1%) and 9 (4.5%) of adenocarcinomas and SCCs, respectively. Mutant *PTPN11*, compared to *PTPN11* wild type, promoted ten-fold IL-3 independent BaF3 cell survival. BaF3, H1703, and H157 cells expressing mutant *PTPN11* exhibited increased *PTPN11*/Shp2 phosphatase activity and phospho-ERK1/2 levels. shRNA was used to silence *PTPN11*/Shp2 in the NSCLC cell line H661, which has an activating *PTPN11* mutation (N58S). Silencing of *PTPN11*/Shp2 led to reduced cell proliferation and decreased phospho-ERK1/2 levels, suggesting that *PTPN11* mutation is crucial for cell tumorigenicity and MAPK pathway activation in H661 cells. Parental H661 (*PTPN11*-mutated, *KRAS*-wild type) and H1703 (*PTPN11/KRAS*-wild type) cells were treated with the novel MEK inhibitor BAY86-9766. IC50 values were 2.88 $\pm$ 0.6 μM in H661 cells and $<$ 50% growth inhibition at 10 μM in H1703 cells. **Conclusions:** *PTPN11*/Shp2 demonstrates the *in vitro* features of a driver oncogene, and potentially represents a new target in NSCLC.

11078 Poster Session (Board #292), Sun, 8:00 AM-11:30 AM

Identifying driver mutations in squamous cell lung cancer (SCC): The Lung Cancer Genomics Ireland (LCGI) study. *First Author: Shereen Rafee, St. James's Hospital, Dublin, Ireland*

Background: Targeting oncogenic drivers has transformed the care of lung adenocarcinoma. However, there is no approved targeted therapy for lung SCC. LCGI aims to identify potential targets in lung SCC. **Methods:** The LCGI study is being carried out in patients with surgically resected lung SCC. We used the platform of Sequenom's MassArray to perform genotyping for 548 somatic hotspot mutations in 49 genes including genes in the MAPK and PI3K pathways. We also evaluated *FGFR1* amplification by fluorescence in situ hybridization (FISH) and MET protein expression by immunohistochemistry (IHC). **Results:** Lung SCCs from 201 patients have been tested by Sequenom MassArray to date. Lung SCCs from 150 patients have been evaluated for MET protein expression and 89 for *FGFR1* amplification. 134 (66.7%) patients were male. The median age of the cohort was 68. The majority of patients were either current (32.8%) or former (64.2%) smokers at the time of diagnosis. 104 (57.1%) were stage I, 68 (33.8%) were stage II, 29 (14.5%) were stage III SCCs. At least one aberrant, potentially targetable oncogene was identified in the SCC of 81 (40.3%) patients (see Table). The presence of *PIK3CA* or *KRAS* mutations, or *FGFR1* amplification did not have a statistically significant impact on median overall survival or recurrence-free survival. However, the presence of two or more aberrations in driver oncogenes in a tumor (patients, n = 19) was associated with a worse median overall survival compared to patients with either a single driver aberration ($p = 0.04$) or no aberrations ($p < .001$). **Conclusions:** 40.3% of lung SCC patients have an aberrant, potentially targetable driver oncogene in their tumor. The presence of two or more aberrant oncogenes is a poor prognostic factor. These findings can be used to guide clinical trials in lung SCC.

Frequency of driver mutations in LCGI compared to The Cancer Genome Atlas (TCGA) study.

Mutation	LCGI (n = 201)	TCGA (n = 178)
FGFR1 amp (n = 89)	12.4%	16.8%
PIK3CA	12.4%	10.1%
KRAS	6.5%	0.6%
PTPN11	4%	1.7%
STK11	1.9%	1.7%
MYC	1.9%	0.0%
NRAS	1.5%	0.0%
BRAF	1.5%	3.9%
HRAS	1.5%	1.7%
CTNNB1	1.5%	1.7%
FBXW7	1.5%	3.4%
MET Overexpression (n = 150)	1.3%	NA
EGFR	0.9%	2.8%
AKT1	0.5%	0.6%
CDK4	0.5%	0.0%
GNA11	0.5%	0.6%
MAP2K1	0.5%	0.6%
DDR2	0%	1.1%

11079 Poster Session (Board #293), Sun, 8:00 AM-11:30 AM

The anti-proliferative effects of RF EMF amplitude-modulated at tumor specific frequencies and mediation by calcium. *First Author: Hugo Jimenez, Wake Forest University Baptist Health, Winston-Salem, NC*

Background: Experimental and clinical evidence shows that whole body administration of low-level radiofrequency electromagnetic fields, amplitude-modulated (AM RF EMF) at specific frequencies ranging from 400 Hz to 21 kHz has efficacy in advanced hepatocellular carcinoma (HCC) (Costa, de Oliveira et al, 2011). In vitro studies demonstrate that AM RF EMF treatment inhibits cancer cell growth in a tumor-specific manner (Zimmerman, Pennison et al, 2012). RNA-seq analysis of HepG2 cells treated with AM RF EMF revealed altered expression of several mRNAs belonging to the IP3/DAG signaling pathway. Given the central modulatory effect of calcium in this pathway, we hypothesized that calcium modulates the growth inhibitory effect of RF EMF. **Methods:** HCC and ovarian cancer cell lines as well as NOD SCID mice, carrying subcutaneous HCC xenografts, were exposed to 27.12 MHz RF EMF modulated at cancer-specific frequencies or random chose frequencies using exposure systems designed to replicate human exposure levels. Huh-7 cells were cultured in the presence or absence of BAPTA, a Ca^{2+} chelator, for three hours daily, seven days in a row. Mice carrying Huh-7 xenografts received treatment three hours daily for six weeks. The specific absorption rate (SAR) of AM RF EMF was 0.4 W/kg, which is identical to the highest SAR measured in patients receiving treatment with this therapy. mRNA expression of key mediators of the IP3/DAG signaling pathway was analyzed. **Results:** Ca^{2+} chelation fully abrogated AM RF EMF inhibition of HCC cell growth. ARHGDIB and S100B mRNA was down regulated in Huh-7 cells treated with cancer-specific AM RF EMF. In vivo Huh-7 was significantly inhibited in mice exposed to AM RF EMF. **Conclusions:** Ca^{2+} is a necessary mediator of AM RF EMF anti-proliferative effects in HCC, which modulate the IP3/DAG signaling pathway (Costa, F. P., et al, 2011. "Treatment of advanced hepatocellular carcinoma with very low levels of amplitude-modulated electromagnetic fields." *Br J Canc* **105**(5): 640-648; Zimmerman, J. W., et al, 2012. "Cancer cell proliferation is inhibited by specific modulation frequencies." *Br J Canc* **106**(2): 307-313).

11080 Poster Session (Board #294), Sun, 8:00 AM-11:30 AM

TBCRC-010: Phase I/II study of dasatinib in combination with zoledronic acid (ZA) for the treatment of breast cancer bone metastasis (MBC-bone). *First Author: Zahi Ibrahim Mitri, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Osteoclast activation and subsequent bone resorption release growth factors that promote tumor growth. These events are blocked by the Src/PDGF inhibitor dasatinib. The tyrosine kinase Src phosphorylates and activates the ER in ligand-independent manner. Dasatinib, by inhibiting Src, may facilitate the antitumor effect of endocrine therapy. **Methods:** A phase I/II study was completed by the TBCRC at three institutions: MD Anderson Cancer Center, Duke University, and University of Chicago. Pts with HER2-negative, MBC-bone received standard dose ZA IV on day 1 and Dasatinib 100 mg QD, days 1-28 of each 28 day cycle. Prior therapy with bone-modifying agents was allowed. Response was assessed by RECIST (non-bone disease) and MDACC criteria for bone. Pts progressing on endocrine therapy continued this therapy to determine dasatinib's effect. Change in urine n-terminal telopeptide levels (NTX) was correlated with response. **Results:** 25 pts were enrolled, 7 in phase I and 18 in phase II. An initial pt developed pleural and pericardial effusions in cycle 1 on dasatinib 70 mg BID, prompting change to 100mg/day for the MTD/RP2D (recommended phase 2 dose) 6 pt run-in cohort (0/6 developed DLT). Most adverse events (AEs) were grade 1-2: rash (32%), fatigue (28%), and nausea (20%). Grade 3 AEs: anemia (4%) and pain (4%). In pts treated at RP2D (n = 24, Table 1), RR (CR, PR) in bone was 5/24 (21%), all PRs. Clinical benefit rate (CR, PR, SD > 6months) in bone was 8/24 (33%). Median TTF was 2.69 months (1.77 - 5.45), 3.61 months (1.84 - 5.71) in ER+ disease and 0.67 months (0.26 – 1.73) in ER- disease. Response was associated with low grade, ER+ disease, and high baseline NTX levels. In ER+ disease pts who had progressed on, but continued their previous endocrine therapy (n = 14), 29% had PR in bone. In pts with metastatic sites outside the bone (n = 12), RR was 3/12 (25%) and CBR 4/12 (33%) for non-bone metastasis. **Conclusions:** Dasatinib and ZA were well tolerated, and may have benefit in a subset of pts. Clinical trial information: NCT00566618.

Characteristics of patients treated at RP2D.

11081 Poster Session (Board #295), Sun, 8:00 AM-11:30 AM

Prognostic significance of β2 adrenergic receptor expression in the patients with non-small cell lung cancer. *First Author: Tomohiro Yazawa, Department of Thoracic and Visceral Organ Surgery, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan*

Background: β2 adrenergic receptor (β2-AR) is highlty expressed in cancer cells and has a relationship with tumor cell progression and metastases. However, it remains unclear about the prognostic role of β2-AR expression in non-small cell lung cancer (NSCLC). The aim of this study is to clarify the clinicopathological importance of β2-AR expression in patients with NSCLC. **Methods:** Three hundreds and twenty eight patients with surgically resected NSCLC were investigated retrospectively. Tumor sections were stained by immunohistochemistry for β2-AR, Ki-67, and microvessel density (MVD) determined by CD34. **Results:** β2-AR was positively expressed in 27% of all patients, 29% of adenocarcinoma (AC) patients, and 24% of non-AC patients, respectively. The β2-AR expression was significantly correlated with lymphatic permeation ($r = 0.240$, $p < 0.001$) and vascular invasion ($r = 0.239$, $p < 0.001$), and Ki-67 ($r = 0.175$, $p = 0.009$) in AC patients, but not non-AC. A positive β2-AR expression indicated poor prognosis of AC patients (overall survival, OS: $p = 0.045$; progression-free survival, PFS: $p = 0.001$), especially stage I (OS, $p = 0.017$; PFS, $p = 0.003$). Multivaritate analysis confirmed that β2-AR expression was an independent factor for predicting poor progression-free survival in stage I AC patients (hazard ratio: 2.220; 95% confidence interval: 1.077-4.573; $p = 0.031$). **Conclusions:** β2-AR expression was identified as an independent prognostic factor for early stage AC patients. β2-AR could be a promising marker for predicting outcome after surgery in lung cancer.

11082 Poster Session (Board #296), Sun, 8:00 AM-11:30 AM

Mutant HRAS as novel target for MEK and mTOR inhibitors. *First Author: Michael Kiessling, University Hospital Zurich, Zurich, Switzerland*

Background: HRAS (Harvey-RAS) is a frequently mutated oncogene in cancer. HRAS is mutated in head and neck cancer (3.9%), bladder cancer (5.1%), vulvar squamous cell carcinoma (9.3%), cutaneous squamous cell carcinoma and lung cancer (3.8%). However, mutant HRAS as a drug target has not been investigated so far. **Methods:** Cell Proliferation and Viability Assays: Cell proliferation was measured with the Cell-Titer-Glo Reagent (Promega) according to manufacturer's instructions. Cells were plated in clear-bottomed 96-well plates at a density of 500 - 2500 cells per well. The next day, drugs were added at indicatend concentrations and cell proliferation was measured 4 days later. Apoptosis assays:Cell lines were treated with indicated concentrations of inhibitors and apoptosis was measured after 48h and 72h. Apoptosis was assessed by AnnexinV–APC (Enzo Lifescience) and propidium iodide (PI) (Sigma-Aldrich) by FACS. **Results:** Here, we show that mutant HRAS activates the RAS and the mTOR pathway in various cancer cell lines including lung, bladder and esophagus cancer. HRAS mutation sensitized toward growth inhibition by the MEK inhibitors AZD6244, MEK162 and PD0325901. Further, we found that MEK inhibitors induce apoptosis in mutant HRAS cell lines but not in cell lines lacking RAS mutations. In addition, knockdown of HRAS by siRNA blocked cell growth in mutant HRAS cell lines. Inhibition of the PI3K pathway alone or in combination with MEK inhibitors did not alter signaling nor had an impact on viability. However, combined inhibition of MEK and mTOR reduced cell growth in a synergistic manner. **Conclusions:** Our results show that HRAS mutations in cancer activate the RAS and mTOR pathways which might serve as a therapeutic option for mutated lung cancer patients.

11083 Poster Session (Board #297), Sun, 8:00 AM-11:30 AM

Stereotactic ablative radiotherapy (SABR) as re-irradiation for an isolated infield lymph node recurrence. *First Author: Neal Bhatt, University of Louisville, Louisville, KY*

Background: Oligometastatic disease presents a unique opportunity for local therapy to provide cure. The aims of this study were to evaluate the safety and efficacy of stereotactic ablative radiotherapy (SABR) as a local treatment for isolated lymph node recurrence in a previously irradiated field. **Methods:** Between January of 2010 and September of 2014, 33 patients were reviewed from a prospectively collected database. Eighteen of 33 patients had biopsy proven recurrence and all patients were shown to have isolated metastases by positron emission tomography (PET)–CT. All patients had previously received full dose radiation treatment with radical intent, with a median total dose of 56 Gy (range, 46-74) delivered with standard fractionation. The median duration from initial radiotherapy to lymph node recurrence was 11.2 months. The overall survival (OS), local control (LC) rate, and disease progression–free survival (DPFS) rate were calculated according to the Kaplan-Meier method. Comparison between prognosis groups and toxicities was performed using log-rank analysis. **Results:** All patients completed the prescribed treatment. The median tumor dose and fractions administered was 40 Gy (range, 24-50) in 5 fractions. The median follow-up was 10 months (range, 1-33). Three grade 3 toxicities were observed including radiation pneumonitis, displaced fracture, and pelvic pain. No Grade 4 toxicities were recorded. Results at last follow up demonstrated a local control of 90.9%, Regional control (adjacent nodal station) of 66.7%, and distant failure of 27.3%. The median time to any failure was 4.5 months with a 1 year OS of 45.5%, and DPFS 62.3%. **Conclusions:** SABR salvage to macroscopic nodal recurrences provides local control and long-term disease-free survival in carefully selected patients with a low incidence of toxicities. Further investigation is warranted to identify those patients who benefit most from this treatment modality.

11084 Poster Session (Board #298), Sun, 8:00 AM-11:30 AM

Germline variants in cancer risk genes detected by NGS-based comprehensive tumor genomic profiling (CGP). *First Author: Michael J. Hall, Fox Chase Cancer Ctr, Philadelphia, PA*

Background: NGS-based CGP is increasingly used in oncology to assess patient eligibility for targeted therapies. Previous work has demonstrated that variant germline/somatic status may be accurately predicted for research use from data generated by CGP (AACR 2014 #1893). The prevalence of germline variants in hereditary cancer risks genes and their potential clinical implications have not been previously reported in patients referred for CGP. **Methods:** Germline variants were predicted in data from 15060 tumor samples analyzed by Foundation Medicine. Variant analyses focused on 20 penetrant hereditary cancer risk genes identified by the ACMG as high priority for disclosure to patients if discovered during genomic testing. Pathogenicity of each variant and association with tumor histology (known vs unexpected) was assessed through expert review of clinical evidence from public variant annotation databases (dbSNP/ClinVar, BIC, HGMD), and other resources (PubMed, Internet). **Results:** Of tumors tested, 30.8% (4633/15060) had >1 germline variant in a cancer risk gene, with 521 unique variants identified overall. A likely pathogenic variant (PV) was found in 3.1% tumors ($n = 466/15060$), and an additional 3.9% (587/15060) had a suspicious variant but conflicting pathogenicity data. PV prevalence appeared higher than in the general population (CGP PV prevalence; estimated population prevalence): *MUTYH* (1.3%; 0.02%), *RET* (0.7%; 0.02%), *BRCA1* (0.6%; 0.001%), *BRCA2* (0.5%; 0.001%); *MLH1* (0.02%; 0.002%), *PMS2* (0.02%; 0.001%) and *TP53* (0.02%; 0.0002%). Early-onset cancer was most strongly associated with PV in *BRCA1*($p < 0.001$). Bladder cancer (4.1%, 10/243 tumors tested), squamous cell lung cancer (4.4%, 13/293) and kidney cancer (3.4%, 5/148) had the most unexpected PV. Data were insufficient to determine clinical pathogenicity for the majority of the missense variants identified. **Conclusions:** Germline PV in cancer risk genes are found in 3-7% of patients tested by CGP. There is a pressing need for further research to determine the association of these variants to disease risk. Additional clinical resources are needed to guide oncologists in the interpretation and management of potential PV uncovered by CGP.

11085 Poster Session (Board #299), Sun, 8:00 AM-11:30 AM

Higher CD3 cell counts in apheresis collection in relation to superior survival in patients with multiple myeloma. *First Author: Sharon Kim, Mayo Clinic, Rochester, MN*

Background: High dose chemotherapy (HDT) and autologous stem cell transplantation (ASCT) remain a standard of care for patients with multiple myeloma (MM). While the impact of transplant is primarily thought to be related to dose intensity, immunological reconstitution also plays a major role. We examined the impact of CD3 content of apheresis product on outcomes. **Methods:** Patients (pts, $n = 1187$) diagnosed with MM between 2006 and 2014 who had a stem cell collection were included. Overall survival (OS) outcomes were correlated with total CD3 collected, CD3/CD34 ratio in the collection, and CD3 infused. **Results:** Among all 1187 pts included (median age 61 years, 57% male), the median CD3 and CD34 content was 4.6×10^8/kg and 8.3×10^6/kg, respectively. Overall, 886 (75%) had undergone HDT. Since the total CD3 count depends on the total goal, we examined the impact of CD3/CD34 ratio on outcomes. The median OS from ASCT was 90 months for those with a ratio of $> 5 \times 10^3$, compared with 68 months for the rest ($p < 0.01$). Specifically looking at the first day CD3 counts, median OS was not reached for those patients with $> 2.3 \times 10^8$/kg compared with 68 months for the rest ($p < 0.01$). In addition, CD3 dose infused was also prognostic for OS. In a multivariable analysis, the prognostic value was independent of the disease status for HDT, timing of HDT, and for the number of prior therapies. Given that the CD3 collection can be a surrogate marker for the immune system, we examined the impact of CD3 content on patients who collected without receiving HDT, estimating the OS from collection date. Among the 301 pts not treated with HDT, the OS from the collection date was not affected by the total CD3 dose or CD3/CD34 ratio, but remained strongly prognostic for those who had HDT. **Conclusions:** The results suggest that we should not only collect enough CD34 for hematopoietic recovery, but also enough CD3 for immunologic recovery with direct impact in clinical outcomes in MM patients undergoing ASCT.

11086 Poster Session (Board #300), Sun, 8:00 AM-11:30 AM

CTEP #8850: A phase I trial of riluzole and sorafenib in patients with advanced solid tumors. *First Author: Kristen Renee Spencer, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: Metabotropic glutamate receptor 1 (GRM1) activates MAPK and PI3K/AKT signaling and is implicated in multiple cancers including breast, prostate and melanoma. GRM1 overexpression stimulates tumor angiogenesis via enhanced microvesicle secretion to facilitate endothelial cell growth. Riluzole (R) is a clinically available inhibitor of GRM1 signaling. Sorafenib (S), a kinase inhibitor that inhibits MAPK and PI3K/AKT signaling through C-RAF and B-RAF inhibition with antiangiogenic effects, was identified in preclinical screens to have synergistic antitumor activity when combined with R. This phase I trial identified the maximum tolerated dose (MTD) of R combined with S in patients (pts) with advanced cancer. **Methods:** Pts with refractory solid tumors were enrolled utilizing a standard 3+3 dose-escalation design. R was given in 28 day cycles at the highest dose used in clinical practice (100 mg BID) in combination with S, beginning at 200 mg daily and escalating in 200 mg increments per cohort. Restaging evaluations were performed every 2 cycles using RECIST criteria. **Results:** 29 pts enrolled, median age 59 (22-85), 13F, 16M, PS 0 (48%), 1 (35%) or 2 (17%). The most common toxicities were nausea (31%), fatigue (62%) and diarrhea (41%), anorexia (31%), rash (27% PPE, 31% other), and hypophosphatemia (34%). Grade 3-4 toxicities included hypophosphatemia (10%), elevated lipase (10%), LFT abnormalities (10%), rash/PPE (14%), and fatigue (13%). The most frequent dose limiting toxicity (DLT) was rash, observed in 3 pts at the MTD, dose level (DL) 4 (R 200 mg bid/S 400 mg bid). Best responses were SD in 9 pts (31%), lasting $>$ 3 months in 1 pt each with sarcoma, lung, colon, ovarian, and melanoma; and 1 GIST (9+ cycles with modest tumor reduction). **Conclusions:** R combined with S is safe with DLT of rash. While rash is a known side effect of sorafenib, its incidence and severity appeared increased in this study. An expansion cohort in pts with melanoma and sarcoma at DL3 (R 200 mg bid/S 400mg qam/200 mg qpm) is ongoing. Planned correlative assessments include circulating microvesicle quantification and immunohistochemical and western blotting to assess changes in activated signaling targets in pre and post treatment tumors. Clinical trial information: NCT01303341.

11087 Poster Session (Board #301), Sun, 8:00 AM-11:30 AM

Identification and functional characterization of a long non-coding RNA driving hormone-independent prostate cancer progression. *First Author: Francesco Crea, BC Cancer Agency, Vancouver, BC, Canada*

Background: Despite recent therapeutic advancements, castration-resistant prostate cancer (CRPC) remains an incurable disease. Most CRPCs display an aberrantly activated androgen receptor (AR) pathway, but the mechanisms underlying this phenomenon are not entirely elucidated. Long non-coding RNAs (lncRNAs) are non-translated transcripts, encoded by more than 50,000 *loci* of the human genome. Some lncRNAs are emerging as crucial mediators of neoplastic progression. We hypothesize that lncRNAs are functionally relevant in CRPC, and therefore they can be exploited as novel therapeutic targets. **Methods:** We developed isogenic pairs of patient-derived, prostate cancer xenografts (PCXs), showing opposite sensitivity to castration. We then profiled the transcriptome of sensitive *vs.* resistant PCXs and set out functional characterization of the most differentially expressed lncRNA. **Results:** Transcriptomic analysis revealed more than 100 lncRNAs specifically up-regulated ($>$ 2 fold) in the castration-resistant models. These uncharacterized genes have been named *HORAS*: *Hormone Resistance Associated Sequences*. The most highly up-regulated lncRNA was *HORAS1*, a gene mapping on chromosome 21. Using qPCR, we have confirmed dramatic *HORAS1* up-regulation in three isogenic castration-resistant/sensitive PCX pairs (5- to 113-fold change). *HORAS1* was highly expressed in AR-positive PCa cell lines and was prevalently localized in the cytoplasm. We then tested the function of *HORAS1* in two PCa cell lines grown in media containing castrate testosterone levels. *HORAS1* silencing induced a dramatic growth arrest and activation of caspase 3/7, 8 and 9 (two distinct small-interfering RNAs vs. negative control; $p < 0.01$, ANOVA and Tukey post-test for all the above mentioned experiments). *HORAS1* silencing also induced down-regulation of AR target genes. RNA Seq. analysis on 208 primary prostate cancer samples revealed that higher *HORAS1* expression predicts shorter disease-free free survival ($p < 0.01$, log-rank test). **Conclusions:** *HORAS1* is a previously uncharacterized regulator of the AR pathway. This lncRNA is required for hormone-independent prostate cancer proliferation.

11088 Poster Session (Board #302), Sun, 8:00 AM-11:30 AM

Characterization of LASEP3 as a serological and prognostic biomarker and a therapeutic target for lung cancer. *First Author: Atsushi Takano, Center for antibody and vaccine, The University of Tokyo, Tokyo, Japan*

Background: Characterization of cancer-specific oncoproteins could lead to the development of novel diagnostic/prognostic biomarkers or therapeutic targets. **Methods:** To develop new cancer biomarkers and therapies targeting oncoproteins, we used the strategies as follows: i) Identification of up-regulated genes in non-small cell lung cancers (NSCLCs) by means of cDNA microarray, ii) Validation of clinicopathological significance of their protein expression by tissue microarray, iv) Examination of the growth/invasive effect on cancer cells by siRNA assay, and v) Measurement of their serum protein levels by ELISA. **Results:** We identified a secreted protein, LASEP3 (lung cancer-associated serum protein 3) as a candidate. Immunohistochemical staining of LASEP3 showed that strong LASEP3 positivity was observed in 198 (54.8%) of 361 earlier stage NSCLCs that had undergone curative surgery. High level of LASEP3 expression was associated with poor prognosis for NSCLC patients. ($P = 0.0183$ by log-rank test). Serum LASEP3 levels were higher in NSCLC patients than in healthy volunteers. The proportion of serum LASEP3-positive cases was 160 (61.8%) of 259 NSCLCs (49.4% for stage I-II, 67.4% for stage III-IV), while 6 (5.5%) of 109 healthy volunteers were falsely diagnosed. Moreover serum LASEP3 levels were significantly higher in breast and colon cancer patients than in healthy volunteers. Furthermore, reduction of LASEP3 by siRNAs suppressed lung cancer cell proliferation and invasion. Flow cytometric analysis of these tumor cells transfected with siRNAs for LASEP3 revealed a significant increase of the cells at the sub G1 phase and induced the apoptosis of the cancer cells. Furthermore, subsequent *microarray* analysis of these cancer cells transfected with siRNAs identified several candidate downstream genes of LASEP3 that relate to cell growth/invasion signals. **Conclusions:** LASEP3 is a possible diagnostic and prognostic biomarker and a therapeutic target for lung and various types of solid cancer.

11089 Poster Session (Board #303), Sun, 8:00 AM-11:30 AM

A prospective validation of plasma ddPCR for rapid *EGFR* and *KRAS* genotyping of advanced NSCLC patients (pts). *First Author: Adrian G. Sacher, Dana-Farber Cancer Inst, Cambridge, MA*

Background: Plasma genotyping of cell-free DNA (cfDNA) has the potential to allow for noninvasive genotyping while avoiding the inherent shortcomings of tissue genotyping and repeat biopsies. We have developed a quantitative droplet digital PCR (ddPCR)-based plasma genotyping assay capable of detecting common *EGFR* and *KRAS* mutations (Oxnard *et al.*, CCR 2014). This is the first prospective study designed to validate the test characteristics of plasma ddPCR in advanced NSCLC. **Methods:** Pts with newly diagnosed or progressive advanced NSCLC were eligible. All pts were required to have a biopsy available or planned for tissue genotyping which was used for gold standard comparison; rebiopsy was required for pts with acquired resistance to EGFR TKI. Pts underwent an initial blood draw and immediate plasma ddPCR for *EGFR* exon 19 del, L858R, T790M and/or *KRAS* G12X. Test turnaround time (TAT) was measured in business days from date of blood draw until test reporting. Test characteristics were studied only in pts completing both plasma ddPCR and tissue genotyping for a given mutation. **Results:** 170 pts have been enrolled: 95 newly diagnosed, 43 with acquired resistance to EGFR TKIs and 32 others with progressive disease. Tumor genotype: 68 *EGFR* exon 19/L858R mutants, 27 *KRAS* G12X mutants, 75 others. Median TAT for plasma ddPCR was 3 days (range 1-5). Specificity of plasma ddPCR was 98% for 19 del/L858R (55/56) and 100% for *KRAS* (57/57), but lower for T790M at resistance (84%, 21/25; $p = 0.03$). Sensitivity of plasma ddPCR was 74% for 19 del/L858R (50/68) and 76% for T790M (19/25) but lower for *KRAS* (48%, 13/27; $p = 0.03$). Sensitivity for *EGFR* or *KRAS* was 78% in pts with extra-pulmonary disease (58/74) but 30% in pts with lung only disease (7/23; $p < 0.01$). **Conclusions:** Plasma ddPCR for driver mutations in *EGFR* and *KRAS* has a rapid TAT and high specificity suggesting it could be used to avoid biopsies for genotyping in some pts with advanced NSCLC. The false positive rate for T790M is likely related to tumor heterogeneity in resistant disease. This assay is currently being transitioned into the pathology laboratory for clinical use. Funding: US Department of Defense, Conquer Cancer Foundation of ASCO, Stading-Younger Cancer Research Foundation

11090 Poster Session (Board #304), Sun, 8:00 AM-11:30 AM

Ocular toxicity with MEK inhibitors in phase I trials: A single centre experience across six clinical trials. *First Author: Vasiliki Michalarea, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: MEK is a crucial signalling protein downstream of multiple receptor and non-receptor protein kinases that drive cancer. A range of allosteric MEK inhibitors have been developed and one has been licensed for use in malignant melanoma. We have assessed ocular toxicity in detail across a range of MEK inhibitors. **Methods:** Patients enrolled in phase I trials of MEK inhibitors between February 2009 and November 2014 were considered eligible for this study. Patients underwent testing of visual acuity by Snellen's chart, ocular pressure assessment and ocular tomography (OCT) at baseline and at various points in each trial. **Results:** 94 (M:F, 42:52) patients were assessed in 6 trials. The most common tumour types included colorectal, lung, ovarian cancer and melanoma. Significant retinal changes on OCT were detected in 30/94 (31%) patients. 15 (50%) of these patients were symptomatic due to peripheral epithelial detachment (PED), central serous detachment (CSR) and a combination (PED+CSR) in 9/15, 3/15 and 3/15 cases. In 15 asymptomatic patients, significant retinal changes on OCT included PED in 13/15 and PED+CSR in 2/15. National Cancer Institute Common Toxicity Criteria (NCI-CTC) Grade 0, 1, 2 and 3 numbered 60, 30, 4 and 2 events respectively. In patients where OCT was performed, there was a statistically significant difference in average thickness and central thickness of the macula ($p = 0.0009$ and $p = < 0.0001$, respectively), but not in total macular volume ($p = 0.67$), between patients who reported any Grade 0-3 ocular toxicities on ANOVA. There were no episodes of toxicity related drug discontinuations or irreversible ocular toxicity. **Conclusions:** Reversible retinal changes occur across a diverse number of MEK inhibitors indicating this to be a class effect. Approximately half of patients were symptomatic; however, with careful monitoring by OCT, appropriate dose delays and dose reductions, it is possible to continue treatment in most instances.

11091 Poster Session (Board #305), Sun, 8:00 AM-11:30 AM

Investigation of non-V600 BRAF mutations commonly found in NSCLC for their sensitivity to dabrafenib or trametinib. *First Author: Amir Noeparast, Medical Oncology, Oncologisch Centrum, UZ Brussel, Brussels, Belgium*

Background: The most common BRAF mutations in non-small cell lung cancer (NSCLC) are non-V600 in contrast to melanoma. BRAF pathway inhibitors have not been systematically investigated in non-V600 mutations *in vitro* and in the clinic. We tested the effect of two clinically available BRAF pathway inhibitors (Trametinib and Dabrafenib) on a subset of clinically identified BRAF mutations in a cohort of lung cancers enriched for adenocarcinoma in patients with no or limited smoking history. **Methods:** NSCLC tumor samples (FFPE) were tested for the presence of EGFR, KRAS, NRAS, HRAS and BRAF mutations by DGGE or NGS-based methods. We generated 15 BRAF expression plasmids, harboring the mutations found in the given cohort and others described in the literature. BRAF mutants were subjected to an *in vitro* kinase assay. BRAF constructs were also expressed in HEK293T cells (with and without wt-CRAF) to study their impact on ERK signaling and determine the effect of inhibitors. **Results:** Among 229 NSCLC patients, 12 patients (5.2%) were found to harbor a BRAF mutation in their tumor: V600 (25%), G469A (16.7%), G469V (8.3%), D594N (25%), D594E (8.3%), G596C (8.3%) and G466V (8.3%). Mutations were characterized as activating or kinase-impaired (in-vitro kinase assay) . Kinase-impaired BRAF mutants could still activate the ERK pathway in a CRAF-dependent manner, more than wt-BRAF/wt-CRAF co-transfectant. A MEK inhibitor (*Trametinib)* and a selective BRAF-inhibitor (*Dabrafenib)* were tested at clinically relevant doses on HEK293T transfectants (either expressing BRAF mutant alone or together with CRAF). ERK signaling induced by activating mutations was reduced in response to both inhibitors separately. *Trametinib*inhibited the CRAF-dependent ERK signaling induced by impaired-kinase BRAF mutations. *Dabrafenib* activated the ERK pathway in cells expressing only CRAF as well as cells co-expressing a kinase-impaired BRAF mutation and CRAF. **Conclusions:** This study predicts sensitivity of activating non-V600 BRAF mutations in lung cancer to *Trametinib* or *Dabrafenib*. Targeting kinase impaired BRAF mutations which signal through CRAF using *Dabrafenib* will require the addition of *Trametinib.*

11092 Poster Session (Board #306), Sun, 8:00 AM-11:30 AM

A functional kinome screen to identify pathways of anthracycline resistance in patient-derived breast cancer cells. *First Author: Hannah Richards, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Despite 5 decades of generalized anthracycline use in breast cancer, rates of progression following exposure remain very high. In order to identify biologic mechanisms contributing to resistance, we performed high-throughput small interfering RNA (siRNA) screens on breast cancer cells from patients whose disease had progressed after anthracyclines. **Methods:** Cells were isolated directly from metastatic tumors and peritoneal or pleural effusions from patients with anthracycline-resistant breast cancer ($n = 26$, recruitment ongoing), expanded in culture, confirmed to be of epithelial origin by expression of keratin and stem cell markers (CD44+, CD24-), and could be grown as organoids. Low passage cells were transfected in triplicate with siRNAs targeting 713 kinases alone (IC0) or in the presence of doxorubicin (IC30, inhibitory concentration 30%) and viability measured at 72 hours. Candidate sensitizer genes were called using the Z-transformed mean normalized viability across all plates, robust Z-score within each plate ($-2 > Z > 2$), and T-test p-value ($p < 0.05$). Pathway enrichment was computed for hits using Gene Ontology, KEGG, and Reactome databases. **Results:** Unsupervised hierarchical clustering of knockdown hits revealed clear separation by doxorubicin exposure for the first 4 patients evaluated (2 luminal b, 2 triple negative cases). Knockdown of 111 kinases resulted in significantly decreased proliferation in the IC0 screen. Knockdown of 228 kinases from the IC30 screen resulted in anthracycline sensitization and the top pathway implicated was ceramide biosynthesis/metabolism. **Conclusions:** For the first time, we demonstrate the feasibility of an individualized systems medicine approach using high-throughput siRNA screening in specimens directly derived from patients. Our top pathway hit identified was the ceramide pathway, only previously observed in anthracycline resistant cell lines. Larger scale RNAi and targeted agent drugs screens are ongoing in additional patients to validate the ceramide pathway and to identify novel drug targets in patients with anthracycline resistant disease toward our goal of reducing the burden of recurrence.

11093 Poster Session (Board #307), Sun, 8:00 AM-11:30 AM

Genomics, transcriptomics, and proteomics in the clinical setting: Integrating whole genome and RNA sequencing with quantitative proteomics to better inform clinical treatment selection. *First Author: Shahrooz Rabizadeh, Nantworks, Culver City, CA*

Background: Genomic panels, limited to a few hundred target mutations, are the current standard to provide therapeutic insights; however, lack of confirmation of expression of mutated genes is a limitation of these targeted genomics approaches. We report the first comprehensive pan-omic approach, overcoming these issues by integrating analysis of whole genome DNA sequencing with RNA data, including pathway analysis to provide predictive and, subsequently, quantitative proteomics to better identify clinically actionable targets in a timely manner. **Methods:** Over 50 unique tumors from primary and metastatic disease were selected for pan-omic tumor profiling. A cloud-based DNA and RNA supercomputing platform was developed to produce copy-number estimates, somatic variants, rearrangements, and RNA-abundance estimates from FFPE biopsies. Machine-read pathway analysis integrated whole genome DNA sequencing and RNA data to infer proteomics and predict drug targets. Quantitative, multiplexed proteomic analysis by mass-spectrometry validated therapeutic targets at attomoles per μg of tissue. **Results:** Approximately 80% of tumors had somatic events in previously published "actionable" genes. Multiple cases showed confirmation between predicted actionable genes and quantitatively increased protein expression; however, many mutations showed little or no expression at the transcriptomic level. These findings were confirmed by quantitative proteomic measurements. Also observed were genomic mutations and protein expression for which approved drugs are available, independent of anatomical tumor type. **Conclusions:** This is the first report of a fully integrated DNA, RNA, and proteomic diagnostic assay to establish a more accurate view of therapeutic interventions for patients, especially in this era of immuno-oncology. We conclude that the molecular signature of a cancer patient is independent of the anatomical tumor type and, given that many gene mutations were not expressed, that an informed clinical treatment decision requires insight into downstream protein expression and not just DNA alterations alone.

11094 Poster Session (Board #308), Sun, 8:00 AM-11:30 AM

Measurement of soluble Programmed Death-Ligand 1 (soluble PD-L1) to predict survival in biliary tract cancer patients treated with chemotherapy. *First Author: Hyerim Ha, Department of Internal medicine, Seoul National University Hospital, Seoul, South Korea*

Background: Programmed death-ligand 1 (PD-L1) expression in cancer cells or tumor microenvironment is under investigation as a candidate biomarker in the new drug development of immuno-oncology field. Preparation of tumor tissues for PD-L1 expression has some challenges. The soluble form of PD-L1 (sPDL1) is suggested as retaining immunosuppressive activity. In this study, we measure the levels of sPDL1 in serum and evaluate its role in prediction of overall survival (OS) in biliary tract cancer (BTC) patients. **Methods:** Seventy seven BTC patients' serum was collected before initiation of standard palliative chemotherapy. sPDL1 was measured using an enzyme-linked immunosorbent assay. Clinical data including neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR), and systemic immune-inflammation index (SII, neutrophil X platelet/lymphocyte) were collected. Cut-off of each variable for OS prediction was determined by ROC curve. **Results:** The primary site of BTCs were;30IHCC, 28 GB ca, 8 EHBTC, 11 AoV ca. OS of all patients was 10.7 months (95% CI; 8.53-14.93) and 1-year overall survival rate was 46.8%. Median sPDL1 level was 1.20 ng/ml (range 0.02-7.3, mean 1.48, SD 1.19). Median values of NLR, PLR, SII were 2.34, 8.81 and 514.8 respectively. High level of sPDL-1 ($>$ 1.10 ng/ml) conferred poor prognosis (OS 7.7 m vs 17.7 m, p = 0.001). High levels of NLR ($>$ 2.10), PLR ($>$ 9.5), SII ($>$ 650) were also significant factors for poor OS (P = 0.029, P = 0.015, P = 0.002). However, in multivariate analysis, only sPDL1 predicts worse survival (HR 2.16, p = 0.008). Patients with high sPDL1 showed decreased albumin level, high NLR, PLR, SII. Among 77 patients, 19 outliers with longer survival (OS $>$ 20m) had lower levels of sPDL1 (P = 0.007). **Conclusions:** The soluble form of PD-L1 (sPDL1) can be measured in the serum of BTC patients, and it has significant impact on the prognosis of BTC patients treated with standard chemotherapy.

11095 Poster Session (Board #309), Sun, 8:00 AM-11:30 AM

Correlation of cancer-associated macrophage-like cells with systemic therapy and pathological stage in numerous malignancies. *First Author: Daniel L Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Recently we published preliminary data on the presence of Cancer Associated Macrophage-Like cells (CAMLs) in a variety of malignancies and their clinical use in tracking cancer progression (Adams et al., PNAS 2014). This report is a follow-up in identifying and tracking CAMLs, with an emphasis on correlating clinical and pathological stage from baseline samples. **Methods:** This multi-institutional prospective pilot study consisted of 105 patient (pt) samples: Stage I-IV; breast (n = 34), prostate (n = 25), pancreatic (n = 39) and lung (n = 7). Evaluators were blinded to the source and stage of the pts. Additionally, 30 non-blinded healthy controls with no known malignant disease were analyzed. 7.5 mL of whole blood was collected; filtered by the CellSieve microfiltration assay; and stained with DAPI, CK 8/18/19, EpCAM and CD45. CAMLs were enumerated and identified as large multinucleated circulating myeloid cells (e.g. CD14+). We report CAML number at clinical stage in relation to healthy controls and compare with patient's pathological stage. **Results:** CAMLs were identified in 98/105 samples (93%), ranging from 0-105 CAMLs per peripheral blood sample at baseline, while 0 were found in 30 healthy controls; Sensitivity = 93.3% (CI95% 87-97%) and Specificity = 100% (CI95% 88-100%). Pts with breast, prostate and pancreatic cancer underwent surgical procedures and pathologically staged (n = 98). The number of CAMLs at baseline had a weak association with clinical stage; stage I (8.7 per sample), Stage II (6.8), Stage III (16), Stage IV (26.1); R^2= 0.82. However, the number of CAMLs at baseline highly correlated with final pathological staging; stage I (4.3), Stage II (6.3), Stage III (14), Stage IV (24.6); R^2= 0.94. **Conclusions:** Our data suggests that 1) CAMLs are circulating immune cells specific to malignant disease and 2) the number of CAMLs is weakly associated with clinical stage but highly correlative with pathological stage in a variety of malignancies. These findings indicate that CAMLS may be a valuable supplement to current screening and staging procedures.

11096 Poster Session (Board #310), Sun, 8:00 AM-11:30 AM

Effect of the timing of sunitinib administration on the predictive value of biomarkers in renal cell cancer (mRCC). *First Author: John Michael Louis Ebos, Roswell Park Cancer Institute, Buffalo, NY*

Background: Angiogenic cytokines influence tumor growth in mRCC patients (pts) and are modulated by diurnal fluctuations. The timing of antiangiogenic tyrosine kinase inhibitor (TKIs) administration may impact efficacy, toxicity and biomarker expression. **Methods:** 34 mRCC pts, randomized to receive sunitinib at 8 AM or 8 PM on a 28 days (d) on/14 d off schedule, had blood sampling before and during Rx on the first cycle for potential biomarkers including: sunitinib and metabolite blood levels, 18 circulating angiogenic factors (CAFs) and 4 circulating angiogenic cell types including circulating endothelial cells (CECs). **Results:** Spearman analysis of the 24 biomarkers obtained on d 14 showed significantly better correlations with OS and PFS in PM-treated pts. Three CAFs in PM-treated pts significantly correlated with both OS and PFS. These included Leptin (r = 0.7182, p = 0.0128 and r = 0.8364, p = 0.0022, respectively), IL-8 (r = -0.635, p = 0.0485 and r = -0.5735, p = 0.031, respectively) and PDGF-$\beta\beta$ (r = -0.8455, p = 0.001 and r = -0.6818, p = 0.0251, respectively). Circulating Leptin levels correlated with sunitinib-metabolite levels in both AM and PM-treated patients (r = 0.7832, p = 0.0038 and r = 0.6848, p = 0.0347, respectively). **Conclusions:** This is the first study to suggest that a consistent sunitinib dosing time may improve the predictive value of some biomarkers for OS and PFS in mRCC pts. A panel of predictive circulating cytokines (Leptin, IL-8, and PDGF-$\beta\beta$) was identified for pts receiving Rx at night. Furthermore, Leptin may have value as a biomarker of sunitinib-metabolite levels independent of dosing timing. The potential impact of Rx-time on the predictive value of some biomarkers may have hampered the discovery of consistently useful predictive biomarkers for sunitinib efficacy in mRCC patients to date. Clinical trial information: OCT125.

11097 Poster Session (Board #311), Sun, 8:00 AM-11:30 AM

Personalized therapy in diverse cancers: Meta-analysis of 32,149 patients in phase II clinical trials. *First Author: Maria Clemence Schwaederle, Center for Personalized Cancer Therapy and Division of Hematology and Oncology, University of California, San Diego, CA*

Background: The benefit of a personalized cancer treatment strategy (matching patients with drugs based on specific biomarkers) is still a matter of debate. We performed a systematic review and meta-analysis of recently published phase II studies in order to compare outcomes between arms that adopted a biomarker-based approach and those that did not. **Methods:** This analysis included 570 phase II studies (641 single-agent arm(s); 32,149 patients) (January 1st, 2010 to December 31st, 2012; Pubmed search). A weighted pooled analysis and a meta-analysis were performed. Response rate (RR), progression-free survival (PFS), overall survival (OS), and death rate were compared for treatment arms that used a personalized strategy versus those that did not. **Results:** Personalized arms (N = 112) accrued 8,078 patients compared to 24,071 patients for non-personalized arms (N = 529 arms). Multivariable analysis (both weighted multiple linear regression and random effect meta-regression) demonstrated that the personalized approach consistently and independently correlated with higher RR (31% vs 10.5%, P $<$ 0.0001), prolonged median PFS (5.9 vs 2.7 months, P $<$ 0.0001) and OS (13.7 vs 8.9 months, P = 0.0001). Non-personalized targeted arms (i.e., targeted agent without biomarker selection) had poorer outcomes compared to either personalized targeted therapy or cytotoxics (211/212 cytotoxic arms were non-personalized): RR 4, 30 and 11.9%, respectively; median PFS, 2.6, 6.9, and 3.3 months (all P $<$ 0.0001); and OS, 8.7, 15.9, and 9.4 months (all P $\leq$ 0.05), respectively. Personalized arms using a "genomic biomarker" had higher RR and longer PFS and OS (all P $<$ 0.05) than those using a "protein biomarker". A lower treatment-related death rate was observed in personalized arms (1.5% vs 2.3%, P = 0.0008). **Conclusions:** Comprehensive analysis of Phase II, single agent arms revealed that, across malignancies, a personalized strategy was an independent predictor of better outcomes and fewer toxic deaths. In addition, non-personalized targeted arms were associated with significantly poorer outcomes than cytotoxic agents, which in turn were worse than personalized targeted therapy.

11098 Poster Session (Board #312), Sun, 8:00 AM-11:30 AM

Identification of subtypes of triple negative breast cancer (TNBC) that are sensitive to CDK4/6 inhibition. *First Author: Uzma Asghar, Institute of Cancer Research, London, United Kingdom*

Background: CDK4/6 inhibitors in combination with hormone therapies have shown activity in estrogen receptor positive (ER+ve) breast cancers. We investigated whether CDK4/6 inhibitors have activity in subsets of Triple Negative Breast Cancer (TNBC), and assessed combination therapeutic approaches. **Methods:** We screened 18 TNBC cell lines for sensitivity to the CDK4/6 inhibitor palbocicilb in long-term clonogenic assays, with assessment of combination effect with Combination Index and Bliss Independence (BI). Cell lines were ascribed to Lehmann subtypes. BRDU proliferation assays, mRNA expression and western blots were conducted to investigate the mechanisms of sensitivity to CDK4/6 inhibition in specific subsets. In addition we interrogated datasets from the TCGA breast cancer cohort to compare gene expression, copy number alterations or cell cycle genes across the different TNBC subtypes. **Results:** TNBC cell lines of the luminal-androgen (LAR) and mesenchymal-stem like (MSL) subsets were sensitive to palbociclib in both in clonogenic and BRDU proliferation assays [$p = < 0.0001$ LAR vs basal-like subtypes]. Sensitivity was associated with expression of androgen receptor ($p = 0.0013$), and the absence/or low levels of cyclin E1 ($p = 0.01$). Resistant mesenchymal (M) and basal TNBC cell lines had elevated levels of cyclin E1 mRNA and protein. Analysis of TCGA data revealed that high-level amplification of cyclin E1 is more common in basal tumours compared to the luminal subgroups ($p = 0.0069$). Sensitivity of TNBC LAR/MSL cell lines to palbociclib was limited by low-level cell cycle entry despite CDK4/6 inhibition. Combination studies highlighted PI3K inhibition was synergistic with CDK4/6 inhibition in *PIK3CA*mutated TNBC cell lines (BI score: $<$ 1.0), with a greater effect in LAR/MSL subgroups compared to M/basal subgroups ($p = 0.015$). The combination induced sustained proliferative arrest compared to palbociclib alone in LAR sub group ($p = 0.0007$). **Conclusions:** We demonstrate that LAR cell lines represent a TNBC subgroup that may benefit from CDK4/6 inhibition. Interestingly, TNBC with *PIK3CA* mutations could also benefit by targeting both cell cycle and PI3K-mTOR signaling.

11099 Poster Session (Board #313), Sun, 8:00 AM-11:30 AM

Squamousness: Next-generation sequencing to reveal shared molecular features across squamous tumor types. *First Author: Maria Clemence Schwaederle, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: In order to gain a better understanding of the underlying biology of squamous cell carcinoma (SCC), we tested the hypothesis that SCC originating from different organs may possess common molecular alterations. **Methods:** SCC samples ($N = 361$) were examined using clinical-grade targeted next-generation sequencing (NGS) (182 or 236 cancer-related genes). **Results:** The most frequent SCC tumor types were head and neck, lung, cutaneous, gastrointestinal and genitourinary. The most common gene alterations were *TP53* (64.5% of patients), *PIK3CA* (28.5%), *CDKN2A* (24.4%), *SOX2* (17.7%), and *CCND1* (15.8%). By comparing NGS results of our SCC cohort to a non-SCC cohort ($N = 277$), we found that *CDKN2A*, *SOX2*, *NOTCH1*, *TP53*, *PIK3CA*, *CCND1*, and *FBXW7* were significantly more frequently altered, unlike *KRAS,* which was less frequently altered in SCC specimens (all $P < 0.05$; multivariable analysis). Therefore, we identified "squamousness" gene signatures (*TP53, PIK3CA, CCND1, CDKN2A, SOX2, NOTCH 1,* and *FBXW7* aberrations, and absence of *KRAS* alterations) that were significantly more frequent in SCC versus non-SCC histologies. A multivariable co-alteration analysis established two SCC subgroups: (i) patients in whom *TP53* and cyclin pathway (*CDKN2A* and *CCND1)* alterations strongly correlated but in whom *PIK3CA* aberrations were less frequent; and (ii) patients with *PIK3CA* alterations in whom *TP53* mutations were less frequent (all $P \leq 0.001$, multivariable analysis). **Conclusions:** We identified a set of eight genes altered with significantly different frequencies when SCC and non-SCC were compared, suggesting the existence of patterns for "squamousness." Targeting the PI3K-AKT-mTOR and/or cyclin pathway components in SCC may be warranted.

11100 Poster Session (Board #314), Sun, 8:00 AM-11:30 AM

Association of paclitaxel-induced sensory peripheral neuropathy with the *ABCB1* genetic variant and age. *First Author: Chikako Shimizu, Natl Cancer Ctr Hosp, Tokyo, Japan*

Background: The development of paclitaxel-induced peripheral neuropathy (PIPN) is influenced by the age and genetic composition of patients. Paclitaxel is known to act as a substrate in *SLCO1B3*-mediated influx, *ABCB1*-mediated efflux from cancer cells, and *CYP2C8*-mediated metabolism. We conducted a prospective study to investigate whether age and these single nucleotide polymorphisms (SNPs) are correlated with PIPN. **Methods:** Breast cancer patients who received adjuvant weekly paclitaxel were genotyped for five SNPs in three genes, including rs4149117 in *SLCO1B3*; rs2032582, rs1045642, and rs1128503 in *ABCB1*; and rs10509681 in *CYP2C8*, using PCR quenching probe method. Clinical data, including the paclitaxel dose and onset and severity of neuropathy, were correlated with the genetic data. **Results:** We enrolled 127 Japanese patients with a median age of 50 years (range, 25–75 years). The mean total paclitaxel dose administered was 933 mg/m^2 (range, 560–960 mg/m^2), and 85% received the full dose intensity treatment (960 mg/m^2 over 12 weeks). The majority of patients (98.4%) developed all grade neuropathy, and 51.9% of patients exhibited grade 2 or higher severity. Severe neuropathy, defined as those requiring a dose delay, dose reduction, or early termination of chemotherapy, occurred in 15.0% of patients. Of the five SNPs evaluated, the *ABCB1* (rs1128503) TT genotype was associated with a grade 2 or higher neuropathy compared with the CC/CT genotype ($p = 0.05$). Of note, patients with the TT genotype aged $>$ 60 years had a higher incidence of grade 2 or higher severity ($p = 0.008$) than those with the CC/CT genotype. Patients without PIPN were all wild type for the five SNPs. Patients aged $>$ 60 years had a higher incidence of grade 2 or higher severity ($p = 0.006$) than younger patients, regardless of the SNPs. **Conclusions:** *ABCB1* rs1128503 SNP and advanced age are correlated with PIPN. This findings may help clinicians determine which patients should avoid paclitaxel. Clinical trial information: UMIN000005294.

11101 Poster Session (Board #315), Sun, 8:00 AM-11:30 AM

Exosomes isolation and characterization in non small cell lung carcinoma patients: Proof of concept study. *First Author: Christian D. Rolfo, Universitair Ziekenhuizen Antwerpen, Antwerp, Belgium*

Background: The liquid biopsy is a noninvasive tool that could change the vision of diagnostic, prognostic and predictive analysis in oncology. In the liquid biopsy potential blood-based biomarkers such as exosomes could be determinate. These biological nanovescicles (40-100 nm) are involved in regulation of tumor progression and it was demonstrated that they transport miRNAs. miRNAs are shown to be key regulators of many biological processes and promising disease biomarkers. The main aim of this study is to investigate whether exosomes isolation from clinical samples (fresh plasma from NSCLC pts) is feasible. Furthermore we have investigated selected exosome miRNAs known to be related with NSCLC. **Methods:** A total of 12 patients with NSCLC (adenocarcinoma) were included in this pilot project, after obtaining the informed consent. Exosomes were isolated from fresh plasma by means of both Density-Gradient centrifugation and commercial isolation kit and characterized through Western-Blot (WB), NanoSight and Trasmission Electron Microscopy (TEM) analysis. The expression of selected miRNAs was performed through Real-Time PCR; miR-1228 was used as endogenous control and the fold change was calculated according the formula $\mathbf{2^{-\Delta\Delta Cq}}$. **Results:** Exosomesof all samples are characterized through WB analysis for ALIX and TSG-101, known as exosome markers, and by NanoSight and TEM analysis where all samples contains particles of size between 40-100nm. Interestingly, miR-30b and -30c are up-regulated in all samples, except for one patient (adenosquamous carcinoma with a predominance of squamous cell carcinoma) in which miR-30c is down-regulated. This result might indicate that miR-30c could be related to squamous histology. In our series we have one EGFR-positive sample (exon19 deletion) that show the highest expression of miR30b, -30c, -103, -195, -221, -222. This is partially in concordance with the results from Garofalo et al., which mir-30b, -30c, -221 and -222 are regulated by EGFR and MET receptor. **Conclusions:** With this pilot study we have demonstrated that exosome analysis and exosomal miRNAs profiling is feasible in NSCLC this might be a noninvasive test for follow up, response and resistance to therapy.

11102 Poster Session (Board #316), Sun, 8:00 AM-11:30 AM

Impact of BMI on survival and toxicity in early breast cancer: An exploratory analysis of prospective randomized phase III study N-SAS BC02 and 03. *First Author: Yoichi Naito, National Cancer Center Hospital East, Chiba, Japan*

Background: Obesity is reported to be associated with worse prognosis in early breast cancer. As obesity is rare and low BMI is relatively common in Japanese population compared to Caucasians, the impact of BMI on survival and toxicity in Japanese cohort should be assessed. Here we report an exploratory analysis of the data included in randomized phase III trials for early breast cancer in Japan. **Methods:** Patients included in phase III trial N-SAS BC02 or BC03 were analyzed. N-SAS BC02 investigated four arms of adjuvant chemotherapy consisted of taxane alone or in combination with anthracycline-containing regimen (median follow up of 6.1 years). NSAS BC03 compared anastorozole with tamoxifen as adjuvant endocrine therapy (median follow up of 6.4 years). The correlations of BMI and overall survival or toxicity were retrospectively analyzed. **Results:** A total of 1726 patients were included in our study. Median age was 56 years, 71.2% of tumors were ER positive, and 9.7% were HER2 overexpressed, 76% had lymph node metastasis. Mean value of BMI was 23.3 and only 4.6% of patients had BMI over 30. 33.1% of patients had BMI under 22 and 4.8% had BMI under 18.5. In the Cox proportional hazards model adjusted randomized arms, lower BMI was significantly associated with worse prognosis (BMI $>=$ 27 vs $<$ 27, HR 0.55, $p = 0.025$). The same trend was observed in adjusted analysis for prognostic factors (HR 0.61, $p = 0.064$). Subgroup analysis of hormone receptor positive cohort showed that higher BMI was correlated with worse prognosis in premenopausal patients; on the other hand, in postmenopausal patients higher BMI was correlated with better prognosis. There was no significant correlation between BMI and toxicity. **Conclusions:** We confirmed that obesity was rare in Japanese patients with early breast cancer. In this non-obese population, lower BMI was correlated with worse prognosis without significant impact on toxicity. Subgroup analysis suggested interaction between menopausal status and BMI on survival. Detrimental effect of higher BMI on survival is limited to premenopausal hormone receptor positive patients.

11103 Poster Session (Board #317), Sun, 8:00 AM-11:30 AM

Precision oncology: the UC San Diego Moores Cancer Center PREDICT experience. *First Author: Barbara A. Parker, UC San Diego Moores Cancer Center, La Jolla, CA*

Background: By profiling their patients' tumors, oncologists now have the option to use molecular results to match patients with drug(s) based on specific biomarkers. **Methods:** In this observational study, clinical outcomes of 348 patients with solid advanced cancers who had next-generation sequencing (NGS, 182 or 236 genes) performed were analyzed under the PREDICT (Profile Related Evidence Determining Individualized Cancer Therapy) study protocol. Progression-free survival (PFS) and responses were recorded for patients that received a matched therapy. **Results:** Of 348 patients analyzed, 47 (13.5%) were treated with a matched therapy after NGS results. Two additional patients were matched but were lost to follow up. Thirty-four percent of patients (16/47) achieved stable disease (SD) $>$ 6months ($n = 7$)/complete response (CR, $n = 0$)/partial response (PR, $n = 9$). The median PFS for the matched patients was 4.0 months ($N = 47$, range, 0.5 to 22.3 months). The median PFS was 9.5 months (range, 3.4 to 22.3 months) for the 16 patients with SD $>$ 6 months/CR/PR. The median PFS (PFS2) of the patients given matched therapies was longer than the median PFS (PFS1) of the available prior therapies (PFS1; $N = 38$ available; $P = 0.038$). There was no difference between the median PFS when the matched drug targeted the alteration "directly" (agent impacts the molecular alteration or its immediate downstream effector) versus "indirectly" ($>$ 1 effector removed from the alteration) ($N = 32$ vs 15 patients; PFS = 3 vs 4 months; $P = 0.74$); if we defined direct matches as including only drugs targeting the alteration itself, and indirect matches when the alteration was $>$ 1 effector removed, the differences in PFS remained insignificant. **Conclusions:** Patients with advanced cancers treated with a biomarker-based approach (matched therapy) achieved a 34% rate of SD $>$ 6 months/CR/PR and had a significantly longer median PFS than that for the available last prior therapies. Although the numbers are small, there were no differences in PFS between patients who received therapy that was directly versus indirectly matched to their alteration(s).

11105 Poster Session (Board #319), Sun, 8:00 AM-11:30 AM

Pharmacodynamic (PD) assessment using FLT-PET/CT imaging in patients treated with an interrupted high-dose axitinib schedule. *First Author: Ludimila Cavalcante, University of Wisconsin, Madison, WI*

Background: Axitinib (AX) is a potent inhibitor of receptor tyrosine kinases (RTK) of VEGFR-1,2,3. We previously showed that exposure to AX resulted in a decrease in tumor proliferation and vascular parameters, and during acute AX withdrawal, a rebound flare (proliferative and vascular) was present during cycle 1 (C1). Here we evaluate the impact of AX dose on the rebound pharmacodynamics, as well as assess whether this flare persists in later cycles of therapy with AX using an intermittent therapy schedule. **Methods:** Pts with prostate cancer or other advanced solid malignancies were enrolled. In the safety cohort, AX was administered at 7 mg BID on a 2 week on, 1 week off schedule. In the PD cohort, static/dynamic FLT PET/CT scans were obtained at baseline, week 2 (on AX), and wk 3 (off AX) in C1, and repeated again in C3 (pre-day 1, wk 2, wk 3). Plasma VEGF and AX PK levels were obtained at each imaging timepoint. **Results:** 24 pts were enrolled (safety cohort $n = 8$, PD cohort $n = 16$). Pts in the safety cohort received AX starting at 7 mg BID. Three pts developed significant hypertension and thrombovascular events; hence it was not felt that this starting dose was appropriate. For the PD cohort, AX dose was administered at 5 mg BID. 14 pts had scans on C1, and 5 pts completed scans during C3. Similar changes in proliferation/vasculature parameters were seen in C1 as previously reported. Decreases in proliferation/vasculature parameters were also seen in C3 (on AX) with rebound flare present at wk 3. **Conclusions:** Although dose-escalation of AX (up to 10 mg BID) has been shown to be feasible in renal cell cancer, use of intermittent AX at a starting dose of 7 mg BID was not feasible in our non-RCC pt population. We confirm previous findings that AX exposure results in a decrease in proliferation/vasculature parameters and that acute AX withdrawal results in a tumor/vasculature flare. We show with ongoing intermittent AX therapy, a similar PD change was observed in pts during C3. This result supports a *sequential strategy* of using intermittent AX in combination with S-phase specific chemotherapy in order to exploit the tumor/vasculature rebound in order to improve the therapeutic index of the cytotoxic chemotherapy. Clinical trial information: NCT01540526.

11106 Poster Session (Board #320), Sun, 8:00 AM-11:30 AM

The long term outcome of clinical trial-based treatment comparing standard treatment for metastatic breast cancer. *First Author: Gun Min Kim, Yonsei University, Seoul, South Korea*

Background: All NCCN guidelines have black box recommendations as "NCCN believes that the best management for any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged". However, we still don't know the level of evidence for this recommendation. We evaluated the clinical impact of clinical trial-based treatment on long term outcome for metastatic breast cancer. **Methods:** The Yonsei Cancer Center Metastatic Breast Cancer Database identified 762 patients with metastatic breast cancer who were diagnosed between 2006 and 2013. We analyzed retrospectively the information about demographics, clinical and pathologic characteristics, survival, and treatments. Descriptive analyses were conducted to investigate on the impact of clinical trial-based treatment comparing standard treatment on long term outcome of MBC. Clinical trial is defined as any clinical trials which were approved by IRB regardless of investigator-initiated or sponsor-initiated trial. **Results:** Of the 762 patients, 179 (23.5%) patients received first-line treatment as clinical trial-based. Baseline demographics showed 534 (70.1%) patients were recurrent MBC and 30% were de novo MBC. The proportion of patient who received clinical-trial based treatment was similar between recurrent MBC (24%) and de novo MBC (22.4%). Median follow-up was 31.8 months (range 0.1-108). Median OS was 47.6 months (95% CI 37.6-57.6) versus 31.5 months (95% CI 27.9-35.1) for patients with clinical trial-based treatment versus standard treatment, respectively. Patient with initial brain metastasis (34, 4.5%) or leptomeningeal metastasis (3, 0.4%) could not be enrolled into the clinical trial. Median OS of patients with CNS metastasis is extremely lower than patients without CNS metastasis (15.1 versus 35.4 months, $p < 0.0001$). Analysis after exclusion of patients with CNS metastasis still showed better outcome for patient who received clinical-trial based treatment as first line therapy (44.9 versus 33.2 months, $p < 0.011$). **Conclusions:** Patient who received clinical trial-based treatment as first-line therapy showed better long term outcome compared to patients who took a standard treatment.

11107 Poster Session (Board #321), Sun, 8:00 AM-11:30 AM

Theranostic biomarkers involved in immunomodulation and the PI3KCA signal transduction pathway in HPV-induced cervical, oropharyngeal, and anal carcinoma. *First Author: Nooshin Hashemi Sadraei, University of Cincinnati, Cincinnati, OH*

Background: Several distinct cancers are caused by human papillomavirus (HPV)- including squamous cell carcinomas of the cervix (CSCC), anal canal (ASCC), and oropharynx (OSCC). Importantly, platinum based chemoradiation protocols are similarly effective in these entities. We assessed CSCC, ASCC, and OSCC for additional evidence of shared characteristics which could be used to identify potential molecular targets across the spectrum of HPV induced cancers. **Methods:** 201 ASCC, 321 CSC and 358 OSCC tumors underwent molecular profiling with a multiplatform approach (Caris Life Sciences). TP53 wild type status was used as a surrogate for HPV. Testing included sequencing (NGS, Sanger), protein expression (IHC) and gene amplification (ISH). The 2-tail Fisher's exact test ($p \leq 0.05$), JMPv10.0 (SAS Institute Inc., Cary, NC) was utilized for statistical analysis. **Results:** Excluding TP53-mutated patients, 197 ASCC, 317 CSCC and 317 OSCC were included in the study. Multiplatform profiling reveals marked similarities among the HPV-induced cancers. None of the frequencies observed displayed statistically significant differences. Selected results appear below. **Conclusions:** Unlike the genomic instability observed in many solid tumors, HPV-induced carcinogenesis yields a more homogenous phenotype. These data support previous work identifying the PIK3CA-AKT-mTOR pathway as a potential target. Given the phenomenon of HPV E6 & E7-induced oncogene addiction following viral integration, the need to explore PD1/PDL1 inhibition in these cancers is implicit.

Frequency (positivity, underexpression#, amplified or mutated): Greyed boxes indicate Rx is NCCN-endorsed

11108 Poster Session (Board #322), Sun, 8:00 AM-11:30 AM

Drug efflux pump expression in 50,000 molecularly-profiled cancer patients. *First Author: Rebecca Feldman, Caris Life Sciences, Phoenix, AZ*

Background: The multidrug resistance (MDR) phenotype reduces the efficacy of various chemotherapies. MDR is linked to the overexpression of ATP-binding cassette (ABC) transporters in cancer cells, including P-glycoprotein (PGP/ABCB1), multidrug resistance protein (MRP1/ABCC1) and breast cancer resistance protein (BCRP/ABCG2). We assessed protein expression patterns of the drug efflux pumps across all tumor types for insight on how to exploit MDR status to circumvent treatment dilemmas. **Methods:** 51,939 patients molecularly profiled with a commercial multiplatform approach (Caris Life Sciences) were evaluated. Protein expression by IHC was assessed. The Caris Registry was queried for patients in this analysis with available clinical outcomes. **Results:** Across all tumors profiled ($n = 51{,}939$), MRP1 positivity (pos.) was highest at 81% (19935/24682), BCRP at 66% (8849/13409) and PGP the lowest at 23% (11969/51313). GI cancers exhibited the most abundant expression of all three drug pumps (80%, 90%, 53%), with highest average combined expression observed in liver cancers (81%). In contrast, brain, thymic and head and neck cancers exhibited the lowest average combined expression of all 3 drug pumps (39%, 40% and 42%, respectively). 6,002 patients were evaluable for co-expression with 29% (1728/6002) exhibiting pos. for all 3 drug pumps (ABC+) (highest frequencies in colon, pancreas, ovary, breast and lung), 42% (2494/6002) pos. for 2/3 drug pumps and 21% (1263/6002) pos. for 1/3 drug pumps. Only 9% (517/6002) exhibited negative status for all 3 drug pumps (ABC-) (highest frequencies in breast, lung, ovary, skin and endometrial). To determine the prognostic role of the drug pumps on patient survival, we assessed the differences in median survival between a cohort of ABC+ ($n = 31$) and ABC – ($n = 27$) patients with breast ($n = 6, 2$), ovary ($n = 12, 6$) and lung cancers ($n = 13,19$). Median survival since specimen used for profiling was collected for ABC + was 596 days compared to 855 days for ABC – patients. **Conclusions:** Tumors show broad and overlapped expression patterns for drug efflux pumps. Further study is needed to determine how transporter expression may impact clinical outcomes (e.g. ABC - status is more favorable than ABC + status).

TPS11109 Poster Session (Board #324a), Sun, 8:00 AM-11:30 AM

The DETECT Study Program: Personalized treatment in advanced breast cancer based on circulating tumor cells (CTCs). *First Author: Amelie Schramm, Universitaetsfrauenklinik Ulm, Ulm, Germany*

Background: The prognostic value of circulating tumor cells (CTC) in metastatic breast cancer (MBC) has been repeatedly shown, but potential implications of CTC presence and CTC phenotypes for treatment decisions are still not well understood. The main aims of the DETECT study program are to evaluate efficacy of individualized breast cancer treatments based on presence and phenotype of CTCs, and to investigate the role of CTCs in predicting specific treatment responses. **Methods:** In the phase III study DETECT III women with HER2-negative MBC but HER2-positive CTCs are randomized to physician´s choice therapy (single-agent endocrine or single-agent chemotherapy) with or without HER2-targeted therapy with lapatinib. The phase II study DETECT IV offers two treatment options for women with HER2-negative MBC and only HER2-negative CTCs. Patients with hormone-receptor positive MBC receive endocrine therapy plus everolimus, and patients with triple-negative MBC or hormone-receptor positive MBC plus indication for chemotherapy receive cytostatic treatment with eribulin. In the phase IIIa study DETECT V, women with HER2-positive and hormone-receptor positive MBC are treated with either endocrine therapy or chemotherapy added to a dual HER2-targeted backbone treatment with trastuzumab and pertuzumab. Clinical efficacy will be estimated by CTC clearance and progression-free survival in DETECT III and DETECT IV. As the focus of DETECT V is on the comparison of safety and quality of life between the two treatment arms, primary and main secondary endpoints are rate of adverse events and quality-adjusted survival (Q-TWiST method). Translational research projects try to identify additional predictive markers of therapy response by molecular characterization of CTCs. Therefore, prevalence of CTCs using the FDA-cleared CellSearch System (Janssen Diagnostics, LLC) and their HER2 status is determined. As of January 2015, more than 1100 patients have been screened for CTCs, making the DETECT study program the worldwide largest trial for MBC. The results will provide crucial information regarding suitability of CTCs as liquid biopsy to guide more individualized therapy decisions. Clinical trial information: NCT01619111/NCT02035813/NCT02344472.

TPS11110 Poster Session (Board #324b), Sun, 8:00 AM-11:30 AM

The genomics of Young Lung Cancer Study. *First Author: Barbara J. Gitlitz, University of Southern California Keck School of Medicine, Los Angeles, CA*

Background: Primary lung cancer is increasingly understood as a heterogeneous disease made up of genomically defined subtypes requiring distinct treatment strategies. We hypothesize young age at diagnosis (< 40 years) is a clinical characteristic associated with an increased chance for a targetable genomic alteration. This ALCMI study will prospectively characterize the somatic and germline genomics of young lung cancer. Our goals are to identify a genomically enriched subtype of lung cancer, facilitate delivery of targeted therapy and lay groundwork for further studies of heritable and environmental lung cancer risk factors. **Methods:** Accrual opened 07/2014. Patients are eligible if they were diagnosed with bronchogenic lung cancer less than age 40. A study specific website allows for virtual consenting so patients can participate remotely from anywhere in the country or the world; and use social media to share our trial. We have an integrated data and biorepository (Open Medicine Institute) that allows for seamless communication and completion of study activities like remote consenting, storage and routing of blood and tumor specimens. We have defined 7 genomic alterations of interest based on the Lung Cancer Mutational Consortium (LCMC) (EGFR, KRAS, HER2, BRAF, ALK, ROS1, RET). On study subjects without a known genotype will undergo comprehensive genomic profiling with the FoundationOne test to ensure that all of these genes have been tested. Subjects with advanced adenocarcinoma who are wild-type for all 7 genes will receive additional genomic profiling using the FoundationOne Heme test with the goal of identifying novel oncogenic drivers. Additional investigational genomics will include blood for germline analysis. All on study genomic analysis is at no cost to the participant. We aim to demonstrate that the prevalence of targetable genomic alterations will be greater in our population compared to the LCMC and have powered our study to show an increase from 35% to 50%; and an improvement in use of targeted therapy from 22% to 40%. The trial is currently accruing (NCT02273336) https://www.openmednet.org/site/alcmi-goyl. (Supported by grants from The Bonnie J. Addario Lung Cancer Foundation, Peter Barker Foundation, Genentech and Schmidt Legacy Foundation.) Clinical trial information: NCT02273336.

TPS11111 Poster Session (Board #325a), Sun, 8:00 AM-11:30 AM

MyPathway: An open-label phase IIa study of trastuzumab/pertuzumab, erlotinib, vemurafenib, and vismodegib in patients who have advanced solid tumors with mutations or gene expression abnormalities targeted by these agents. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: While many targeted agents are approved for specific cancers, molecular profiling has increasingly led to the identification of genetic abnormalities in tumor types for which targeted agents are not currently approved. MyPathway explores the activity and safety of therapies that target HER2, EGFR, BRAF, and Hedgehog pathways in cancers for which these treatments are not FDA-approved. **Methods:** MyPathway (trial registration NCT02091141) is a multicenter, non-randomized, phase IIa study of patients with advanced solid tumors that have progressed following standard therapy or for which there is no approved treatment. Eligible patients have a tumor with a potentially actionable genetic alteration, as determined by a Clinical Laboratory Improvement Amendments-certified laboratory. Patients with >1 mutation are treated based on the mutation considered most critical by the investigator; they may later enroll based on a different mutation, if initial therapy fails. For each pathway, treatments are dosed based on the approved regimen. Patients are evaluated for response after 2 cycles of therapy; those with an objective response or stable disease may continue therapy until tumor progression or unacceptable toxicity. Safety is monitored in real time and reviewed every 3–6 mos. The primary outcome is response rate. Secondary outcomes are disease control rate, progression-free survival, and 1-year survival. Outcomes will be studied by tumor type and pathway (tumor-pathway cohorts). Sample sizes for tumor-pathway cohorts are based on Simon's 2-stage design procedure. Use of the master protocol will allow possible future exploration of additional pathways as new agents become available. Evidence of activity in this trial may be studied in larger dedicated trials. Clinical trial information: NCT02091141.

Pathway	Molecular alteration	Treatment(s)
HER2	Overexpression of HER2 or activating mutation	Trastuzumab and pertuzumab
EGFR	EGFR-activating mutation	Erlotinib
BRAF	BRAF-activating mutation (V600E and others)	Vemurafenib
Hedgehog	SMO-activating mutation, PTCH-1 loss-of-function mutation	Vismodegib

TPS11112 Poster Session (Board #325b), Sun, 8:00 AM-11:30 AM

NRG Oncology/NSABP B-51/RTOG 1304: Phase III trial to determine if chest wall and regional nodal radiotherapy (CWRNRT) post mastectomy (Mx) or the addition of RNRT to breast RT post breast-conserving surgery (BCS) will reduce invasive cancer events in patients (pts) with positive axillary (Ax) nodes who are ypN0 after neoadjuvant chemotherapy (NC). *First Author: Eleftherios P. Mamounas, NRG Oncology/NSABP, and the MD Anderson Cancer Center Orlando, Pittsburgh, PA*

Background: This phase III post-NC trial will evaluate if CWRNRT post Mx or whole breast irradiation (WBI) with RNRT after BCS significantly reduces the invasive breast cancer recurrence-free interval (IBCR-FI) rate in pts presenting with positive Ax nodes that are negative after NC. Secondary aims are OS, LRR-FI, DRFI, DFS-DCIS, and second primary cancer as well as comparing RT effect on cosmesis in reconstructed Mx pts. Correlative science examines RT effect by tumor subtype, molecular outcome predictors for residual disease pts, and predictors for the degree of reduction in loco-regional recurrence. **Methods:** Clinical T1-3, N1 IBC pts with positive Ax nodes (FNA or core needle biopsy) complete ≥ 12 wks of NC (anthracycline and/or taxane). HER2-positive pts receive anti-HER2 therapy (tx). After NC BCS or Mx is performed with a sentinel node biopsy (≥ 3 nodes) and/or Ax dissection with histologically negative nodes. ER/PR and HER-2 neu status before NC is required. Pts receive required systemic tx. Radiation credentialing with a facility questionnaire and a case benchmark is required. Randomization for Mx pts is to no CWRNRT or CWRNRT and for BCS pts to WBI or WBI RNRT. **Statistics:** 1636 pts to be enrolled over 5 yrs with definitive analysis at 7.5 yrs. Study is powered at 80% to test that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction in the 5-yr cumulative rate of 4.6%. Intent-to-treat analysis with 3 interim analyses at 43, 86, and 129 events, with a 4th/final analysis at 172 events will occur. Accrual as of 1/15/15 is 96. Pt-reported outcomes focusing on RT effect will be provided by 736 pts before randomization and at 3, 6, 12, and 24 mths. **Support:** U10 CA 12027, 69651, -37377, -69974; -2166; -180868, -180822; CA189867; Elekta Clinical trial information: NCT01872975.

11113 Poster Session (Board #323), Sun, 8:00 AM-11:30 AM

Randomized phase II trial comparing molecularly targeted therapy based on tumor molecular profiling versus conventional therapy in patients with refractory cancer: Results of the SHIVA trial. *First Author: Christophe Le Tourneau, Institut Curie, Department of Medical Oncology, Paris, France*

Background: Non-randomized studies suggested that selecting molecularly targeted agents (MTAs) based on the molecular profile of pts' tumors, independently of tumor location and histology, improves outcome. We evaluated this histology-agnostic approach in pts who have failed standard of care therapy. **Methods:** Eligible pts underwent a biopsy of a metastatic site in order to establish the molecular profile of their tumor. Pts for whom a molecular alteration was identified and matched a MTA according to a pre-specified treatment algorithm (Table), were stratified according to the molecular pathway and randomly allocated to matching MTA or treatment at physician's choice (TPC). MTAs were only allowed outside their licensed indication and if not previously given. The primary end point was PFS. **Results:** Among 741 included pts, 195 were randomized. 82, 89 and 24 pts were allocated to the HT, PI3K and RTK/MAPK subgroups. G3/4 AEs rates were 43% and 35% in the MTA and TPC arms. ORR was 4.1% in the MTA arm vs 3.4% in the TPC arm. Global PFS and according to the molecular pathway are presented in the Table. **Conclusions:** The SHIVA trial did not demonstrate that the administration of MTAs outside their indications according to the pre-specified treatment algorithm improves PFS as compared to TPC in heavily pretreated pts. This histology-agnostic approach warrants further investigation in the RTK/MAPK pathway. Clinical trial information: NCT01771458.

			Median PFS (months)			
Molecular pathways	Molecular alterations	MTAs	TPC arm (n = 96)	MTA arm (n = 99)	HR (95%CI)	p-value
